Technical Report Overview

Report: 2021 Chronic Toxicity Program - Elk Valley Testing to Satisfy Permit Requirements

Overview: This report presents the results of quarterly and semi-annual chronic toxicity tests undertaken in 2021 for Teck's steelmaking coal mining operations in the Elk Valley. This report interprets results by evaluating correspondence between water chemistry and laboratory toxicological responses and identifies recommendations for revision or augmentation of planned future programs.

This report was prepared for Teck by Golder Associates Ltd. and relies on laboratory testing completed by Nautilus Environmental.

Technical Summary

Golder Associates Ltd. (Golder) was retained by Teck Coal Limited (Teck) to prepare this interpretive report on quarterly and semi-annual chronic toxicity tests undertaken in 2021 for Teck's coal mining operations in the Elk Valley. To inform Management Questions identified in the Adaptive Management Plan (AMP), and to support implementation of the Elk Valley Water Quality Plan (EVWQP), this report presents and interprets the results from 2021 chronic toxicity testing and identifies recommendations for revision or augmentation of planned future programs. The 2021 chronic toxicity testing program included quarterly testing with a cladoceran (*Ceriodaphnia dubia*) and a unicellular green alga (*Pseudokirchneriella subcapitata*) and semi-annual testing with an amphipod (*Hyalella azteca*; Q2 and Q4), early-life stage rainbow trout (*Oncorhynchus mykiss*; Q2 and Q4), and early-life stage fathead minnows (*Pimephales promelas*; Q1 and Q3).

To help answer Management Questions, the analysis of chronic toxicity data consisted of five steps:

- Reviewed data quality to confirm that results met acceptability criteria.
- Standardized the data to help discern toxicological responses from other sources of variability.
- Considered the size of response in each test and how it compared to responses in tests of reference waters (not influenced by mining) to categorize each result as "no adverse response", "possible adverse response", or "likely adverse response".
- Evaluated the correspondence between test responses and indicators of mine-related water quality. This evaluation included statistical assessment of patterns and specialized laboratory tests (toxicity identification evaluations) designed to identify causes of toxicity.
- Compared 2021 test results to previous years (2015 to 2020) to identify potential patterns in toxicity responses and provide insight into potential causation.

The following bullets summarize key findings from the 2021 interpretive report.

- **Data Quality**—The data generally met acceptability criteria and were fit for the intended purpose. In the few cases where data quality was suspect, actions were taken to process and interpret the data to avoid improper influence on findings. For example:
  - There were atypical findings observed for algae in Q1 and Q4. Many of the test sites had mean cell yield that was affected systematically (reduced growth) across the batch, despite the tested sites having different water quality profiles. These unusual findings did not warrant outright rejection as invalid test outcomes, but instead were identified as a source of increased uncertainty for this endpoint relative to previous years.
  - There were atypical findings for amphipod dry weight in Q3 where high inter-reference variability resulted in the identification of potential adverse responses for several test sites. Most adverse responses for this endpoint did not match previous tests, nor did findings associate strongly with water quality. These unusual findings did not warrant outright rejection as invalid test outcomes, but instead were identified as a source of increased uncertainty for this endpoint relative to previous years.

- There were atypical findings for Q1 fathead minnow tests for two reference sites (i.e., Elk River and Michel Creek). Results from these reference waters were excluded from statistical analysis because had anomalously low survival relative to the historical dataset, and only results from the remaining two references were used to categorize site water responses. Exclusion of these references made the identification of adverse responses more likely in test site waters but was adopted as a conservative screening approach.
- Where there was evidence of microbes in fathead minnow and rainbow trout tests, the results were flagged as being potentially confounded. The potential for confounding of test endpoints was partially controlled through administration of copper, which prevented large disruptions to the test endpoint performance, but did not eliminate presence of microbes entirely. Comparisons of results for replicates with and without evidence of microbe presence indicated potential for a small downward bias in survival and viability of tested fish. Per direction from the EMC, tests with microbes were included in statistical analyses and compared to water quality guidelines and benchmarks.

- **Initial Categorization**—The 2021 quarterly (quarters named as Q1, Q2, Q3, and Q4) test results categorized as “no adverse response”, “possible adverse response”, or “likely adverse response” are illustrated on Figure TS-1 and summarized by station at the end of this technical summary (Figure TS-2):
  - For all species, most tests were categorized as exhibiting no adverse response. Likely adverse responses, where observed, were most common for water flea reproduction and least common for rainbow trout and fathead minnow (one adverse response for survival for both fish species).
  - The number of samples with likely adverse responses was low across all quarters, ranging from three (Q2 and Q4) to four (Q1 and Q3). A higher proportion of samples had possible adverse effects in Q1, Q3, and Q4, although most of these tests were linked to atypical results for algal cell yield (Q1 and Q4) and amphipod dry weight (Q3), as indicated above.
  - The proportion of samples exhibiting adverse effects for fathead minnow and rainbow trout endpoints was low—the introduction of copper to control the prevalence and confounding effects of microbes has greatly improved the reliability of that test endpoint relative to early rounds of testing.
  - Stations FR_FRCP1 (Fording River below Cataract Creek), CM_MC2 (Michel Creek below Corbin Creek), and LC_DCDS (Dry Creek downstream of sedimentation ponds) exhibited the highest frequency of possible or likely adverse responses. This pattern is consistent with other recent years of testing.
  - The addition of FR_FRABCH and integration of the Line Creek and regional monitoring programs has improved the spatial characterization of sampling in the mainstem Fording and Elk rivers. The results from 2021 provide evidence that several stations of the mainstem Fording River downstream of FR_FRCP1 (i.e., FR_FRABCH, GH_FR1, and LC_LC5) have lower frequency and magnitude of chronic toxicity.
- **Causation Assessment**—The constituents identified as potential causes of toxicity in 2021 tests with adverse effects are summarized in Figure TS-2. Key findings were:
  - Nickel showed the greatest evidence of contributing to observed effects, it was identified as a causal factor for all adverse responses in water flea tests and approximately one half of adverse responses in amphipod tests.

  - In the Fording River (FR_FRCP1) and its tributary Dry Creek, nickel was identified in the greatest number of tests as having the greatest evidence of causing the observed effects to crustaceans (i.e., water flea reproduction and amphipod growth at FR_FRCP1 and LC_DCDS). The magnitude of toxicity observed at FR_FRCP1 in 2021 was lower than in other recent years, possibly reflecting the lower concentrations of major ions (i.e., TDS components and sulphate) measured in site water which have previously been identified as casual factors. The influence of nickel in the Fording River is spatially limited as nickel has not been identified as a contributing factor to observed effects to crustaceans at any stations downstream of FR_FRCP1.
  - At CM_MC2 in Michel Creek, nickel was the only constituent identified as a causal factor for adverse responses observed to crustaceans (i.e., water flea reproduction and amphipod survival and growth). This interpretation is consistent with previous years of water quality and toxicity monitoring. The influence of nickel in Michel Creek is limited spatially, as the crustacean tests at the downstream station (RG_MIDAG) showed improvement relative to CM_MC2.

- High inter-reference variability was identified in Q3 for amphipods and in Q1 for fathead minnow. The variability observed among references for these species increased uncertainty with respect to whether identified responses were representative of an adverse response to test water, or alternatively were a reflection of the background variance in test organism performance due to factors other than water quality.
- Other identified potentially contributing factors were microbes (in one fathead minnow test [Q1] and one rainbow trout test [Q4]) and nitrate (one rainbow trout test [Q4]).

- **Temporal Assessment**—The broad findings of this program were similar to 2020, with most stations exhibiting a low proportion of significant toxicity outcomes, water flea remaining a sensitive indicator for influence of mine-related constituents, and the greatest frequency of mine-related responses observed in the Upper Fording River (FR_FRCP1), in Dry Creek (LC_DCDS), and Michel Creek (CM_MC2). Key findings from the 2021 program, when compared to findings from previous years, are as follows:
  - At FR_FRCP1, there was a trend over time with more frequent and larger responses for water fleas observed from the beginning of monitoring in 2015 until Q1 of 2018. Since that time, although responses still occurred, fewer and smaller magnitude responses for water fleas have been observed. Teck has initiated several actions to better understand and manage water quality in the upper Fording River, including the Swift-Cataract Diversion, and associated improvements in water quality have been observed, including reduction of sulphate and total dissolved solids (TDS). Where toxicological responses at FR_FRCP1 have been historically observed, they appear to be linked to sulphate, TDS, and nickel, although nickel was the only constituent identified as a suspected causal factor in 2021.
  - At LC_DCDS, nitrate was identified as potentially causing observed effects in some tests with water fleas, amphipods, and rainbow trout between 2018 and 2021; this corresponded with an observed increase in nitrate in these years compared to concentrations in previous years. In addition, nickel was identified as potentially causing observed effects in some tests with water fleas and amphipods in 2021 but had not been identified in previous years at this station. Teck has initiated several actions under the AMP Response framework, and submitted the Nitrogen Source Control Plan Annual Report which encompasses water management and blasting practices at LCO related to nitrogen management. In addition, Teck also has initiated the conveyance and supplementation project in LCO Dry Creek which

is intended to improve water quality in Dry Creek in the earliest timeframe possible (pending approval, scheduled to be operational in Q1 2023). Longer-term mitigation to manage water quality in Dry Creek, incorporating water treatment, is being developed by Teck for operation in 2026.

- At CM_MC2, responses to nickel-sensitive crustaceans have been observed in historical testing, and this continued in 2021. However, the frequency and magnitude of toxicity has decreased in recent years (2019 to 2021) relative to 2017 and 2018. There was a pattern of nickel being identified as a potential or likely cause of observed effects in most of these tests. Spatially, nickel concentrations decreased from upstream to downstream in Michel Creek. At the station further downstream on Michel Creek (RG_MIDAG), nickel concentrations were lower relative to CM_MC2 (e.g., average nickel concentration of 5 µg/L at RG_MIDAG compared to 17 µg/L at CM_MC2, for H. azteca tests in 2021) and adverse test responses to crustaceans were reduced. Teck has initiated several actions under the Adaptive Management Plan response framework to better understand and manage water quality in Michel Creek. These actions include:
  - Expanding monitoring at CMm.
  - Initiating studies to support the development of site-specific effects benchmarks for nickel in the Elk Valley.
  - Modifying pit dewatering activities at CMm to minimize the effect of 34 pit pumping on downstream concentrations of nickel and other mine-influenced constituents.
  - Developing nickel tank and non-tank-based removal technology.
  - Evaluating mitigation options for nickel at CMm.
- At other stations, there was no apparent consistent pattern of responses and no clear evidence of causal factors. The elevated incidence of adverse effects to amphipods in Q3 and algae in Q1 and Q4 did not occur in a concentration-dependent manner, are inconsistent with previous patterns, and appear to be related to high inter-reference variability (amphipods) or the systematic depression of responses across varying water chemistries (algae).

Categories for 2021 test results are summarized by test site in Figure TS-2, with a narrative summary for each test site (ordered upstream to downstream) in the bullets below.

- **FR_FRCP1**—This location is on the Fording River downstream of Cataract Creek. Possible and/or likely adverse responses were observed for water flea reproduction (Q1, Q3 and Q4), algal cell yield (Q1), amphipod dry weight (Q3), rainbow trout (Q4) and fathead minnow (Q1). Analysis of correlations between test responses and water quality indicated:
  - Water flea reproduction—nickel was identified as a potential contributor to the observed responses.
  - Algal cell yield—this test was associated with elevated levels of uncertainty due to the systematic depression of cell yield observed in this quarter across test sites despite dissimilar water quality profiles. No water quality constituent could be identified as potentially contributing to the observed response.
  - Amphipod dry weight—this test was associated with elevated levels of uncertainty, as high inter-reference variability was observed in this quarter. No water quality constituent could be identified as potentially contributing to the observed response.

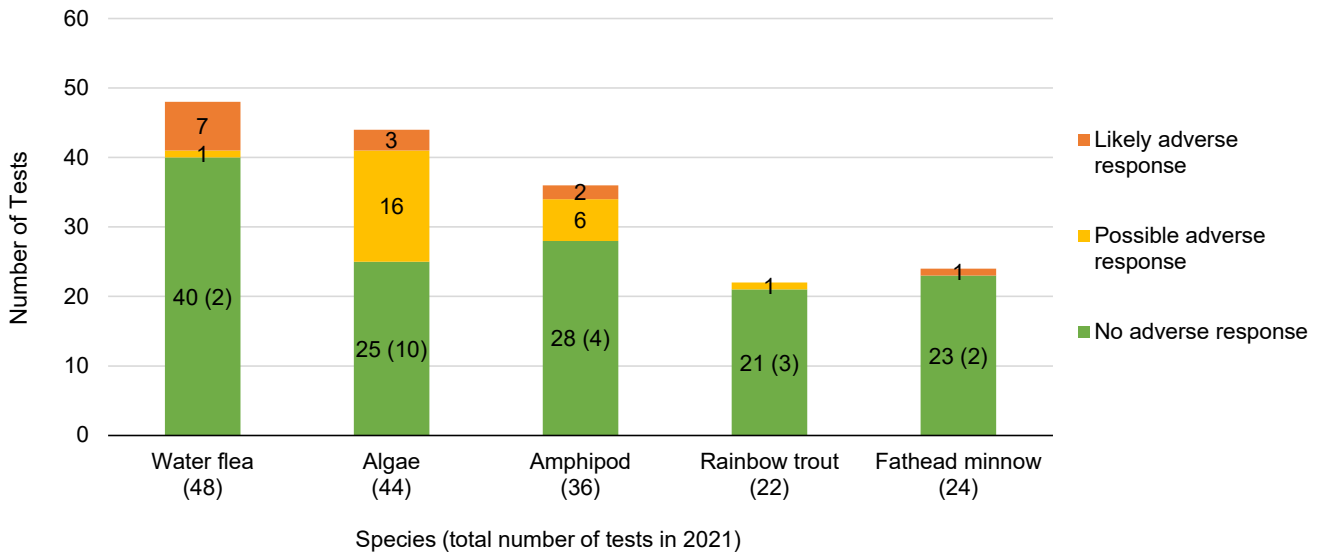
  - Rainbow trout survival—nitrate was identified as potentially contributing to the observed effects in Q4, although there was also evidence of microbial growth in this test.
  - Fathead minnow survival—this test was associated with elevated levels of uncertainty, as high inter-reference variability was observed in this quarter. No water quality constituent could be identified as potentially contributing to the observed responses.

- **FR_FRABCH**—This station, which is approximately 5 km downstream of FR_FRCP1, was added to the program in Q4 2018 to better represent mainstem Fording River water quality and reduce the confounding influence of mid-winter Cataract Creek flows at FR_FRCP1. This station was adopted as the new Fording River Compliance Point in 2021. Possible adverse responses were observed for algal cell yield (Q1) and amphipod dry weight (Q3); however, these responses were observed in tests with elevated uncertainty. The Q1 2021 algal test was associated with an increased uncertainty due to a systematic depression of cell yield observed across test sites despite variability in water chemistries. The Q3 amphipod test also exhibited elevated uncertainty, as high inter-reference variability unrelated to water quality was observed in this quarter. No water quality constituent was identified as potentially contributing to the observed responses.
- **GH_FR1**—This station is on the Fording River downstream of Greenhills Creek. Possible adverse responses were observed for algal cell yield (Q2) and amphipod dry weight (Q3). The Q3 amphipod test exhibited elevated uncertainty, as high inter-reference variability unrelated to water quality was observed in this quarter. No water quality constituent was identified as potentially contributing to the observed responses.
- **LC_LC5**—This station is on the Fording River downstream of Line Creek. Likely or possible adverse responses were observed for algal cell yield (Q1, Q2, and Q4) and amphipod dry weight (Q3); however, these responses were observed in tests with elevated uncertainty. The Q1 and Q4 2021 tests for algal cell yield were associated with an increased uncertainty due to systematic depression of cell yield observed across test sites despite variability in water chemistries. The Q3 amphipod test also exhibited elevated uncertainty, as high inter-reference variability unrelated to water quality was observed in this quarter. No water quality constituent was identified as potentially contributing to the observed responses.
- **LC_DCDS**—This station is on Dry Creek downstream of the sedimentation ponds. Likely or possible adverse responses were observed for water flea reproduction (Q3 and Q4), algal cell yield (Q1 and Q3), and amphipod dry weight (Q4). The Q1 2021 test for algal cell yield was associated with elevated uncertainty due to systematic depression of cell yield observed across test sites despite variability in water chemistries; no water quality constituents were identified as potentially contributing to the observed responses in algal tests. Nickel and nitrate were identified as potential causal factors in the observed responses in crustaceans in most tests with adverse effects after Q4 2018 This is likely due to the observed increase in nitrate and nickel concentrations compared to previous years.
- **GH_ERC**—This station is in the Elk River upstream of the Fording River confluence. Possible adverse responses were observed for algal cell yield (Q3 and Q4) and amphipod dry weight (Q4). The Q4 2021 test for algal cell yield was associated with elevated uncertainty due to the similar magnitude of adverse responses despite variability across water chemistries. No water quality constituent was identified as potentially contributing to the observed responses.

- **EV_HC1**—This station is in Harmer Creek, which flows into Grave Creek and then into the Elk River downstream of Sparwood. Possible adverse responses were observed for algal cell yield in Q3 and Q4; however, Q4 2021 algal cell yield was associated with elevated uncertainty due to systematic depression of cell yield observed across test sites despite variability in water chemistries. No water quality constituent was identified as potentially contributing to the observed responses.
- **CM_MC2**—This station is on Michel Creek downstream of Corbin Creek. Possible adverse responses were observed for algal cell yield in Q1 and Q4; however, results were associated with elevated uncertainty due to systematic depression of cell yield observed across test sites despite variability in water chemistries. No water quality constituent was identified as potentially contributing to the observed responses in algal tests. Likely adverse responses were observed for water fleas (Q1 and Q4) and amphipods (Q2 and Q3). These two crustacean species are known to be sensitive to dissolved nickel exposure, and multiple lines of evidence have implicated nickel as contributing to adverse responses at this sampling location.
- **RG_MIDAG**— This station, which is approximately 2 km downstream of CM_MC2, is not a permit location but was added to the program to characterize the spatial extent of effects observed in previous CM_MC2 testing. No adverse responses were observed in any quarter for any endpoint.
- **EV_MC2**—This station is located on Michel Creek downstream of Bodie Creek. Possible adverse responses were observed for algae cell yield in Q1 and Q4; however, results were associated with elevated uncertainty due to systematic depression of cell yield observed across test sites despite variability in water chemistries. No water quality constituent was identified as potentially contributing to the observed response.
- **LC_LC3**—This station is in Line Creek downstream of West Line Creek and immediately downstream of the active water treatment facility outfall. Possible adverse responses were observed in Q4 for water flea reproduction and in Q1 for algal cell yield. A likely adverse response was observed in Q2 for algal cell yield. Nickel was identified as a potential contributor to the observed response on water flea reproduction. No water quality constituent was identified as potentially contributing to observed responses in algal tests; Q1 2021 algal cell yield was associated with elevated uncertainty due to systematic depression of cell yield observed across test sites despite variability in water chemistries.
- **LC_LCDSSLCC**—This station is in Line Creek downstream of South Line Creek. A possible adverse response was observed for algal yield in Q4; however, Q4 2021 algal cell yield was associated with elevated uncertainty due to systematic depression of cell yield observed across test sites despite variability in water chemistries. No water quality constituent was identified as potentially contributing to the observed response.

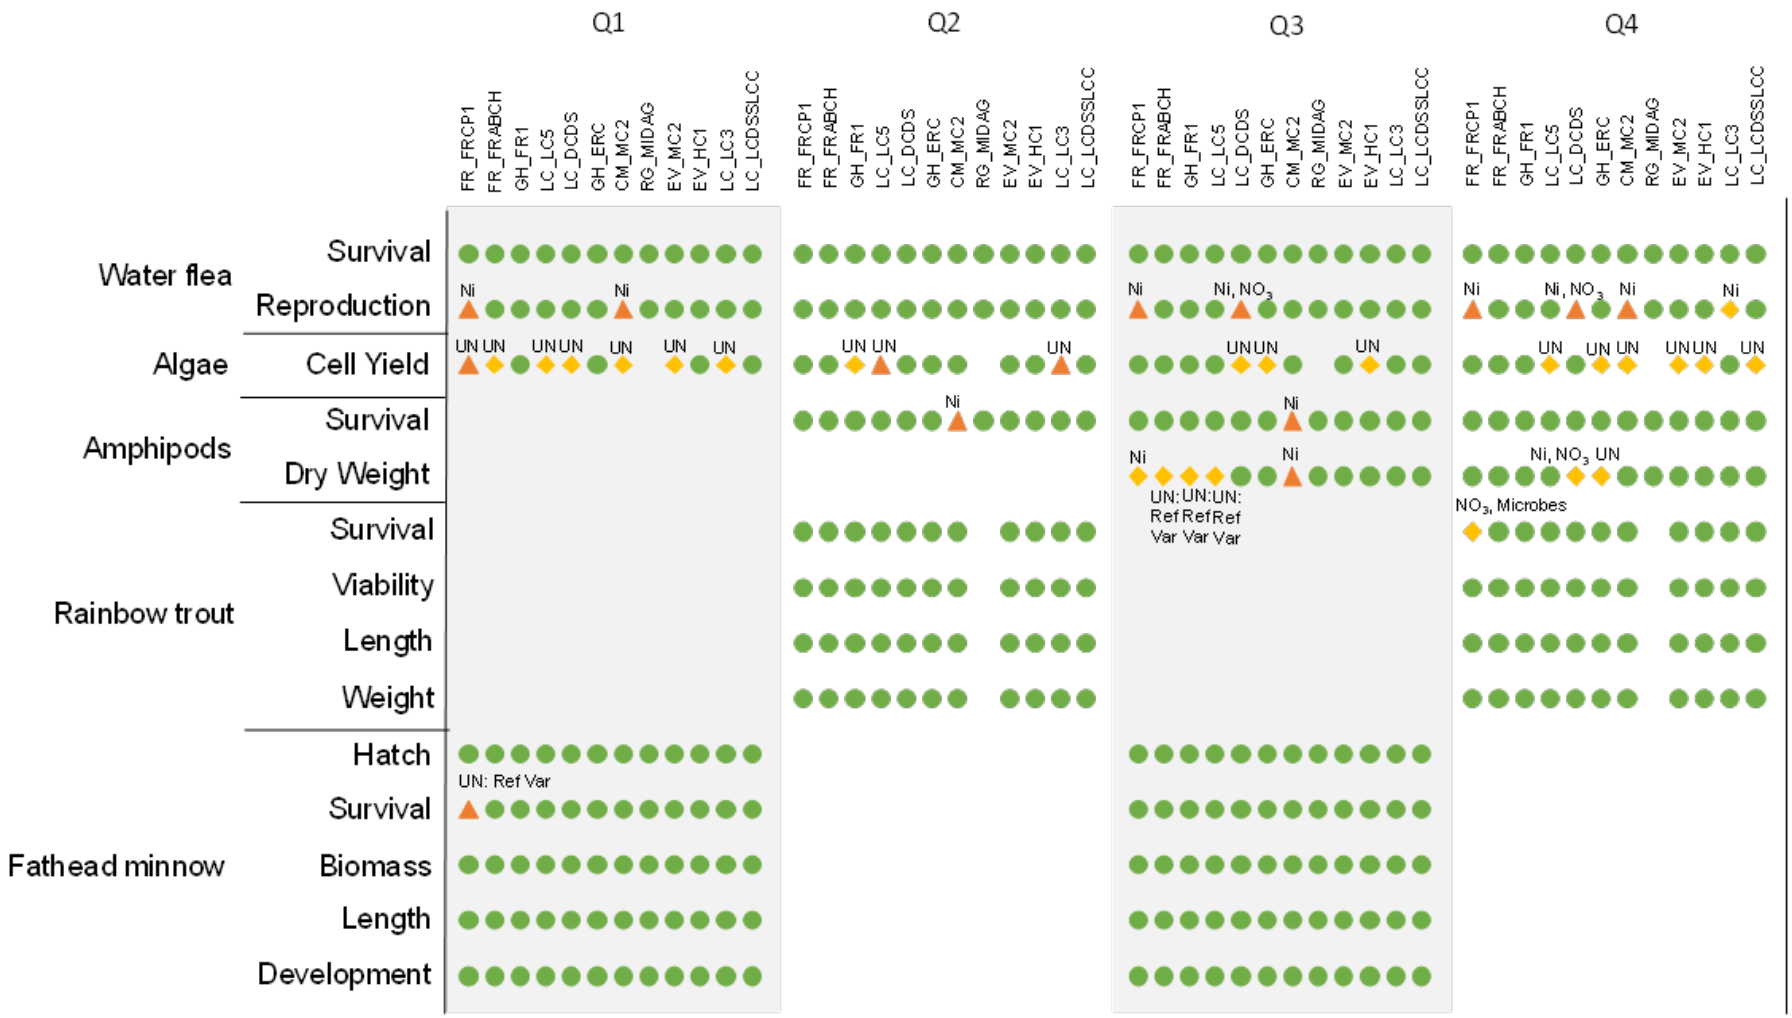
Recommendations from the 2021 testing program include minor refinements to test procedures to reduce confounding factors (i.e., factors that obscure responses to mine-related substances), continuing the recently expanded reference water testing to support interpretation of test water responses, and revisiting the potential contribution of nickel in historical test results using the site-specific benchmarks expected in 2022.

Figure TS-1: Summary of 2021 test results by species.



Note: Results are categorized in Section 3.3.1. The number of tests in each category is provided in bar labels. Values in parentheses are the number of tests with endpoint(s) significantly lower than one or more reference but categorized as no adverse response according to the decision framework in Figure 2.3-1.

Figure TS-2: Summary of Constituents Identified as Potentially Contributing to Observed Responses in 2021



Note: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Due to a lab technician error in the Q2 amphipod test, the Fording River reference was re-tested in Q2 resulting in two sets of survival results for this station (see Section 3.3.1.2). Both results for the Fording River reference in Q2 were categorized as no adverse response and have been combined in this figure. All stations were re-tested in Q3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. Ref Var = high inter-reference variability; Ni = nickel; NO_3 = nitrate; UN = unknown: no water quality constituent was identified. Toxicity Identification Evaluations were conducted to support the causation assessment for water flea and amphipod tests.

Study Limitations

This report was prepared for the exclusive use of Teck Coal Limited. Any use that a third party may make of this report, or any reliance on or decisions made based on it, is the responsibility of the third parties. We disclaim responsibility for consequential financial effects on transactions or property values, or requirements for follow-up actions and costs.

We have relied in good faith on information provided by others as noted. We assume that the information provided is factual and accurate. We accept no responsibility for any deficiency, misstatement or inaccuracy contained in this report as a result of omissions, misinterpretations or fraudulent acts of persons interviewed or contacted.

The services performed as described in this report were conducted in a manner consistent with the level of care and skill normally exercised by other members of the engineering and science professions currently practising under similar conditions, subject to the time limits and financial and physical constraints applicable to the services. The content of this report is based on information collected during our investigation, our present understanding of site conditions, the assumptions stated in this report, and our professional judgement in light of such information at the time of this report. This report provides a professional opinion and, therefore, no warranty is expressed, implied, or made as to the conclusions, advice and recommendations offered in this report. This report does not provide a legal opinion regarding compliance with applicable laws. 1.0 INTRODUCTION

Golder Associates Ltd. (Golder) is pleased to provide Teck Coal Limited (Teck) with the following interpretive report summarizing quarterly and semi-annual chronic toxicity tests undertaken in 2021 for Teck's coal mining operations in the Elk Valley. This study represents the seventh full year of the regional chronic toxicity testing and interpretation to satisfy requirements under Permit 107517 and associated regulatory approvals.

1.1 Objective

The objective of this interpretive report is to present results from the combined 2021 chronic toxicity monitoring program (Permits 107517 and 106970), interpret test results by comparing site water to reference water responses, evaluate correspondence between water chemistry and toxicological responses, and identify recommendations for revision or augmentation of planned future programs. This report is provided to Teck to meet the chronic toxicity related reporting requirements of Permit 107517 Section 8.9.

1.2 Linkages to Broader Monitoring and Management

1.2.1 2021 Chronic Toxicity Testing

Quarterly and semi-annual chronic toxicity testing was conducted in 2021 under two subprograms:

- Regional Chronic Toxicity Testing Program. This subprogram addresses Permit 107517 requirements in Section 8.9 (Appendix A). Species requiring quarterly testing include a cladoceran (*Ceriodaphnia dubia*) and a unicellular green alga (*Pseudokirchneriella subcapitata*). On a semi-annual basis, tests using an amphipod (*Hyalella azteca*; Q2 and Q4), early-life stage rainbow trout (*Oncorhynchus mykiss*; Q2 and Q4), and early-life stage fathead minnows (*Pimephales promelas*; Q1 and Q3) are also required.
- Upper Fording River Chronic Toxicity Study. This subprogram was a special study for 2021 developed in consultation with the Environmental Monitoring Committee (EMC); it addressed Permit 107517 requirements in Section 4D2.5. Testing in 2021 aligned with the study design, which was designed to evaluate the cause, extent, and magnitude of potential chronic effects in the upper Fording River. The upper Fording River study included the same test species and testing frequency as the regional program, except that green alga is not tested.

This report presents the results for the 2021 regional chronic toxicity testing program. Results for the upper Fording River chronic toxicity study are reported in Golder (2022).

1.2.2 Water Quality Adaptive Management Plan for Teck

As required in Permit 107517 Section 10, Teck has developed an Adaptive Management Plan (AMP) to support implementation of the EVWQP to achieve water quality targets including calcite targets. The purpose of the AMP (Teck 2021) is to provide confidence that human health and the environment are protected or restored where necessary, and to facilitate continuous improvement of water quality in the Elk Valley. Following an adaptive management framework, the AMP identifies six Management Questions (MQs) that will be re-evaluated at regular intervals as part of AMP updates throughout EVWQP implementation. Triggers have been identified for specific MQs, which if reached, initiate action under the AMP Response Framework. The AMP also identifies key uncertainties that need to be reduced to fill gaps in current understanding and support achievement of the EVWQP objectives.

The results presented in this report provide information relevant to two of the six MQs and many of the key uncertainties identified in the AMP. Chronic toxicity testing results, along with data collected from other programs, are being used to re-evaluate the answers to MQ2 ("Will the aquatic ecosystem be protected by meeting the long-term Site Performance Objectives [SPOs]?"). Chronic toxicity testing results are also used as a line of evidence in the RAEMP (Minnow 2021) to answer MQ5 ("Does monitoring indicate that mine-related changes in aquatic ecosystem conditions are consistent with expectations?"). Reaching an answer of "no" or "uncertain" to an MQ would lead to action under the Response Framework in the AMP, as discussed further in Section 2.2.2.

Chronic toxicity testing results also assist in reducing key uncertainty (KU) 2.1 ("How will the science-based benchmarks be validated and updated?"), KU 2.2 ("How will the integrated assessment methodology used to derive area-based SPOs be validated and updated?"), and KU 5.1 ("How will monitoring data be used to identify potentially important mine-related effects on the aquatic ecosystem?"). Progress on reducing these key uncertainties, and associated learnings, are described in Annual AMP Reports.

1.2.3 Ecological Implications of Chronic Toxicity Tests

The regional chronic toxicity testing program is one of several programs that Teck conducts to monitor and evaluate potential effects of mining operations in the Elk Valley on aquatic receptors. Chronic toxicity tests are conducted using field-collected waters, thereby providing evidence for potential effects of surface water on aquatic receptors.

As discussed at the February 2022 EMC meeting, chronic fish toxicity results are an important line of evidence in the evaluation of potential effects of mine-related water quality on fish in the receiving environment. For the upper Fording River (UFR), this linkage is particularly important given that the abundance of Westslope Cutthroat Trout *(WCT; Oncorhynchus clarkii lewisi)* adults and sub-adults declined substantially between fall 2017 and fall 2019 (EoC 2021), with population recovery efforts now underway. For Harmer Creek, this linkage is also important in recognition of the WCT recruitment failure (i.e., a negligible number of individuals added to the population) for the 2018 and 2019 spawning-year cohorts and the reduced WCT recruitment in the 2016 and 2017 cohorts (i.e., recruitment was insufficient for population replacement; Thorley et al. 2021.

Ecological implications of chronic toxicity tests with early life stages of fish (rainbow trout and fathead minnow) on fish in the receiving environment depend on several factors, including:

- Timing of chronic embryo-alevin fish tests with seasonal fish development cycles for the corresponding watercourse to identify the quarter(s) when early life stages of fish could be present.
- Spatial and temporal overlap of chronic toxicity testing with fish use information to evaluate how chronic toxicity results overlap with fish distribution.
- Relative sensitivity of embryos/alevins and other life stages. As discussed at the February 2022 EMC meeting, early life stages of fish tend to be relatively sensitive to water quality stressors relative to older life stages (Environment Canada 1998). Therefore, chronic toxicity results for early life stages of fish can be relied upon as a conservative screen for potential effects to other fish life stages; if no adverse response is observed in early life stage tests, then no adverse response would be expected for older life stages. However, because early life stages tend to be relatively sensitive to water quality relative to other fish life stages (Environment Canada 1998), and because spawning of site residents is seasonal, adverse responses for early life stage testing may not be indicative of potential effects to juveniles and adults under field conditions.

- Reliability of test results, including consideration of testing artifacts such as microbial influence. Laboratory conditions are expected to increase the likelihood of accumulation and/or transmission of microbes in chronic toxicity tests in a way that would not be expected to occur in the environment (Section 2.3.3.2).

In the UFR, Dry Creek, and Harmer Creek, WCT is the only fish species present. Early life stages of WCT could be present from mid-May to August in the UFR and Dry Creek and from mid-June to October in Harmer Creek. These windows align with the timing of the Q2 early life stage rainbow trout testing (18 May to 15 June 2021) but not other sampling quarters. Therefore, the Q2 rainbow trout results are considered the most relevant for evaluating potential effects on early life stages of the congenic WCT. In other watercourses within the chronic toxicity program (Elk River, Michel Creek, lower Fording River, Line Creek), there are two or more fish species present with different spawning windows for each species. Given the range of spawning periods observed in these other watercourses, it is possible that early life stages of fish could be present in any month. For these watercourses, the most relevant chronic embryo-alevin fish test result would depend on the species in question and the spawning window in the corresponding watercourse.

The information presented above was used in this report to provide an initial interpretation of the potential implications of the 2021 chronic toxicity results on fish in the receiving environment. A formal evaluation of potential ecological implications of chronic toxicity results will be provided in the next RAEMP report, so that the chronic toxicity results (an indirect indication of aquatic health) can be interpreted in the context of biological monitoring results (a more direct indication of aquatic health).

1.3 Incorporating Feedback from the Environmental Monitoring Committee

Technical advice was provided by EMC members on the 2021 chronic toxicity interpretive report via the February 2022 conference call. Key changes made in response to EMC advice were:

- Evaluated the strength of evidence for microbial contribution in 2021 fish tests. For the 2021 fish tests with microbial observations, responses were compared for replicates with and without microbial observations (Section 2.3.3.2).
- Discussed seasonal trends in microbial occurrences in relation to timing of copper amendments and implementation of the microbial protocol by Nautilus (Section 2.3.3.2)
- Discussed linkages between the timing of quarterly fish toxicity tests and when early life stages may be present in the receiving environment (Section 1.2.3), and the potential implications of adverse effects in chronic fish tests on WCT in the UFR (Sections 3.4, 3.5, 4.0).
- Discussed linkages between the chronic toxicity testing results and the adaptive management plan (Section 1.2.2), including supplemental testing that was conducted as part of the AMP response framework (Section 2.2.2) and actions taken in response to the framework (Section 4.0).
- *P. promelas* normal ranges were calculated with and without Q1 2021 Elk and Michel reference tests, which had anomalously low survival relative to the historical dataset (Section 3.2.3.5).

- Results in 2021 were compared to historical results to identify potential seasonal patterns (i.e., are adverse responses observed in the same quarter and test species in each year?) and to evaluate any consistencies in the concentration-response analysis (i.e., are adverse responses attributed to the same constituents in each year?) (Section 3.4). Although this approach is consistent with previous interpretative reports, the causation assessment was strengthened this year by recategorizing historical results and incorporating historical microbial observations.

1.4 Report Organization

The remaining sections of this report present the methods (Section 2.0) and results (Section 3.0) of the 2021 regional chronic toxicity testing program, including causation assessment and comparisons to previous findings. Following those base findings, an integrated summary of findings (Section 4.0), uncertainty assessment (Section 5.0), and recommendations (Section 6.0) are provided. A summary of the acute toxicity testing conducted in 2021 is presented in Appendix B.

2.0 METHODS

2.1 Field

Water samples were collected from reference locations upstream of mine-related influences and from test sites downstream of mining every quarter or semi-annually in 2021, as shown in Table 2.1-1 and Figure 2.1-1. Water samples were submitted to Nautilus Environmental (Nautilus; Burnaby, BC and Calgary, AB) for toxicity testing (Section 2.2) and to ALS Environmental (Calgary, AB or Burnaby, BC) for chemical analysis. Weekly refresh samples were collected for toxicity tests with exposure duration longer than 7 days. Water samples were submitted for chemical analysis each time samples (whether for test initiation or weekly refresh) were collected. Water collection dates are provided in Appendix B.

Rationales for inclusion of stations in Table 2.1-1 are:

- All four reference stations (FR_UFR1, GH_ER2, CM_MC1, LC_SLC) were incorporated by Teck to provide information on responses in Elk Valley waters for samples upstream of the zone of mine-related influence. The four reference locations are not specified in the Permit but are included to assist with the interpretation of responses observed in mine-influenced waters. Over the last seven years, the breadth of reference water testing has increased, as it has been demonstrated that responses (and associated variation) in reference water are helpful for understanding and interpreting site water responses.
- Eleven of twelve test sites evaluated in 2021 (i.e., all except RG_MIDAG) were included in the integrated chronic toxicity program developed from combined Permit 107517 and Permit 106960 requirements.
- RG_MIDAG is not a Permit location, but rather was incorporated in the integrated chronic toxicity testing program by Teck in 2019 to characterize the spatial extent of nickel effects to invertebrates in Michel Creek (RG_MIDAG).[1,2] This station was added following the AMP Response Framework (see Section 2.2.2 for more details).

[1] In Michel Creek, the station used to characterize the spatial extent of effects was changed from CM_MC3 in 2018 testing to RG_MIDAG in 2019 testing. As discussed at the June 2019 EMC meeting, CM_MC3 was not representative of mainstem Michel Creek in the winter due to an ice jam. Therefore, station RG_MIDAG was selected as a replacement station in consideration of safe access, consistency with the biological monitoring program, and review of aqueous nickel concentrations.

[2] Testing at RG_MIDAG has been primarily conducted with *C. dubia* and *H. azteca* to characterize the spatial extent of potential nickel effects to invertebrates. Because crustaceans are the most sensitive group of test organisms for nickel, effects to fish and algae are not expected at measured nickel concentrations at RG_MIDAG.

Table 2.1-1: Reference Locations and Tests Sites used in the 2021 Regional Quarterly and Semi-Annual Toxicity Testing

Watercourse	Reference or Test Site	Teck WQ Station ID[(a)]	EMS ID	Station Name
Fording River	Reference	FR_UFR1	E216777	Fording River upstream of Henretta Creek.
	Test Site	FR_FRCP1	E300071	Fording River downstream of Cataract Creek.
		FR_FRABCH	E223753	Fording River upstream of Chauncey Creek.
		GH_FR1	200378	Upper Fording River downstream of Greenhills Creek [Order Station FR4].
		LC_LC5	200028	Fording River downstream Line Creek [Order Station FR5].
Dry Creek	Test Site	LC_DCDS	E295210	LCO Dry Creek downstream of sedimentation ponds
Elk River	Reference	GH_ER2	200389	Elk River upstream of Greenhills Operations.
	Test Site	GH_ERC	E300090	Elk River downstream of Thompson Creek.
Michel Creek	Reference	CM_MC1	E258175	Michel Creek upstream of Operations.
	Test Site	CM_MC2	E258937	Michel Creek upstream of Andy Goode Creek.
		RG_MIDAG [(b)]	—	Michel Creek downstream of Andy Goode Creek.
		EV_MC2	E300091	Michel Creek at Highway 3 Bridge.
Harmer Creek	Test Site	EV_HC1	E102682	Harmer Spillway at Elk Valley Operations.
South Line Creek	Reference	LC_SLC	E282149	South Line Creek West Side of Main Rock Drain.
Line Creek	Test Site	LC_LC3	200337	Line Creek downstream West Line Creek and AWTF outfall.
		LC_LCDSSLCC	E297110	Line Creek downstream of South Line Creek.

Reference stations marked with grey highlight.

(a) Stations are listed from upstream to downstream for each watercourse.

(b) RG_MIDAG not part of Permit requirements as of 2021 but added to characterize spatial extent of effects in Michel Creek. No EMS ID is available for RG_MIDAG.

ID = Identification; WQ = water quality; — = no EMS ID.

2.2 Laboratory

2.2.1 Quarterly and Semi-Annual Testing Program

Test organisms and procedures used in the quarterly and semi-annual testing program followed the general requirements outlined in Permit Section 8.9, with only minor refinements (developed over time with the review and endorsement of EMC). An overview of this program is provided in Table 2.2-1. Laboratory reports for each round of quarterly and semi-annual testing are provided in Appendix B, including detailed methodology, raw data, laboratory notes, quality assurance overview, and statistical significance tests, per protocol requirements.

For *C. dubia*, the Environment Canada test protocol specifies that test duration must be 7 ± 1 day, with the test being terminated on the day that at least 60% of control organisms have produced three broods. Both Golder and the toxicity testing laboratory (Nautilus Environmental) have encountered cases where a marginal achievement of the control brood criterion can introduce high uncertainty in the interpretation of the remaining test treatments. To better evaluate potential effects on brood patterns, per discussions with EMC, the 2021 tests were extended to a maximum of 8 days, regardless of the timing of controls reaching 60% with three broods. This test extension was also conducted in 2019 and 2020 testing. In the laboratory reports (Appendix B), the main body of each report contains results per Environment Canada protocol requirements; Appendix A of each laboratory report contains the raw data for both test durations. In this interpretive report, per discussions with EMC, results per standard protocol requirements were used in statistical analyses. This was done to be consistent with reporting in previous years, with comparisons between the two enumeration methods conducted separately. The methods to compare and analyze the two test durations, and corresponding evaluation of differences in timing and quantity of reproductive output, are described in Section 2.3.3, with results presented in Section 3.3.1.1.

Table 2.2-1: Summary of Quarterly and Semi-Annual Toxicity Tests

Test Species	Test Duration [days]	Endpoint(s)	Test Protocol	Number of Replicates per Test	Frequency of Testing
Water flea—*Ceriodaphnia dubia*	7 ± 1[(a)]	Survival and reproduction.	Environment Canada (2007a)	10	Quarterly
Green alga—*Pseudokirchneriella subcapitata* (formerly *Selenastrum capricornutum*, reclassified as *Raphidocelis subcapitata*)	3	Cell yield (growth inhibition).	Environment Canada (2007b)	8 (references and laboratory control); 4 (test sites)	Quarterly
Rainbow trout—*Oncorhynchus mykiss*	30	Survival, viability (which incorporates incidence of deformities), length, dry weight, behaviour[(b)].	Environment Canada (1998) embryo-alevin test	4	Semi-annual
Amphipod—*Hyalella azteca*	28	Survival and growth.	Modified from US EPA (2000), as described in Norberg-King et al. (2014)	5	Semi-annual
Fathead minnow—*Pimephales promelas*	28 days post-hatch[(c)]	Survival, hatch, length, biomass, normal development.	US EPA (1996) and ASTM (2013)	4	Semi-annual

(a) Protocol test duration is 7 ± 1 days, *C. dubia* tests were extended to maximum of 8 days in 2021 tests to evaluate potential brood effect.

(b) The behaviour endpoint is limited to documentation of unusual behaviours, rather than a quantitative endpoint. Permit 107517 also specifies hatching as an endpoint, although hatch rate is not part of the Environment Canada (1998) protocol. The survival endpoint provides an appropriate measure of successful hatch since the test is terminated shortly following hatch (Appendix B).

(c) Test duration is from <24-hour post-fertilization eggs until the organisms reach 28 days post-hatch. Total test duration is usually between 30 and 32 days (James Elphick, pers. comm.).

Table 2.2-2 summarizes the number of tests conducted in 2021 for each test species and station. Following permit requirements, quarterly (*C. dubia* and *P. subcapitata*) and semi-annual (*H. azteca*, *P. promelas*, and *O. mykiss*) chronic toxicity tests were conducted using water collected from 11 of 12 test sites listed in Table 2.1-1, plus additional testing at RG_MIDAG. Laboratory negative control water tests were also conducted for each species and test date, as specified in Appendix B.

For *H. azteca*, semi-annual testing usually occurs in Q2 and Q4. In Q2, tests were conducted as planned and survival data were recorded; however, due to a lab technician error, test organisms were disposed prior to measuring dry weight (see Section 3.1). In response to this, all stations were re-tested in Q3. The upper Fording River (UFR) chronic toxicity study stations were re-tested immediately in Q2, resulting in the Fording River reference (FR_UFR1) being tested for both endpoints (survival and growth) in both Q2 and Q3. The number of tests by station and endpoint is presented in Table 2.2-2.

For some tests, minor amendments of site waters were incorporated to improve the ability of the tests to identify mine-related responses, as distinct from spurious adverse effects caused by a natural biological agent (e.g., microbes causing fungal infections in fish) or lack of nutritional elements for laboratory organisms (e.g., low halides inhibiting crustacean development). These adjustments, which consisted of additional or trace amounts of copper or halides, were carefully designed to avoid introduction of adverse responses—the adjustments reduce variation in test responses without introducing analytical bias.

Per the 18 January 2019 amendment to Permit 107517, *P. promelas* and *O. mykiss* tests in 2021 were conducted in copper-amended water to curtail growth of microbes in site water; this test revision incorporates the outcome of previous investigations of anomalous responses (i.e., sporadic mortality phenomenon). For both fish species, waters were augmented with up to 20 µg/L copper in consideration of key toxicity-modifying factors including water hardness, pH, and dissolved organic carbon (DOC).[3]

[3] Per discussions with EMC on 30 November 2016 and subsequent approval by BC ENV (MoE 2016), non-amended *P. promelas* test results from previous sampling years (2015 and Q1 2016) are not included in the statistical analysis of quarterly test results due to their low reliability for assessing toxicant-based responses.

Table 2.2-2: Summary of Quarterly and Semi-Annual Tests Conducted in 2021[a,b]

Watercourse	Reference [c] or Test Site	Teck WQ Station ID	*C. dubia*	*P. subcapitata*	*O. mykiss* [d]	*H. azteca* [e]	*P. promelas* [d]

Total number of tests per species			**64**	**60**	**30**	**33 (growth) 49 (survival)**	**32**

(a) Stations are listed from upstream to downstream for each watercourse.

(b) Except where noted as "×2", one test was conducted per test species, quarter, and station (i.e., each Q in this table represents one test). Q1 = quarter 1; Q2 = quarter 2; Q3 = quarter 3; Q4 = quarter 4. "—" indicates that the test was neither conducted nor required under Permit 107517 or 106970.

(c) Reference locations (highlighted in grey) are not specified in the Permit but are included to assist with the interpretation of responses observed in mine-related influenced waters.

(d) *O. mykiss* and *P. promelas* tests were conducted using copper-amended samples (Appendix B).

(e) *H. azteca* Q2 test organisms were disposed prior to measured dry weight due to a lab technician error (see Section 3.1), and therefore the initial Q2 tests have only survival data. In response to this, tests were repeated in Q3 for all stations. Stations for the UFR chronic toxicity study (Golder 2022) were repeated immediately in Q2, resulting in FR_UFR1 being tested for both endpoints in both Q2 and Q3.

(f) RG_MIDAG is not currently part of Permit requirements but added to characterize spatial extent of effects in Michel Creek.

—: species not tested.

2.2.2 Toxicity Identification Evaluation and Linkage to Adaptive Management

Findings in chronic toxicity monitoring were reviewed in relation to MQ2 (“Will the aquatic ecosystem be protected by meeting the long-term SPOs?”) and MQ5 (“Does monitoring indicate that mine-related changes in aquatic ecosystem conditions are consistent with expectations?”) of the AMP. Unexpected findings would potentially indicate a “no” or “uncertain” answer to these questions, and therefore prompted an evaluation of potential actions under the AMP Response Framework.

For the 2021 regional chronic toxicity testing program, supplemental tests were conducted to evaluate potential cause(s) of responses observed in FR_FRCP1 tests (Section 2.2.2.1) and CM_MC2 tests (Section 2.2.2.2). Following the AMP Response Framework, Toxicity Identification Evaluations (TIEs) were conducted to investigate the potential cause of adverse responses in FR_FRCP1 tests and to further evaluate the interpretation of nickel as the suspected cause of adverse responses in CM_MC2 tests. To provide context for these supplemental studies, additional information on AMP response actions related to these findings is briefly summarized below and will be discussed further in annual reporting under the AMP.

An overview of methods for supplemental testing and context of related adaptive management responses is provided below. An overview of TIE data analysis in the context of the causation assessment is provided in Section 2.3.4,

2.2.2.1 FR_FRCP1 Adaptive Management Responses

Seasonally variable responses have been observed in previous chronic toxicity testing at FR_FRCP1 (Golder 2021a); this finding has triggered further evaluation and investigation under the AMP response framework. Water quality monitoring data show strong seasonal variation in conditions, which is now understood to reflect a seasonal pattern of subsurface flow in the Fording River. The channel bed of the UFR changes from bedrock near the Fording River Operations South Tailings Pond to alluvial sediments in downstream reaches. Due to greater permeability of alluvial sediments, a portion of the Fording River flow naturally enters subsurface in this area and travels underground for several kilometres before re-emerging as surface flow. The effect of this subsurface flow on surface hydrology (and associated water quality) is most pronounced in winter when flow in the Fording River is lowest.

The effect of subsurface flow on water quality in the UFR is to reduce the dilution available for inputs of mine-affected tributaries entering the Fording River mainstem. In particular, inputs from Cataract Creek have historically had a pronounced effect on winter water quality at FR_FRCP1, which is located approximately 525 metres downstream of the mouth of Cataract Creek. Water quality at FR_FRCP1 was reported to exceed one or more compliance limits for selenium, nitrate, and sulphate during winter low-flow conditions from 2015 until the Cataract Creek diversion was constructed in August 2019 (discussed further below). Seasonal peaks of mine-related constituents occurred between November and March of each year, reflecting the influence of Cataract Creek inputs (with low or no dilution from upstream surface flow of the Fording River during periods when a relatively large portion of the Fording River flows subsurface).

Given the current understanding of seasonal hydrology and water quality at FR_FRCP1, Teck has initiated several actions:

- First, diversion of Cataract Creek flows upstream to the Swift Creek Ponds was initiated by Teck in August 2019, prior to Q3 testing. This conveyance is ultimately intended to divert Cataract Creek water for treatment through Swift Ponds, but it also prevents discharge of surface flows from Cataract Creek into the Fording River in a reach that seasonally dries. Commencing conveyance prior to constructing the active water treatment facility (AWTF) was proposed as a short-term mitigation action to ameliorate water quality in the reach of the Fording River with low or no winter surface flow [4].
- Second, the Fording River Operations compliance location was relocated from FR_FRCP1 to FR_FRABCH, where the Fording River has returned to surface. The new location better attains the objective of a compliance location to monitor fully mixed conditions in the receiving environment downstream of FRO and captures and reflects all or most point and non-point source discharges from the mine site. FR_FRABCH is immediately upstream of the confluence with Chauncey Creek. Monitoring at this location is expected to reflect mixed Fording River conditions that are less dominated by midwinter flows of Cataract Creek water in the Fording River channel and capture subsurface flow from Kilmarnock Creek that surfaces downstream of FR_FRCP1. Station FR_FRABCH was added to the regional chronic toxicity testing program in Q4 2018, and testing continued at the station in all quarters of 2021, as a better representation of potential effects in mixed Fording River conditions.
- Third, Teck has continued TIE studies in all quarters in 2021 to better understand the potential cause(s) of toxicity at FR_FRCP1. Methods for the 2021 FR_FRCP1 TIE included (Appendix B-6):
  - Treatments were conducted with *C. dubia* and *H. azteca*, which have been shown to be sensitive to some mine-related constituents of potential concern.
  - *C. dubia* water collection dates were April 13 (Q1), May 18 (Q2), August 10 (Q3), and October 12 (Q4). *H. azteca* water samples were collected on a weekly basis between May 18 to June 8 (Q2)[5], August 10 to 31 (Q3 re-test) and October 12 to November 9 (Q4).
  - Treatments were designed to identify whether toxicity was caused by divalent metal cations (using ethylenediaminetetraacetic acid [EDTA] treatment). Treated and untreated samples were tested concurrently, so that any effect of the treatment could be discerned.
  - Results of the Fording River TIEs are discussed in Sections 3.4.1 (*C. dubia*) and 3.4.3 (*H. azteca*).
- Fourth, Teck conducted the 2021 UFR chronic toxicity study (Golder 2022) to evaluate the cause, extent, and magnitude of potential chronic effects in the UFR. This special study was implemented in parallel with the existing regional program for one year to maximize the value of additional data collected above the Swift-Cataract Diversion (FR_FR2 and FR_MULTIPLATE) and below (FR_FR4 and FR_FRRD).

[4] The portion of the Upper Fording River that is primarily subsurface flow varies based on flow conditions and is greatest in winter. In December 2018, the spatial extent of limited surface flow was approximately 2 km (i.e., surface flows reappeared near the confluence with Porter Creek), although most of the subsurface flow returned to surface several kilometres downstream (i.e., closer to Chauncey Creek).

[5] *H. azteca* Q2 test organisms were disposed prior to the measurement of dry weight due to a lab technician error (see Section 3.1). In response to this, all stations were then re-tested in Q3. The UFR chronic toxicity study stations were re-tested immediately in Q2, resulting in the Fording River reference (FR_UFR1) being re-tested in both Q2 and Q3.

2.2.2.2 CM_MC2 Adaptive Management Responses

Adverse responses have been observed in previous chronic toxicity testing at CM_MC2 (Golder 2018), with a general trend of increasing frequency and magnitude of responses in crustacean tests from 2015 to 2019. In addition, biological monitoring in 2015, 2016, 2017, 2018, and 2019 reported reduced abundance of mayflies (a sensitive benthic invertebrate taxon) at Michel Creek downstream of Corbin Creek relative to previous years and relative to upstream portions of Michel Creek. These findings triggered further evaluation and investigation under the AMP response framework.

In 2017, a TIE was initiated to investigate the cause of adverse responses observed in CM_MC2 chronic toxicity tests. Nautilus (2018) identified nickel as the likely cause of toxicity in these tests. This interpretation was supported by:

- nickel toxicity data that indicated a potential for effects on sensitive invertebrate species at concentrations near 5 µg/L, below the BC water quality guideline of 150 µg/L for high-hardness waters (≥ 180 mg/L $CaCO_3$).
- water quality data that indicated the increasing trend in chronic toxicity test responses corresponded with an increasing trend in aqueous nickel concentrations between 2015 (generally ranged from 5 to 15 µg/L) to 2017 (generally ranged from 10 to 45 µg/L; Golder 2018).

As a result of identifying nickel as a potential toxicant in CM_MC2 tests, Teck has initiated several actions:

- First, Teck has expanded monitoring at Coal Mountain Mine (CMm) to better understand and delineate potential effects. Station CM_MC3 was added to the chronic toxicity testing program in Q1 2018 and was replaced with station RG_MIDAG in 2019 (see Section 2.1 for details). RG_MIDAG is not a Permit location but was added to the program to characterize the spatial extent of potential effects in chronic toxicity tests. Biological monitoring was conducted at CMm under the RAEMP between 2015 and 2017. In 2018, monitoring under the RAEMP was expanded to include additional sites in Michel Creek. A formalized local aquatic effects monitoring program (LAEMP) for CMm was developed and implemented in 2019 based on Permit 107517 requirements.
- Second, Teck has continued TIE studies in 2021 to further support the interpretation of nickel as the cause of adverse responses in CM_MC2 crustacean tests. Methods for the 2021 Michel Creek TIE included (Appendix B-7):
  - Treatments were conducted with *C. dubia* and *H. azteca,* which have been shown to be sensitive to nickel.
  - Treatments were conducted using CM_MC2 and RG_MIDAG water. *C. dubia* water collection dates were 13 April (Q1), 18 May (Q2), 10 August (Q3), and 12 October (Q4). *H. azteca* water samples were collected on a weekly basis between 18 May to 8 June (Q2), 10 to 31 August (Q3)[6] and 12 October to 2 November (Q4).

[6] *H. azteca* Q2 test organisms were disposed prior to measured dry weight due to a lab technician error (see Section 3.1). In response to this, tests were repeated in Q3 for all stations. Therefore, Q2 tests have only survival data while Q3 and Q4 tests have both survival and dry weight data.

  - Treatments were designed to identify whether toxicity was caused by divalent metal cations (using EDTA treatment). Treated and untreated samples were tested concurrently, so that any effect of the treatment could be discerned.
  - Results of the Michel Creek TIEs are discussed in Sections 3.4.1 (*C. dubia*) and 3.4.3 (*H. azteca*).
- Third, Teck initiated studies to support the development of site-specific effects benchmarks for nickel in the Elk Valley. This work includes an ongoing series of laboratory-based toxicity studies and desktop data analyses to better understand the toxicity of nickel in Elk Valley waters, the influence of water chemistry factors on toxicity, and to what extent nickel may be contributing to observed effects in the chronic toxicity and biological monitoring programs. The outcome of this work is expected to be a set of site-specific benchmarks that will support evaluation and management of nickel at CMm and throughout the Elk Valley.
- Fourth, Teck has modified pit dewatering activities at CMm to minimize the effect of 34 pit pumping on downstream concentrations of nickel and other mine-influenced constituents. The changes in pit dewatering have reduced peak concentrations of nickel since 2019. This has been associated with a reduction in the frequency and magnitude of chronic toxicity test results in 2019, 2020 and 2021 as compared to 2017 and 2018.
- Fifth, Teck has developed nickel tank and non-tank-based removal technology.
- Sixth, Teck is evaluating mitigation options for nickel at CMm. This evaluation is proceeding in parallel to the toxicity investigation work described in the preceding bullet.

2.3 Data Analysis

Data analyses for 2021 quarterly and semi-annual tests consisted of the following five steps:

- Review and summarize quality assurance/quality control information from laboratory reports to establish that organism performance in the laboratory control water met acceptability criteria for the protocol (Section 2.3.1).
- Address key sources of variance that could affect responses observed in test waters, so that the ability to detect a true toxicological response is improved (Section 2.3.2).
- Categorize 2021 test results as no, possible, or likely adverse response, based on the response size in the test and how the response compares to the typical range observed in local and regional reference waters (Section 2.3.3).
- Conduct a causation assessment to examine potential causes of responses observed in 2021 tests categorized as possible or likely (Section 2.3.4).
- Compare 2021 test results to previous years to identify potential response patterns (i.e., were adverse responses observed in the same quarter and test species in 2021 and previous years) and potential causation patterns (i.e., were adverse responses attributed to the same constituents in 2021 and previous years?) (Section 2.3.5).

2.3.1 Quality Assurance/Quality Control

Laboratory reports for each round of quarterly and semi-annual testing include a quality assurance section (Appendix B). Quality assurance information was reviewed and summarized to establish that organism performance in the laboratory control water met acceptability criteria for the protocol as it pertains to the health histories and sensitivity of the organisms, and that no deviations from test procedures occurred that would influence the reliability of the data.

2.3.2 Sources of Variance

Responses observed in test waters are subject to several sources of variance, including:

- Variation in test organism performance (Section 2.3.2.1).
- Variation in test organism sensitivity to toxicants (Section 2.3.2.2).
- Variation in background water quality characteristics (e.g., environmental and toxicity modifying factors) and their effect on test responses (Section 2.3.2.3).
- Variation in concentrations of toxicants in test waters (Section 2.3.2.4).
- Other random inter-individual variability that manifests as experimental “noise”.

One of the objectives of the quarterly and semi-annual interpretive report is to identify toxicological responses and distinguish these responses from other sources of variance. The ability to detect a true toxicological response is improved when confounding effects of the other sources of variance are minimized. Therefore, the following sections outline the approach used to evaluate and address the first four sources of variance. Addressing the first four sources of variance is expected to substantially improve the ability to identify a true toxicological response; therefore, no methods were applied to estimate other factors contributing to experimental noise.

2.3.2.1 Organism Performance

To control for temporal variation in test organism performance (batch sensitivity) as a potential confounding factor, response data (including reference waters and test waters) were control normalized[7] before performing data analyses. Individual replicate values were control normalized for each species endpoint. The species endpoint means and standard deviations that are presented herein were calculated from the control normalized replicate values. The objective of control normalization was to use control responses to reduce or eliminate variation in test organism performance among test batches, such that the ability to detect a true toxicological response between test site waters and reference waters is improved. Control normalization was implemented for all endpoints except for *P. subcapitata* cell yield, per agreement at the 5 February 2018 conference call with the EMC. *P. subcapitata* cell yield was excluded from normalization because it is largely influenced by the variability in nutrient concentrations and ionic strength of lab water and site water.

2.3.2.2 Organism Sensitivity

To evaluate whether temporal variation in test organism sensitivity was a potential confounding factor, reference toxicant test data were summarized from laboratory reports and compared across test batches. For each test species and endpoint, effect concentrations from reference toxicant tests were expressed as a percentage of the historical mean reference toxicant effect concentration and plotted for visual examination. Values greater than 100% indicate that organisms in that batch are less sensitive relative to the historical mean, whereas values less

[7] $control\ normalized\ response = \left(\frac{site\ water\ response}{laboratory\ control\ response}\right) \times 100$

than 100% indicate organisms are more sensitive relative to the historical mean. Observations of organism sensitivity were conducted by visually assessing whether responses in reference toxicant tests varied above or below the historical mean for an extended period. Organism sensitivity was considered stable if reference toxicant results remained close to the historical mean (i.e., within 15%). Reference toxicant results that deviated farther from the historical mean were evaluated for patterns (e.g., multiple consecutive values above or below the historical mean, temporal trends in sensitivity). As discussed in Appendix B, the sensitivity of organisms used in the toxicity tests is considered appropriate if the mean response in reference toxicant tests falls within two standard deviations of historical results obtained from the laboratory.

2.3.2.3 Background Conditions (Normal Ranges)

To evaluate whether temporal or spatial variation in background water quality and its effect on test responses might be a confounding factor, normal ranges (NRs) were developed for responses in reference waters. For each endpoint, two types of NRs were calculated:

- Local NR—Local NRs were developed separately for each reference location. Each NR was inclusive of findings from multiple batches of tests (e.g., Fording River NR included all tests conducted to date with Fording River reference water).
- Regional NR—The regional NR was inclusive of findings from multiple batches and multiple reference locations (Fording River, Elk River, Michel Creek, and South Line Creek references).

NRs were developed using the combined 2015 to 2021 quarterly results from Elk River and Fording River reference sites, the 2017 to 2021 quarterly results from the Michel Creek reference site, and the 2018 to 2021 quarterly results from the South Line Creek reference site.[8] Per discussions with the EMC at the February 2018 meeting, NRs were defined as the 2.5th to 97.5th percentiles of mean test results (i.e., NRs were intended to identify results that fall at the tails of the distribution, with an overall 5% chance that a randomly selected result would fall outside the NR). Percentiles were estimated using the normal distribution function in Systat^{TM}. For some endpoints, assumptions of normality were not met (i.e., p value <0.05), indicating that a normal distribution may not be appropriate for the dataset. This generally occurred when the sample size was small or the variance in reference test results was low. Because normality was not met in all datasets, NRs in some cases may deviate slightly from the central 95% of the statistical distribution; however, NRs were still considered to be useful to characterize the typical range of responses observed in reference waters. Responses in reference waters tested between 2015 and 2021 were also plotted for visual assessment.

The approach used herein to develop local and regional NRs, as well as the NRs themselves, are based on the cumulative reliable findings to date; each year of monitoring improves the characterization of inter- and intra-station variations for reference waters. The approach and NRs developed herein are expected to undergo refinement with future chronic toxicity testing results. For example, the preliminary NRs based on low sample sizes will be recalculated for future years of monitoring and will achieve the sample sizes required for derivation of reliable NRs.

Per the recommendation in the 2020 report (Golder 2021a), the NRs developed in this year's report were used to re-assign historical test results (2015 to 2020) into narrative categories of no, possible, or likely adverse response (see Section 2.3.3 for more details). This was done to improve interpretation of historical comparisons and amend historical results that were previously classified as "no category".

[8] Reference tests with unreliable results were not included in normal range calculations, as outlined in the results (Section 3.2.3). Discussion of reliable and unreliable results was vetted through EMC prior to finalizing the normal ranges.

2.3.2.4 Variation in Concentrations of Toxicants

To evaluate variation in concentrations of toxicants in test waters, coefficients of variation (CVs) were calculated for mean water chemistry concentrations in the longer duration tests and reviewed to assess variability in weekly concentrations. The CV is a measure of relative variability, calculated as the ratio of the standard deviation to the arithmetic mean. If a concentration was below the reported detection limit, the full detection limit was used. CVs were calculated for *H. azteca*, *O. mykiss*, and *P. promelas* tests, as these are the only tests with weekly refresh samples. *C. dubia* and *P. subcapitata* tests are conducted using water collected on a single day (Section 2.1); therefore, this source of variance is not expected to be a confounding factor for these species.

2.3.3 Evaluation of 2021 Test Results

Per the recommendation in the 2020 report (Golder 2021a), the NRs developed in this year's report were used to re-assign historical test results (2015 to 2020) into narrative categories of no, possible, or likely adverse response. The historical and 2021 test results were evaluated using the following three statistical comparisons:

- **Batch-specific comparison**—Pairwise comparisons of test site responses to reference responses, with analysis limited to batch-specific findings (i.e., test site results for each quarter were compared to all references tested in that quarter). Each quarterly laboratory report includes statistical analyses using CETIS™ (Comprehensive Environmental Toxicity Information System; Tidepool Scientific Software 2013) to identify test sites with mean results statistically significant (p <0.05; herein referred to as 'significantly') lower than the mean response in associated Fording River, Elk River, Michel Creek, or South Line Creek reference waters.
- **Local reference comparison**—Mean test site responses were compared to local NRs. As described in the previous section, local NRs were inclusive of findings from multiple batches at a single reference location. Each test site was paired with the best reference match *a priori* based on geography. When available, test sites were paired with an upstream reference in the same local watershed. If an upstream reference was not available, then the test site was paired with the upstream reference on the watercourse that the tributary flows into (e.g., Dry Creek is a tributary of Fording River, so the Fording River reference was used for LC_DCDS). Pairings are provided in Table 2.3-1.
- **Regional reference comparison**—Mean test site responses were compared to regional NRs. As described in the previous section, regional NRs were inclusive of findings from multiple batches and multiple reference locations.

Table 2.3-1: Reference and Test Site Pairings used in the Local Normal Range Comparison

Test Site	Local Reference Comparison	Rationale
FR_FRCP1	Fording River (FR_UFR1)	Reference is located on the same watercourse.
FR_FRABCH[(a)]		
GH_FR1		
LC_LC5		
LC_DCDS		LCO Dry Creek is a tributary to Fording River
GH_ERC	Elk River (GH_ER2)	Reference is located on the same watercourse.
EV_HC1		Harmer Creek (via Grave Creek) is a tributary to Elk River.
CM_MC2	Michel Creek (CM_MC1)	Reference is located on the same watercourse.
RG_MIDAG[(b)]		
EV_MC2		
LC_LC3	South Line Creek (LC_SLC)	Reference is located on the same watercourse.
LC_LCDSSLCC		

(a) FR_FRABCH has been adopted as the Fording River permitted site as of March 2021.
(b) RG_MIDAG is not part of Permit requirements as of 2021 but added to characterize spatial extent of effects in Michel Creek.

Test site results were categorized as no, possible, or likely adverse response according to the methods in Figure 2.3-1. Categories for 2021 test results were presented by test species and test site. Test results were interpreted as follows:

- A test was considered to reflect **no adverse response** if the mean result was:
  - not significantly lower[9] than any reference in the batch (per statistical comparisons in laboratory reports [Appendix B]) or
  - significantly lower than one or more references in the batch but within the local NR and mean effect size[10] was less than 20%
- A test was considered to reflect a **possible adverse response** if the mean result was significantly lower than one or more references in the batch, but was:
  - within the local NR and the mean effect size was between 20 and 50% or
  - below the local NR but within the regional NR

  Tests in this category were considered to have uncertainty regarding whether the result represents an adverse response to toxicants in the test water or alternatively may reflect variance in test organism performance related to background water quality.
- A test was considered to reflect a **likely adverse response** if the mean endpoint result was significantly lower than one or more references in the batch and:
  - within the local NR but the effect size was greater than 50% or
  - below the regional NR

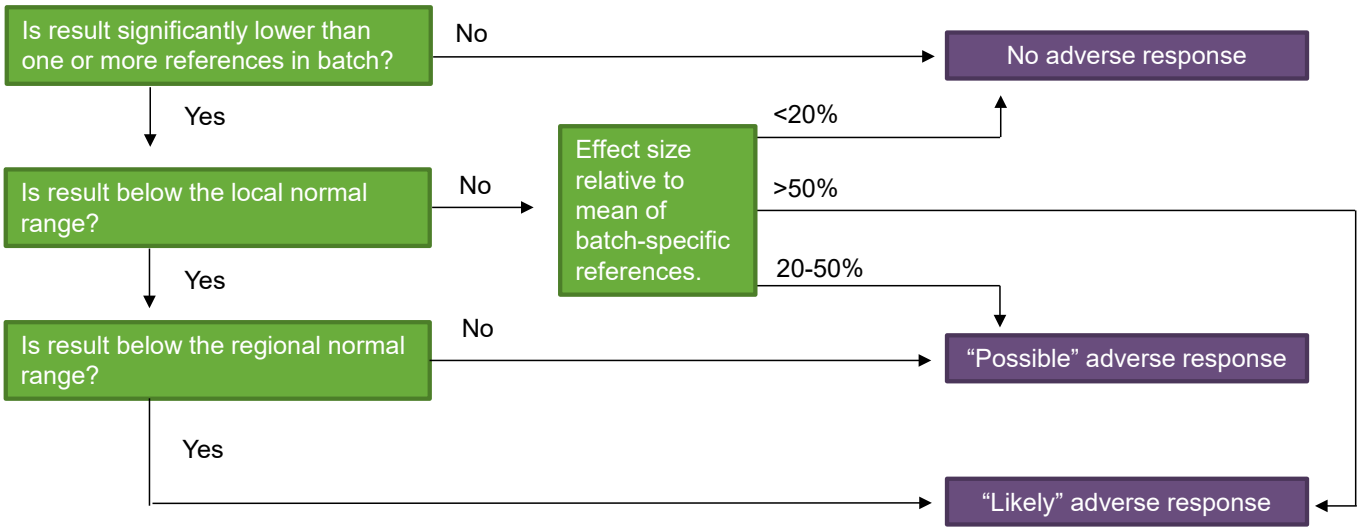
Any endpoint categorized as a possible or likely adverse response in one or more tests conducted in 2021 was carried forward to the causation assessment (Section 2.3.4). If an endpoint was carried forward, then all available tests for that endpoint were included in the concentration-response analysis (i.e., tests conducted with reference and test site waters between 2015 and 2021).

Although the statistical comparisons to NRs remain the primary basis for classification of test results, the effect size decision point recognizes that there can be different levels of test variance (and statistical power) in individual rounds of testing. The effect size decision rule helps to discern results that are statistically significant but with low magnitude of response from those that are larger in response magnitude. The use of the 50% effect size threshold provides a means of flagging larger responses, but for which the variance in NRs is wide (i.e., low statistical power to identify an adverse response).

[9] Responses are defined as “lower” when the endpoint result is smaller when expressed as the positive aspect of performance (i.e., lower survival, reduced growth, reduced reproduction). In other words, the result is lower when the adverse effect size is greater.

[10] Effect size relative to the mean of batch-specific reference results.

Figure 2.3-1: Decision framework for inclusion of endpoints and constituents in the concentration-response analysis.



Individual replicate and mean results were plotted for all endpoints. Example data plots are provided in Figure 2.3- 2 (individual replicate results) and Figure 2.3-3 (mean results) with annotation to explain how data plots were interpreted in Section 3.3. As shown on Figure 2.3-3 (mean results), local and regional NRs were shown to illustrate the normal range of test organism responses observed in reference waters tested between 2015 and 2021. Test sites were paired with a single reference for comparison to the local NR.

As discussed in Section 2.3.5, mean responses in chronic toxicity tests were plotted over time (2015 to 2021) to compare 2021 responses to previous years. The annotation on Figure 2.3-3 (mean results for 2021) also applies to how data plots were interpreted in Section 3.5 (mean results for 2015 to 2021).

Figure 2.3-2: Example data plot for individual replicate results.

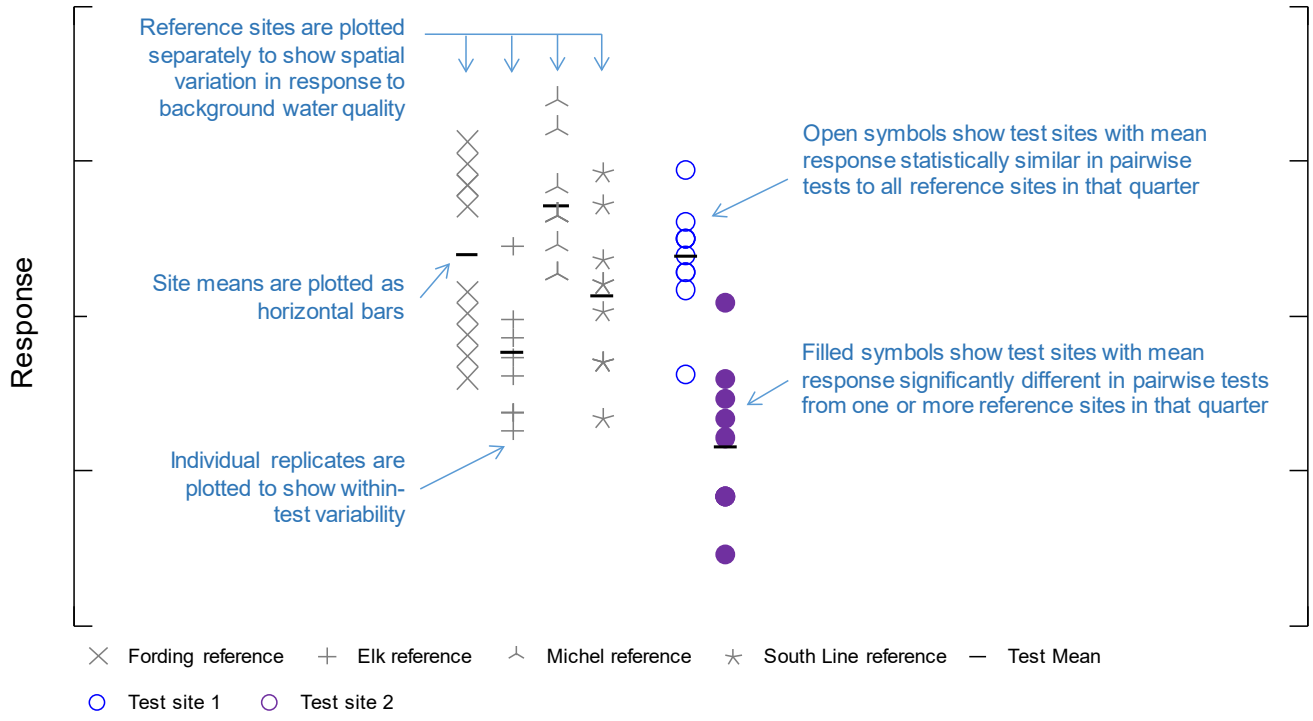


Figure 2.3-3: Example data plot for mean results.

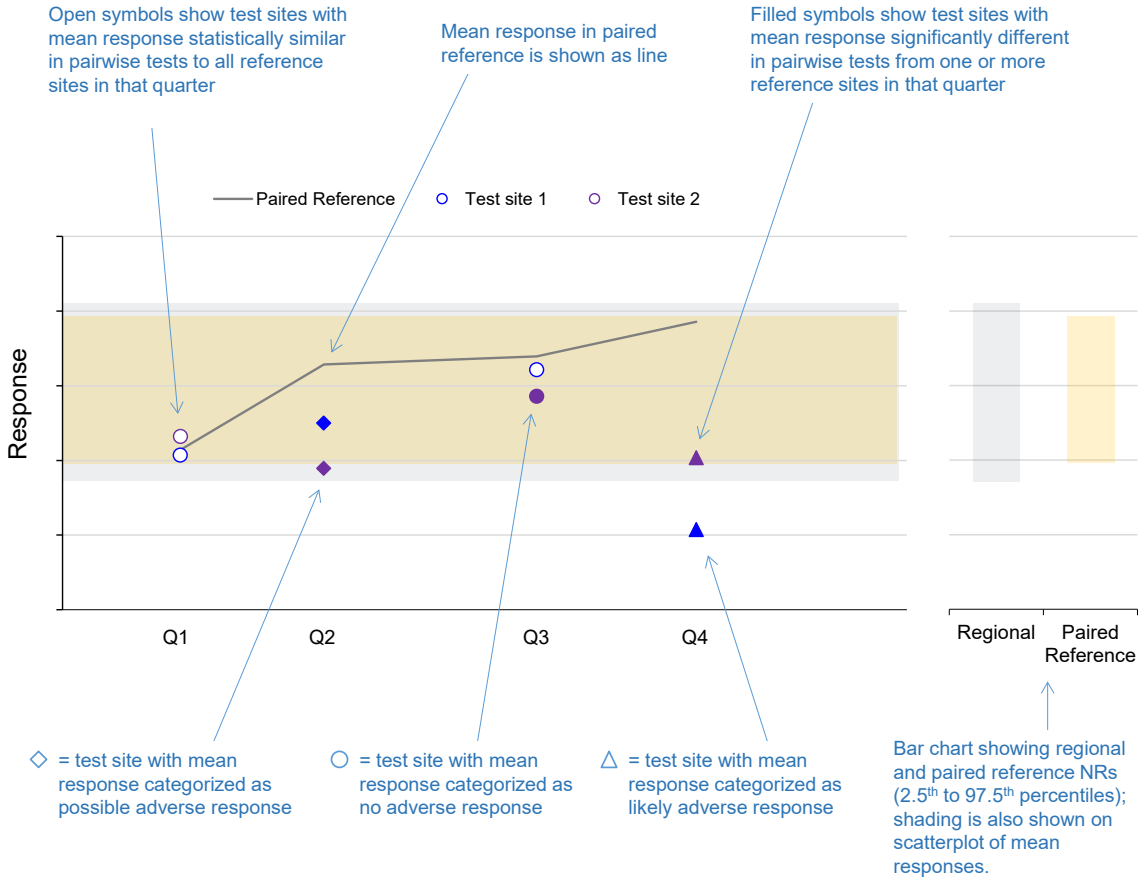


2.3.3.1 Evaluation of *Ceriodaphnia dubia* Broods

Potential implications of the Environment Canada test protocol on *C. dubia* reproduction were discussed with the EMC at the October 2018 meeting, February 2019 conference call, May 2019 meeting, and March 2020 conference call. The *C. dubia* test protocol specifies that the test ends when ≥60% of controls produce three or more broods. This has implications for the chronic toxicity testing program, as the reproductive output in reference and/or test site waters could be biased low by tests being terminated just before the third brood in site waters is counted. The third brood accounts for approximately 50% of the reproductive output (James Elphick, pers. comm.), which means that minor differences in brood output can have a large impact on reproduction results. Furthermore, a minor delay in reproduction, either due to toxicological processes or due to random variations, can cause large variations in enumerated reproductive output. Each replicate that does not produce a third brood prior to test termination could theoretically result in a reduction of the overall reproductive output by 5% (e.g., if zero of 10 replicates have a third brood, then the reproductive output could be reduced by 50%; if two of 10 replicates have a third brood, then the reproductive output could be reduced by 40%, and so on). To evaluate the potential effects on reproductive output, 2021 *C. dubia* testing was conducted two ways based on input from the EMC:

- According to standard Environment Canada protocol (i.e., 7 ± 1 days).
- With results of the test extended to a maximum of 8 days, regardless of the timing of controls reaching 60% with three broods.

The bench sheets for each *C. dubia* reproduction test were tabulated by the laboratory. The number of neonates in the first three broods was recorded for the Environment Canada protocol test termination, and separately for the 8-day test (regardless of what day the third brood was produced). Any reproductive output from a fourth or greater brood was omitted from the data prior to statistical analysis. The proportion of adults producing three broods was also calculated separately for each of the two test variants. An analysis of variance (ANOVA) was used to identify test sites with mean results significantly lower than the batch-specific mean response in associated Fording River, Elk River, Michel Creek, or South Line Creek reference waters in the 8-day tests. The results of the ANOVAs were compared to the batch-specific comparisons conducted by the laboratory on Environment Canada protocol tests to determine if differences in conclusions occurred between the two test terminations.

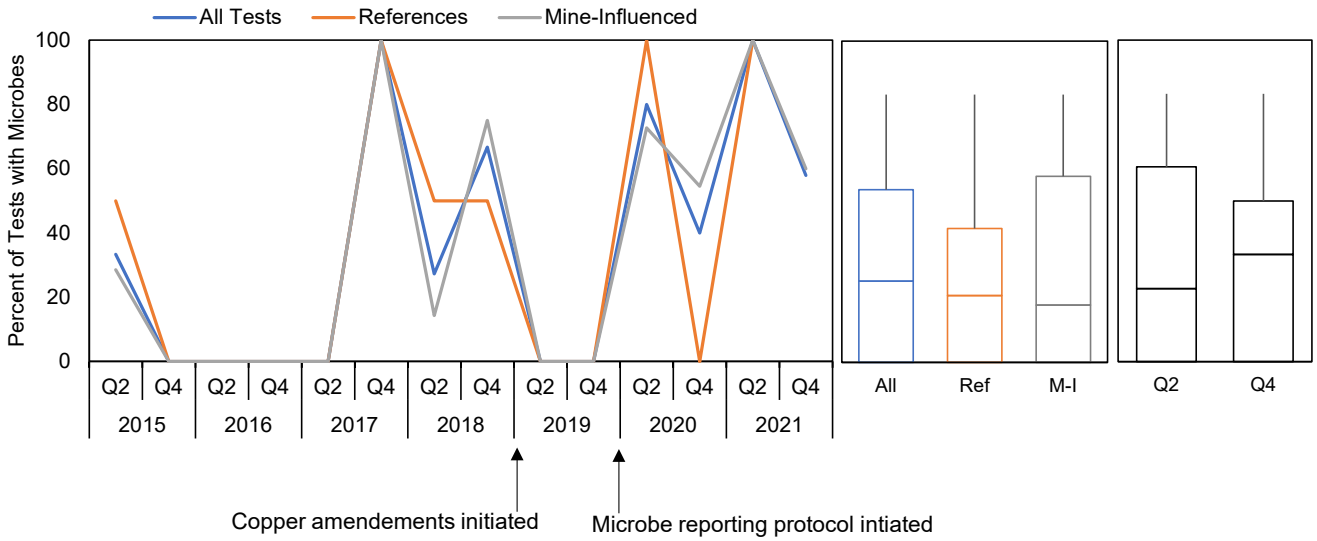
2.3.3.2 Evaluation of Potential Microbial Interferences in Fish Tests

The effects of microbes and fungus in tests with early life stages of *P. promelas* has been well documented in the literature. *P. promelas* are susceptible to adverse effects caused by fungi and/or bacteria, which is recognized as “sporadic mortality phenomenon” (Grothe and Johnson, 1996; Kszos et al., 1997; Downey et al. 2000). This phenomenon typically produces mortality starting as early as day 4 of a 7-day larval stage test, or day 6 of tests beginning with the egg stage and produces high variability in rates of survival among replicates and nonmonotonic dose responses (Downey et al. 2000). In a 32-day survival and growth test, adverse effects associated with microbial growth generally cease by day 13 of the test (Nautilus 2020a). Over the history of the regional chronic toxicity testing program, *P. promelas* tests have been identified as having effects consistent with sporadic mortality phenomenon (e.g., Golder 2021b) and measures have been adopted to reduce the confounding effect of microbes.

Golder is not aware of literature documentation of microbial-related effects to early life stages of *O. mykiss* encountered during laboratory tests. However, fungal or microbial growth has been commonly observed in site-specific testing with early life stages of *O. mykiss* in the regional chronic toxicity monitoring program (e.g., Golder 2021a) and in some cases, survival has been noted by the laboratory to be lower in microbial-affected tests relative to tests without microbial observations. Microbial or fungal growth is typically observed as a white mass of hyphae covering the surface of eggs, or loose aggregations of fungal hyphae may also be observed on the bottom of the test container (Nautilus 2020b). Figure 2.3-6 shows microbial growth observed on *O. mykiss* eggs in Q2 2021 testing.

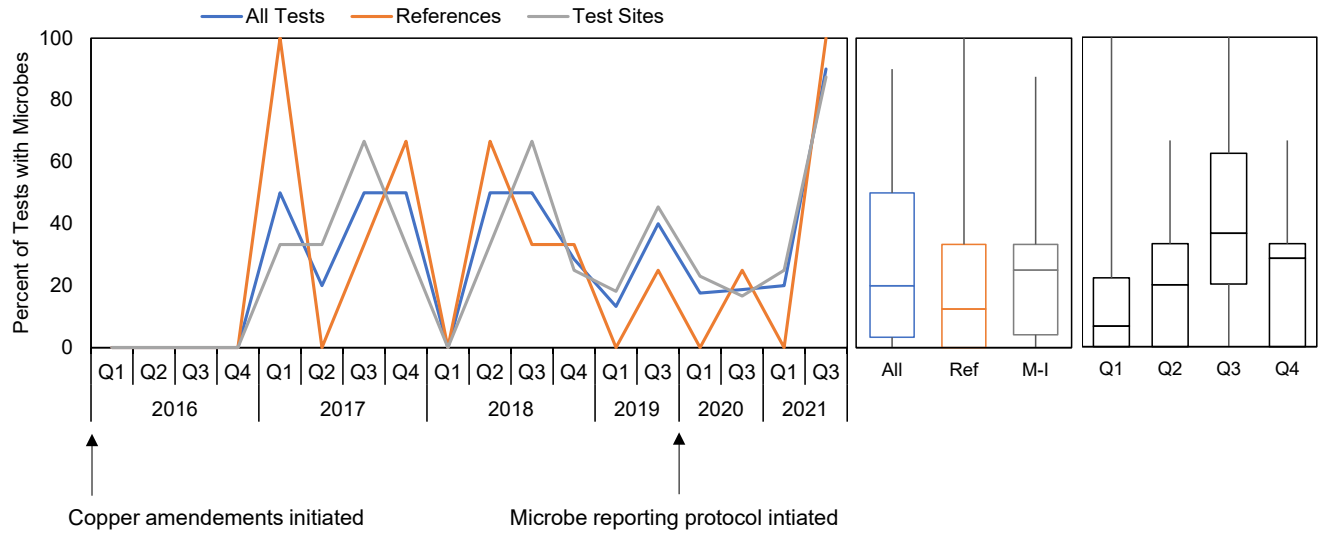
The incidence rate of microbial observations in *O. mykiss* and *P. promelas* tests has been variable from 2015 to 2021 (Figures 2.3-4; Figure 2.3 -5). For a given quarter, the percentage of tests in which microbes were documented in at least one replicate was similar for tests conducted for *O. mykiss* (0% to 100%) and *P. promelas* (0% to 90%); ranges were similar for testing conducted before and after implementation of the formal protocol to document microbial presence. For *O. mykiss*, the variability in microbial influence does not appear to be driven by seasonal influences (i.e., no pattern observed among quarters) or station type (i.e., no pattern observed between reference and test site responses). The incidence rate of microbial observations in *O. mykiss* tests was identical between reference and test site waters (36%). For *P. promelas*, no apparent pattern was identified for station type (reference versus test site); across quarters, there was a trend for a higher prevalence of microbial observations in Q3 relative to other quarters. The incidence rate of microbial observations in *P. promelas* tests was nearly identical for reference (27%) and test site (28%) waters. In aggregate, the microbial incidence rate generally shows a lack of patterns over time, which is not surprising given the sporadic nature of this phenomenon.

Figure 2.3-4: Microbial incidence rate in *O. mykiss* tests between sampling years (left panel), reference versus mine-influenced sites (centre panel), and quarters (right panel).



Notes: In the box plots in center and right panel, the top whisker indicates the maximum, the top of the box indicates the third quartile, the center indicates the median and the bottom of the box indicates the first quartile. Microbes were not documented in the bench sheets for Q4 2017; however, Nautilus concluded that observed effects were consistent with microbial growth (Nautilus 2018a).

Figure 2.3-5: Microbial incidence rate in *P. promelas* tests between sampling years (left panel), reference versus mine-influenced sites (centre panel), and quarters (right panel).



Notes: For the center and right panels, the top and bottom whiskers indicate the maximum and minimum, the top of the box indicates the third quartile, the center indicates the median and the bottom of the box indicates the first quartile. Frequency of microbes in 2015 tests are not available; however, subsequent TIE testing concluded that adverse effects in these tests were likely caused by microbiological components of these samples (Nautilus 2016).

Figure 2.3-6: Microbial growth on *O. mykiss* eggs in Q2 2021 testing (photos provided by Nautilus Environmental).

As discussed at the June 2021 EMC conference call, microbial interferences are expected to be an artifact of laboratory conditions, rather than an environmentally relevant stressor under natural field conditions, based on the rationale provided below. This rationale is summarized from a response to EMC advice received on the March 2021 EMC conference call.

- Laboratory tests have static renewal conditions (daily replacement of ~80% water, with ~20% water carried over during each water renewal), which increases the likelihood of accumulation of microbial loading in a small water volume relative to flushing under site conditions.
- Laboratory tests have several fish exposed in each container, which increases the likelihood of transmission between organisms in an individual replicate relative to unconstrained site conditions. This cross-transmission of microbes often results in strong adverse effects across individual replicates, as the response can spread rapidly in the confined test chamber. Figure 2.3-7 shows an example of a test container for one replicate in an *O. mykiss* embryo-alevin test. Figure 2.3-6 shows a small section of a test container, but the proximity between microbial-affected fish and unaffected fish (at the time of the photo) is evident.
- Laboratory tests tend to have higher temperature, which increases the likelihood of transmission relative to lower temperatures reflective of site conditions.

In summary, laboratory conditions are expected to increase the likelihood of accumulation and/or transmission of microbes within a test replicate in a way that would not be expected to occur in the environment. This is an important consideration when interpreting chronic toxicity test results because inclusion of replicates with microbial observations could introduce a negative bias (i.e., responses identified that would not be observed in the natural environment).

Potential effects of microbes in 2021 fish tests were visually assessed by comparing responses in replicates with and without microbial observations by the laboratory. For *P. promelas*, for which the timing of infection has been well documented (approximately days 5 to 13), the timing of microbial observations was also reviewed to inform the strength of evidence for microbial-related effects. Per discussions at the February 2022 EMC meeting, although several fish tests had microbes identified, these tests were carried forward and included in statistical analyses (e.g., PCA, Spearman Rank correlations).

Figure 2.3-7: Test container for single replicate in *O. mykiss* embryo-alevin testing conducted in Q2 2021 (photo provided by Nautilus Environmental).

2.3.4 Causation Assessment

A causation assessment was conducted to identify potential contributors to adverse responses observed in 2021 quarterly and semi-annual tests. The assessment was conducted for all endpoints for which one or more "possible" or "likely" adverse responses were identified in 2021.

To support this assessment, responses in chronic toxicity tests were paired with matching water chemistry data. The selection of matched (concurrent and co-located) chemistry data depended on the duration of the test, as some tests entailed collection of multiple water samples on a weekly basis with measurements of chemical constituents in each sample. Tests with *C. dubia* and *P. subcapitata* were conducted using water collected on a single day and were paired with water chemistry collected on that day. For other test species, effects data were paired with the mean concentration of the weekly submitted samples collected over the duration of the test.

The causation assessment consisted of five components:

- TIEs (when applicable).
- Comparison of water quality data against water quality guidelines (WQGs) and EVWQP benchmarks.
- Spearman rank order correlations between response and explanatory variables.
- Graphical analysis of concentration-response.
- Identification of potential contributors to adverse responses.

The first four components are used as lines of evidence to support the fifth (combined identification of potential contributors). Components are described in the following sections.

Toxicity Identification Evaluations

The TIE results (Appendices B-6 and B-7) were reviewed and summarized as to whether treatments reduced toxicity (improved response) in TIE testing (Section 2.2.2). If a treatment significantly improved the response relative to the unamended sample, the constituent group associated with that treatment was identified as a potential contributor to toxicity in the unamended sample. For example, if a response was improved in the EDTA- treated sample, then divalent metals were identified as a plausible contributor to toxicity in the unamended sample.

Water Quality Screening

Water chemistry samples collected concurrently with chronic toxicity samples (Section 2.1) were screened against the lowest level 1 EVWQP benchmarks (cadmium, nitrate[11], selenium, sulphate; Teck 2014) or long-term chronic WQGs, hereby referred to as chronic WQGs, and short-term acute WQG, hereby referred to as acute WQG (other constituents; BC ENV 2019b, 2021)[12]. For nitrate and sulphate, Teck has developed updated effect concentrations under the MQ2 project (Golder 2021b) that combines results from spiking studies conducted both before and after the EVWQP; as discussed in Golder (2021c), updated effect concentrations provide an improved understanding of effects to representative species (e.g., *C. dubia*, *O. mykiss*) relative to the EVWQP benchmarks. WQGs derived by BC ENV were used preferentially because BC ENV develops guidelines to be specifically protective of aquatic life in BC. If a WQG was not available, guidelines or probable no effect concentrations derived by the Canadian Council of Ministers of the Environment (CCME) or Environment and Climate Change Canada (ECCC) were used. As discussed in Section 2.3.2.4, CVs were calculated for the mean concentrations and reviewed to assess variability in weekly concentrations. Interpretation of screening results is provided in the last subsection (identification of potential contributors).

Spearman Rank Correlation

Spearman rank order correlations were conducted using paired response and water chemistry data from all reference and test sites.[13] Although correlation does not necessarily indicate causation, the analysis of correspondence between test results and water quality may provide insight into potential causes. The correlation analysis included reference locations and test sites; the analysis was conducted with two datasets: 1) 2015 to 2021 data (inclusive) and 2) 2021 data.

Total concentrations were used for constituents that have a chronic WQG for the total fraction (e.g., zinc) or that lack a WQG (e.g., silicon). Dissolved concentrations were used for constituents with a WQG for the dissolved fraction (e.g., cadmium). Water quality variables were $\log_{10}$ transformed prior to conducting the Spearman rank order correlations.

[11] For nitrate, the Elk River hardness-dependent benchmark equation was used to screen nitrate concentrations from the Elk River reference site, GH_ERC, EV_HC1, and EV_MC2. The Fording River hardness-dependent benchmark equation was used to screen nitrate concentrations from the remaining reference and test sites.

[12] Nickel was screened against the interim level 1 screening value (5.3 µg/L), which is based on potential effects to invertebrates.

[13] Some *P. promelas* and *O. mykiss* tests were excluded from the Spearman rank correlation due to evidence of microbial growth in tests prior to 2021, or quality assurance/quality control criteria were not met in tests, per rationale provided in annual interpretive reports.

Correlations were also conducted using responses paired with principal components (PCs) identified via principal component analysis (PCA) of water quality data, and responses paired with the sum of toxic units (∑TU). The objective of this analysis was to test whether responses could be explained by an overall indicator of mine water influence on water quality (PCA) or mixture effects (∑TU), in addition to testing individual water quality constituents. These explanatory variables are explained further in the following bullets:

- A PCA is a multivariate analysis technique used to describe patterns of inter-correlations among variables of interest. It calculates dominant components of variance from a matrix of chemical variables to reduce the multidimensional nature of the data while retaining much of the information from the original variables. The PC scores were used in the Spearman rank correlation as an overall indicator of mine water influence on water quality.[14] Water quality variables were $\log_{10}$ transformed prior to conducting the PCA in Systat™. The PCAs were conducted with two separate datasets (i.e., 2021 only, and pooled data from 2015 to 2021) to evaluate whether the relationship between test responses and PCs (i.e., indicators of overall mine influence) differed in 2021 relative to the pooled dataset. For example, if water quality differed slightly in 2021 relative to previous years, then the relationship between test responses and PCs may be different for 2021 relative to the pooled dataset. For each PC, component loadings (i.e., the water quality constituents that are strongly correlated with the PC) were reviewed to identify similarities and differences between the two datasets.
- The ∑TU is an exposure metric for mixtures. For each constituent in the mixture with a WQG, the measured concentration was divided by the chronic WQG to calculate toxic units (TUs). If a chronic WQG was not available, the short-term WQG was used. Where total and dissolved guidelines were available (i.e., iron), the total guideline was used because total concentrations were above WQGs more frequently than dissolved concentrations. For nickel, because recent studies conducted by Teck have indicated potential effects attributable to nickel at concentrations lower than the WQG, 5.3 µg/L was used in the denominator[15]. Calculated TUs for all constituents in the mixture were summed. The TUs for each mixture was calculated two ways: 1) using the WQG in the denominator (i.e., as described above) and 2) using the lowest level 1 benchmark from the EVWQP in the denominator (Teck 2014; applies to sulphate, nitrate, and dissolved cadmium). Per discussions with the EMC at the 5 February 2019 conference call, selenium was excluded from the ∑TU calculation because benchmarks reflect bioaccumulation-based exposures over long periods and not direct toxicity in standardized toxicity tests. The ∑TUs were conducted with separate datasets (i.e., 2021 only versus pooled 2015 to 2021) to evaluate whether the relationship between test responses and ∑TUs (i.e., indicators of potential mixture effects) differed in 2021 relative to the pooled dataset.

[14] The number of PCs retained for correlation analysis was determined from the inflection point of a plot of eigenvalues (the PCA "'scree plot"). The PCs were retained if they had an eigenvalue greater than 1 and were in the steep portion of the scree plot to the left of the inflection point. The PCs with eigenvalues less than 1 and/or to the right of the inflection point are relatively uninformative in terms of patterns of covariation among water quality variables.

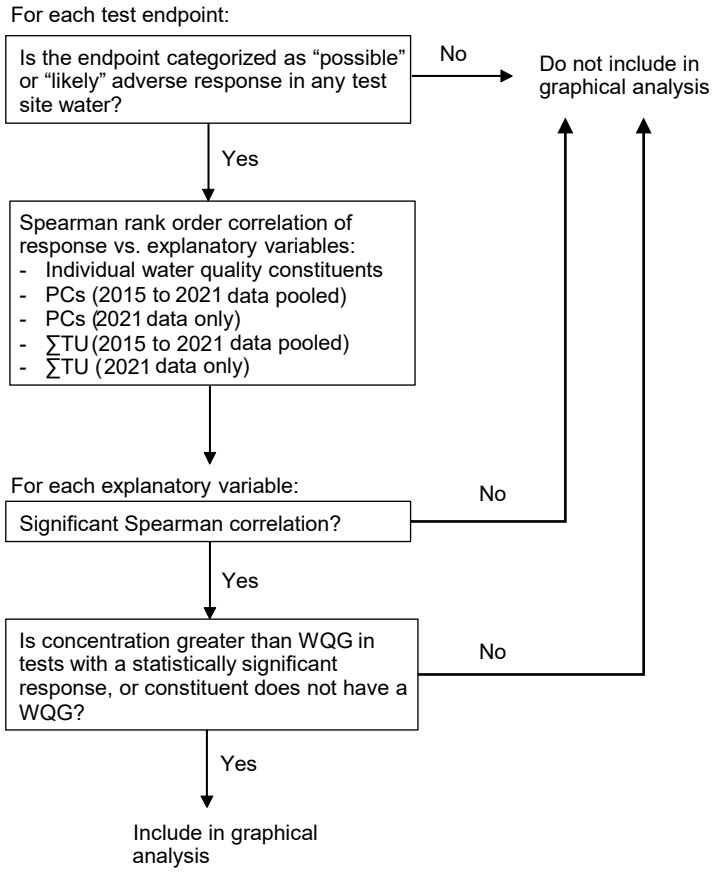
[15] Per concurrence at the March 2019 EMC meeting, the interim screening value of 5.3 µg/L was used herein. This value corresponds to the lowest level 1 screening value used in recent aquatic health assessments conducted for Teck in the Elk Valley. This value could change pending further evaluation of site-specific toxicity data.

Per discussions during the March 2020 EMC conference call, a *p* value of 0.005 was used to identify constituents that could potentially be explanatory variables in the causation assessment. Because of the large number of correlation analyses being conducted (more than 50 per endpoint), there is an inflated chance of obtaining a significant result by chance (i.e., spurious significant outcomes due to simultaneous multiple comparisons). The potential for spurious correlations is also affected by the generally high degree of covariance among water quality variables in mine-influenced water. Therefore, the statistical significance results presented herein should be interpreted as indicative of a potential relationship between test responses and water quality, not strong evidence that a relationship exists. A Spearman rank correlation coefficient of 0.4 was used herein to identify potential explanatory variables with strong correlations for discussion purposes, except for *C. dubia* where 0.6 was used to capture patterns relative to species specific results.

Graphical Analysis

Figure 2.3-8 outlines how the screening against WQGs and EVWQP benchmarks and Spearman rank correlation were used to identify explanatory variables for graphical analysis.

Figure 2.3-8: Decision framework for inclusion of endpoints and explanatory variables in the graphical analysis.



Note: Order constituents are screened against lowest level 1 EVWQP benchmarks, nickel is screened against the interim screening value of 5.3 µg/L per concordance at the March 2019 EMC meeting, and all other constituents are screened against applicable WQGs. WQG = water quality guideline; PCs = principal components; ∑TU = sum of toxic units.

For constituents with significant correlations, screening results in tests categorized as possible or likely were reviewed. Constituents with concentrations lower than the chronic WQG were not carried forward for graphical analysis.[16] If the concentration was greater than a chronic WQG or if the constituent did not have a chronic WQG, then the constituent was carried forward to the graphical analysis.

Graphical analyses (endpoint responses plotted against explanatory variables) were conducted for all constituents that had statistically significant correlations and that were either greater than a chronic WQG or did not have a chronic WQG. For constituents with hardness-dependent water quality guidelines or benchmarks, a hazard quotient was calculated and plotted to account for test specific hardness, as suggested by the EMC. The EVWQP benchmarks used in the concentration-response plots are receptor-specific, where invertebrate species are plotted using the level 1 invertebrate benchmark and fish species are plotted using the level 1 fish benchmarks. *P. subcapitata* was plotted with the lowest level 1 benchmark. The PC scores and ∑TUs with statistically significant correlations were also included in the graphical analysis as a combined indicator of exposure to mine-influenced water (PC scores) or a combined indicator of potential mixture effects (∑TUs).

For constituents that lack a chronic WQG but are commonly assessed as a component of total dissolved solids (TDS; e.g., calcium), the individual constituents were not plotted; instead, responses were plotted against the concentration of TDS. For *C. dubia*, responses were also plotted against a multi-ion toxicity (MIT) hazard quotient, calculated based on the chronic EC_{20} models developed by Mount et al. (2019).[17] The sulphate and TDS effect concentrations (site-specific) and MIT effect concentrations (literature-based) are alternative ways of characterizing effects of major ion mixtures.[18] Therefore, these are alternative ways to evaluate the contribution to toxicity from the same set of ions, calculated either from the concentration of the major anion (sulphate), cations (calcium and magnesium), or osmolarity (cations and anions that comprise TDS).

Concentration-response plots were visually examined to assess the consistency of correspondence between constituent concentrations and test responses. A consistent concentration-response relationship is visually apparent when there is broad overlap in responses measured in different tests but at similar concentrations.

Identification of Potential Contributors to Toxicity

Results from TIEs, screening against WQGs and EVWQP benchmarks, Spearman rank correlations, and graphical analysis were reviewed together for each test categorized as a possible or likely adverse effect to identify potential contributors to adverse responses.

[16] Nickel was an exception to this rule because recent studies conducted by Teck have indicated potential effects attributable to nickel at concentrations lower than the WQG.

[17] Mount et al. (2019) developed two sub-models: 1) a sub-model developed to characterize general ion toxicity, and 2) a sub-model developed to characterize calcium and magnesium specific toxicity. Because of the observed independent action between magnesium-specific and general ion toxicities, these sub-models were formulated and applied separately, and whichever indicated greater toxicity was applied for an exposure of interest (Erickson et al. 2018; Mount et al. 2019). That is, hazard quotients were calculated for both sub-models and the higher of the two values (i.e., greater effect at a given exposure) was used.

[18] The site-specific sulphate testing (and the resulting sulphate and TDS effect concentrations) has evaluated toxicity of multiple ion mixtures that include sulphate, its counter-ions, and the hardness and alkalinity conditions under which high sulphate concentrations occur in the Elk Valley. Sulphate was introduced into test solutions as calcium sulphate and magnesium sulphate in a calcium-to-magnesium ratio that is comparable to that observed in the Elk Valley. Thus, the effect concentrations from site-specific testing studies reflect effects of site-relevant ion mixtures.

For water quality, a specific constituent in a test categorized as possible or likely toxicity was considered unlikely to cause the observed effects, provided that:

- The measured concentration was lower than concentrations measured in reference tests and tests categorized as no adverse response; or
- the WQG or lowest level 1 EVWQP benchmark for the constituent (if available) was not dependent on modifying factors (e.g., hardness).[19]

Conversely, to evaluate whether the constituent could be contributing to observed effects, published toxicity data were reviewed if a constituent in a test categorized as possible or likely had a measured concentration higher than:

- Concentrations measured in reference tests and tests categorized as no adverse response and greater than WQG or lowest level 1 EVWQP.
- Concentrations measured in reference tests and tests categorized as no adverse response and where no WQG is available.

Explanatory variables (i.e., water quality variables, ∑TUs, PC scores) identified as having statistically significant Spearman rank correlations and/or exhibited consistent exposure-response relationship in the graphical analysis were discussed for tests categorized as possible or likely to determine if they potentially contributed to toxicity.

2.3.5 Comparison of 2021 Results to Previous Years

Similarities and differences between test results in the 2021 program and previous programs (2015 to 2020) were summarized, focusing on the incidence of adverse responses by season and station. The objectives for this comparison were to identify potential seasonal patterns (i.e., were adverse responses observed in the same quarter and test species in 2021 and previous years?) and potential causation patterns (i.e., were adverse responses attributed to the same constituents in 2021 and previous years?). Results were summarized by test species/endpoint and test site, as described below.

To summarize by test species and endpoint, mean responses in chronic toxicity tests were plotted against time for all endpoints. Responses were control normalized for all endpoints except *P. subcapitata* cell yield (Section 2.3.2.1). Local and regional NRs, developed using the approach described in the Section 2.3.2.3, were shown on plots to illustrate the normal range of test organism responses observed in reference waters tested in 2015 to 2021 inclusive. As was done for 2021 test results (Section 2.3.3), test sites from previous years were paired with a single reference for comparison to the local NR. Therefore, four plots were made for each endpoint. Regional NRs were shown on all plots. An example data plot is shown in Figure 2.3-3 (2021 responses) and is annotated to explain how plots were interpreted in Section 3.5 (2015 to 2021 responses). The symbols on each plot indicate whether the mean response was categorized as no (circle), possible (diamond), or likely (triangle). Per recommendations in the 2020 annual interpretive report (Golder 2021a), historical tests were re-evaluated and re-categorized using the NRs developed herein.

To summarize by test site, test categories were plotted against time for all endpoints. The symbols on each plot indicate whether the test endpoint was categorized as no (circle), possible (diamond), or likely (triangle). For tests categorized as possible or likely, symbols are annotated where a potential toxicant was identified.

[19] In cases where the measured concentration of either the dissolved or total fraction was higher than concentrations measured in reference tests and tests categorized as no adverse response, but no WQG or benchmark exists for the respective fraction, the remaining fraction for that constituent was compared to its respective WQG or benchmark.

3.0 RESULTS

3.1 Quality Assurance/Quality Control

Detailed laboratory quality assurance/quality control (QA/QC) information is provided in the Nautilus reports (Appendix B). The following bullets summarize QA/QC information for all quarterly and semi-annual tests:

- Health histories of the test organisms used in the exposures were acceptable and met requirements of the test protocols.
- Water quality constituents remained within ranges specified in the protocol throughout the tests.
- Results of reference toxicant tests fell within the acceptable range for organism performance of mean and two standard deviations based on historical results obtained by the laboratory (i.e., sensitivity of organisms used in the tests was acceptable), except for the following:
  - Q3 *P. promelas* test—The reference toxicant result for survival (LC_{50} = 3.9 g/L sodium chloride) was below the historical two standard deviation range (LC_{50} = 4.1 to 9.7 g/L sodium chloride); this is expected to occur by chance alone in 5% of cases (Appendix B-3). The laboratory investigated the health histories of *P. promelas* and concluded that all testing and culturing procedures were followed appropriately, and the Q3 results were considered by the laboratory to be acceptable.
- There were no deviations from the test methodologies, except for the following:
  - Planned modification to the *C. dubia* test duration—tests were extended to 8 days to support the evaluation of potential brood impacts on reproductive output (see details in Section 2.3.3).
  - Planned modification to the *H. azteca* method—All site waters were supplemented with 25 mg/L chloride and 0.02 mg/L bromide using sodium chloride and sodium bromide according to recommendations of the *Hyalella* Advisory Group (chaired by Chris Ingersoll, United States Geological Survey) (Norberg-King et al. 2014) because low concentrations of these halides are known to impair growth of this species (Appendix B).
  - Planned modification to the *P. promelas* and *O. mykiss* tests—Tests were conducted on copper-amended samples (up to 20 µg/L depending on site-specific toxicity-modifying factors) to reduce potential adverse effects caused by fungi and microbes that have previously been observed in Elk Valley samples (Appendix B).
  - Planned modification to the *O. mykiss* tests—Eggs were exposed using a blocked design (i.e., eggs from one fish were used for replicate A of each test concentration, eggs from the second fish for replicate B, and so on); this approach deviates from the Environment Canada test method, which indicates that the eggs should be pooled prior to testing (Appendix B). This modification is appropriate because it reduces the risk of non-viable eggs affecting the test results (Appendix B). Pooling of eggs without blocking introduces a higher risk that the test will yield a negative control failure, or have a large uncertainty related to inconsistent egg quality that is dispersed throughout the test results (Appendix B). Additionally, eggs are usually pooled from two or more suppliers to decrease the risk of poor-performing egg batches. In Q2 2021, eggs in one of the four replicates were considered non-viable (Appendix B-2). These results were excluded from statistical analyses, thereby leaving three replicates with viable eggs for analysis.

- Unplanned modification to the *C. dubia* water refresh protocol in Q4—On day 7 of the *C. dubia* test, no water replenishment or water quality was performed due to insufficient sample (Appendix B-4). Neonates were still removed, and the test tubes were fed a 3:1 ratio of algae:trout chow and Cerophyl™. This deviation is not expected to influence results of the tests.
- Unplanned modification to the *H. azteca* holding conditions in Q4—Upon arrival of the *H. azteca* organisms, the temperature of the holding water measured between 20.0 to 20.5°C (a change of greater than 3°C during transport) and the dissolved oxygen measured less than 80% (Appendix B-4). The organisms and holding water were acclimated overnight to increase the temperature (to 23 ± 1 °C) and dissolved oxygen percentage. This deviation is not expected to influence results of the tests.
- Unplanned modification to the *H. azteca* testing schedule—*H. azteca* testing was conducted in Q2 and Q4, per Permit 107517. Tests in Q2 were successfully conducted and survival was measured; however, test organisms were disposed prior to measuring dry weight due to a lab technician error. Tests were repeated in Q2 for the UFR chronic toxicity study stations (Golder 2022) and tests were repeated for all stations in Q3.

- Some tests with *P. promelas* and *O. mykiss* exhibited indications of microbial influence, despite addition of copper up to a maximum of 20 µg/L. This was recognized in advance to be a possibility because copper amendment was constrained to avoid toxicity from copper itself. The observation of microbial influence, on its own, does not invalidate a test result, but rather warrants further investigation to evaluate influence on toxicological results. Nautilus identified microbe presence per their protocol for identifying microbes in fish tests (Nautilus 2020a,b):
  - Q1 *P. promelas* tests (CM_MC2)—Microbial growth was observed on one replicate in this test, which was amended with 20 µg/L copper. Instances of microbial growth were observed during a timeframe spanning day 16 to day 18 of testing.
  - Q2 *O. mykiss* tests (all stations)—Microbial growth was observed on one or more replicates of all tests, which were amended with 20 µg/L copper. All fish with observed microbes died during the test period. Instances of microbial growth were observed during a timeframe spanning day 21 to day 29 of testing.
  - Q3 *P. promelas* tests (all stations except EV_MC2 and LC_DCDS)— Microbial growth was observed on all test organisms in one or more replicates of these tests, which were amended with 10 µg/L to 20 µg/L copper. Microbial growth was also observed in the 10 µg/L copper amended laboratory control. Instances of microbial growth were observed during a timeframe spanning day 3 to day 20 of testing.
  - Q4 *O. mykiss* tests (GH_ER2, LC_SLC, FR_FRABCH, FR_FRCP1, GH_FR1, GH_ERC, LC_DCDS, LC_LCDSSLCC)—Microbial growth was observed in one or more replicates of these tests, which were amended with 20 µg/L copper. Instances of microbial growth were observed during a timeframe spanning day 16 to day 27 of testing.

- In the *P. promelas* Q1 test, the Elk River and Michel Creek reference tests had reduced survival, biomass (Michel Creek reference only), and normal development relative to the laboratory control. The laboratory was unable to identify the reason for the poor performance. No microbial observations were reported for these tests, the laboratory control performed well for this endpoint, and the reference toxicant test produced results that were within the acceptable range of performance for *P. promelas*, albeit on the lower end of acceptability (see Section 3.2). Copper amendments in the Elk River (10 µg/L) and Michel Creek (15 µg/L) were below toxicity thresholds for the endpoints with significant reductions, indicating that copper did not contribute to the observed response.[20] Per the February 2022 EMC conference call, Q1 *P. promelas* results for Elk River and Michel Creek reference tests were excluded from statistical analyses herein (e.g., NR calculation, Spearman rank correlations). As a sensitivity analysis, NRs were calculated with and without these tests. However, the NRs that excluded these tests were used to categorize test results. Exclusion of these references made the identification of adverse responses more likely in test site waters but was adopted as a conservative screening approach.

3.2 Sources of Variance in Test Water

3.2.1 Organism Performance

Performance in the negative laboratory control varied by less than 15% between quarters for all species and endpoints, except for *P. subcapitata* cell yield (21%) and *H. azteca* dry weight (45%). For other endpoints, laboratory control performance in 2021 quarterly tests varied from 0% (*C. dubia* survival) to 9% (*P. promelas* survival). Although variability for most endpoints was small, control normalization was used to reduce the variability in test organism performance among 2021 batches.

Raw results and control normalized results (for all endpoints except *P. subcapitata* cell yield) are presented in Section 3.3. Analyses presented herein are based on control normalized results.

3.2.2 Organism Sensitivity

Reference toxicant results from quarterly reports (Appendix B) are plotted in Figure 3.2-1.

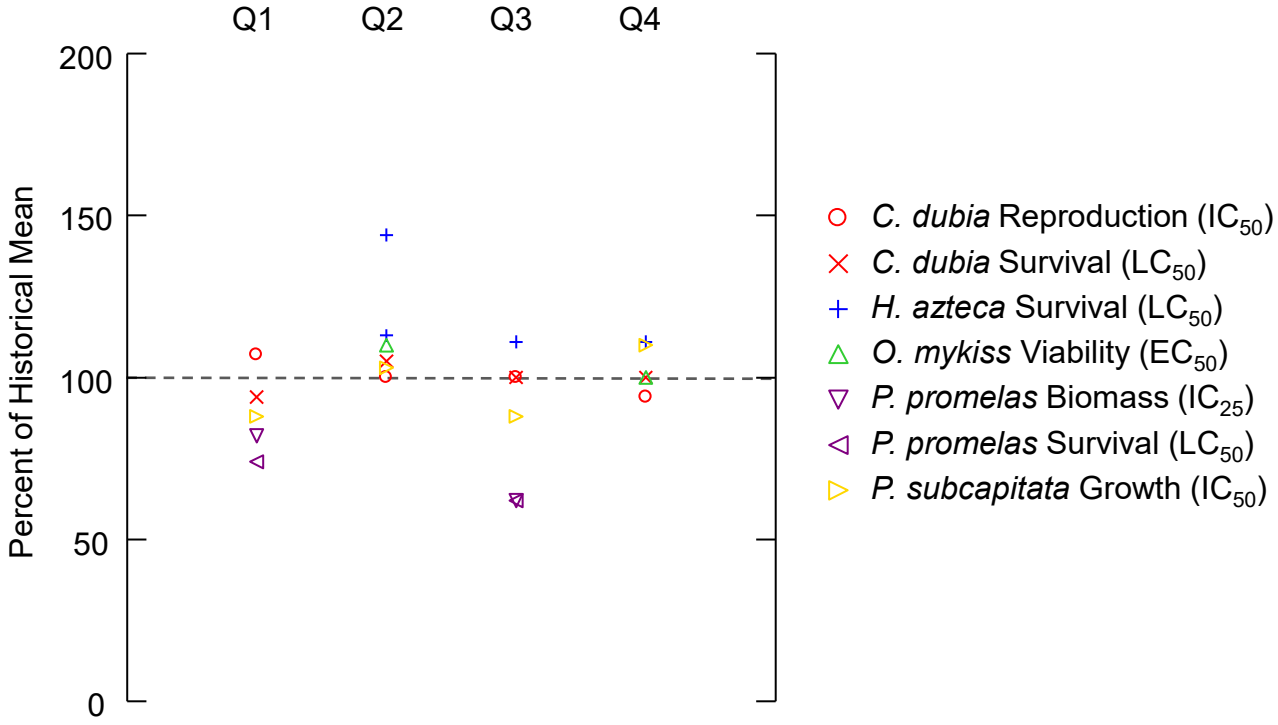
Of the 22 reference toxicant results, 17 tests fell within 15% of the historical mean, indicating that test organism sensitivity was usually stable (Figure 3.2-1). The largest positive deviation from the historical mean was observed in Q2 for *H. azteca* survival (144% of the historical mean) and the largest negative deviation was observed in Q3 for *P. promelas* survival and biomass (both endpoints 62% of the historical mean). All but one of the reference toxicant results were within two standard deviations of the historical mean (which is considered an appropriate sensitivity by the laboratory [Appendix B]); the single exception was *P. promelas* survival in the test initiated on 17 August (Q3). In this test, the LC_{50} for *P. promelas* survival was 3.9 g/L, just outside the range of two standard deviations of the historical mean (4.1–9.7 g/L) which may indicate that organisms used in this test were more sensitive than those used in historical tests. A result this extreme is expected to occur by chance alone in 5% of cases. Most endpoints were not consistently above or below the historical mean, with the exceptions of:

[20] The Brix et al. (2020) pooled, chronic multiple linear regression model for copper was used to estimate copper effect concentrations for fathead minnow by adjusting toxicity data reported in Besser et al. (2005) to sample-specific hardness, DOC, and pH (the average measured by Nautilus in the toxicity test). In the Elk River test, the copper amendment of 10 µg/L was equal to the growth maximum allowable toxicant concentration (MATC) of 10.3 µg/L and approximately two times below the no-observed effect concentration for survival of 19.9 µg/L; in this test, significant effects were observed for survival only. In the Michel Creek test, the copper amendment of 15 µg/L was below the growth MATC of 17.2 µg/L and the survival NOEC of 40 µg/L; in this test, significant effects were observed for growth and survival.

- *H. azteca* survival, which was above the historical mean in Q2, Q3, and Q4, but remained within two standard deviations.
- *P. promelas* biomass and survival, which were below the historical mean in both Q1 and Q3. Results for biomass remained within two standard deviations for both Q1 and Q3. Results for survival remained within two standard deviations for Q1. However, as discussed above, results for Q3 were below the range of two standard deviations of the historical mean (4.1–9.7 g/L).

Overall, variation in test organism sensitivity does not appear to be a confounding factor in the interpretation of toxicity testing results among test batches.

Figure 3.2-1: Reference toxicant data from 2021 laboratory reports (Appendix B).



Notes: IC_{50} = concentration resulting in 50% inhibition; IC_{25} = concentration resulting in 25% inhibition; LC_{50} = concentration resulting in 50% lethality; EC_{50} = concentration resulting in 50% effect. Dashed line indicates reference toxicant result is equal to the mean historical effect concentration.

3.2.3 Background Conditions (Normal Ranges)

As outlined in Section 2.3.2.3, local and regional NRs were developed for mean responses in reference waters. Development of NRs was intended to address potential confounding effects of background water quality and its effect on test responses. The following sections present the results of the evaluation of background conditions for each endpoint, concluding with a statement on how the reference responses may influence the interpretation of test responses.

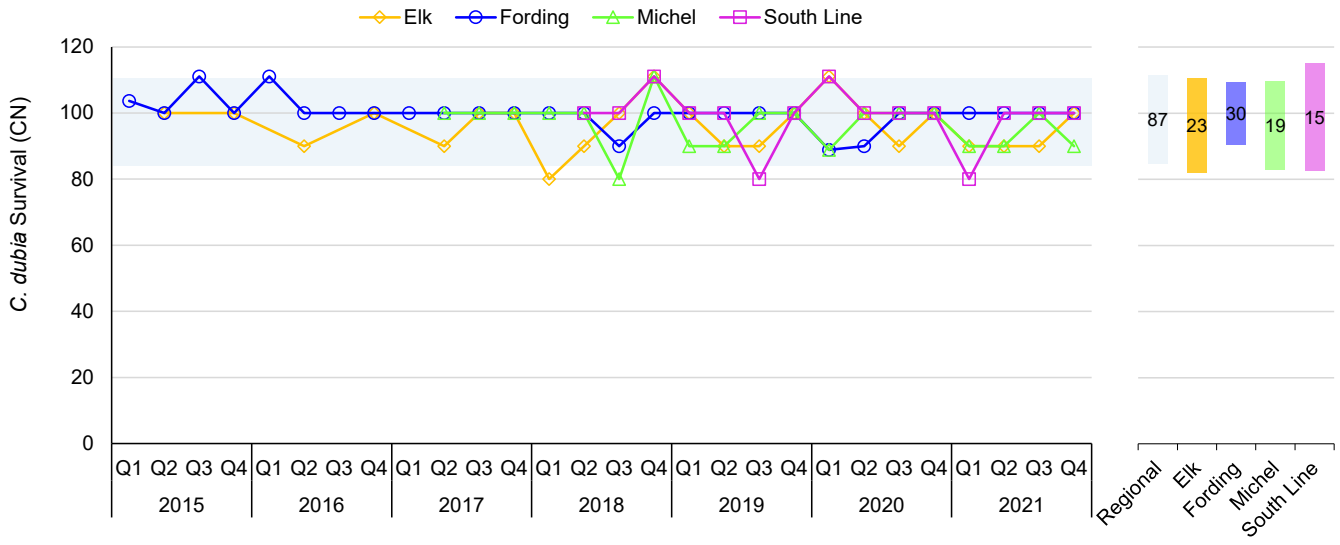
3.2.3.1 *Ceriodaphnia dubia*

Mean control normalized responses for *C. dubia* tests in reference waters are plotted in Figure 3.2-2 (survival) and Figure 3.2-3 (reproduction). Results for NRs are as follows:

- Mean survival ranged from 80% to 111% in reference tests from 2015 to 2021 (Figure 3.2-2). Mean survival was similar across references and years, which resulted in broad overlap in the regional NR (85% to 111%) and the local NRs for the Elk River (82% to 110%), Fording River (91% to 109%), Michel Creek (83% to 110%), and South Line Creek (83% to 115%).
- Mean reproduction ranged from 66% to 131% in reference tests from 2015 to 2021 (Figure 3.2-3). Mean reproduction was less variable across references in 2021 compared to previous years, except in Q1 2021 when reproduction was lower at South Line Creek compared to other references. The mean mortality in Q1 2021 was 20% which may have contributed to the reduced reproduction in the South Line Creek test. The regional NR (70% to 123%) and local NRs for the Elk River (69% to 120%), Fording River (76% to 122%), Michel Creek (67% to 130%), and South Line Creek (67% to 119%) had broad overlap.

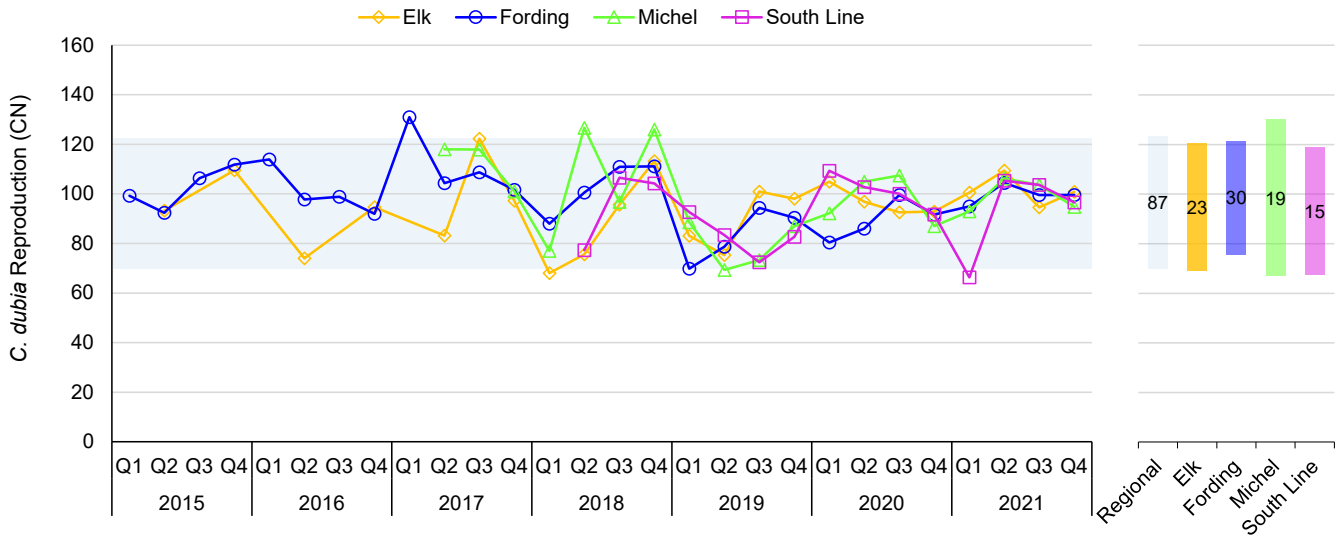
The evaluation of long-term reference responses for *C. dubia* tests indicates that, in any round of quarterly testing, one or more reference stations may yield a mean reproduction response that differs from the other reference waters. However, there was no long-term systematic difference in mean reproduction among reference stations, which is expected because the water quality at all reference stations is broadly similar. There are some fluctuations in mean reproduction over time (e.g., Q1 2019 reproduction in the Fording River reference was slightly lower than the long-term average). In aggregate, these findings indicate that comparisons to regional mean reproduction (averaged across all references) within a batch provide the most reliable basis for identifying deviations from normal reproduction.

Figure 3.2-2: Mean results for *C. dubia* survival in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. Sample size for each normal range is provided on the bar chart. CN = control normalized.

Figure 3.2-3: Mean results for *C. dubia* reproduction in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. Sample size for each normal range is provided on the bar chart. CN = control normalized.

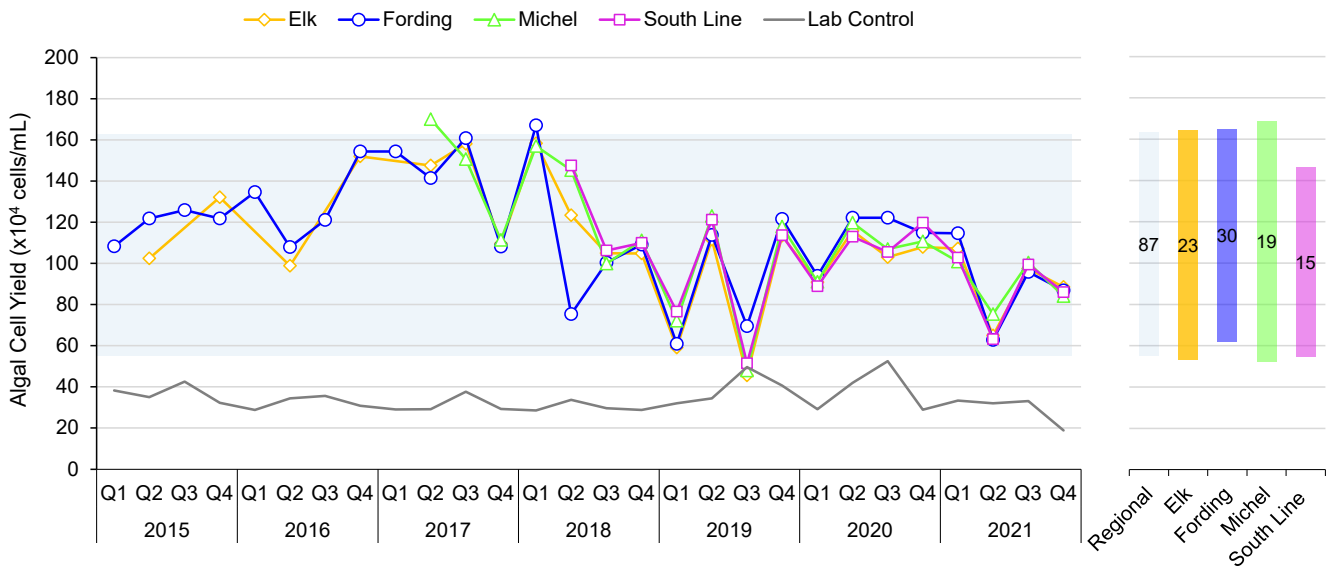
3.2.3.2 *Pseudokirchneriella subcapitata*

Mean cell yield ranged from 46 × 10^4 to 170 × 10^4 cells/mL in reference tests from 2015 to 2021 (Figure 3.2-4). Mean cell yield has been historically similar across references, except: (1) in Q2 2017 when cell yield in the Michel Creek reference was approximately 15% to 20% higher than the Elk and Fording River references; and (2) in Q2 2018 when cell yield in the Elk River, Michel Creek, and South Line Creek references were approximately 90% to 100% higher than the Fording River reference. Cell yield often varied across quarters within the same sampling year, including 2021 where cell yield was lower in Q2 compared to other quarters. This variability across quarters contributed to wide NRs for the regional NR (55 to 163 ×10^4 cells/mL) and local NRs for the Elk River (53 to 164 ×10^4 cells/mL), Fording River (62 to 165 ×10^4 cells/mL), Michel Creek (52 to 169 ×10^4 cells/mL), and South Line Creek (54 to 146 ×10^4 cells/mL).

Because cell yield is the only endpoint that is not control normalized (per discussions with EMC), mean cell yield in the negative laboratory control is shown on Figure 3.2-4. In all but one quarter (Q3 2019), cell yield in reference tests was approximately 2 to 5 times higher than cell yield in the negative laboratory control, which ranged from 19 to 53 ×10^4 cells/mL across all years. This finding is not unusual, since the higher ionic strength associated with the reference waters is expected to stimulate cell growth of this species relative to the low ionic strength associated with the laboratory control water (Appendix B).

In aggregate, these findings indicate that comparisons to regional mean cell yield (at all references) within a batch provide the most reliable basis for identifying deviations from normal cell yield.

Figure 3.2-4: Mean results for *P. subcapitata* cell yield in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. Sample size for each normal range is provided on the bar chart.
mL = millilitre.

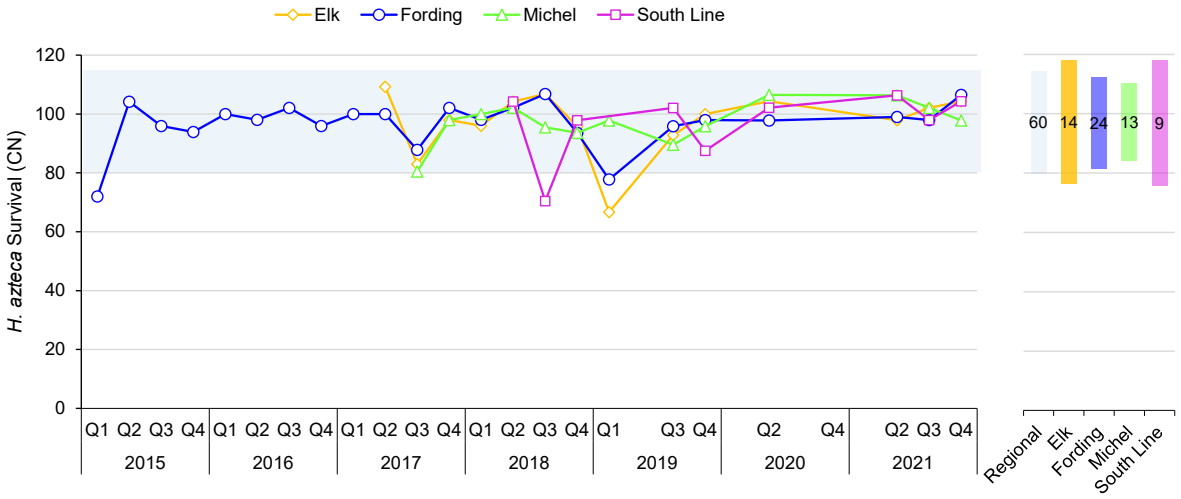
3.2.3.3 *Hyalella azteca*

Mean control normalized responses for *H. azteca* tests in reference waters are plotted in Figure 3.2-5 (survival) and Figure 3.2-6 (dry weight). Results for NRs are as follows:

- Mean survival extended from 67% to 109% in reference tests from 2015 to 2021 (Figure 3.2-5). Mean survival was similar among references except for Q3 2018 and Q1 2019 in which mean survival for Michel Creek and South Line Creek tests were lower compared to other years. This variability contributed to wider local NRs for South Line Creek (76% to 118%) and Michel Creek NR (84% to 110%) compared to Elk River (76% to 118%) and Fording River (81% to 112%). The regional NR was 80% to 114%.
- Mean dry weight extended from 56% to 180% in reference tests from 2015 to 2021 (Figure 3.2-6). Mean dry weight was variable across references tested in the same quarter. High variability in Q3 2017, Q3 and Q4 2018, Q1, Q3, Q4 2019, and Q3 2021 resulted in wide NRs for the regional NR (46% to 148%) and local NRs for the Elk River (40% to 140%), Fording River (47% to 151%), Michel Creek (54% to 150%), and South Line Creek (44% to 141%).

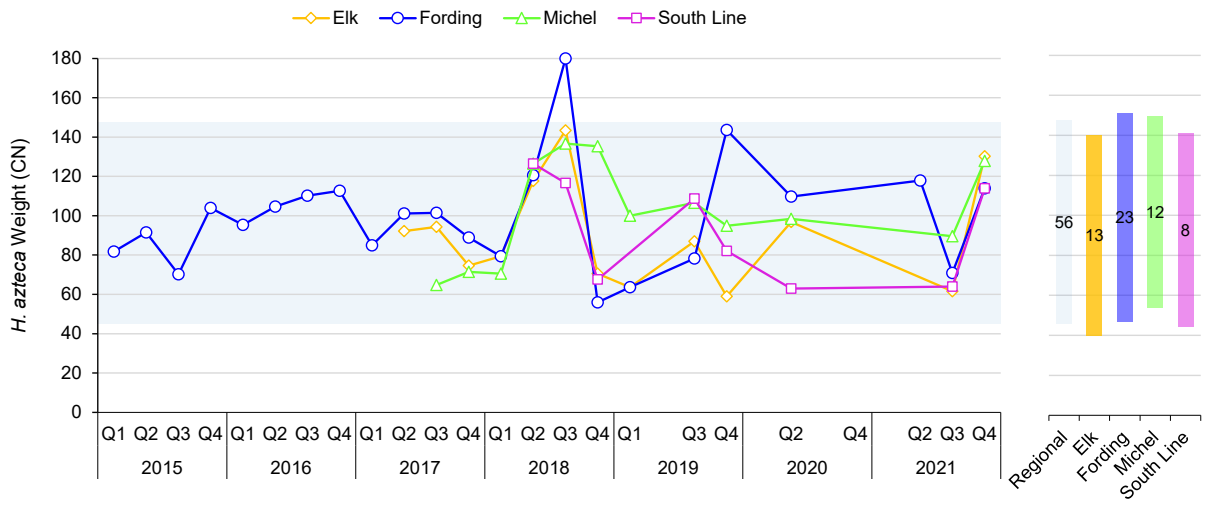
There are no long-term systematic differences between references, as reflected in the similar NRs among references, but the differences between quarters and within a quarter can be large, particularly for the dry weight endpoint. For example, in Q3 2021, mean control normalized dry weight in the Michel Creek reference (89%) was higher than the other three references (61% for GH_ER2 to 71% for FR_UFR1). As discussed in Section 3.3, this resulted in several test sites having significantly lower responses relative to the Michel reference but not the other references. Dry weight responses in 2021 were lower in Q3 compared to Q2 and Q4; however, responses remained within the range observed in previous years. In aggregate, these findings indicate that comparisons to regional mean responses (at all references) within a batch provide the most reliable basis for identifying deviations from normal *H. azteca* survival and growth.

Figure 3.2-5: Mean results for *H. azteca* survival in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. Sample size for each normal range is provided on the bar chart.
Per agreement with the EMC at the March 2021 conference call, Q4 2020 results were excluded from the NR calculations. Due to a lab technician error, Q2 *H. azteca* tests were disposed prior to the measurement of dry weight (see Section 3.1). Tests were repeated in Q2 for the Fording River reference and then repeated for all references in Q3. Result presented for the Fording River reference is an average of the survival results for the initial Q2 test and Q2 re-test. CN = control normalized

Figure 3.2-6: Mean results for *H. azteca* weight in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. Sample size for each normal range is provided on the bar chart.
Per agreement with the EMC at the March 2021 conference call, Q4 2020 results were excluded from the NR calculations. Due to a lab technician error, Q2 *H. azteca* tests were disposed prior to the measurement of dry weight (see Section 3.1). Tests were repeated in Q2 for the Fording River reference and then repeated for all references in Q3. Result presented for the Fording River reference is from the Q2 re-test. CN = control normalized.

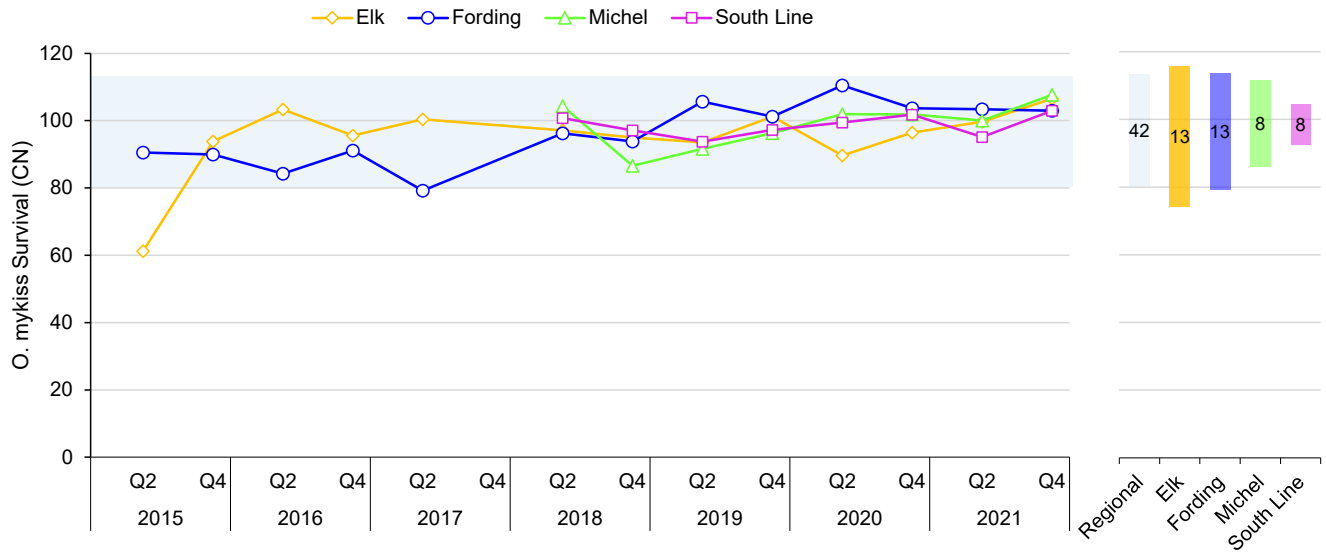
3.2.3.4 *Oncorhynchus mykiss*

Mean control normalized responses for *O. mykiss* tests in reference waters are plotted in Figure 3.2-7 (survival), Figure 3.2-8 (viability), Figure 3.2-9 (length), and Figure 3.2-10 (weight).

- Mean survival extended from 61% to 110% in reference tests from 2015 to 2021 (Figure 3.2-7). Although mean survival has previously been variable between reference waters tested in the same quarter (e.g., Q2 2015 and 2017), mean survival was similar across 2021 reference tests. It is possible that the copper amendment helped to reduce microbial toxicity in later years which would be expected to reduce the variability in responses. The regional NR (80% to 113%) and local NRs for the Elk River (74% to 116%), Fording River (79% to 114%), and Michel Creek (86% to 112%) had broad overlap. The local NR for South Line Creek (93% to 104%) is narrow compared to other local NRs; this is a result from a smaller sample size (n = 8) and the low variability of survival across the tests for South Line Creek which ranged from 94% in Q2 2019 to 103% in Q4 2021.
- Mean viability extended from 62% to 113% in reference tests from 2015 to 2021 (Figure 3.2-8). Although mean viability has previously been variable in reference waters tested in the same quarter (e.g., Q2 2015 and 2017), mean viability was similar across 2021 reference tests. The regional NR (80% to 114%) and local NRs for the Elk River (74% to 116%), Fording River (79% to 115%), and Michel Creek (84% to 113%) had broad overlap. As with the survival endpoint, the local NR for South Line Creek (93% to 105%) is narrow for this endpoint compared to other local NRs.
- Mean length extended from 92% to 110% in reference tests from 2015 to 2021 (Figure 3.2-9). Mean length was similar across references and years, which resulted in narrow NRs and a broad overlap between the regional NR (95% to 108%) and the local NRs for the Elk River (95% to 108%), Fording River (95% to 108%), Michel Creek (96% to 107%), and South Line Creek (93% to 106%).
- Mean weight extended from 93% to 119% in reference tests from 2015 to 2021 (Figure 3.2-10). Mean weight was similar across references and years, which resulted in narrow NRs and a broad overlap between the regional NR (93% to 114%) and the local NRs for the Elk River (93% to 116%), Fording River (95% to 109%), Michel Creek (96% to 112%), and South Line Creek (90% to 116%). Mean weight in Q2 2021 was higher than previously observed; however, all results had a <15% difference to their counterparts in Q2 2020.

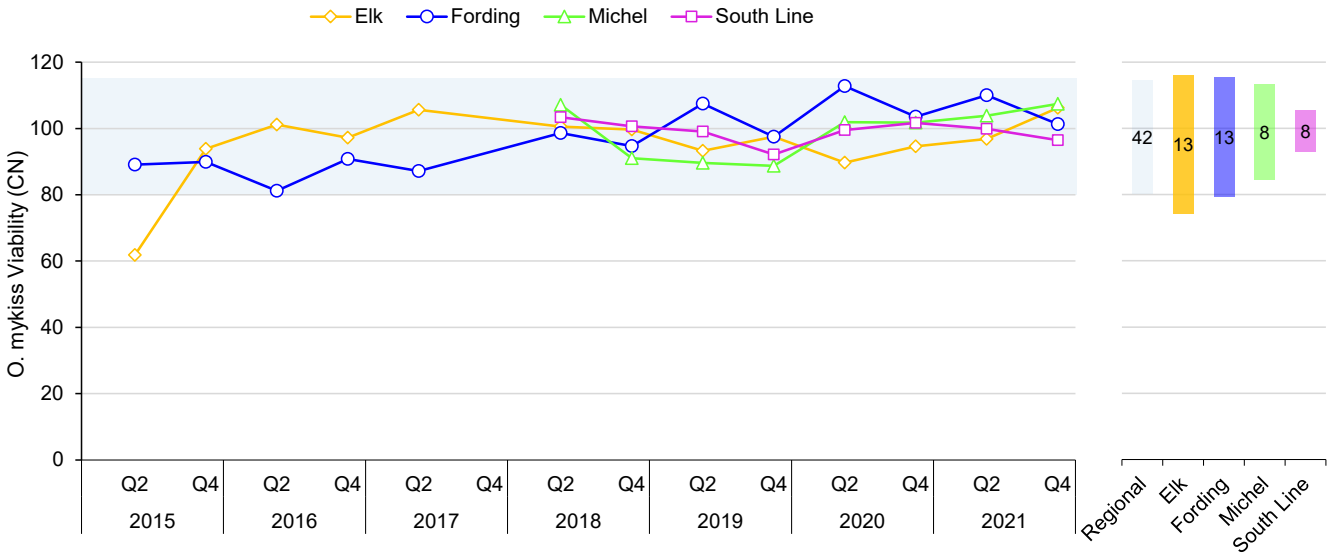
The pattern of reference responses for *O. mykiss* in 2021 indicates that the mean organism sensitivity was similar in 2021 to previous years. There were no long-term systematic differences between reference site performances over the long term, as reflected in the similar normal ranges among references. In aggregate, these findings indicate that comparisons to regional mean reproduction (at all references) within a batch provide the most reliable basis for identifying deviations from normal *O. mykiss* survival and development.

Figure 3.2-7: Mean results for *O. mykiss* survival in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



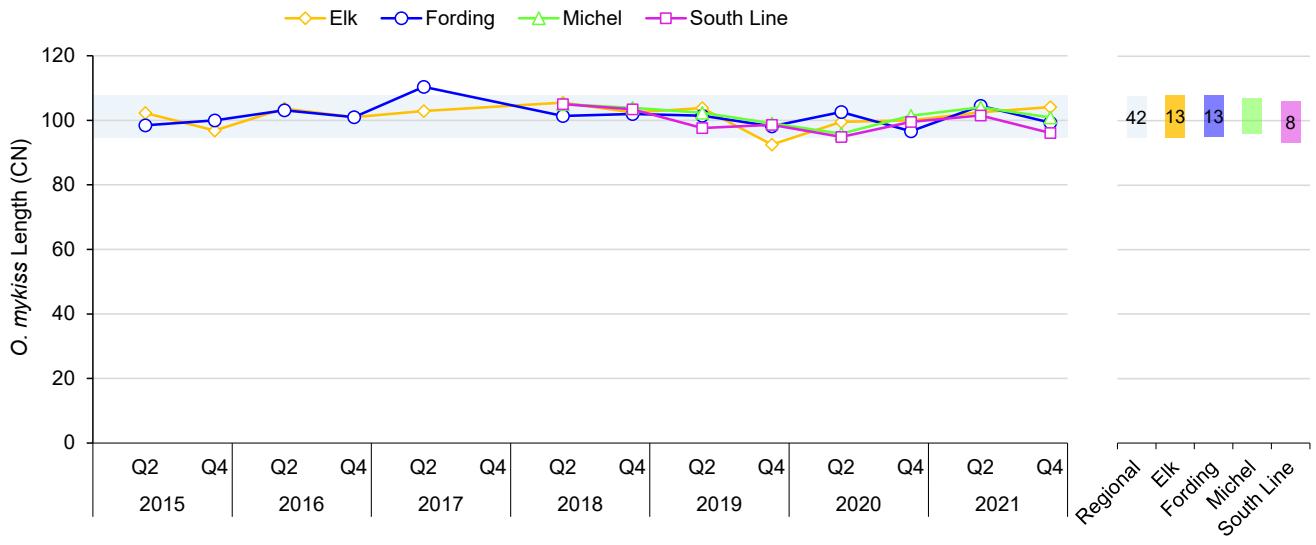
Notes: Blue shading on scatterplot is the regional normal range. The Q4 2017 tests were removed from reference envelope calculations because pronounced microbial effects were observed in these tests. Sample size for each normal range is provided on the bar chart.
CN = control normalized.

Figure 3.2-8: Mean results for *O. mykiss* viability in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



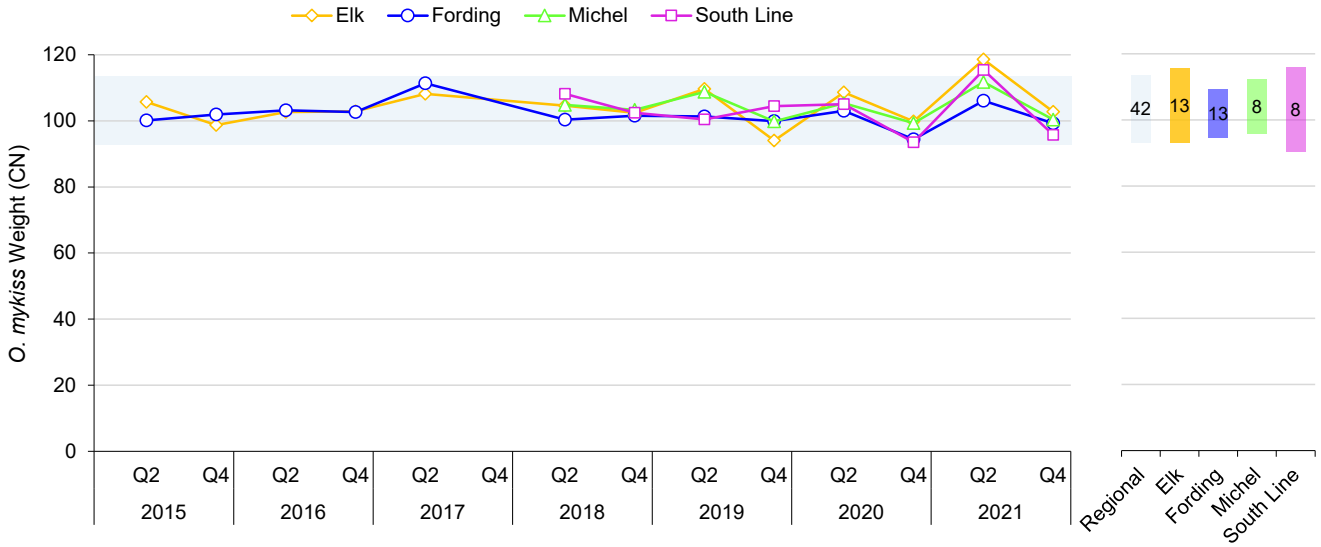
Notes: Blue shading on scatterplot is the regional normal range. The Q4 2017 tests were removed from reference envelope calculations because pronounced microbial effects were observed in these tests. Sample size for each normal range is provided on the bar chart.
CN = control normalized.

Figure 3.2-9: Mean results for *O. mykiss* length in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. The Q4 2017 tests were removed from reference envelope calculations because pronounced microbial effects were observed in these tests. Sample size for each normal range is provided on the bar chart.
CN = control normalized.

Figure 3.2-10: Mean results for *O. mykiss* weight in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. The Q4 2017 tests were removed from reference envelope calculations because pronounced microbial effects were observed in these tests. Sample size for each normal range is provided on the bar chart.
CN = control normalized.

3.2.3.5 *Pimephales promelas*

Mean control normalized responses for *P. promelas* tests in reference waters are plotted in Figure 3.2-11 (hatch), Figure 3.2-12 (survival), Figure 3.2-13 (biomass), Figure 3.2-14 (length), and Figure 3.2-15 (normal development).

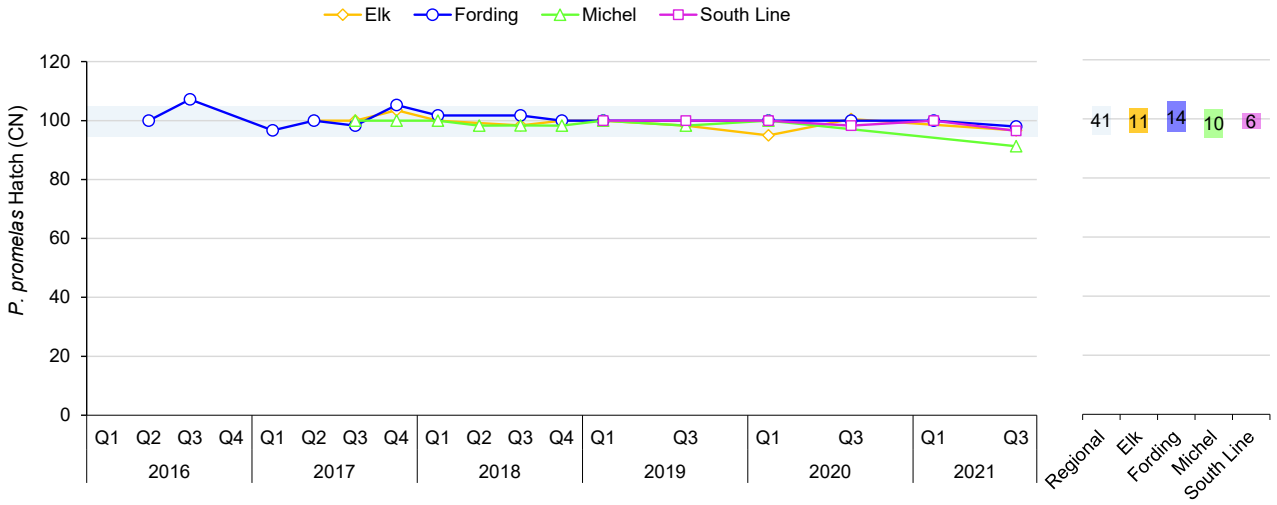
Results for NRs (excluding Q1 Elk and Michel references; see Section 3.1) are as follows[21]:

- Mean hatch extended from 91% to 107% in reference tests (Figure 3.2-11). Mean hatch was similar across references and years, which resulted in narrow NRs and a broad overlap between the regional NR (95% to 104%) and the local NRs for the Elk River (95% to 103%), Fording River (95% to 106%), Michel Creek (94% to 103%), and South Line Creek (97% to 102%).
- Mean survival extended from 60% to 121% in reference tests (Figure 3.2-12). Mean survival was often higher and less variable in the Fording River reference tests compared to the other reference, contributing to the local NRs for Elk River (65% to 111%), Michel Creek (58% to 119%), and South Line Creek (59% to 126%) extending below the Fording River NR (80% to 114%). The regional NR was 66% to 118%.
- Mean biomass extended from 54% to 130% in reference tests (Figure 3.2-13). Mean biomass was often higher and less variable in the Fording River reference tests compared to the other reference, contributing to the local NRs for Elk River (59% to 130%), Michel Creek (54% to 122%), and South Line Creek (62% to 111%) extending below the Fording NR (73% to 120%). The regional NR was 61% to 123%.
- Mean length extended from 82% to 109% in reference tests (Figure 3.2-14). Mean length was similar across references, which resulted in broad overlap in the regional NR (84% to 110%) and the local NRs for the Elk River (85% to 113%), Fording River (85% to 107%), Michel Creek (82% to 108%), and South Line Creek (88% to 109%).
- Mean normal development ranged from 94% to 108% in reference tests (Figure 3.2-15). Mean normal development was similar across references, which resulted in broad overlap in the regional NR (95% to 105%) and the local NRs for the Elk River (96% to 105%), Fording River (96% to 104%), Michel Creek (96% to 106%), and South Line Creek (93% to 107%).

The pattern of reference responses for *P. promelas* in 2021 indicates that the mean organism sensitivity was broadly similar in 2021 to previous years for *P. promelas* endpoints. There are no long-term systematic differences among reference site performances, as reflected in the similar normal ranges among references. Variation was high among references for the biomass endpoint, but with no consistent pattern among years. In aggregate, these findings indicate that comparisons to regional mean reproduction (at all references) within a batch provide the most reliable basis for identifying deviations from normal *P. promelas* survival and development.

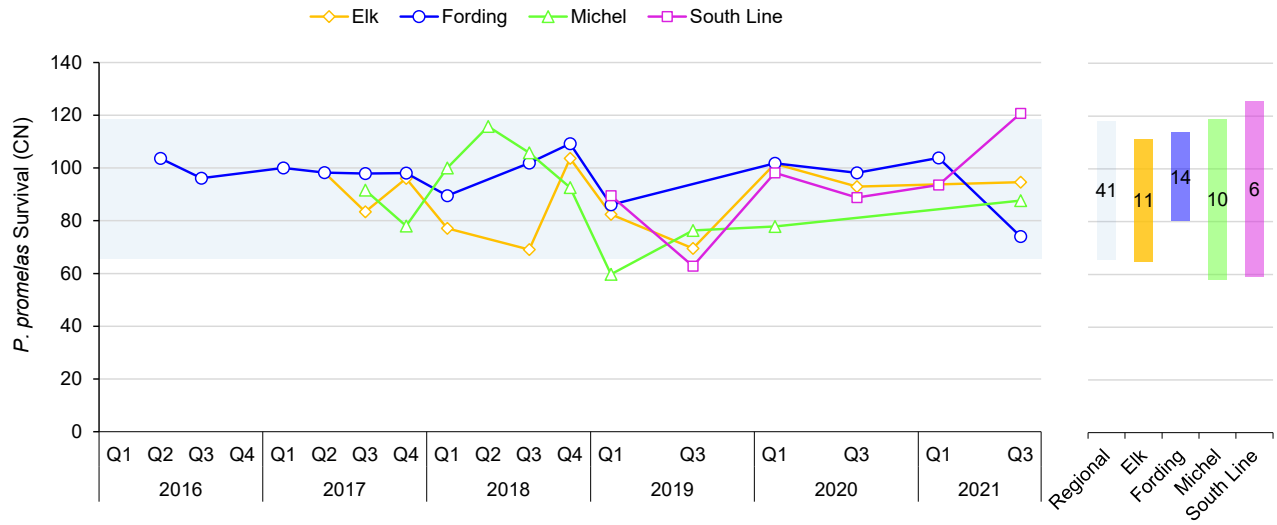
[21] Per the February 2022 EMC conference call, Q1 *P. promelas* results for Elk River and Michel Creek reference tests were excluded from the calculation of NRs due to anomalously low results. If these tests had been included, the NRs would have been as follows. Elk: 95% to 103% (hatch), 47% to 120% (survival), 51% to 131% (biomass), 85% to 113% (length), 90% to 108% (normal development). Michel: 94% to 103% (hatch), 51% to 120% (survival), 51% to 121% (biomass), 83% to 108% (length), 86% to 112% (normal development). Regional: 94% to 104% (hatch), 57% to 122% (survival), 58% to 124% (biomass), 85% to 109% (length), 91% to 109% (normal development). Inclusion of the anomalous Elk and Michel tests has the largest impact on the survival and biomass NRs compared to other endpoints. For example, the 2.5th percentile for survival for the regional NR is 66% when these tests are excluded and 57% when these tests are included.

Figure 3.2-11: Mean results for *P. promelas* hatch in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



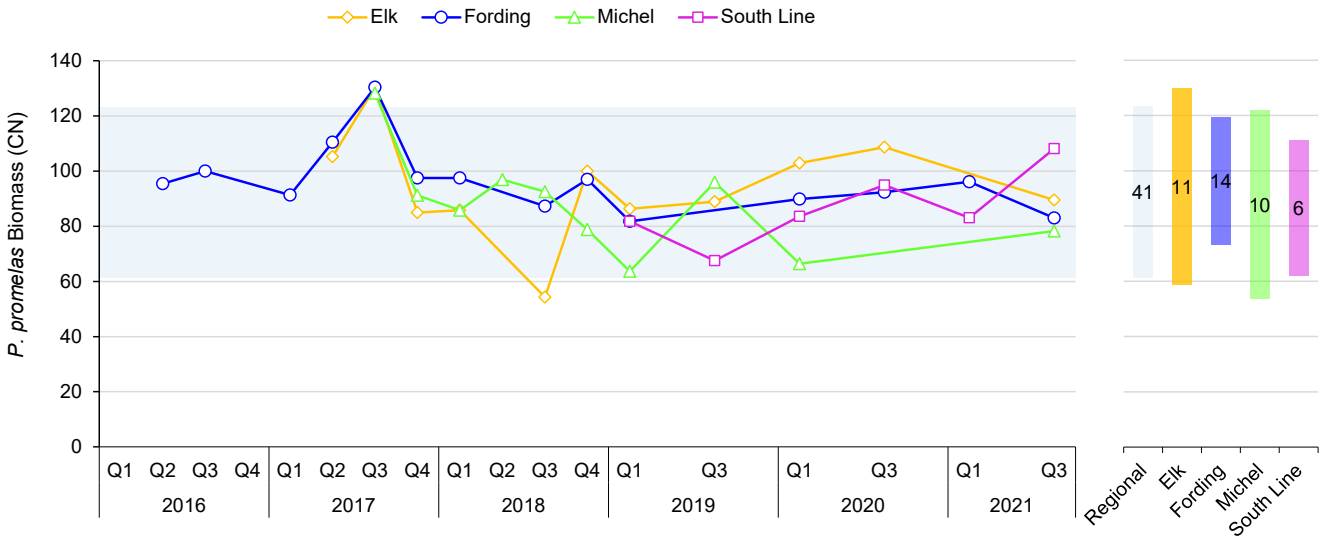
Notes: Blue shading on scatterplot is the regional normal range. The following tests were excluded from normal range calculations: Q1 2016 (test waters were not amended with copper), Q4 2016 (dissolved oxygen concentrations fell below typical levels), Q2 2018 for Fording and Elk and Q3 2019 for Fording (microbial effects were observed in these tests), Q3 2020 for Michel Creek (anomalous results), Q1 2021 for Elk and Michel Creek (anomalously low results). Sample size for each normal range is provided on the bar chart. CN = control normalized.

Figure 3.2-12: Mean results for *P. promelas* survival in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



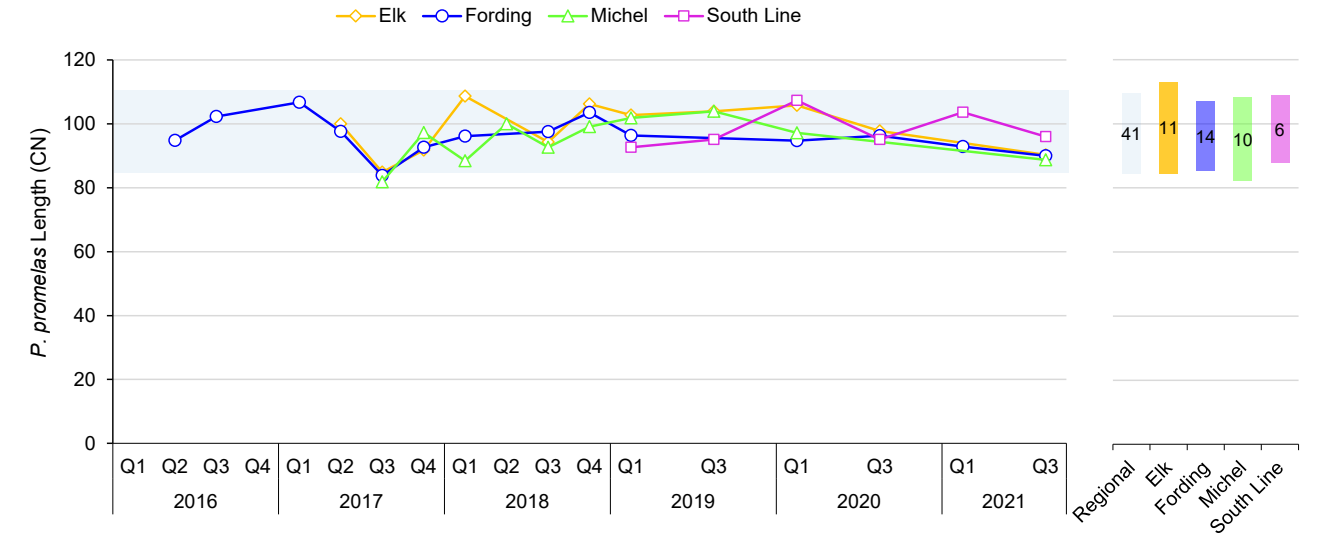
Notes: Blue shading on scatterplot is the regional normal range. The following tests were excluded from normal range calculations: Q1 2016 (test waters were not amended with copper), Q4 2016 (dissolved oxygen concentrations fell below typical levels), Q2 2018 for Fording and Elk and Q3 2019 for Fording (microbial effects were observed in these tests), Q3 2020 for Michel Creek (anomalous results), Q1 2021 for Elk and Michel Creek (anomalously low results). Sample size for each normal range is provided on the bar chart. CN = control normalized.

Figure 3.2-13: Mean results for *P. promelas* biomass in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



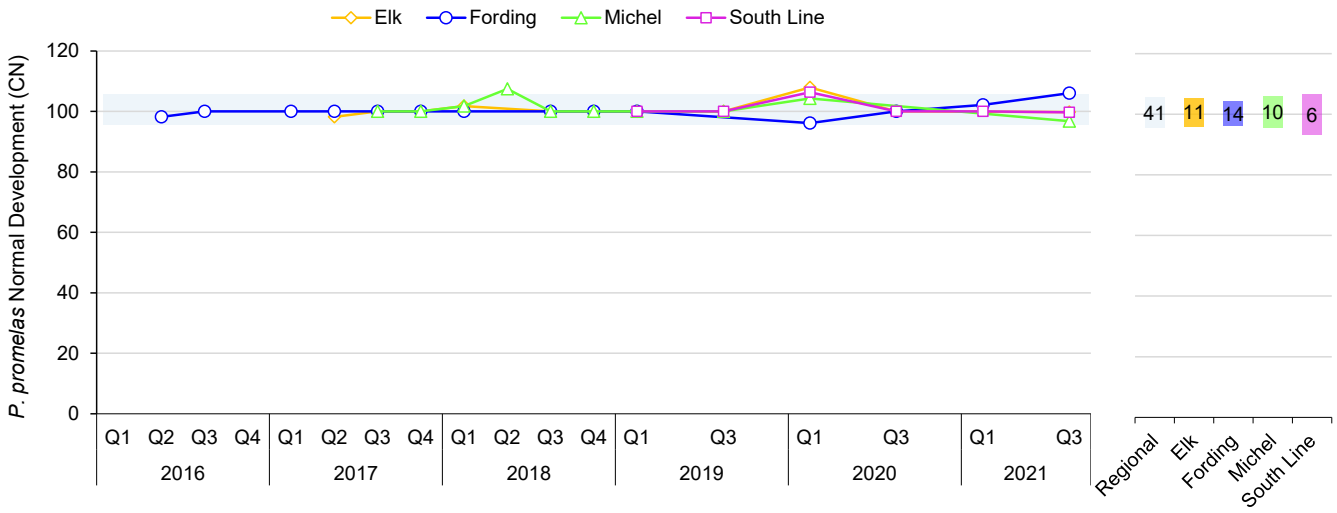
Notes: Blue shading on scatterplot is the regional normal range. The following tests were excluded from normal range calculations: Q1 2016 (test waters were not amended with copper), Q4 2016 (dissolved oxygen concentrations fell below typical levels), Q2 2018 for Fording and Elk and Q3 2019 for Fording (microbial effects were observed in these tests), Q3 2020 for Michel Creek (anomalous results), Q1 2021 for Elk and Michel Creek (anomalously low results). Sample size for each normal range is provided on the bar chart. CN = control normalized.

Figure 3.2-14: Mean results for *P. promelas* length in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. The following tests were excluded from normal range calculations: Q1 2016 (test waters were not amended with copper), Q4 2016 (dissolved oxygen concentrations fell below typical levels), Q2 2018 for Fording and Elk and Q3 2019 for Fording (microbial effects were observed in these tests), Q3 2020 for Michel Creek (anomalous results), Q1 2021 for Elk and Michel Creek (anomalously low results). Sample size for each normal range is provided on the bar chart. CN = control normalized.

Figure 3.2-15: Mean results for *P. promelas* normal development in Elk River reference, Fording River reference, Michel Creek reference, and South Line Creek reference tests (left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panel).



Notes: Blue shading on scatterplot is the regional normal range. The following tests were excluded from normal range calculations: Q1 2016 (test waters were not amended with copper), Q4 2016 (dissolved oxygen concentrations fell below typical levels), Q2 2018 for Fording and Elk and Q3 2019 for Fording (microbial effects were observed in these tests), Q3 2020 for Michel Creek (anomalous results), Q1 2021 for Elk and Michel Creek (anomalously low results). Sample size for each normal range is provided on the bar chart. CN = control normalized.

3.2.4 Variation in Concentrations of Toxicants (Coefficients of Variation)

Coefficients of variation are presented in Appendix C. CVs were below 0.25 for most constituents, indicating that variability in concentrations among weekly refresh samples is generally low. This finding is consistent with previous investigations of variance in water quality constituents, in which only minor variations have been observed over a few weeks (i.e., the duration of the longest Permit-based tests) relative to the larger seasonal variations. When constituent concentrations were greater than chronic WQGs or lowest level 1 EVWQP benchmarks in one or more weekly refresh samples, CVs were generally either below 0.25 or comparable to CVs measured at reference locations for the same quarter and test. Some exceptions were observed in 2021, listed below by species and quarter:

- P. promelas Q1—CM_MC2 (total chromium), CM_MC2, FR_FRCP1, LC_LC3, LC_LCDSSLCC, RG_MIDAG (fluoride), LC_DCDS (total nickel, and total selenium)
- H. azteca Q2—RG_MIDAG, CM_MC2 (total chromium), EV_MC2 (total beryllium, total chromium, total iron, and total nickel), EV_MC2, FR_FRCP1 (total selenium)
- *O. mykiss* Q2—CM_MC2 (total chromium), CM_MC2, EV_MC2, FR_FRABCH, FR_FRCP1 (total selenium), EV_MC2 (total beryllium, total chromium, total iron, and total nickel)
- H. azteca Q3—CM_MC2, FR_FRABCH (fluoride)
- P. promelas Q3—CM_MC2, FR_FRABCH, LC_LC3 (fluoride)
- H. azteca Q4—FR_FRABCH, LC_LC3 (fluoride), FR_FRCP1 (nitrite), GH_FR1 (total selenium)
- *O. mykiss* Q4—FR_FRABCH, GH_FR1 (fluoride), FR_FRCP1 (nitrite), GH_FR1 (total selenium)

This source of variance is not expected to affect the overall interpretation of the quarterly and semi-annual toxicity results of this study. The weekly variations reflect, in part, natural variance in water quality expected in the field, and the weekly changes were small in magnitude relative to seasonal changes in water quality. Furthermore, because weekly refresh samples were screened individually against chronic WQGs and EVWQP benchmarks (see Section 2.3.4), any constituents potentially contributing to observed responses were captured in the overall causation assessment.

3.3 Evaluation of 2021 Results

Raw results (mean and standard deviation) are presented in Table 3.3-1. Control normalized results (mean and standard deviation for all species except *P. subcapitata*) are presented in Table 3.3-2. Categories for 2021 test results (no, possible, or likely adverse response) are discussed below by test species (Section 3.3.1) and by test site (Section 3.3.2).

Notes: (a) Results presented as survival or mean ± standard deviation. Results are from laboratory reports in Appendix B. Control normalized results are provided in Table 3.3-2.
(b) *H. azteca* tests in Q2 were successfully conducted and survival was measured; however, test organisms were disposed prior to measuring dry weight due to a lab technician error. Tests were repeated for the Fording River reference in Q2 and for all stations in Q3, resulting in two Q2 survival results for the Fording reference.
(c) Results for copper-amended samples are provided; reference site results are samples amended with 10 to 20 µg/L. Laboratory control results are provided for laboratory control + 10 to 20 µg/L copper (Cu).
(d) For *P. promelas*, the Q1 Elk River and Michel Creek references were excluded from pooled batch references due to anomalous results.
(e) Statistical analysis for *C. dubia* protocol results are completed by Nautilus and statistical analysis for *C.dubia* 8-day results are completed by Golder.
I = initial; R = retest; mg = milligrams; mL = millilitre; mm = millimetres;% = percent; ± = plus or minus.
Value = result significantly lower than one or more reference **Value** = result significantly lower than Fording River reference. *Value* = result significantly lower than Michel Creek reference. Value = test categorized as no adverse response. Value = test categorized as likely adverse response.
Value = result significantly lower than Elk River reference. *Value* = result significantly lower than South Line Creek reference Value = test categorized as possible adverse response. M= test had evidence of microbes in one or more replicates.

Notes: (a) Results presented as survival or mean ± standard deviation. Results are from laboratory reports in Appendix B. Raw results are provided in Table 3.3-1.

(b) *H. azteca* tests in Q2 were successfully conducted and survival was measured; however, test organisms were disposed prior to measuring dry weight due to a lab technician error. Tests were repeated for the Fording River reference in Q2 and for all stations in Q3, resulting in two Q2 survival results for the Fording reference.

(c) Results for copper-amended samples are provided; reference site results are samples amended with 10 to 20 µg/L. Laboratory control results are provided for laboratory control + 10 to 30 µg/L copper (Cu).

(d) For *P. promelas*, the Q1 Elk River and Michel Creek references were excluded from pooled batch references due to anomalous results.

(e) Statistical analysis for *C. dubia* protocol results are completed by Nautilus and statistical analysis for *C.dubia* 8-day results are completed by Golder.

I = initial; R = retest; mg = milligrams; mL = millilitre; mm = millimetres; % = percent; ± = plus or minus.

Value = result significantly lower than one or more references **Value** = result significantly lower than Fording River reference. *Value* = result significantly lower than Michel Creek reference. Value = test categorized as no adverse response. Value = test categorized as likely adverse response.

Value = result significantly lower than Elk River reference. *Value* = result significantly lower than South Line Creek reference. Value = test categorized as possible adverse response. M= test had evidence of microbes in one or more replicates

3.3.1 Results by Test Species

3.3.1.1 *Ceriodaphnia dubia*

Standard Permit-based Testing

Individual replicate results are provided in Figures 3.3-1 and 3.3-2. Mean test results are provided in Tables 3.3-1 and 3.3-2 and Figures 3.3-3 and 3.3-4.

There was no evidence of statistically significant adverse effects on mean *C. dubia* survival (Figure 3.3-1; Figure 3.3-3). The few individual replicates for which mortality was observed were insufficient to cause a statistically significant response. Replicate results for survival are dichotomous (either 0% or 100%) because each replicate consists of a single female. Results of other testing of Elk Valley waters, conducted with additional replication of the survival endpoint, confirmed that adult survival is a relatively insensitive test endpoint (Golder 2018); the observation of an occasional mortality to an adult female (including in reference samples) is believed to occur due to random events not associated with chemical toxicity.

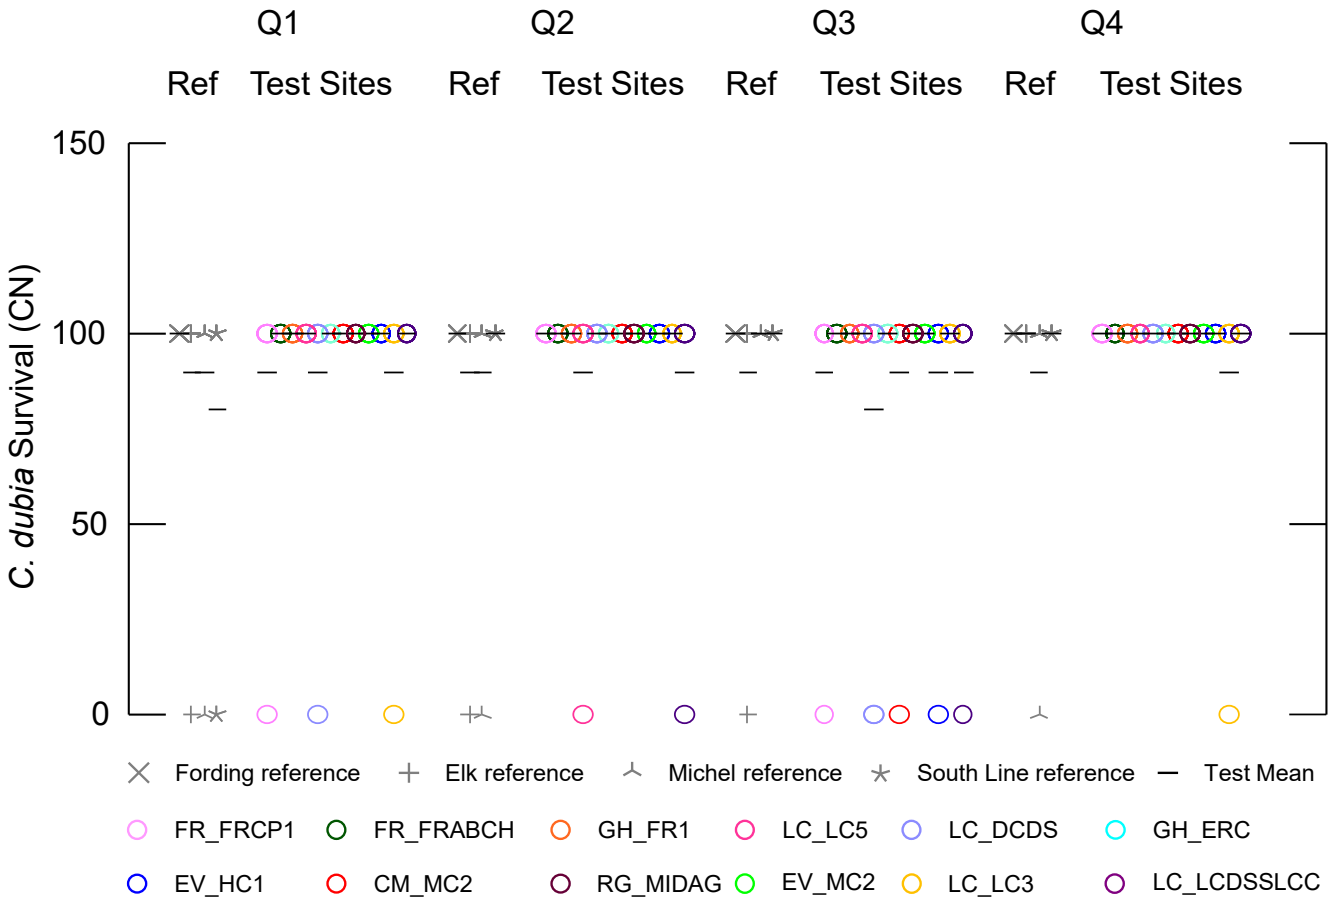
Reproduction was significantly reduced relative to one or more references in 10 of 48 tests (Figures 3.3-2; Figure 3.3-4; Table 3.3-1; Table 3.3-2), including three FR_FRCP1 tests (Q1, Q3 and Q4), two LC_DCDS tests (Q3 and Q4), two CM_MC2 tests (Q1 and Q4), one RG_MIDAG test (Q4), one EV_HC1 test (Q4), and one LC_LC3 test (Q4).

Based on the decision framework in Figure 2.3-1, *C. dubia* tests were categorized as follows:

- **No adverse response (40 of 48 tests):** Most tests were categorized as no adverse response, including 2 of the 10 tests with significantly reduced reproduction. Compared to the mean response in batch-specific references, the effect size in significant tests categorized as no adverse response ranged from 17% (EV_HC1 Q4) to 18% (RG_MIDAG Q4).
- **Possible adverse response (1 of 48 tests):** Q4 test with LC_LC3. Compared to the mean response in batch-specific references, the effect size in this test was 24%.
- **Likely adverse response (7 of 48 tests):** Q1 tests with FR_FRCP1 and CM_MC2; Q3 tests with FR_FRCP1 and LC_DCDS; Q4 tests with FR_FRCP1, LC_DCDS, and CM_MC2. Compared to the mean response in batch-specific references, the effect size in tests categorized as likely adverse response ranged from 30% (FR_FRCP1 Q4) to 43% (FR_FRCP1 and LC_DCDS Q3).

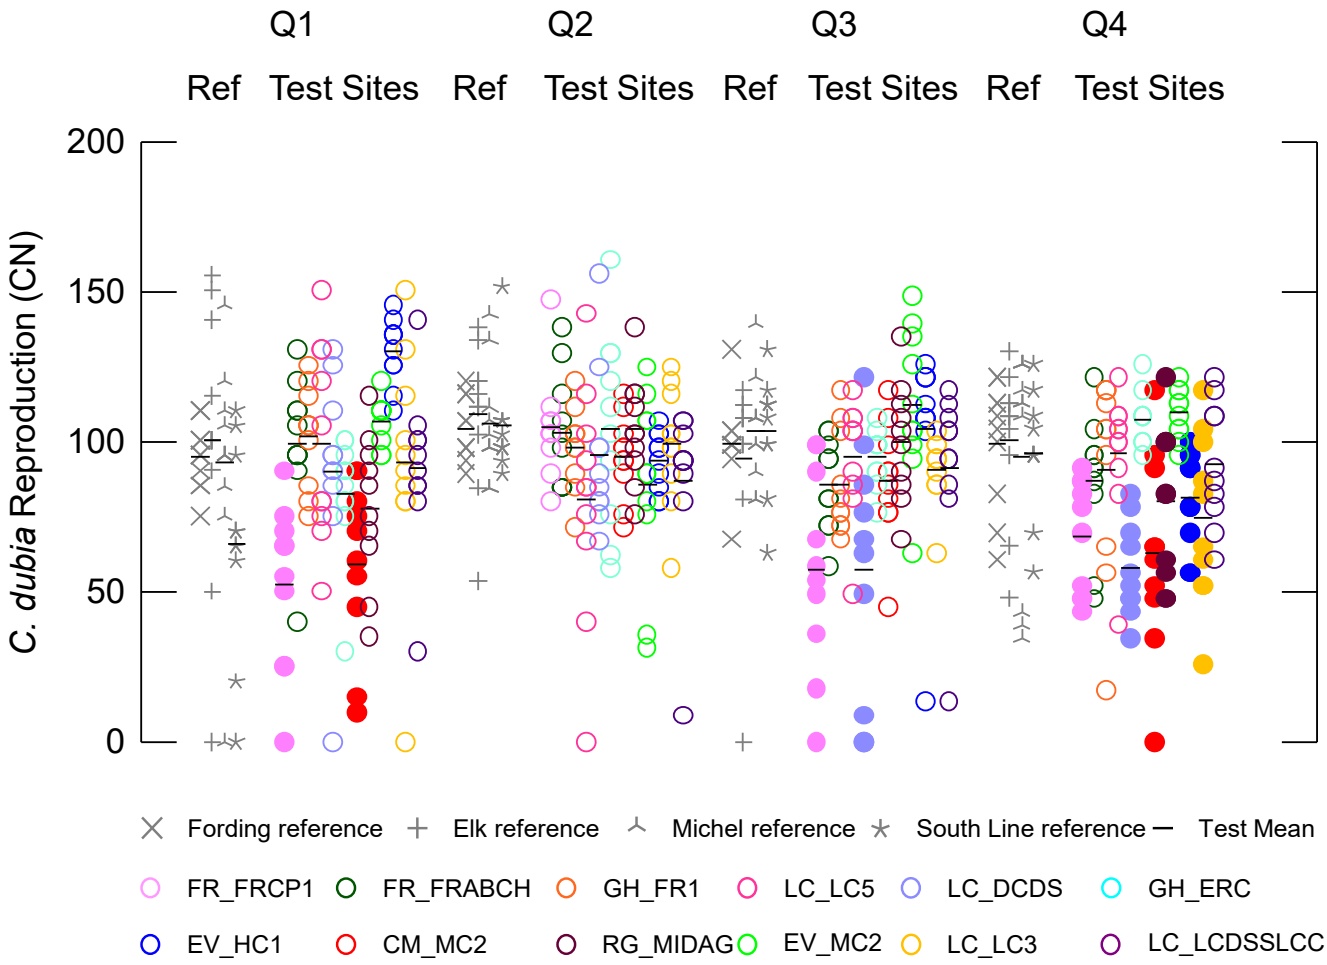
The causation assessment for *C. dubia* reproduction is presented in Section 3.4.1.

Figure 3.3-1: Individual replicate and mean results for *C. dubia* survival in reference (Ref) and test site waters.



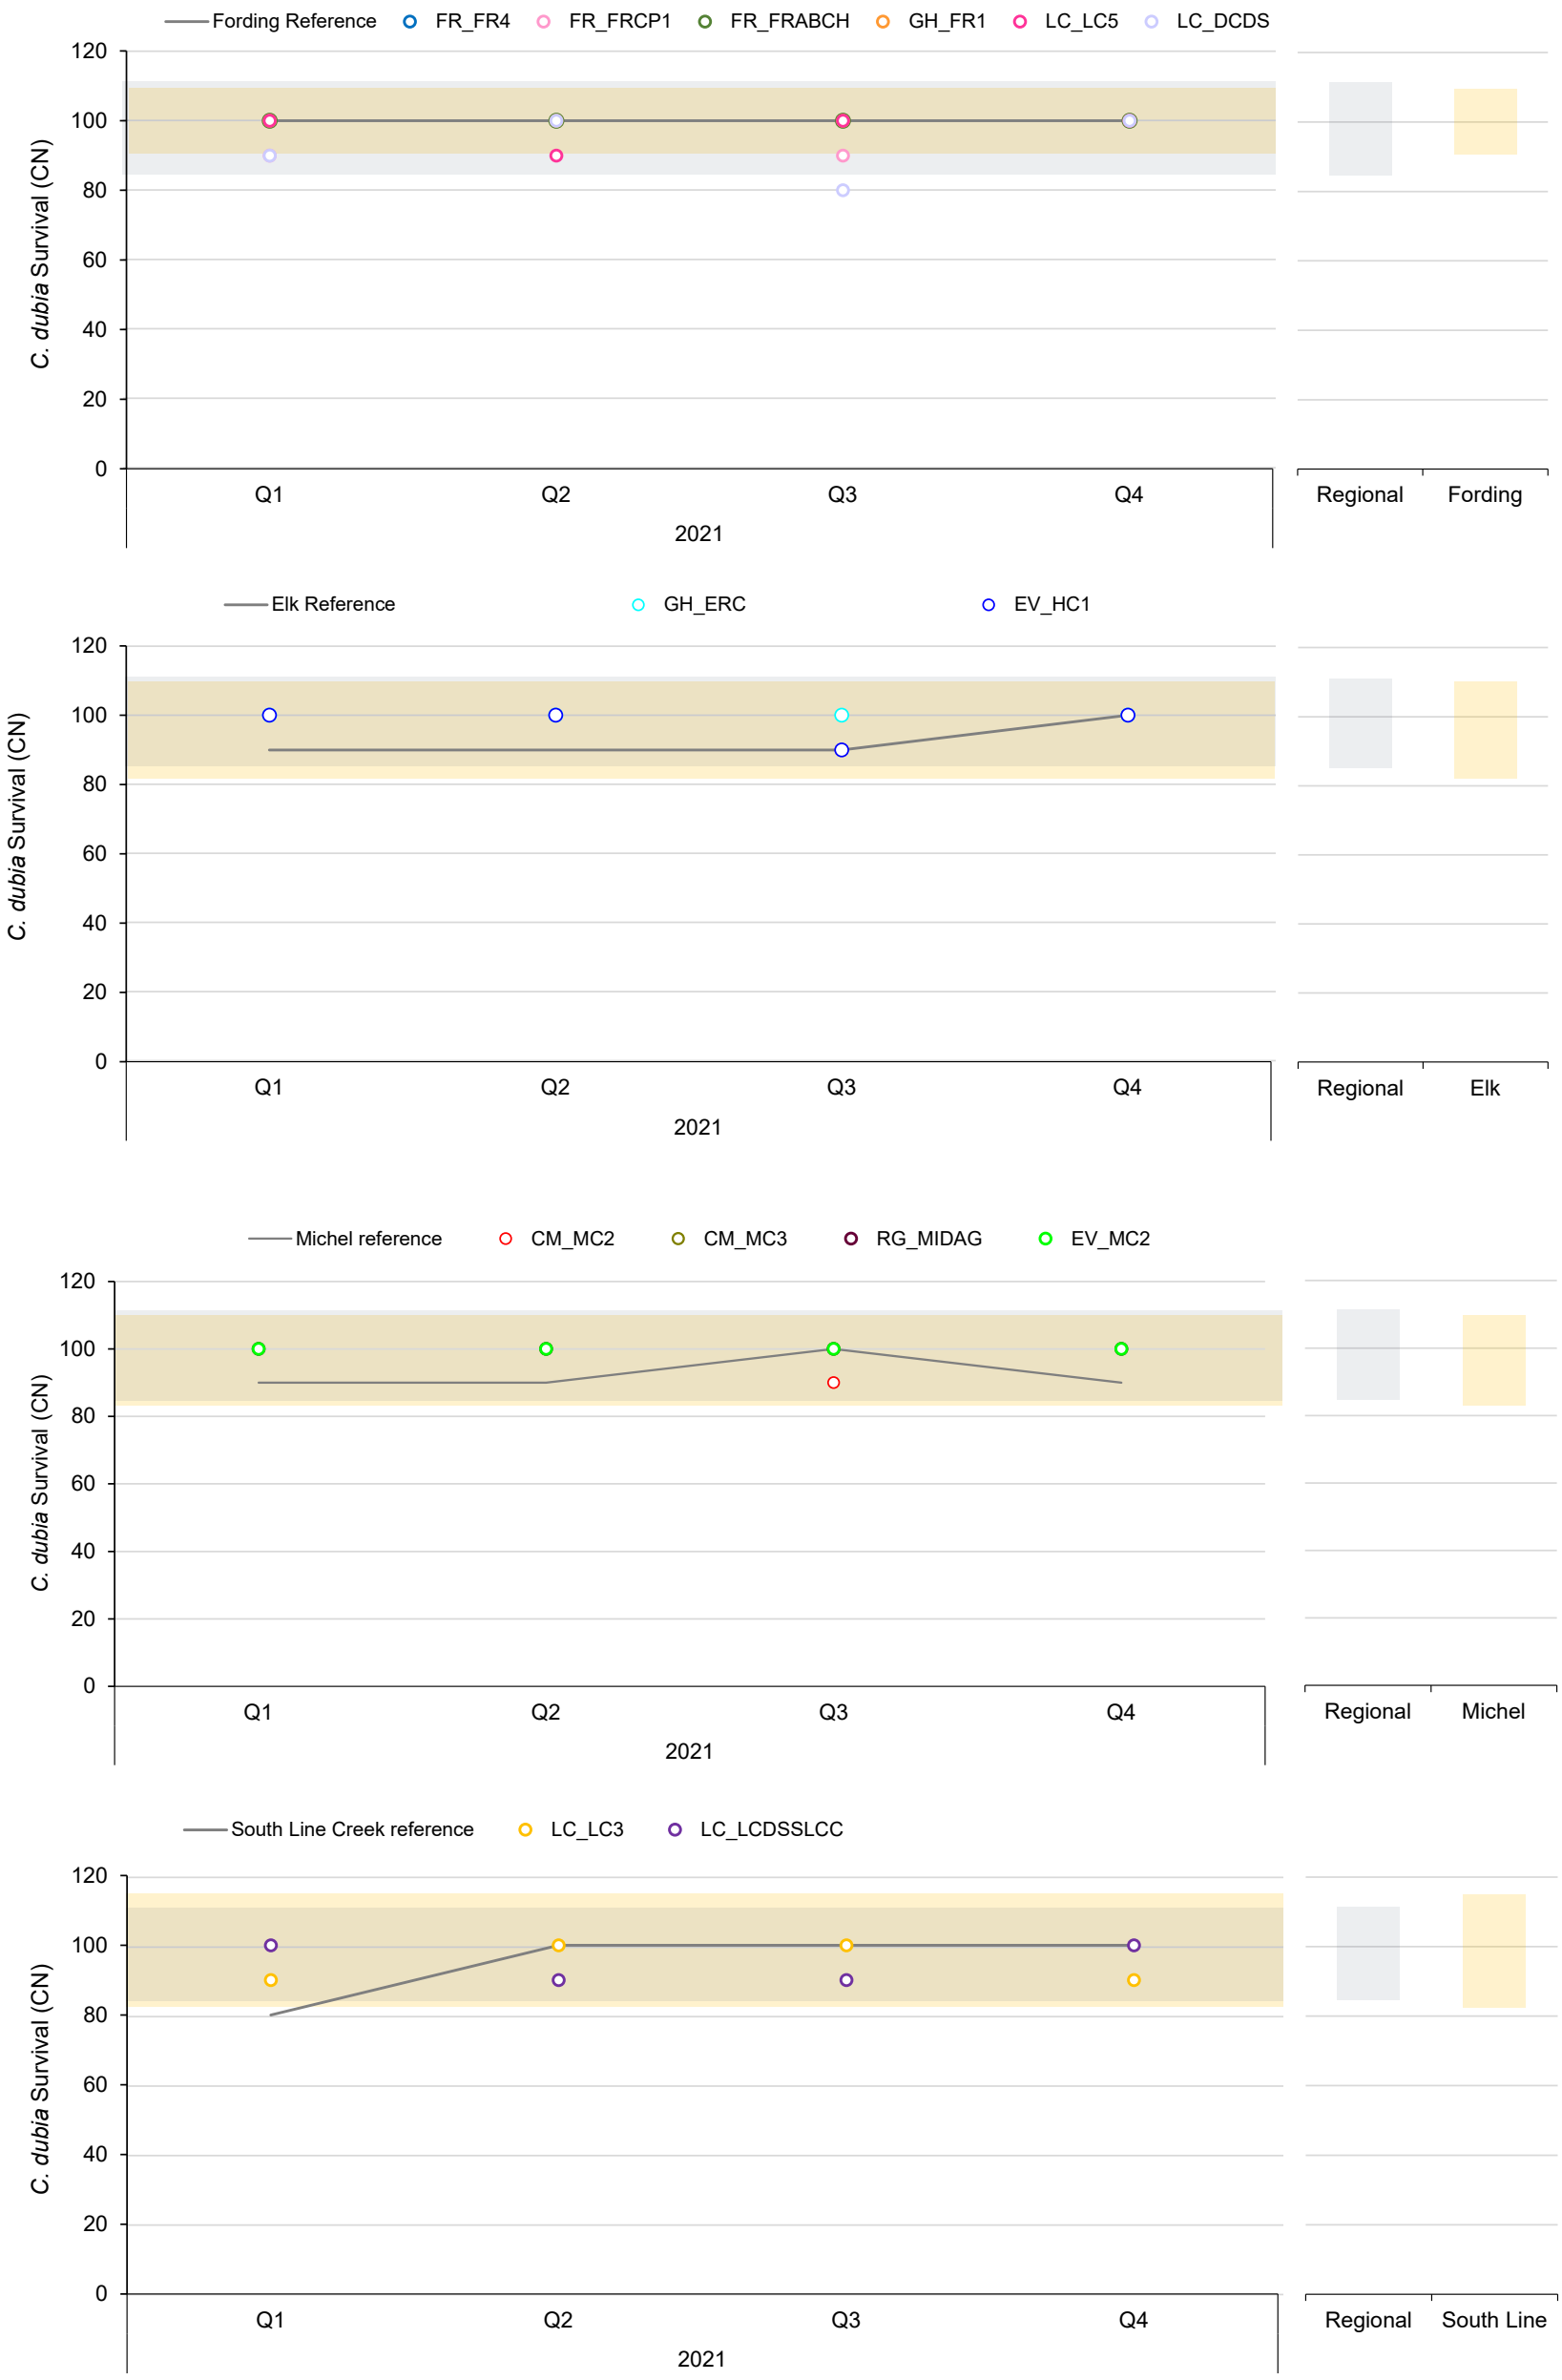
Note: See Figure 2.3-2 for description of lines and symbols. Replicate results are either 100% or 0% because there is a single adult female daphnid in each replicate. Mean results represent the combined data from ten replicates per treatment. CN = control normalized.

Figure 3.3-2: Individual replicate and mean results for *C. dubia* reproduction in reference (Ref) and test site waters.



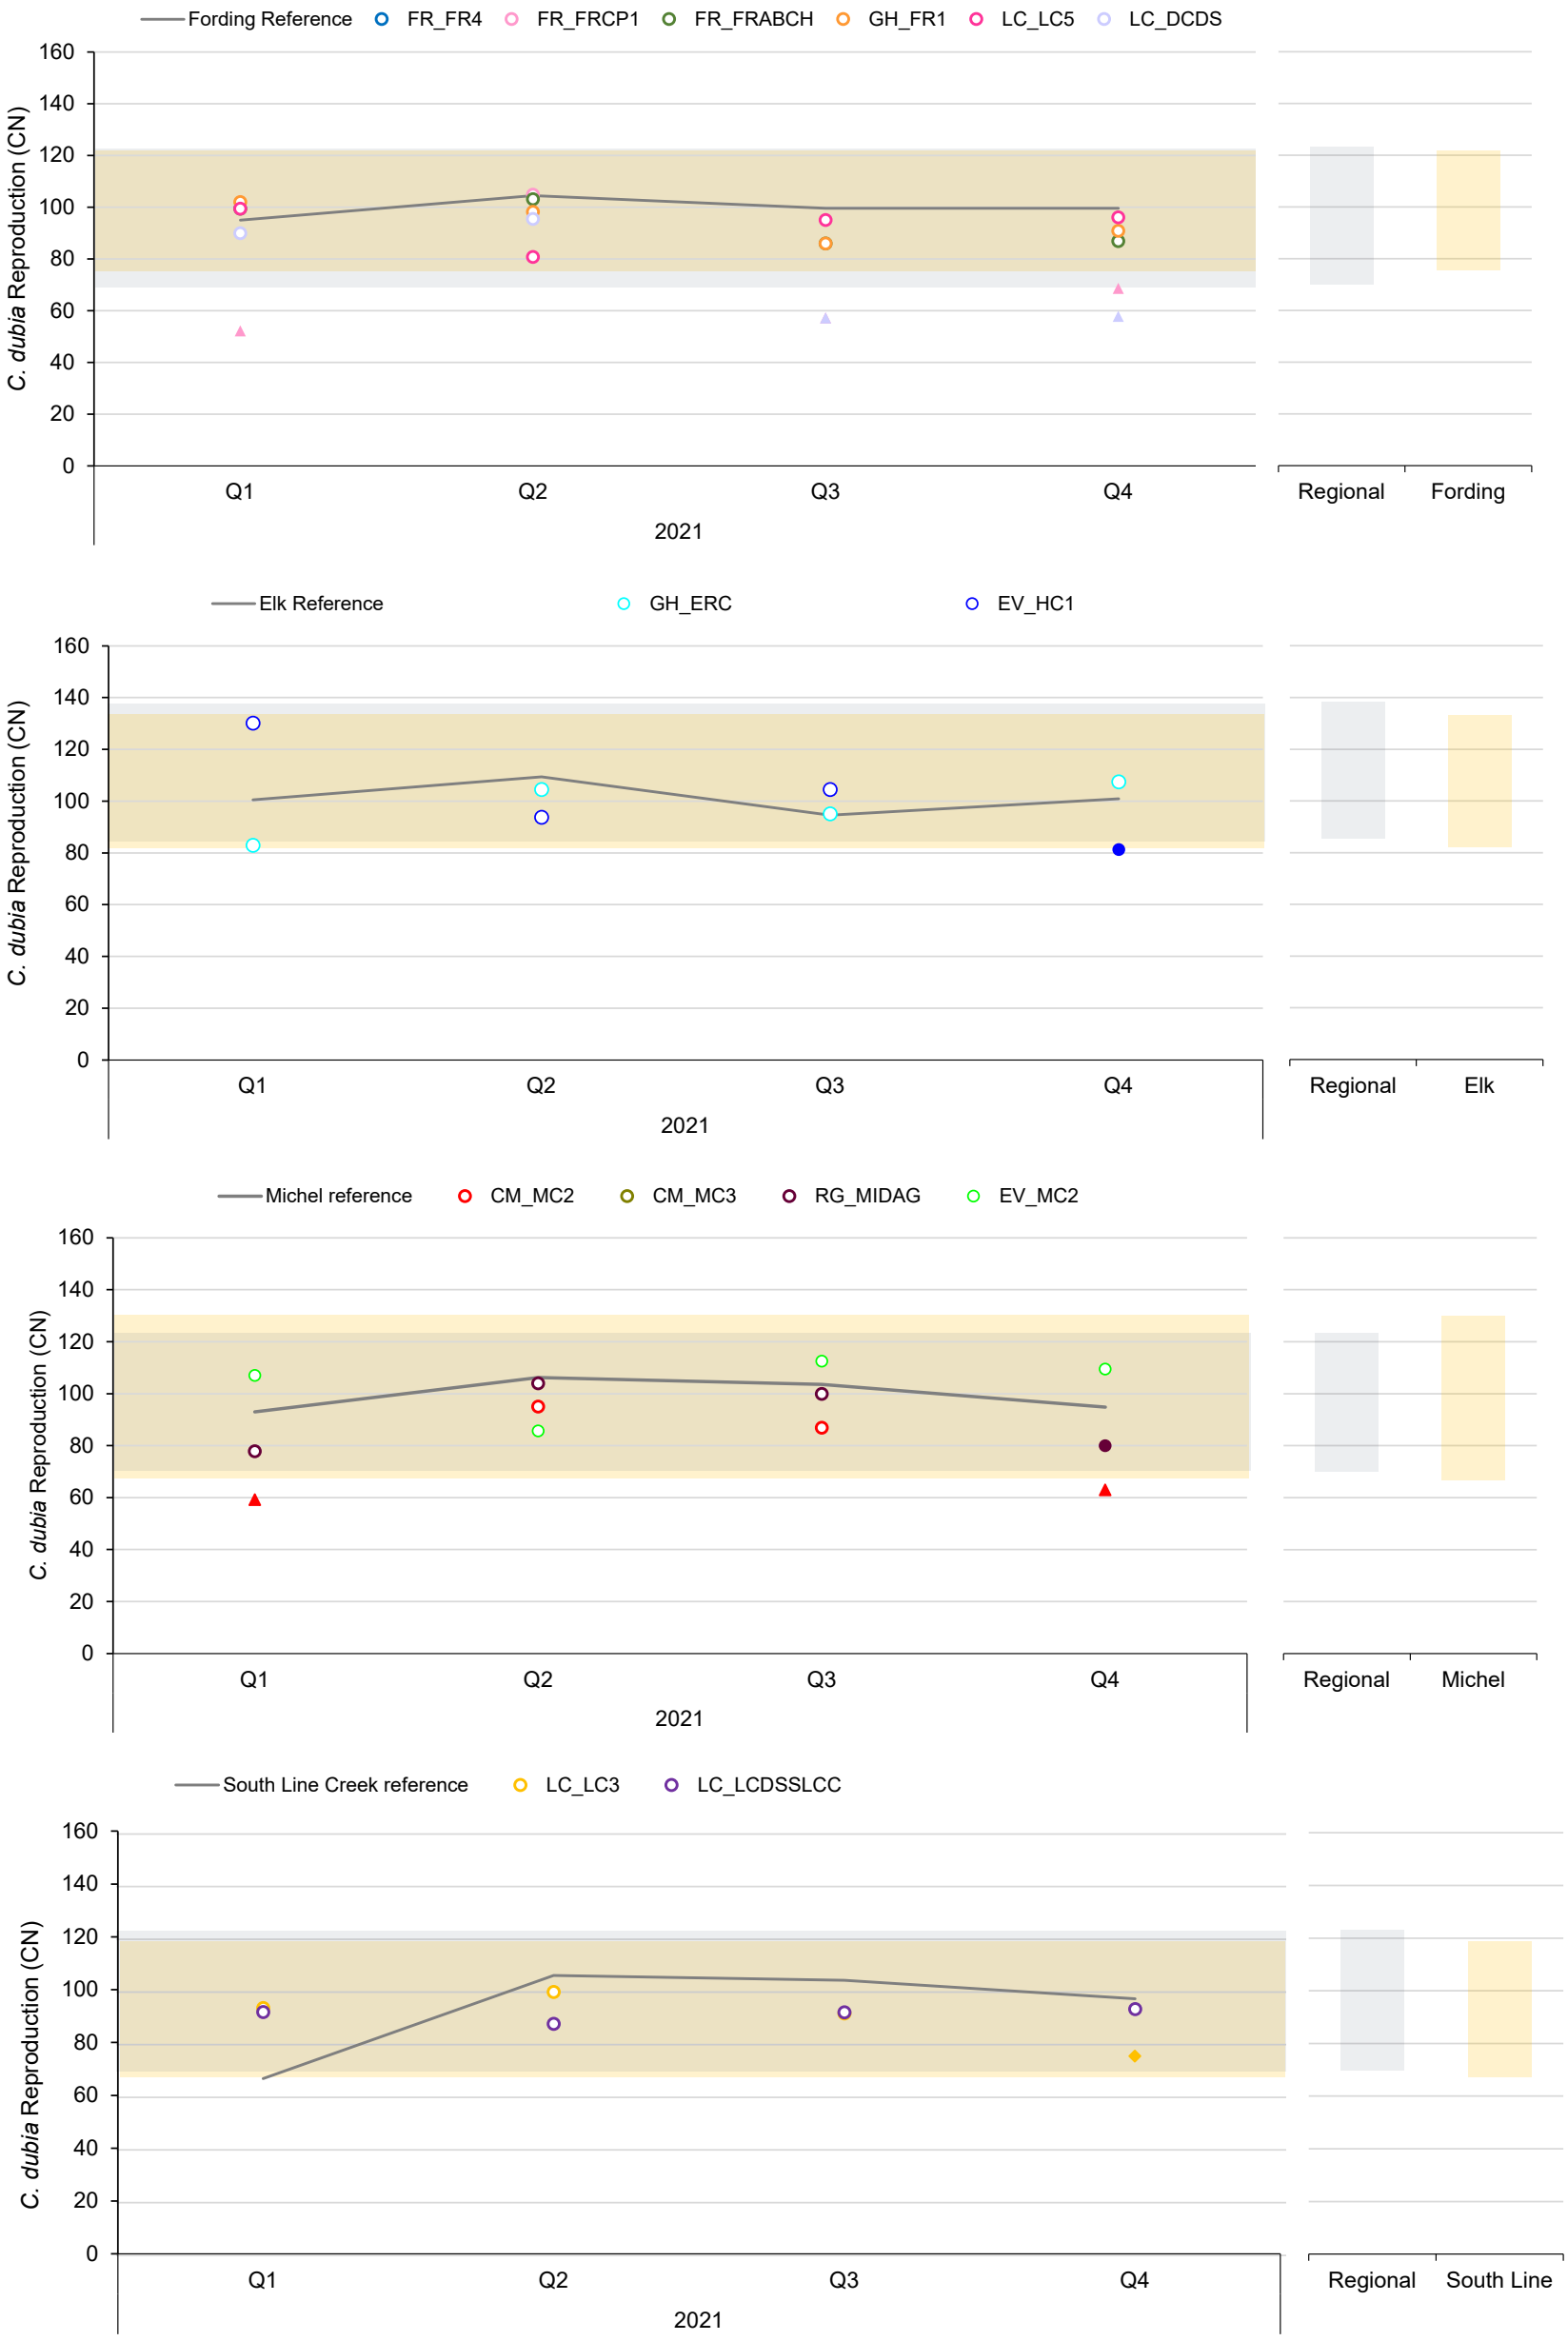
Note: See Figure 2.3-2 for description of lines and symbols. CN = control normalized.

Figure 3.3-3: Mean results for *C. dubia* survival in the Fording River reference and its paired test site waters (top left panel), the Elk River reference and its paired test site waters (second left panel), the Michel Creek reference and its paired test site waters (third left panel), and the South Line Creek and its paired test waters (bottom left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).



Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3).CN = control normalized.

Figure 3.3-4: Mean results for *C. dubia* reproduction in the Fording River reference and its paired test site waters (top left panel), the Elk River reference and its paired test site waters (second left panel), and the Michel Creek reference and its paired test site waters (third left panel), and the South Line Creek and its paired test waters (bottom left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).



Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3). CN = control normalized.

Consideration of *Ceriodaphnia dubia* Broods

A comparison of *C. dubia* brood output between the Environment Canada protocol tests and 8-day tests is provided in Figure 3.3-5. At a broad level, the differences between the two methods of quantifying reproductive output were not large. There was no statistical difference between the mean neonates counted using either method in 23 of 68 tests (33%) conducted across the four quarters. Of the 23 tests where a difference was observed, the percent difference of mean number of neonates in the 8-day protocol was ≤15% greater relative to the protocol test, except for two Q2 tests (22% [EV_MC2] and 42% [LC_DCDS])) and six Q4 tests (26% [FR_FRCP1], 33% [CM_MC2], 31% [RG_MIDAG], 24% [EV_HC1], 21% [LC_DCDS], and 20% [LC_LC3]).

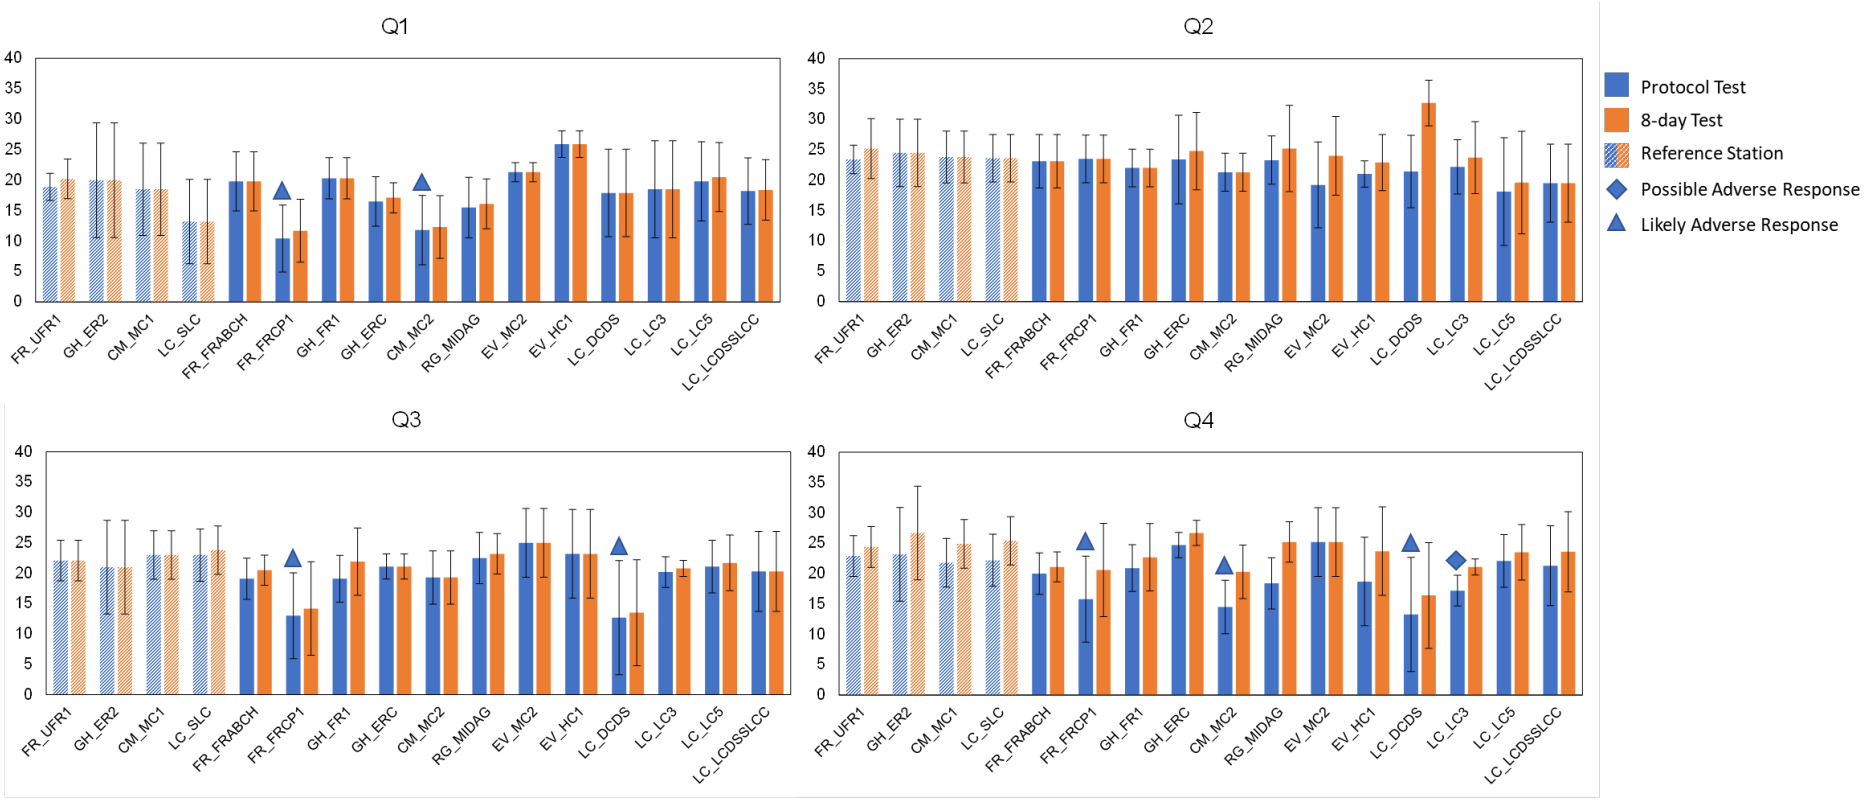
Tests that were significantly lower than one or more reference in the Environment Canada protocol test were also significantly lower than one or more reference in the 8-day test, except for the Q4 RG_MIDAG test. Reproduction for Q4 RG_MIDAG was significantly lower than the Fording and Elk reference tests in the Environment Canada protocol test but was similar to all batch-specific references in the 8-day test. The Q4 RG_MIDAG test was categorized as no adverse response, indicating that the conclusions would not have differed between the two test terminations.

The comparison of results from the Environment Canada protocol test and the 8-day tests provides the following important information:

- Termination of the test based on negative control performance can occasionally result in loss of information from a third brood, and this was most notably demonstrated in Q4 of 2021. This occurs in an unpredictable manner throughout the historical test record because the Environment Canada test duration of 6, 7, or 8 days is subject to high uncertainty (and can be arbitrary when the test is terminated in the middle of the third brood event).
- Early termination of Q4 tests in 2021 following the Environment Canada protocol (Day 6) can result in estimates of reproduction that are negatively biased when the objective is to characterize the full reproductive output from three broods. This bias may impact reference and test sites differently, as observed in Q4 2020 where the downward bias acted only on the reference site waters (Golder 2021a).

Although the reproductive output was sometimes biased low (i.e., in Q4 2021), there were no differences in the assigned effect categorization. The 2021 analysis confirmed that the samples showing reduced reproduction in the Environment Canada test were not an artifact of test termination date.

Figure 3.3-5: Mean Number of *Ceriodaphnia dubia* Neonates in Protocol and 8-day Tests in 2021.



Notes: Error bars represent the standard deviation of number of neonates.

3.3.1.2 *Pseudokirchneriella subcapitata*

Cell yield was significantly reduced relative to one or more references in 29 of 44 tests (Figure 3.3-6; Figure 3.3-7; Table 3.3-1), including all Q1 tests except GH_FR1 and GH_ERC; Q2 tests with GH_FR1, LC_LC5, EV_HC1, LC_LC3, and LC_LCDSSLCC; Q3 tests with FR_FRABCH, LC_DCDS, GH_ERC, EV_HC1, and LC_LC3; and all Q4 tests except FR_FRCP1.

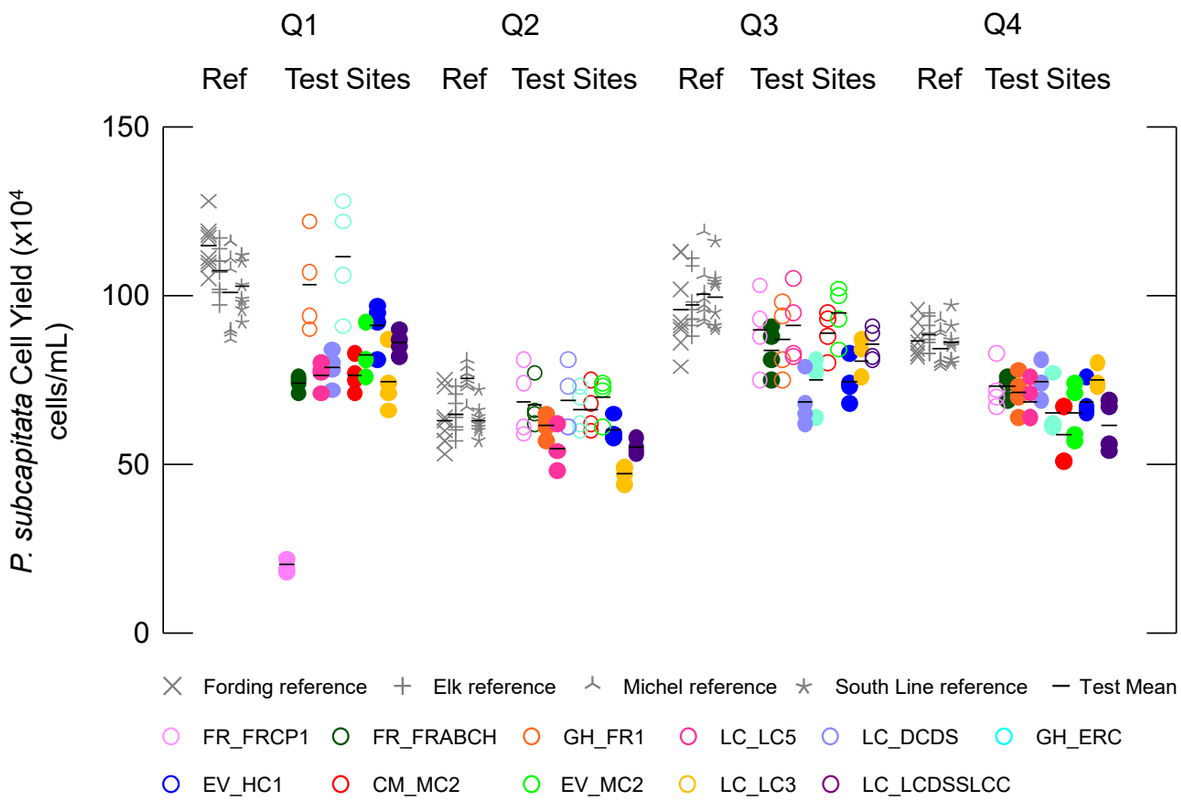
The highest frequency of significant responses was observed in Q1 and Q4. Many of the test sites had mean cell yield that was affected systematically (reduced growth) across the batch, despite the tested sites having different water quality profiles. The reason for the systematic depression is unknown. As discussed as the February 2022 EMC meeting, one potential explanation is nutrient complexation[22], which has been identified as a potential confounding factor in algal test method guidance (e.g., OECD 2019).

Based on the decision framework in Figure 2.3-1, *P. subcapitata* tests were categorized as follows:

- **No adverse response (25 of 44 tests)**: Approximately two thirds of tests were categorized as no adverse response, including 10 tests with significant results. Compared to the mean response in batch-specific references, the effect size in significant tests ranged from 9.5% (EV_HC1 Q2) to 19% (LC_LCDSSLCC Q1).
- **Possible adverse response (16 of 44 tests)**: Q1 tests with FR_FRABCH, LC_LC5, LC_DCDS, CM_MC2, EV_MC2, and LC_LC3; Q2 test with GH_FR1; Q3 tests with LC_DCDS, GH_ERC, and EV_HC1; Q4 tests with LC_LC5, GH_ERC, CM_MC2, EV_MC2, EV_HC1, and LC_LCDSSLCC. Compared to the mean response in batch-specific references, the effect size in tests categorized as possible adverse response ranged from 8% (GH_FR1 Q2) to 32% (CM_MC2 Q4).
- **Likely adverse response (3 of 44 tests)**: Q1 test with FR_FRCP1 and Q2 tests with LC_LC5 and LC_LC3. Compared to the mean response in batch-specific references, the effect size in tests categorized as likely adverse response ranged from 18% (GH_FR1 in Q2) to 81% (CM_MC2 Q4).

The causation assessment for *P. subcapitata* cell yield is presented in Section 3.4.2.

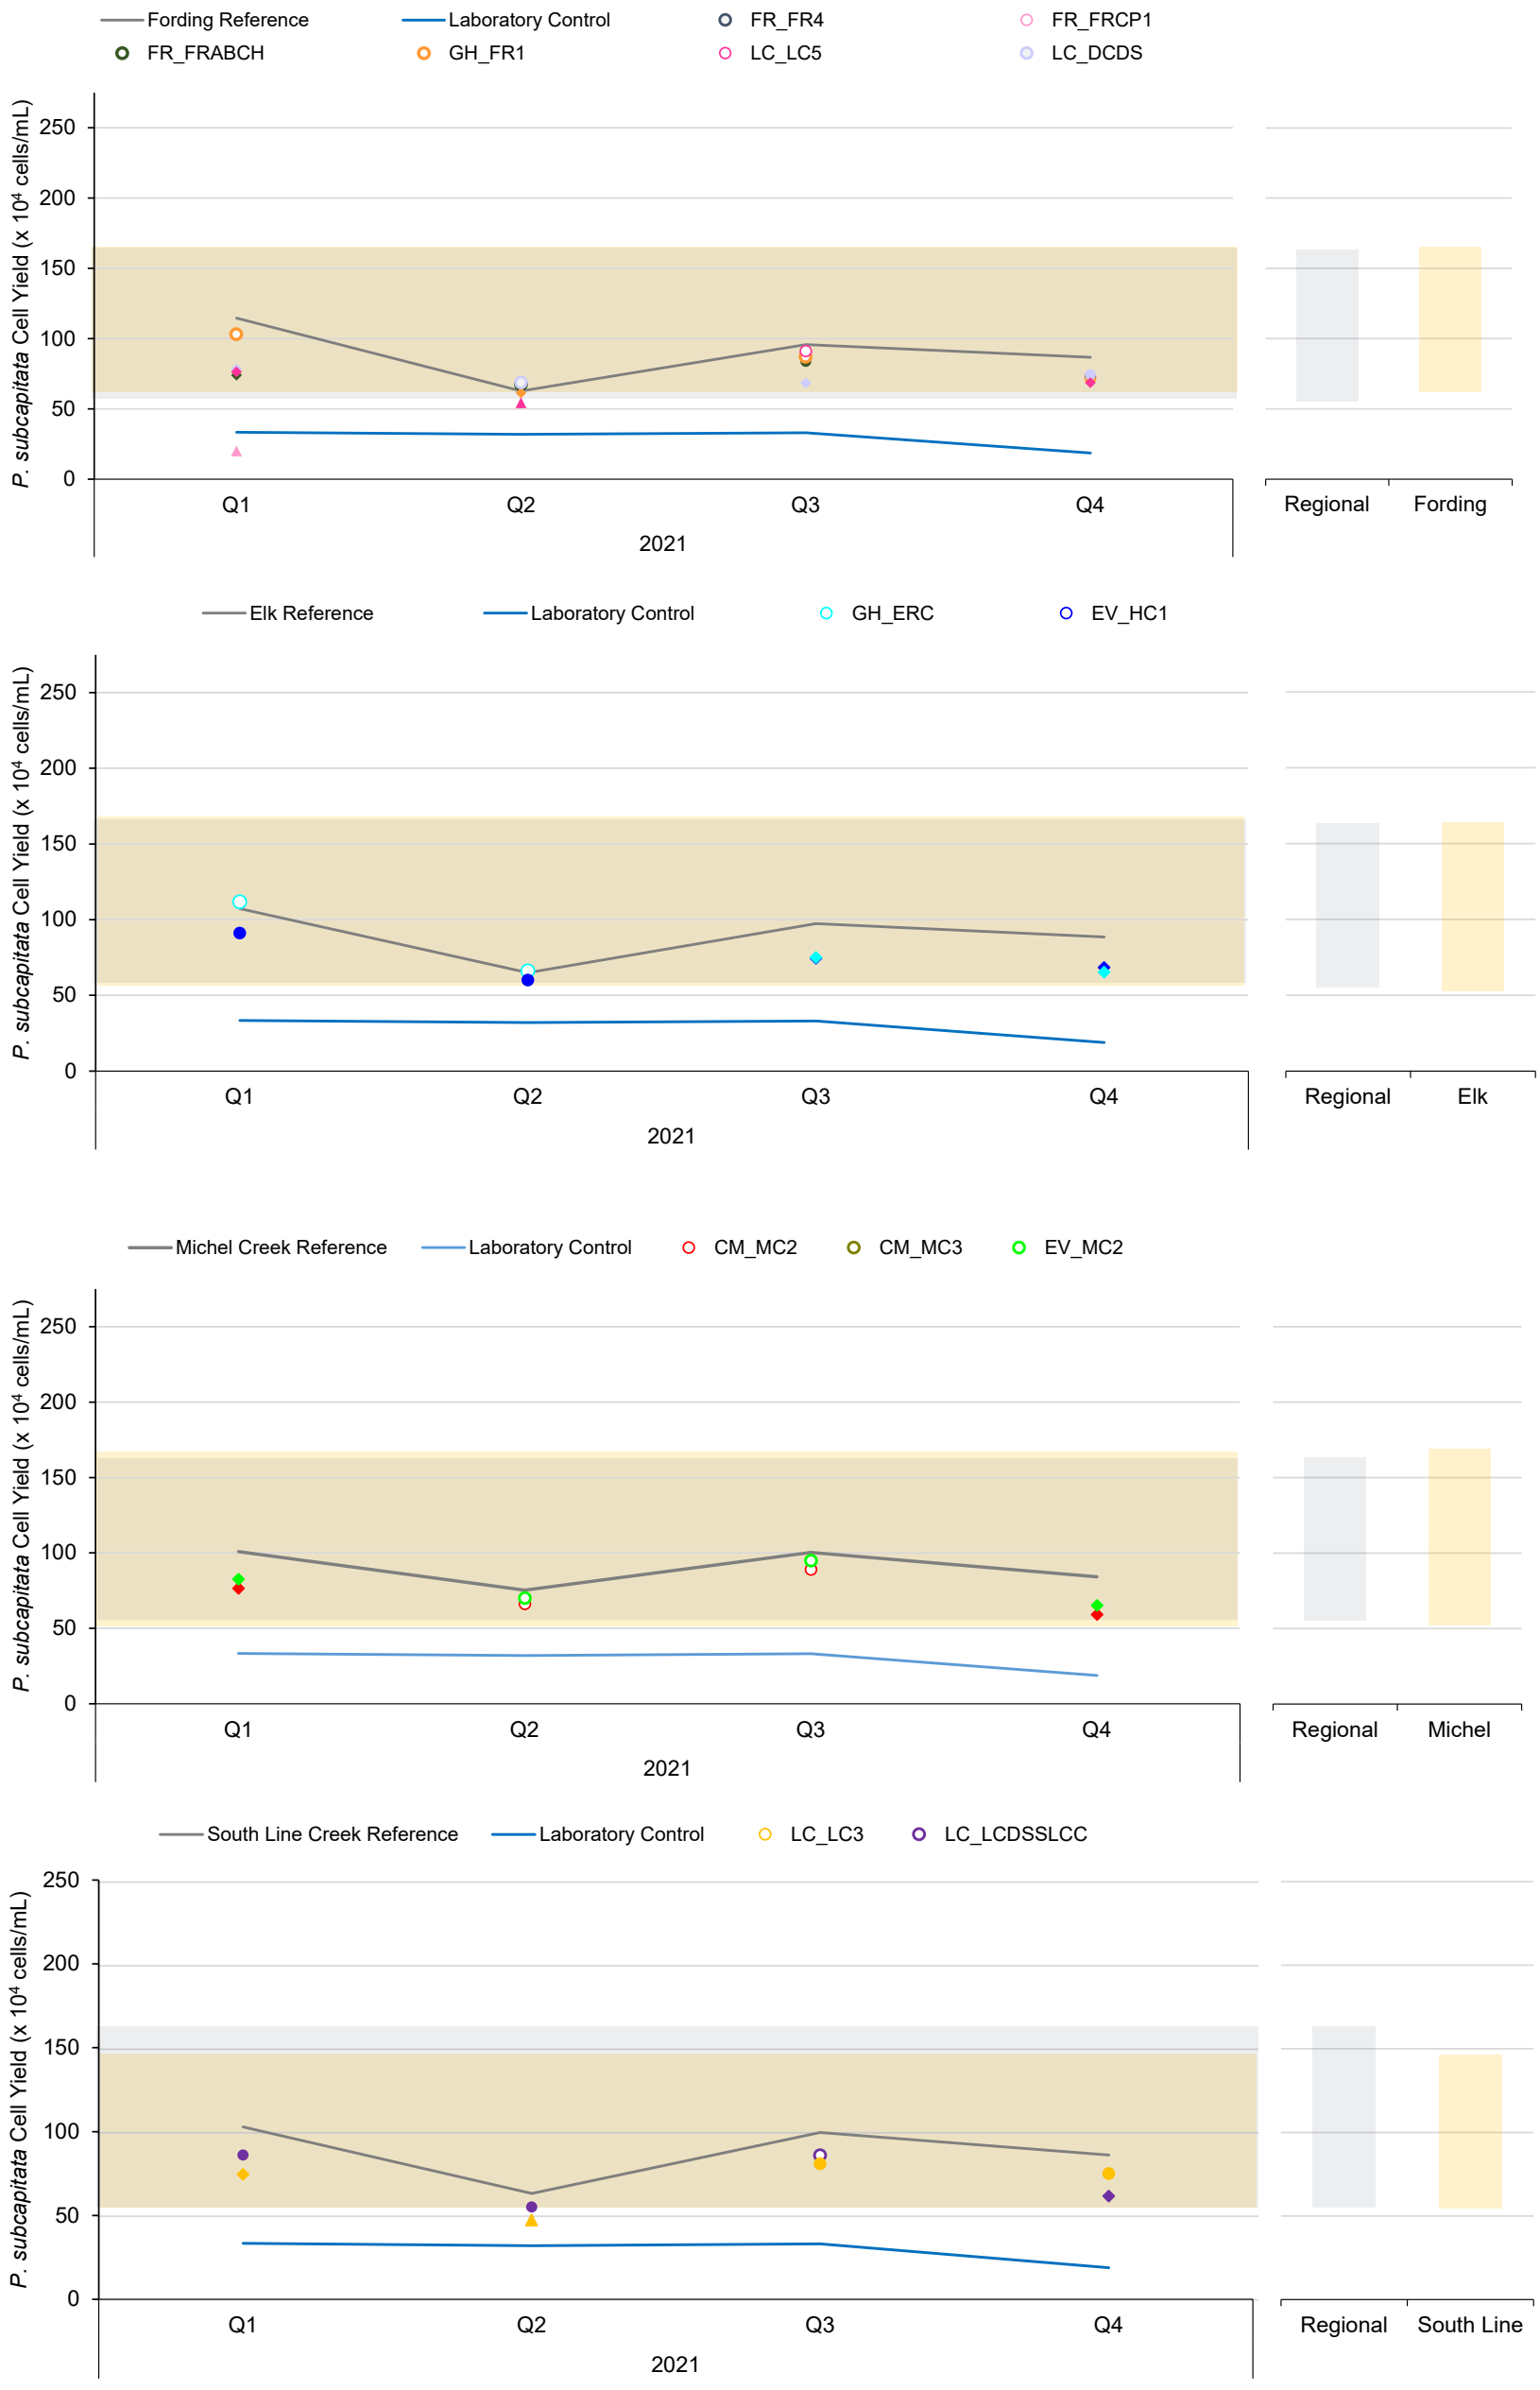
Figure 3.3-6: Individual replicate and mean results for *P. subcapitata* cell yield in reference (Ref) and test site waters.



Note: See Figure 2.3-2 for description of lines and symbols.

[22] Site water chemistry may affect the bioavailability and/or solubility of nutrients, which could reduce cell yield.

Figure 3.3-7: Mean results for *P. subcapitata* cell yield in the Fording River reference and its paired test site waters (top left panel), the Elk River reference and its paired test site waters (second left panel), and the Michel Creek reference and its paired test site waters (third left panel), and the South Line Creek and its paired test waters (bottom left panel). Regional and local normal ranges (2.5th and 97.5th percentile) are shown as bars (right panels).



Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3)

3.3.1.3 *Hyalella azteca*

Survival was significantly reduced in 3 of 36 tests (CM_MC2 Q2 and Q3 and LC_DCDS Q4) (Figure 3.3-8; Figure 3.3-10; Table 3.3-1; Table 3.3-2). In one of three tests with significantly reduced survival (LC_DCDS Q4), mean survival indicated no adverse response; compared to the mean response in batch-specific references, the effect size was 19.9%. In two of three tests with significantly reduced survival, mean survival indicated a likely adverse response to the test water; compared to the mean response in batch-specific references, the effect sizes were 28% (CM_MC2 Q2) and 60% (CM_MC2 Q3).

Dry weight was significantly reduced in 11 of 24 tests[23] (Figure 3.3-9; Figure 3.3-11; Table 3.3-1; Table 3.3-2), including most tests in Q3 (all except RG_MIDAG, EV_MC2 and EV_HC1) and two tests in Q4 (LC_DCDS and GH_ERC). In 4 of 11 tests with significantly reduced dry weight relative to one or more references (Q3 LC_DCDS, GH_ERC, LC_LC3 and LC_LCDSSLCC), mean dry weight was categorized as no adverse response; compared to the mean response in batch-specific references, the effect size ranged from 5.7% (LC_DCDS [Q3]) to 19% (GH_ERC [Q3]). In 6 of 11 tests with significantly reduced dry weight relative to one or more references, mean dry weight was categorized as possible adverse response (Q3 tests with FR_FRCP1, FR_FRABCH, GH_FR1, and LC_LC5 and Q4 tests with LC_DCDS and GH_ERC); effect sizes for tests categorized as possible adverse response ranged from 20% (Q3 GH_FR1) to 27% (Q3 FR_FRCP1). In the remaining test with significantly reduced dry weight relative to one or more references (Q3 CM_MC2), mean dry weight was categorized as likely adverse response; compared to the mean response in batch-specific references, the effect size for this test was 48%.

The highest frequency of significant dry weight responses was observed in Q3. As discussed in Section 3.2.3.3 and at the February 2022 EMC meeting, mean control normalized dry weight in the Q3 Michel Creek reference (90%) was higher than the other three references (which ranged from 62% to 71%). This resulted in all test sites having significantly lower responses relative to the Michel reference only. Except for CM_MC2, Q3 test site responses were statistically similar to all other batch-specific references. Therefore, it is unlikely that the Q3 dry weight results represent an adverse response to toxicants in the test water, but rather reflect natural variance in test organism performance unrelated to water quality.

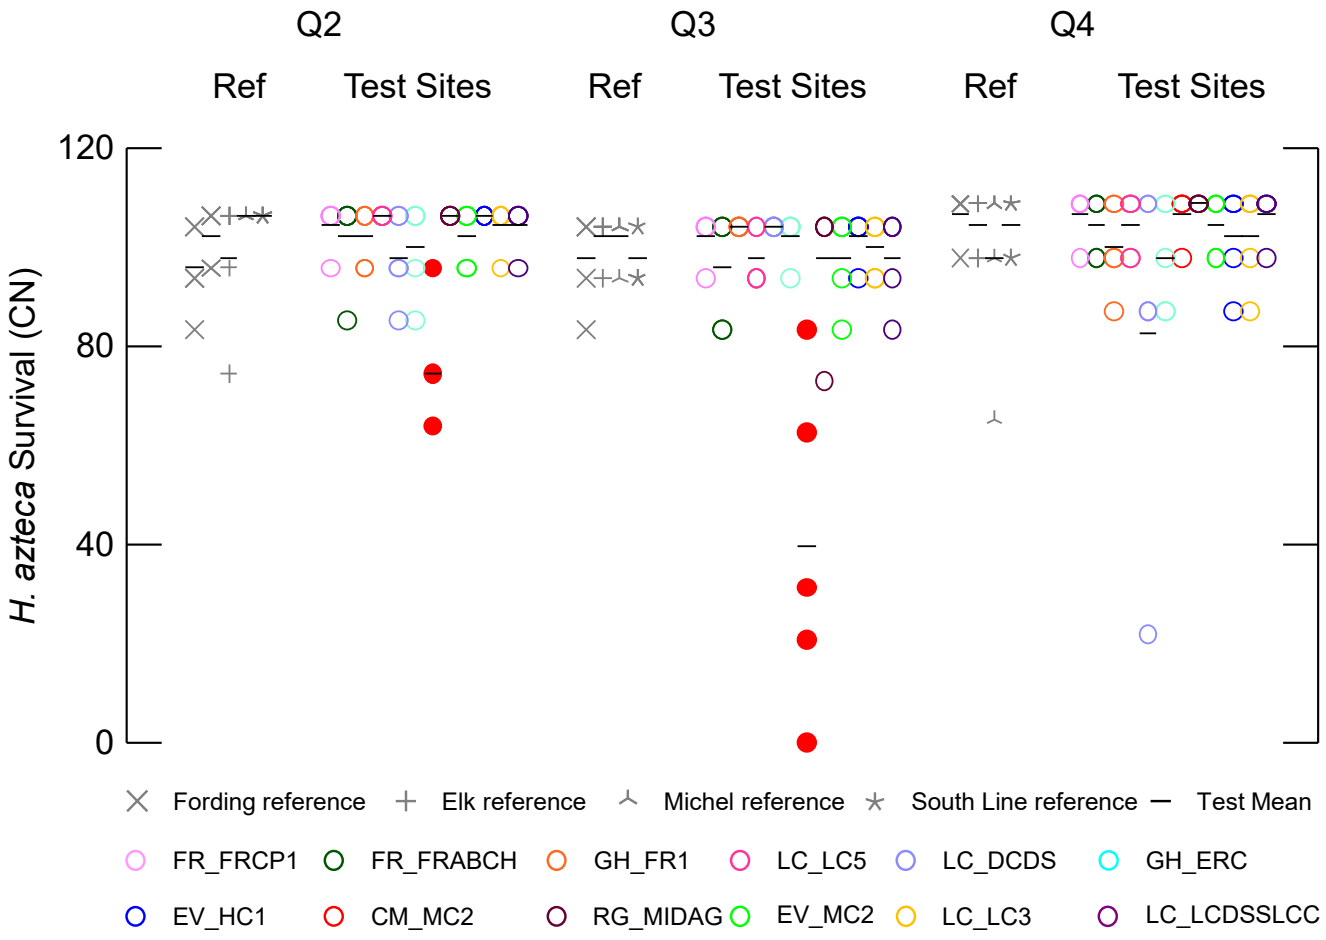
Based on the decision framework in Figure 2.3-1, *H. azteca* tests were categorized as follows:

- **No adverse response (28 of 36 tests)**: All Q2 tests except CM_MC2; Q3 tests with LC_DCDS, GH_ERC, RG_MIDAG, EV_MC2, EV_HC1, LC_LC3 and LC_LCDSSLCC; all Q4 tests except LC_DCDS and GH_ERC.
- **Possible adverse response (6 of 36 tests)**: Q3 tests with FR_FRCP1, FR_FRABCH, GH_FR1, and LC_LC5; and Q4 tests with LC_DCDS and GH_ERC.
- **Likely adverse response (2 of 36 tests)**: Q2 and Q3 tests with CM_MC2.

The causation assessment for *H. azteca* survival and dry weight is presented in Section 3.4.3.

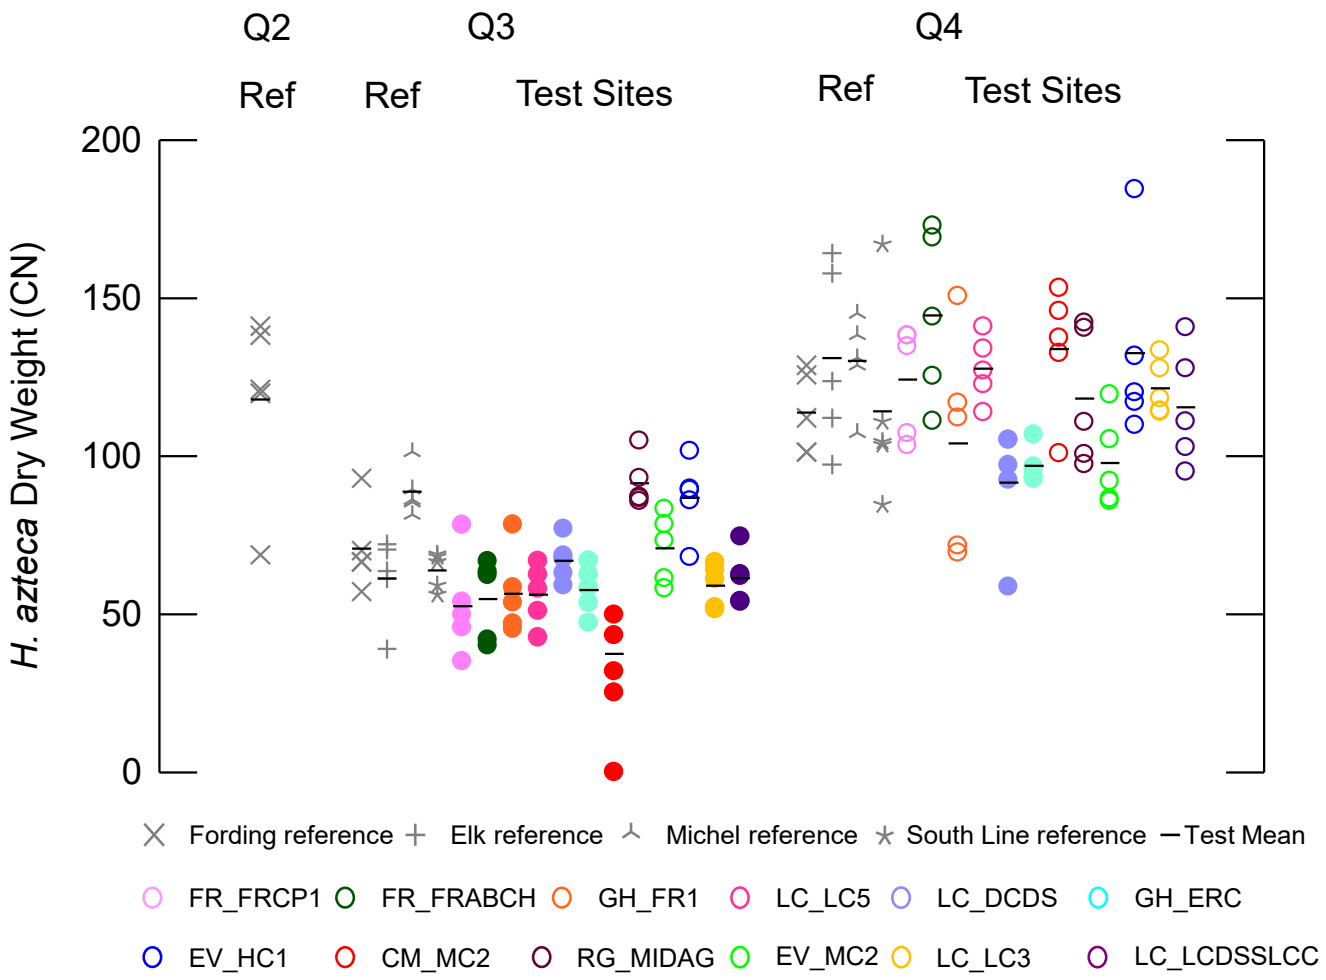
[23] *H. azteca* tests in Q2 were successfully conducted and survival was measured; however, test organisms were disposed prior to measuring dry weight due to a lab technician error. Tests were repeated for all stations in Q3, resulting in 24 of the 36 tests conducted having dry weight results only.

Figure 3.3-8: Individual replicate and mean results for *H. azteca* survival in reference (Ref) and test site waters.



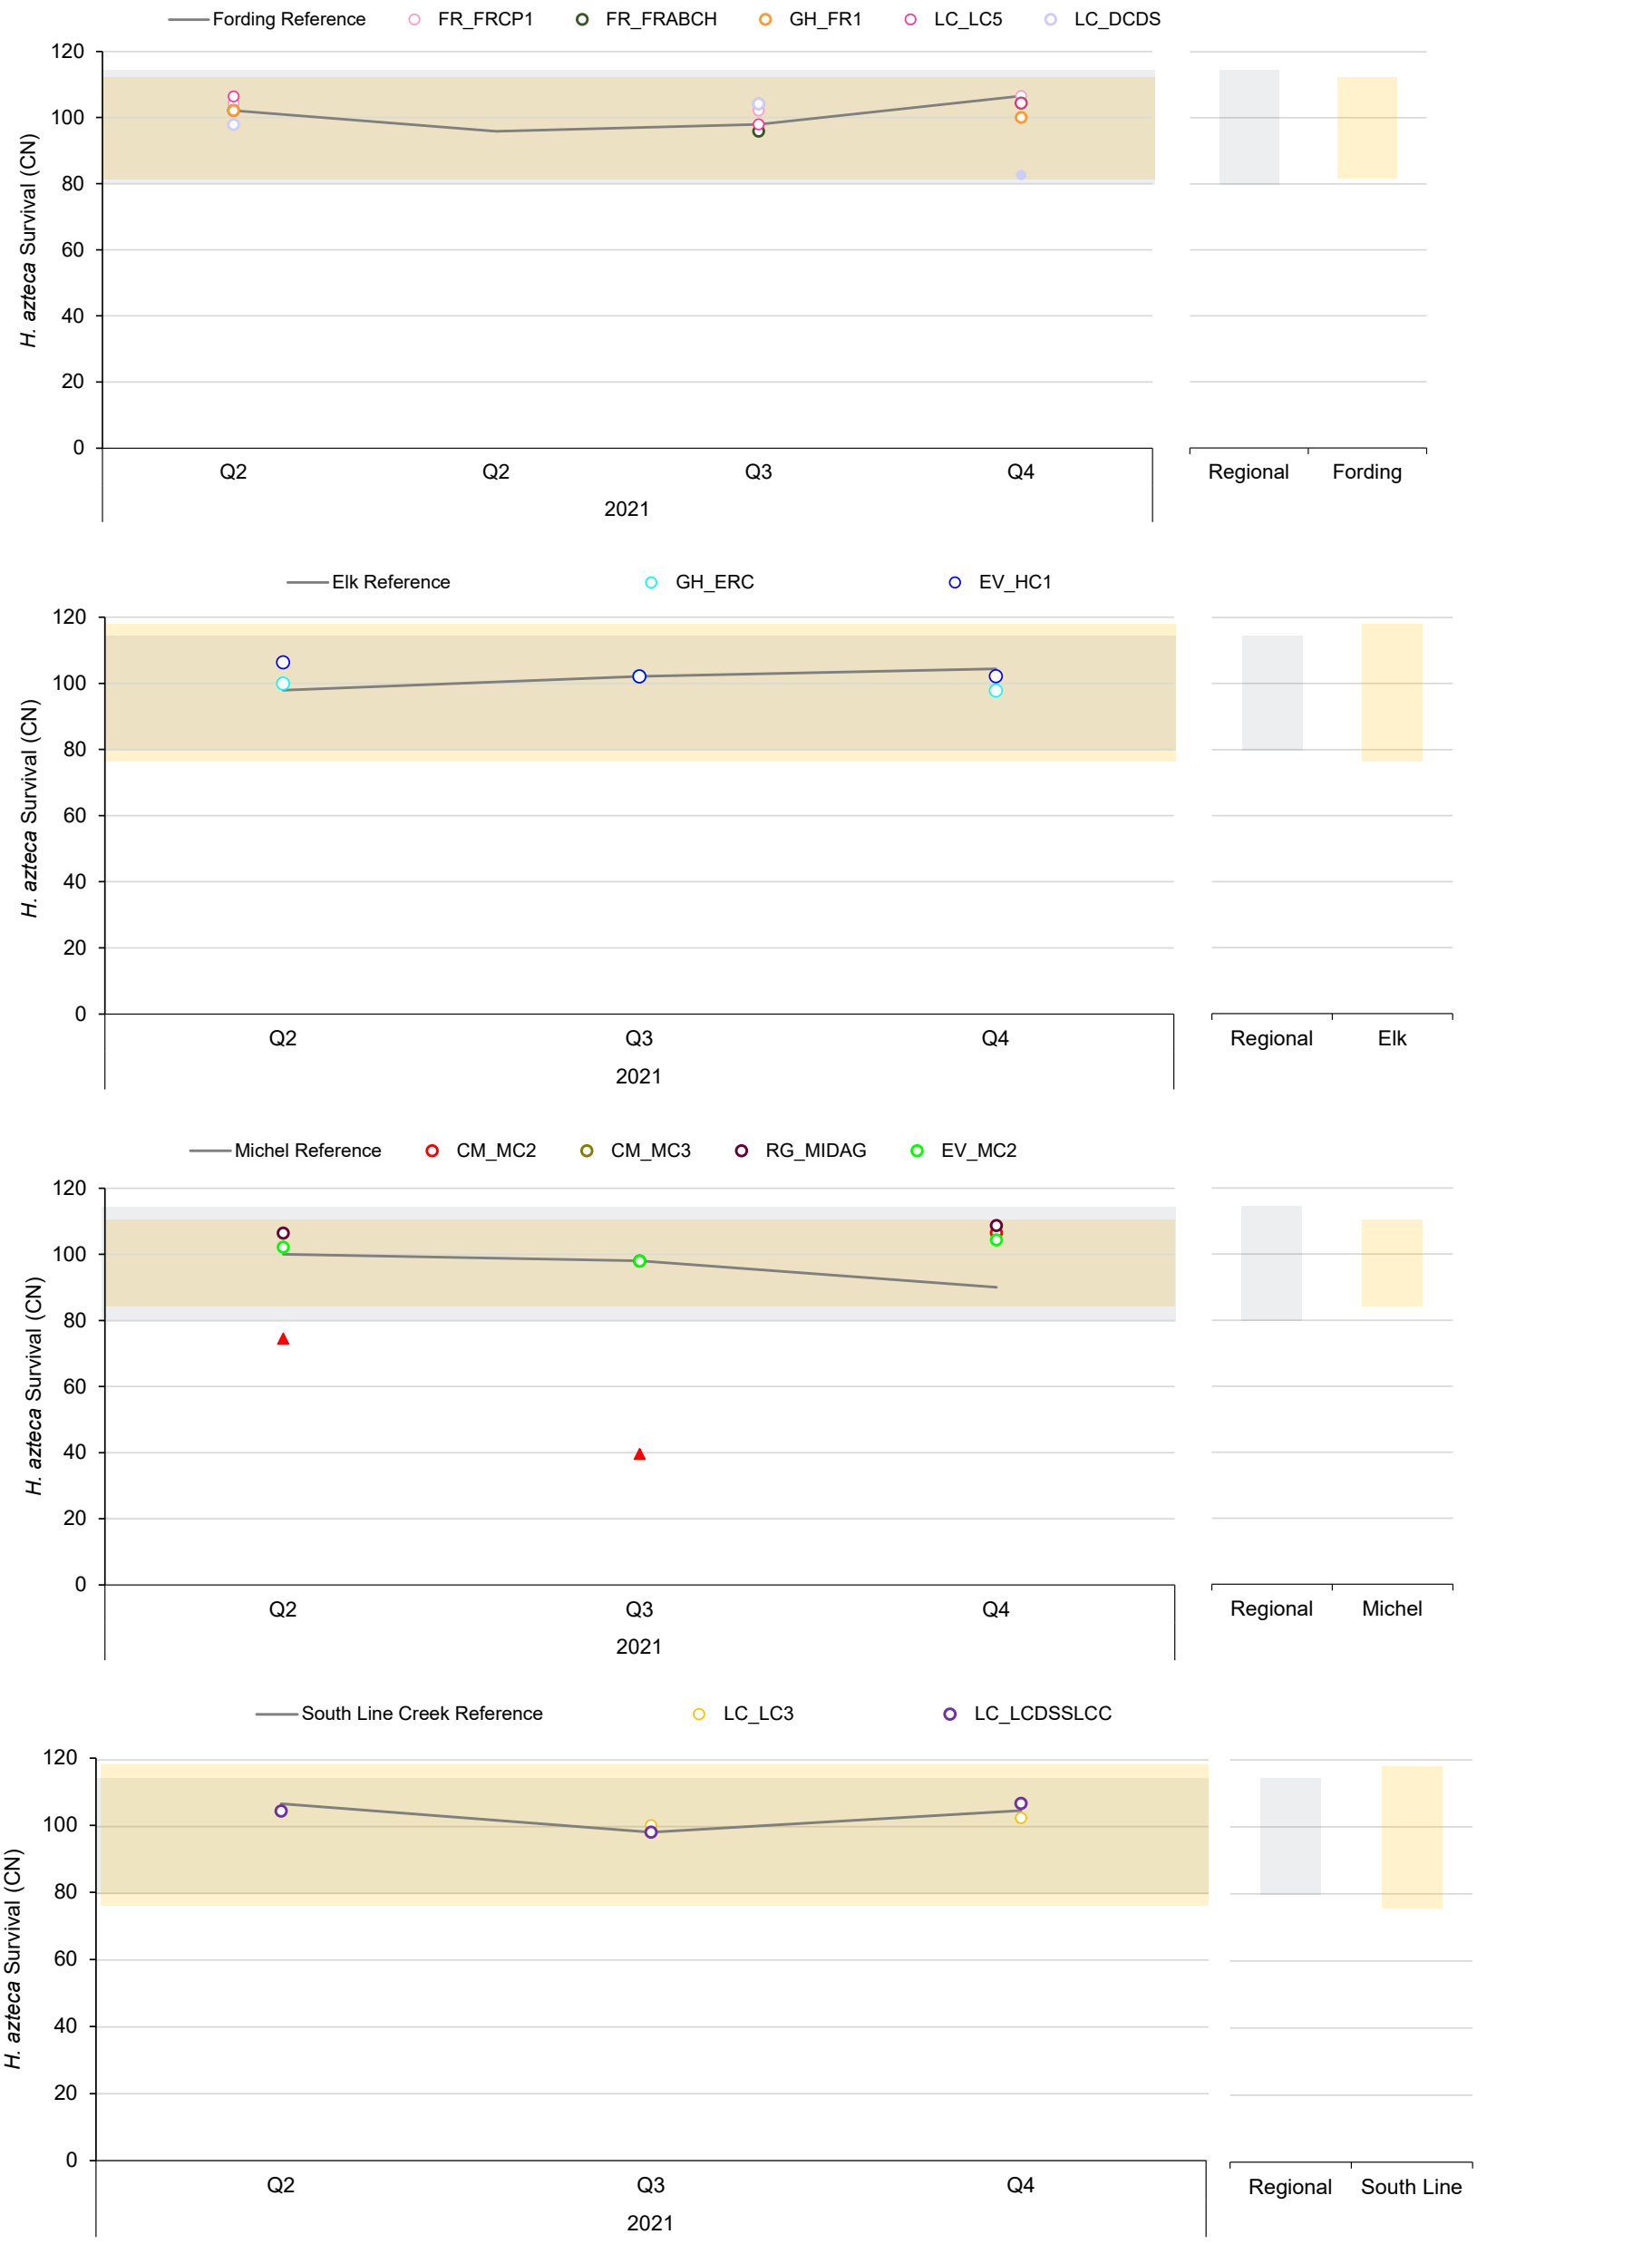
Note: See Figure 2.3-2 for description of lines and symbols. Due to a lab technician error, Q2 *H. azteca* tests were disposed prior to the measurement of dry weight (see Section 3.1). Tests were repeated in Q2 for the Fording River reference and then repeated for all stations in Q3 resulting in the Fording River reference being re-tested in both Q2 and Q3. CN = control normalized.

Figure 3.3-9: Individual replicate and mean results for *H. azteca* dry weight in reference (Ref) and test site waters.



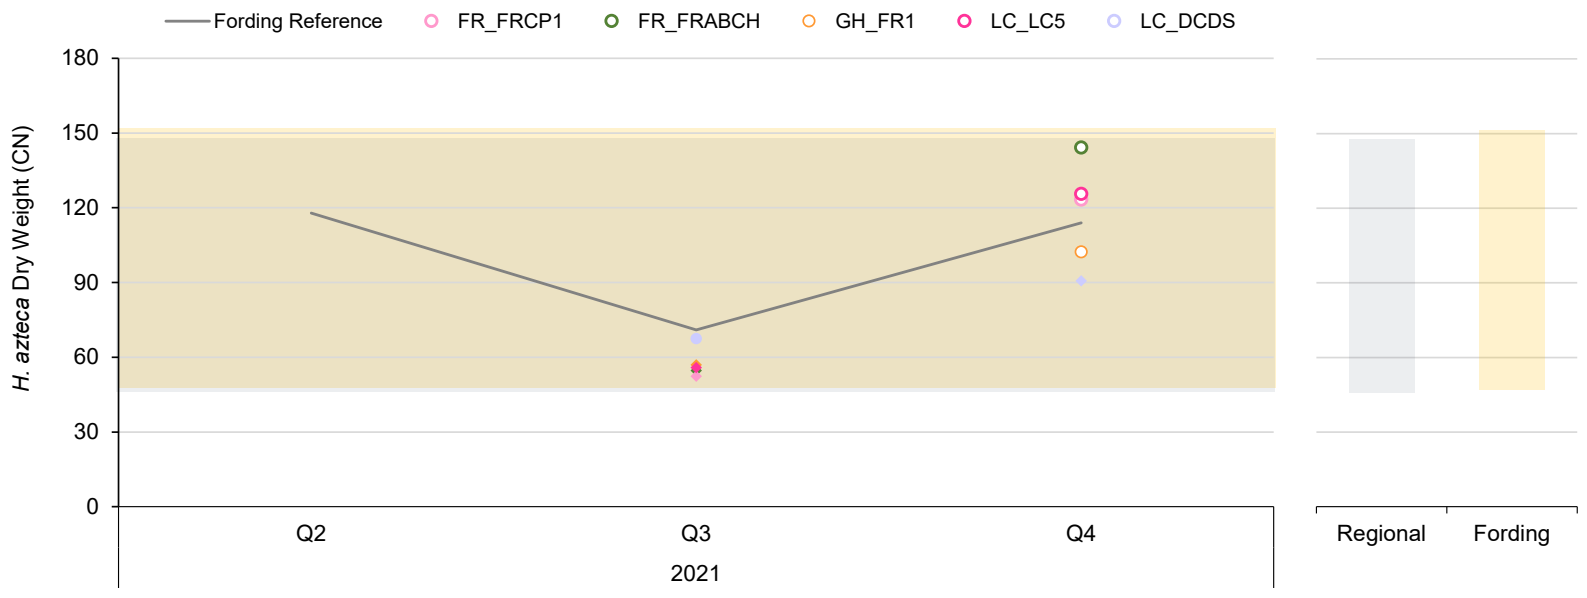
Note: See Figure 2.3-2 for description of lines and symbols. Due to a lab technician error, Q2 *H. azteca* tests were disposed prior to the measurement of dry weight (see Section 3.1). Dry weight results for the Fording River reference in this figure are from the Q2 re-test. CN = control normalized.

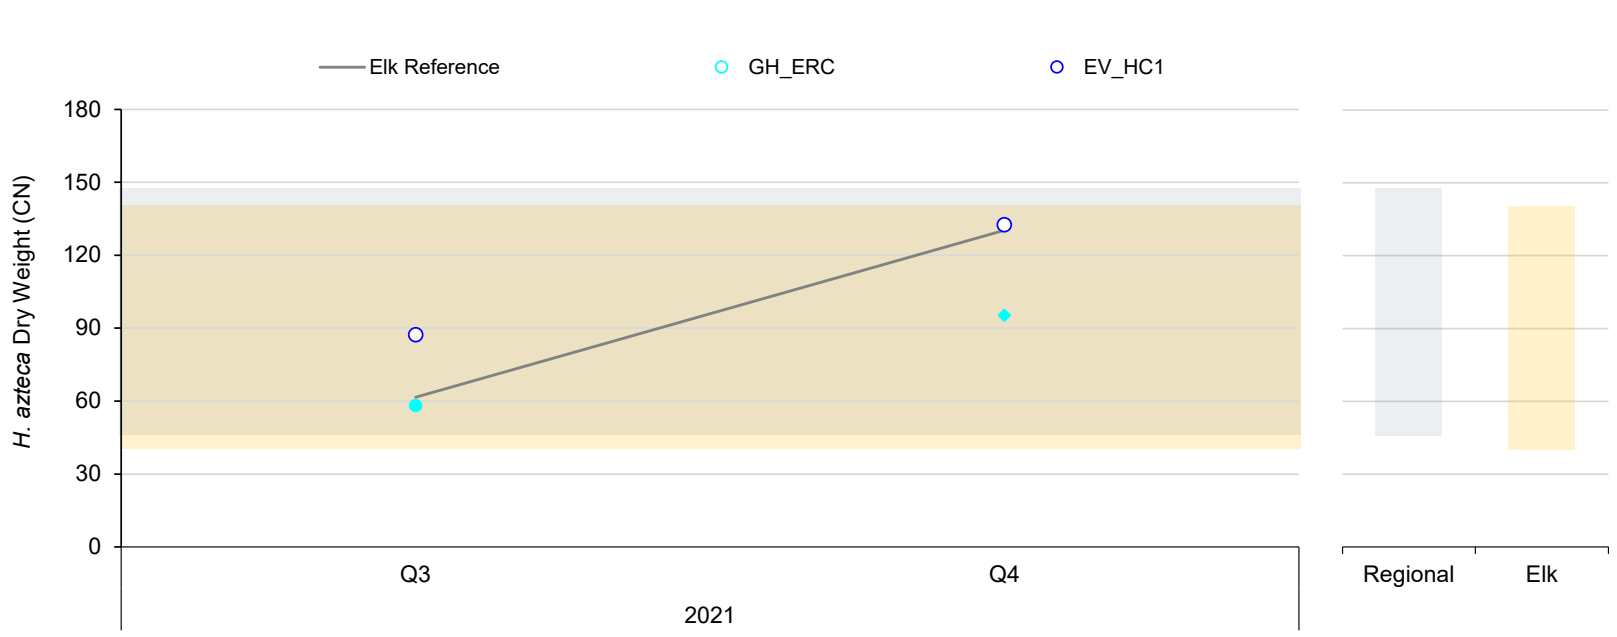
Figure 3.3-10: Mean results for *H. azteca* survival in the Fording River reference and its test site waters (top left panel), the Elk River reference and its paired test site waters (second left panel), the Michel Creek reference and its paired test site waters (third left panel), and the South Line Creek reference and its paired test site waters (bottom left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).

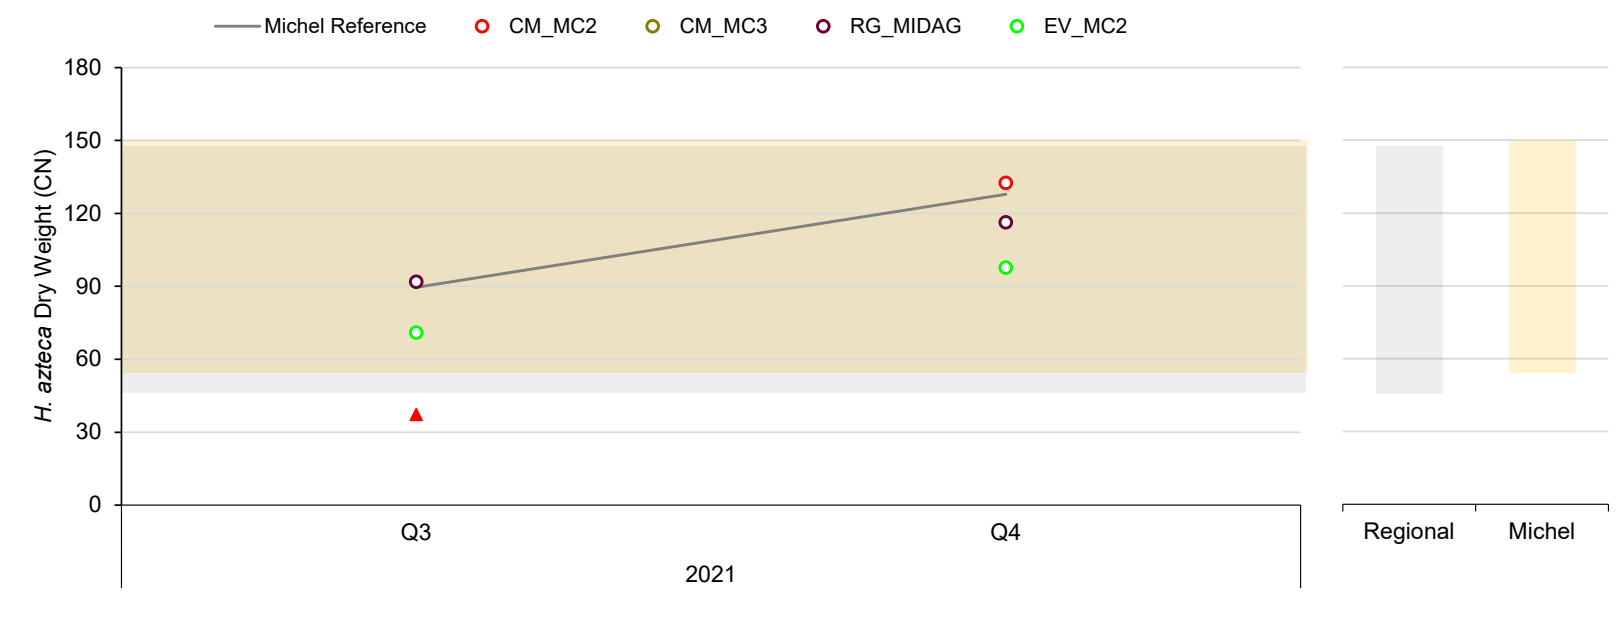


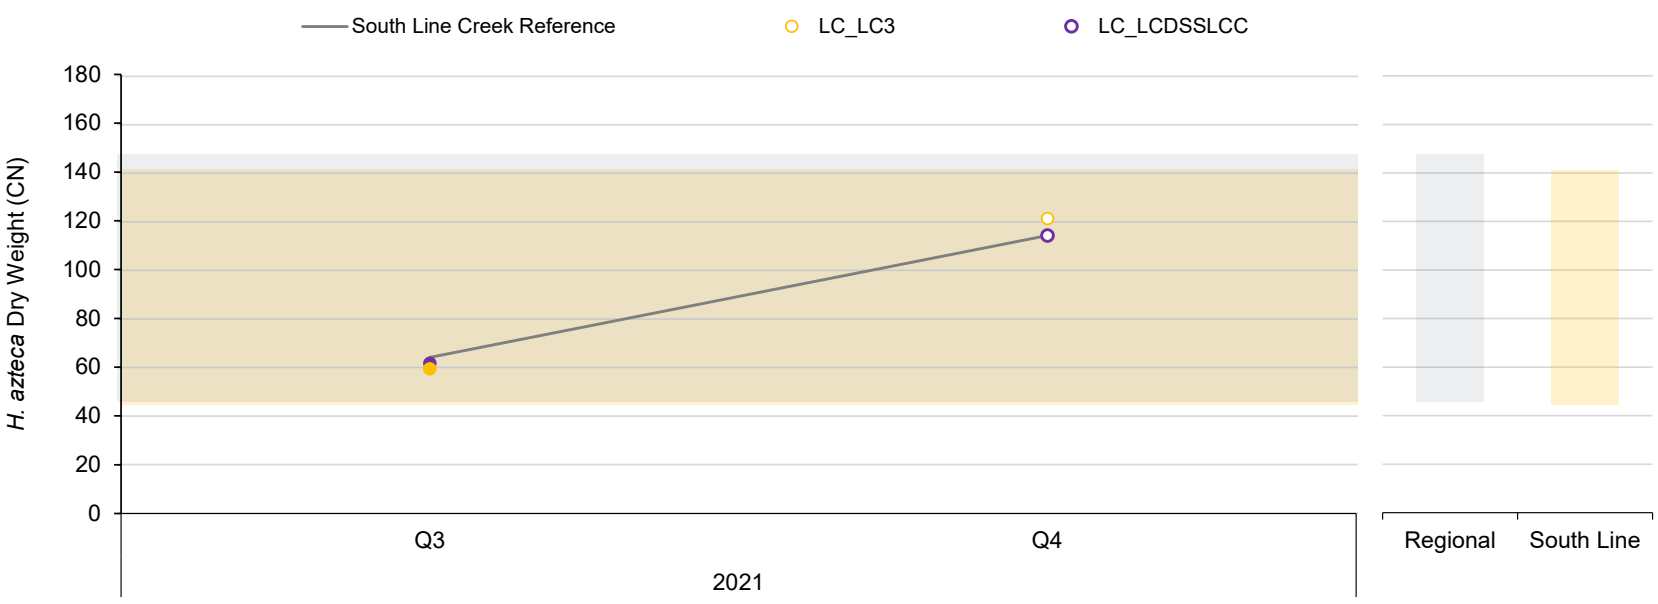
Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3). *H. azteca* tests in Q2 were successfully conducted and survival was measured; however, test organisms were disposed prior to measuring dry weight due to a lab technician error. Tests were repeated for the Fording River reference in Q2 and for all stations in Q3, resulting in two Q2 survival results for the Fording reference. CN = control normalized.

Figure 3.3-11: Mean results for *H. azteca* dry weight in the Fording River reference and its test site waters (top left panel), the Elk River reference and its paired test site waters (second left panel), the Michel Creek reference and its paired test site waters (third left panel), and the South Line Creek reference and its paired test site waters (bottom left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).









Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3). As discussed in Sections 3.1 and 3.2.3.3, Q4 2020 results were not included in updated NR calculations. Test sites were compared to their paired local NR (Section 2.3.3). *H. azteca* tests in Q2 were successfully conducted and survival was measured; however, test organisms were disposed prior to measuring dry weight due to a lab technician error. Tests were repeated for the Fording River reference in Q2 and for all stations in Q3, resulting in two Q2 survival results for the Fording reference. Q2 results presented are from the Q2 re-test. CN= control normalized.

3.3.1.4 *Oncorhynchus mykiss*

There were no adverse behavioural responses of *O. mykiss* in 2021 tests. The survival and viability endpoint responses were numerically similar, indicating a low rate of deformities in all samples (Appendix B). These results are expected given that rainbow trout alevins are not sufficiently developed to exhibit indications of deformations or behaviour that are more commonly assessed at the fry stage.

Survival was significantly reduced relative to one or more references in 4 of 22 tests (Figure 3.3-12; Figure 3.3-16; Table 3.3-1; Table 3.3-2), including two Q2 tests (GH_FR1 and LC_LC5) and two Q4 tests (FR_FRCP1 and GH_FR1). In three of four tests with significantly reduced survival relative to one or more references, mean survival was categorized as no adverse response; compared to the mean response in batch-specific references, the effect sizes in these three tests ranged from 11% (GH_FR1 Q2) to 16% (LC_LC5 Q2). In the Q4 FR_FRCP1 test, mean survival indicated a possible adverse response; compared to the mean response in batch-specific references, the effect size was 21%.

Viability outcomes were similar to those for survival. Viability was significantly reduced relative to one or more references in 4 of 22 tests (Figure 3.3-13; Figure 3.3-17; Table 3.3-1; Table 3.3-2), including two Q2 tests (GH_FR1 and LC_LC5) and two Q4 tests (FR_FRCP1 and GH_FR1). In all tests with significantly reduced viability relative to one or more references, mean viability was categorized as no adverse response; compared to the mean response in batch-specific references, the effect sizes in significant tests categorized as no adverse response ranged from 9.5% (GH_FR1 Q2) to 19% (FR_FRCP1 Q4).

There were no tests where length or weight were significantly reduced relative to one or more references. Lack of growth responses (length or weight) is consistent with historical testing of this species, which indicate survival and viability are the most sensitive endpoints.

As discussed in the Q2 and Q4 laboratory reports (Appendices B-2 and B-4), microbial growth was observed in one or more replicates of all Q2 tests and Q4 tests with FR_FRCP1, FR_FRABCH, GH_FR1, LC_DCDS, GH_ERC, and LC_LCDSSLCC.[24] All reference and test site waters were amended with 20 µg/L copper. Based on these results, it appears that 20 µg/L copper was insufficient to completely curtail microbial growth, although it may have reduced the magnitude of microbe growth and consequences for organism performance. Microbial growth was observed in all tests with a mean test result that was statistically lower than one or more batch-specific reference responses. Although microbes were ubiquitous, infestations that substantially affected the toxicity tests were rare. In tests with significant responses, results were sometimes lower than the test mean in replicates with microbes observed (e.g., Q2 LC_LC5, Q4 FR_FRCP1) but this was not always the case (e.g., Q2 and Q4 GH_FR1).

Using the decision framework presented in Figure 2.3-1, 21 of 22 tests were categorized as no adverse response and one test (Q4 FR_FRCP1) was categorized as having a possible adverse response.

The causation assessment for *O. mykiss* survival is presented in Section 3.4.4.

[24] Per discussions at the March 2021 EMC meeting, although several *O. mykiss* tests had microbes identified, these tests were included in statistical analyses conducted herein (e.g., PCA, Spearman Rank correlations).

Figure 3.3-12: Individual replicate and mean results for *O. mykiss* survival in reference (Ref) and test site waters.

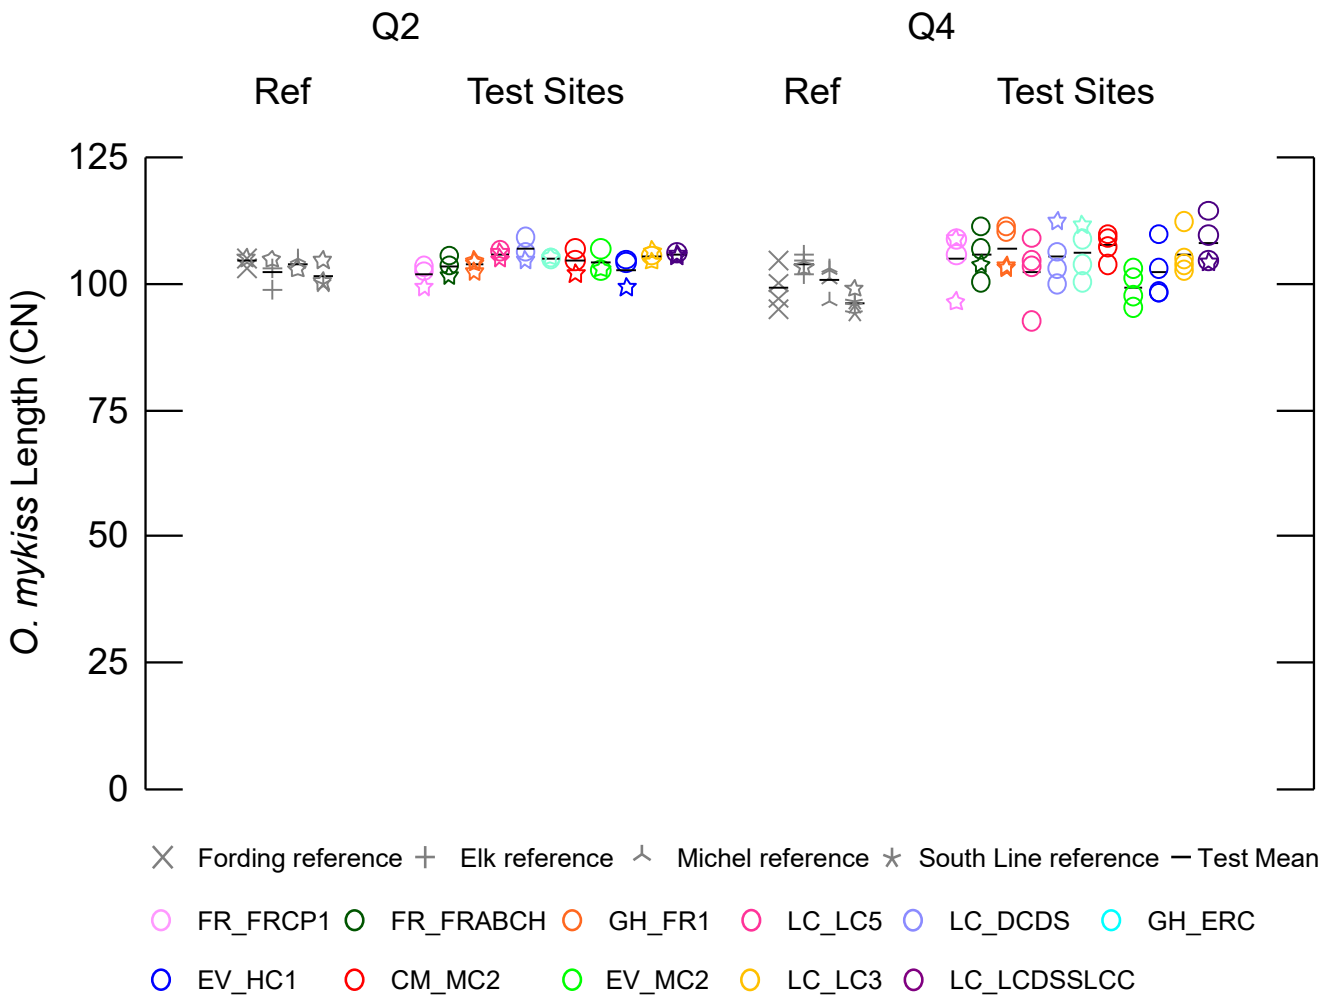
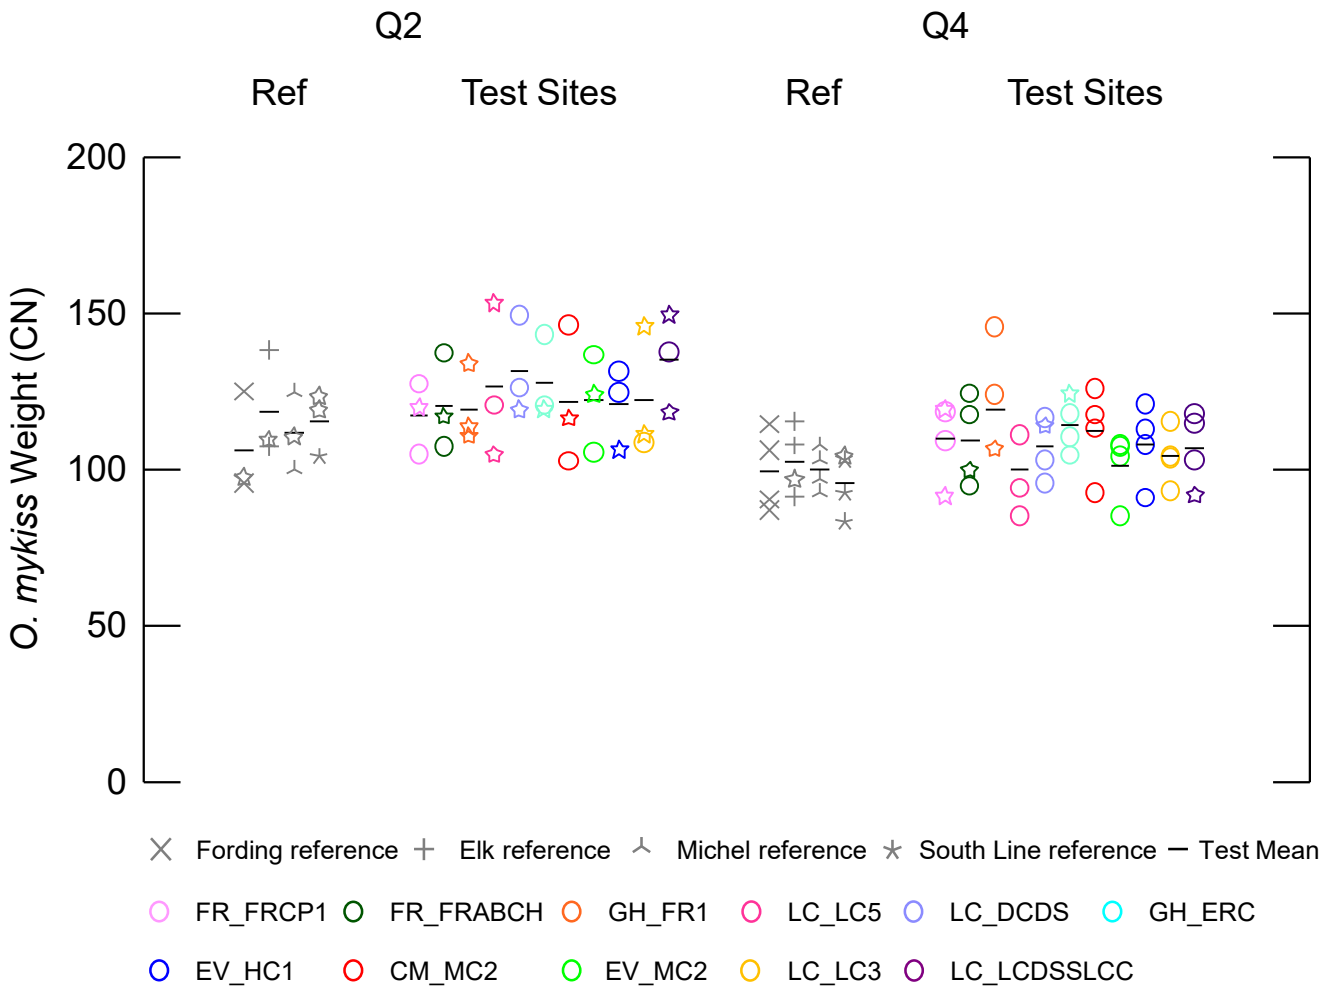
Note: Star symbols indicate a test replicate documented to exhibit presence of microbes; see Figure 2.3-2 for description of other lines and symbols. CN = control normalize.

Figure 3.3-14: Individual replicate and mean results for O. mykiss length in reference (Ref) and test site waters.



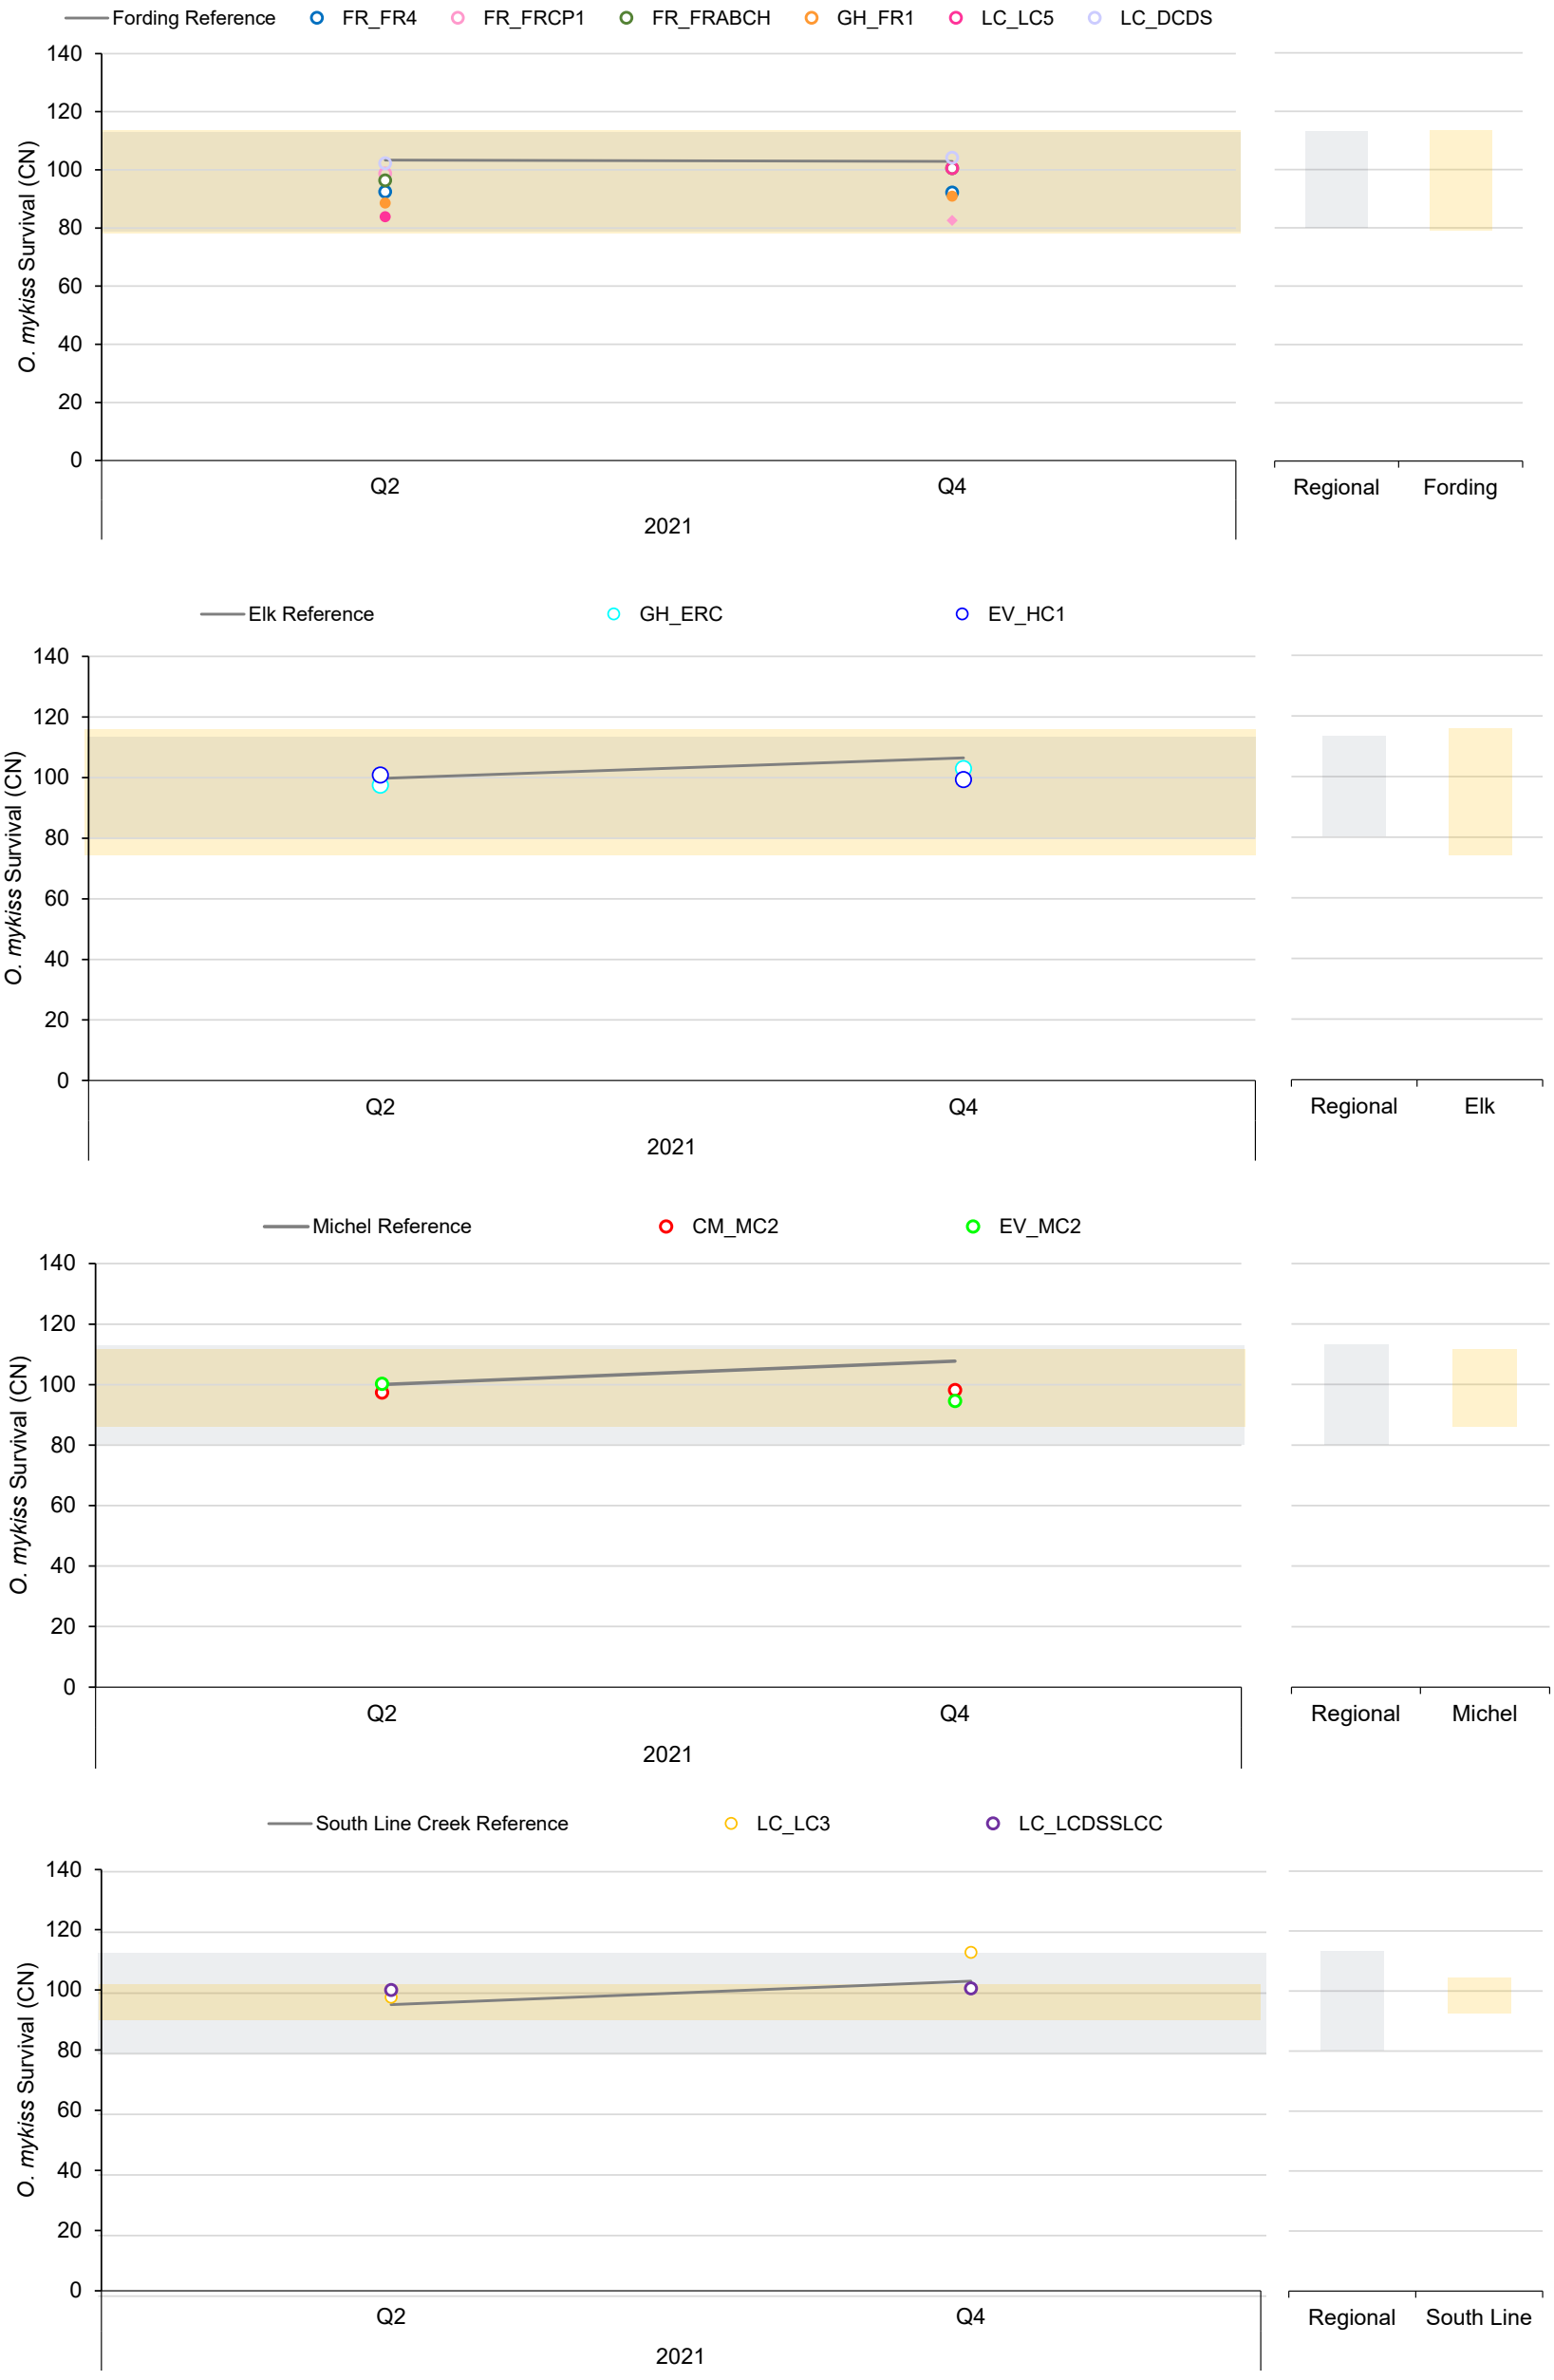
Note: Star symbols indicate a test replicate documented to exhibit presence of microbes; see Figure 2.3-2 for description of other lines and symbols. CN = control normalized.

Figure 3.3-15: Individual replicate and mean results for *O. mykiss* weight in reference (Ref) and test site waters.



Note: Star symbols indicate a test replicate documented to exhibit presence of microbes; see Figure 2.3-2 for description of other lines and symbols. CN = control normalized.

Figure 3.3-16: Mean results for *O. mykiss* survival in the Fording River reference and its test site waters (top left panel) and the Elk River reference and its paired test site waters (second left panel), Michel Creek reference and its test site waters (third left panel), and the South Line Creek reference and its test site waters (bottom left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).

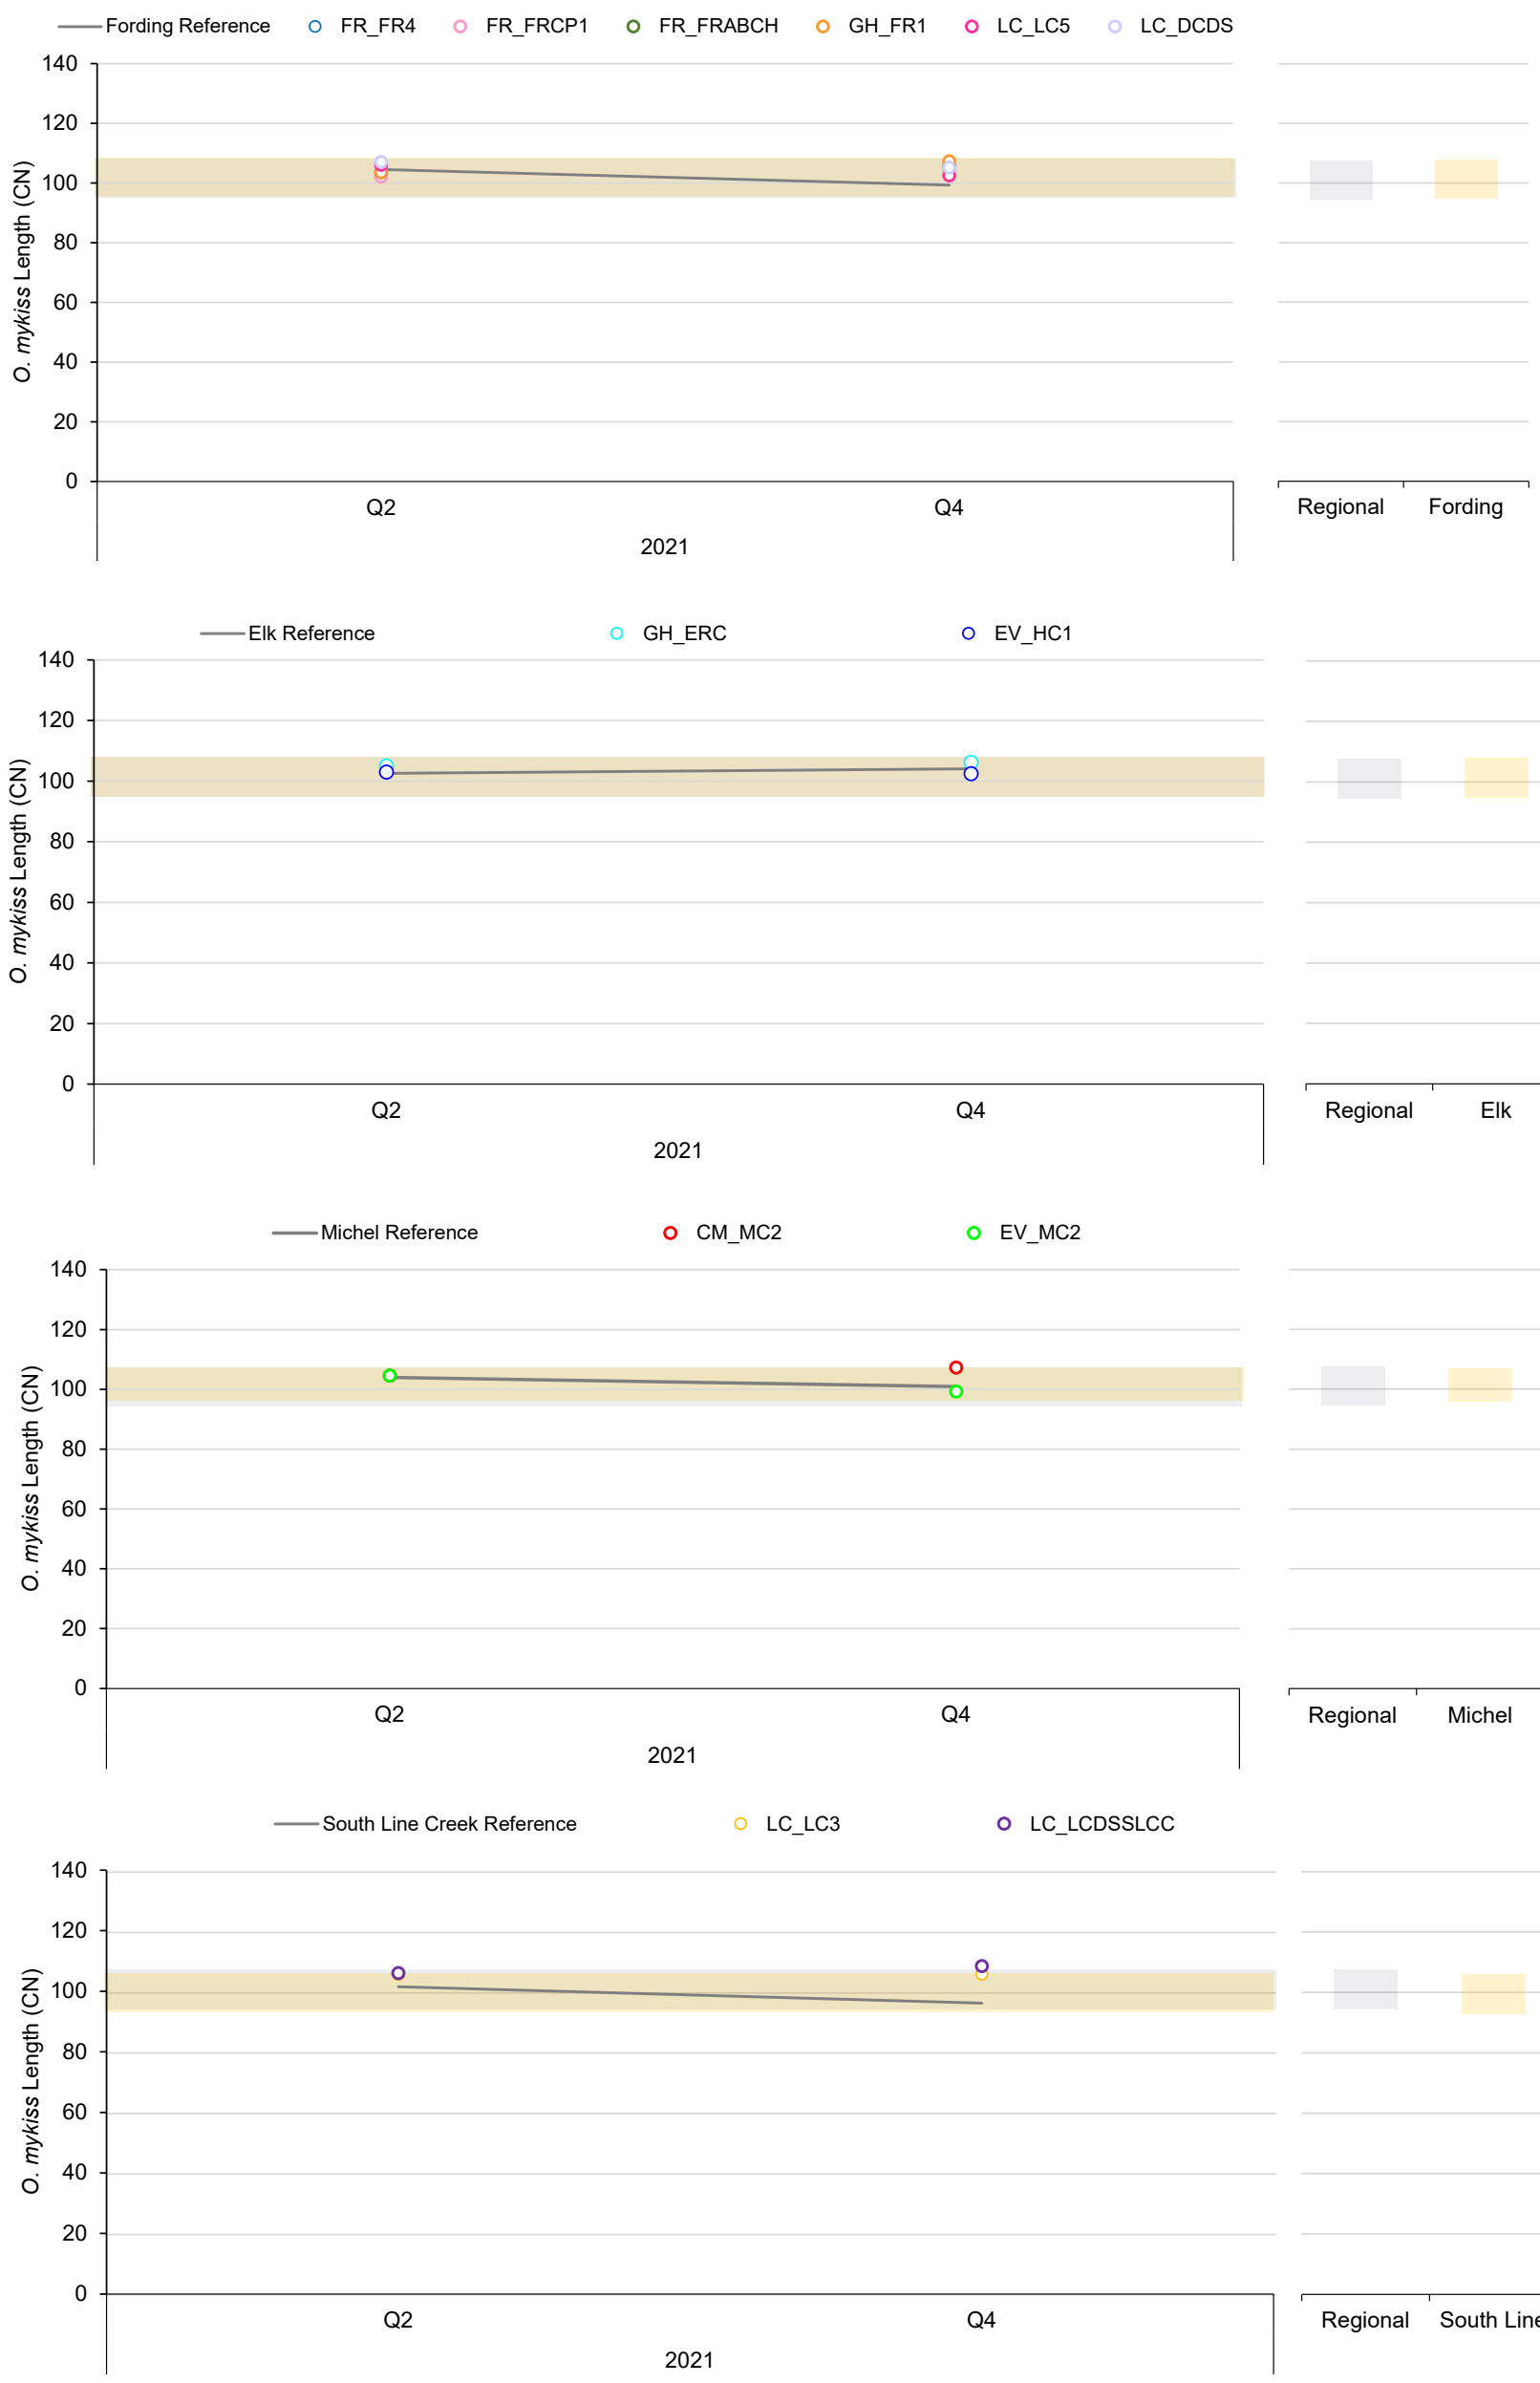


Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3). Evidence of microbes were observed in all Q2 tests and Q4 GH_ER2, LC_SLC, FR_FRABCH, FR_FRCP1, GH_FR1, GH_ERC, LC_DCDS, and LC_LCDSSLCC *O. mykiss* tests (Section 3.1).

Figure 3.3-17: Mean results for *O. mykiss* viability in the Fording River reference and its test site waters (top left panel) and the Elk River reference and its paired test site waters (second left panel), Michel Creek reference and its test site waters (third left panel), and the South Line Creek reference and its test site waters (bottom left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).

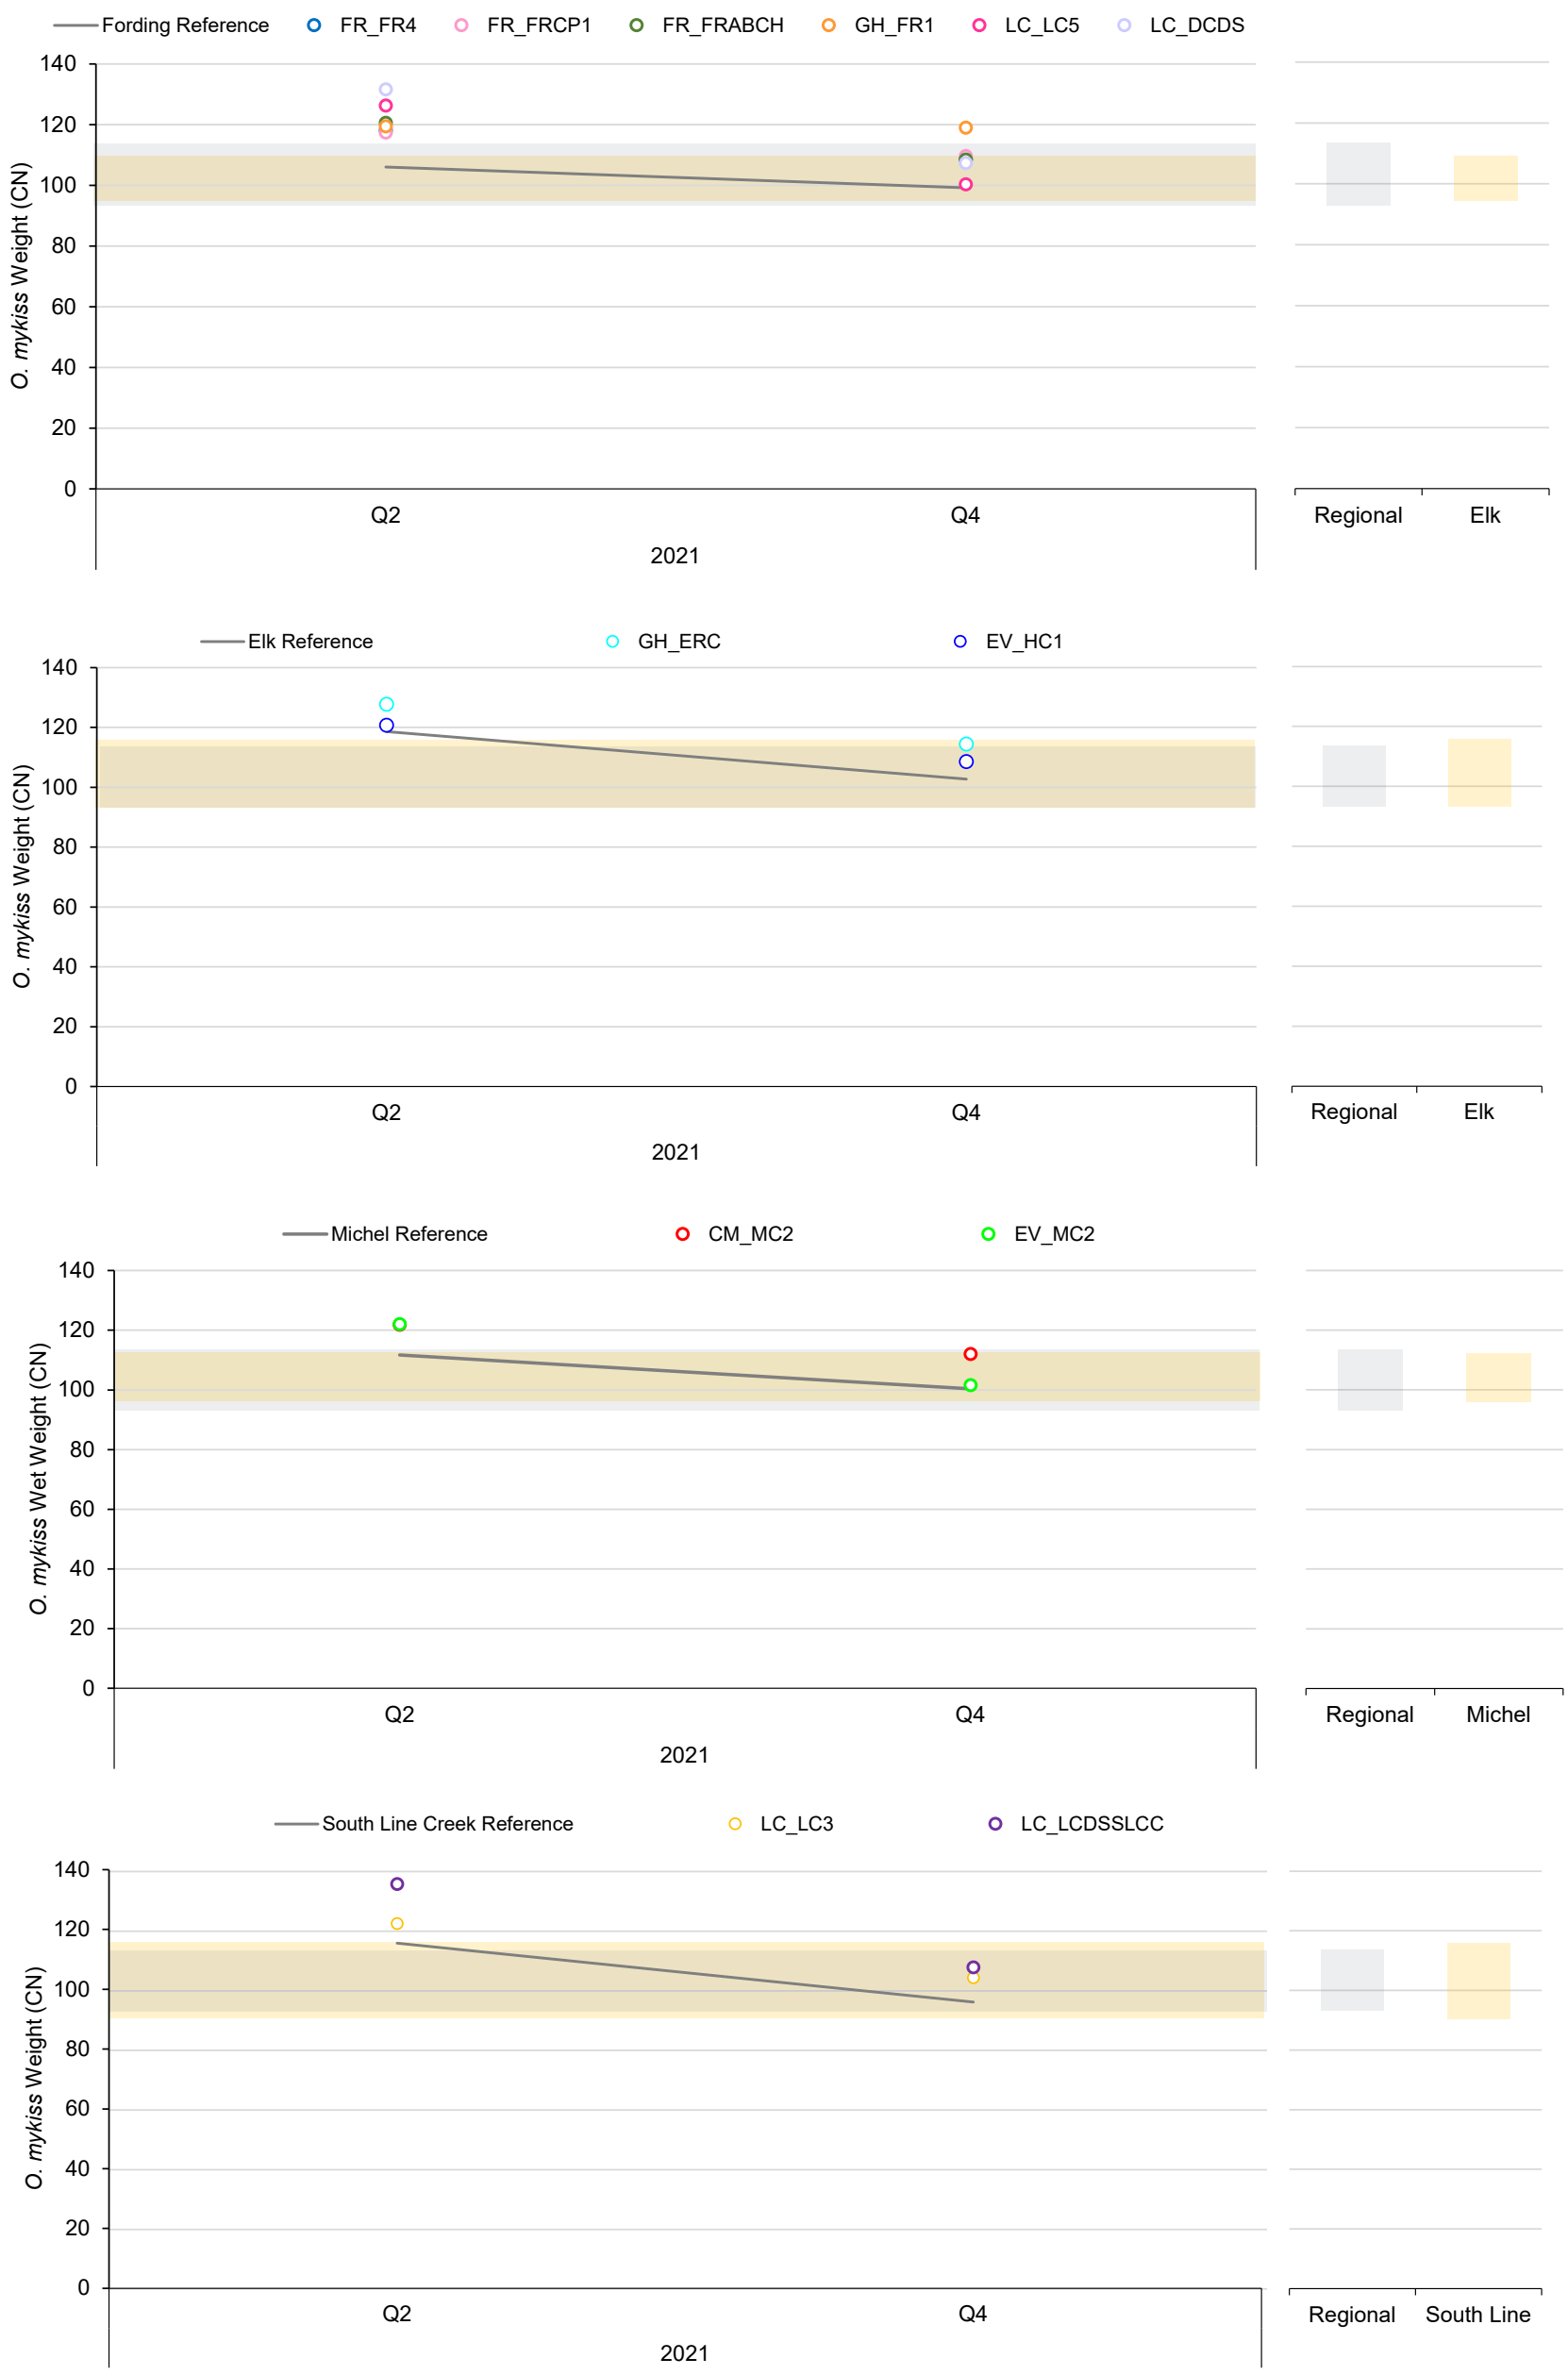
Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3). Evidence of microbes were observed in all Q2 tests and Q4 GH_ER2, LC_SLC, FR_FRABCH, FR_FRCP1, GH_FR1, GH_ERC, LC_DCDS, and LC_LCDSSLCC *O. mykiss* tests (Section 3.1).

Figure 3.3-18: Mean results for *O. mykiss* length in the Fording River reference and its test site waters (top left panel) and the Elk River reference and its paired test site waters (second left panel), Michel Creek reference and its test site waters (third left panel), and the South Line Creek reference and its test site waters (bottom left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).



Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3). Evidence of microbes were observed in all Q2 tests and Q4 GH_ER2, LC_SLC, FR_FRABCH, FR_FRCP1, GH_FR1, GH_ERC, LC_DCDS, and LC_LCDSSLCC *O. mykiss* tests (Section 3.1).

Figure 3.3-19: Mean results for *O. mykiss* weight in the Fording River reference and its test site waters (top left panel) and the Elk River reference and its paired test site waters (second left panel), Michel Creek reference and its test site waters (third left panel), and the South Line Creek reference and its test site waters (bottom left panel). Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).



Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3). Evidence of microbes were observed in all Q2 tests and Q4 GH_ER2, LC_SLC, FR_FRABCH, FR_FRCP1, GH_FR1, GH_ERC, LC_DCDS, and LC_LCDSSLCC *O. mykiss* tests (Section 3.1

3.3.1.5 *Pimephales promelas*

There was no evidence of adverse effects on hatch rate (Figure 3.3-20; Figure 3.3-25), biomass (Figure 3.3-22; Figure 3.3-27), length (Figure 3.3-23; Figure 3.3-28), or normal development (Figure 3.3-24; Figure 3.3-29) in any of the 2021 tests.

Survival was significantly reduced relative to one or more references in 3 of 24 tests (Figure 3.3-21; Figure 3.3-26), including the Q1 test with FR_FRCP1 and Q3 tests with EV_HC1 and LC_LCDSSLCC. In two of three tests with significantly reduced survival relative to one or more references, mean survival was categorized as no adverse response (Q3 EV_HC1 and LC_LCDSSLCC); compared to the mean response in batch-specific references, the effect size in both tests was 19%. In the Q1 FR_FRCP1 test, mean survival was categorized as a likely adverse response; compared to the mean response in two of the four batch-specific references, the effect size was 41% (FR_FRCP1 Q1). However, there is uncertainty associated with the categorization of likely adverse response because of the variability observed in Q1 reference waters, and associated filtering of reference data to exclude underperforming reference stations. Specifically, as discussed in Section 3.2.3.5 and at the February 2022 EMC meeting, the Q1 reference results were unusual in that two of the four references had control normalized survival that was comparable to the negative laboratory control (Fording reference = 103% and South Line reference = 94%) and the remaining two references had survival that was much lower (Elk reference = 34% and Michel reference = 56%). As discussed in Section 3.1, the reason for the reduced survival is unknown. The Q1 Elk River and Michel Creek references were excluded from normal range and effect size calculations, thereby increasing the likelihood of categorizing site water results as likely adverse responses even where responses were similar to half of the reference data. Survival in the FR_FRCP1 test was higher than both the Elk River and Michel Creek reference tests. Therefore, it is uncertain whether the FR_FRCP1 results represent an adverse response to toxicants in the test water or alternatively may reflect natural variance in test organism performance unrelated to water quality. Furthermore, there was an inconsistency in response among replicates exposed to the same site water in this test, where survival in replicates ranged from 42% to 87% for FR_FRCP1 in Q1.

As discussed in the Q1 and Q3 laboratory reports (Appendices B-1 and B-3), microbial growth was observed in the Q1 test with CM_MC2 and in all Q3 tests except LC_DCDS and EV_MC2. For tests with microbes, microbial growth was observed in all replicates except for the Q1 test with CM_MC2 and Q3 tests with FR_FRCP1, RG_MIDAG, and EV_HC1. Both reference and test site exposures were amended with 10 to 20 µg/L copper. Based on these results, it appears that 10 to 20 µg/L copper was insufficient to completely curtail microbial growth most samples.

As with previous test events in which microbial growth was observed, the mortalities occurred predominantly between days 6 and 12 of exposure, which is consistent with the conclusion that the adverse responses were associated with microbial growth (i.e., concentrated mortality approximately one week into the test). These infrequent mortalities were insufficient to result in large changes to the mean survival endpoint in any treatment.

Using the decision framework presented in Figure 2.3-1, all tests except for Q1 FR_FRCP1 were categorized as no adverse response. The remaining test, Q1 FR_FRCP1, was categorized as having a likely adverse response.

The causation assessment for *P. promelas* survival is presented in Section 3.4.5.

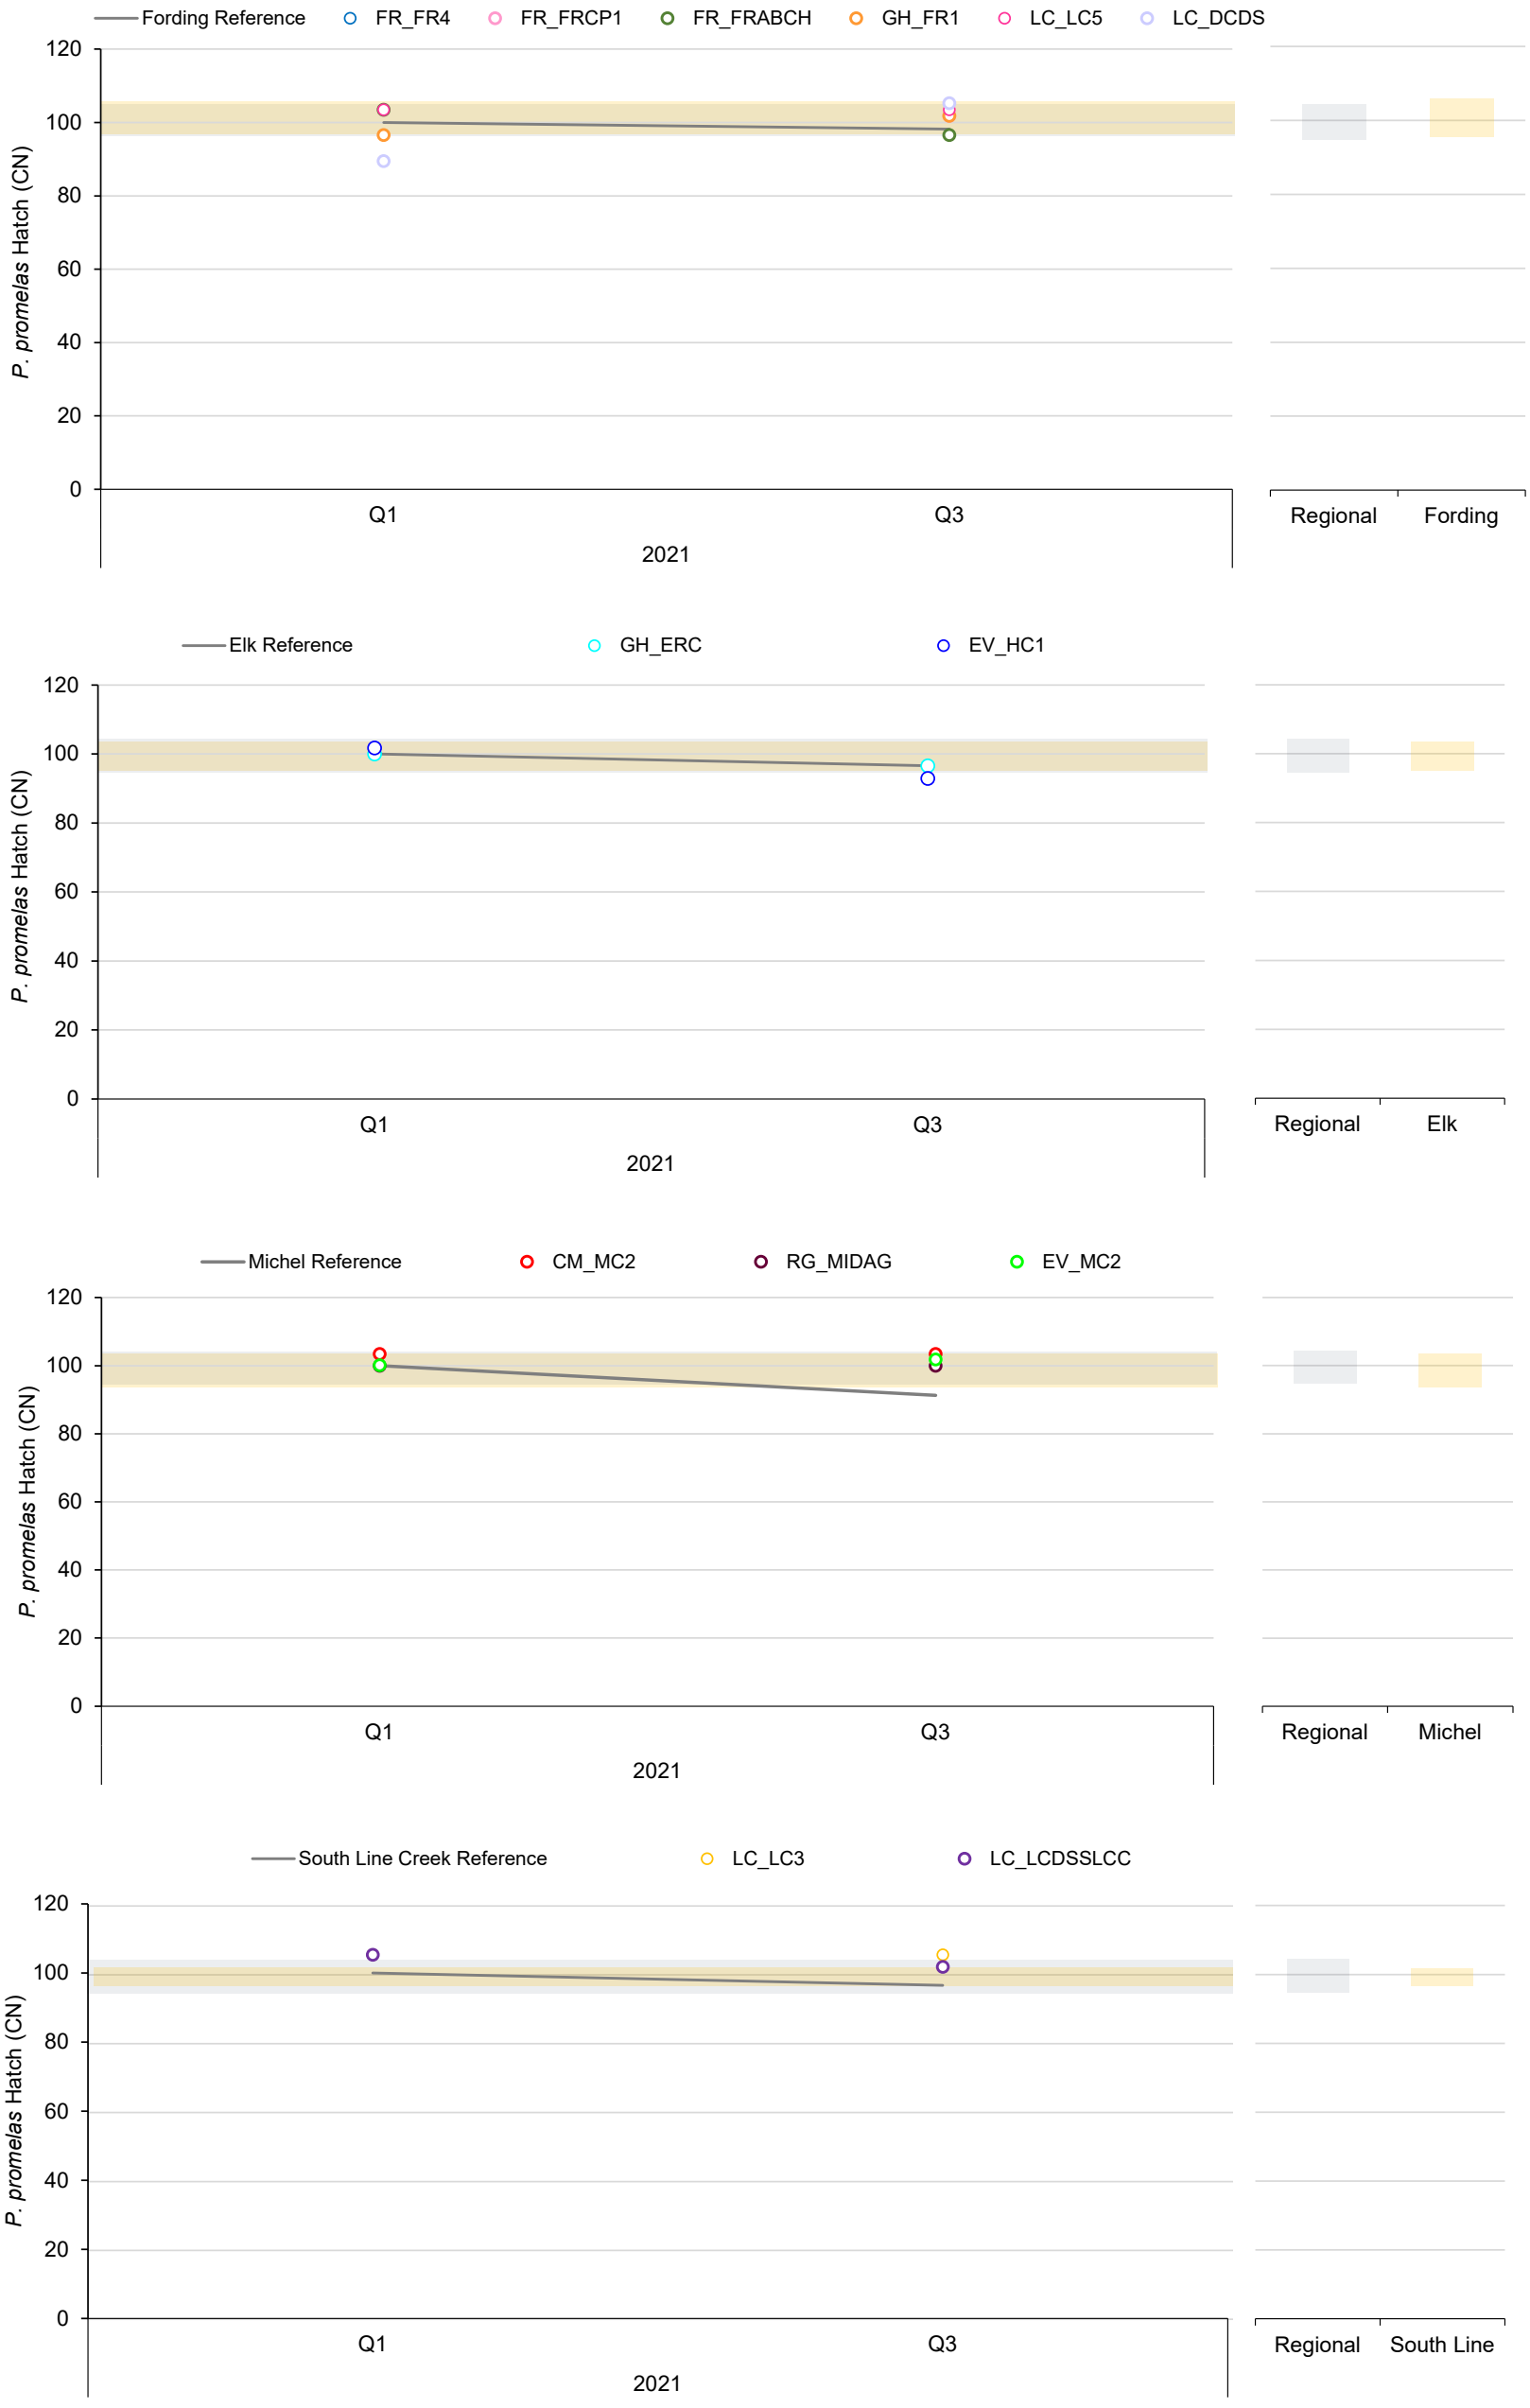
Regional and local normal ranges (2.5th to 97.5th percentile) are shown as bars (right panels).



Note: See Figure 2.3-3 for description of lines and symbols. Test sites were compared to their paired local NR (Section 2.3.3). Evidence of microbes were observed in Q1 CM_MC2 and all Q3 tests except EV_MC2 and LC_DCDS (Section 3.1). Results from the Q1 Elk and Michel references are shown here for informational purposes but were excluded from statistical calculations; see Section 3.2.3.5. CN= control normalized.

3.3.2 Results by Test Site

Presentation of the combined results of chronic toxicity tests at each test site provides a means of assessing the strength of evidence for toxicity, including consistency of responses across multiple tests and multiple sampling stations and quarters. Results are summarized in Figure 3.3-30.

- **FR_FRCP1**—No adverse responses were observed in any quarter for 9 of 14 endpoints: *C. dubia* survival, *H. azteca* survival, *O. mykiss* viability, length, and weight, and *P. promelas* hatch, biomass, length, and development. Possible adverse responses were observed in 2 of 14 endpoints: *H. azteca* dry weight (Q3) and *O. mykiss* survival (Q4). Likely adverse responses were observed in 3 of 14 endpoints: *C. dubia* reproduction (Q1, Q3, and Q4), *P. subcapitata* cell yield (Q1) and *P. promelas* survival (Q1).
- **FR_FRABCH**—No adverse responses were observed in any quarter for 12 of 14 endpoints: all *C. dubia* endpoints, *H. azteca* survival, *O. mykiss* survival, viability, length, and weight, and all *P. promelas* endpoints. Possible adverse responses were observed for 2 of 14 endpoints: *P. subcapitata* cell yield (Q1) and *H. azteca* dry weight (Q3).
- **GH_FR1**—No adverse responses were observed in any quarter for 12 of 14 endpoints: *H. azteca* survival, and all *C. dubia, O. mykiss,* and *P. promelas* endpoints. Possible adverse responses were observed for 2 of 14 endpoints: *P. subcapitata* cell yield (Q2) and *H. azteca* dry weight (Q3).
- **LC_LC5**—No adverse responses were observed in any quarter for 12 of 14 endpoints: *H. azteca* survival, and all *C. dubia, O. mykiss* and *P. promelas* endpoints. Possible adverse responses were observed for 2 of 14 endpoints: *P. subcapitata* cell yield (Q1 and Q4) and *H. azteca* dry weight (Q3). A likely adverse response was observed for *P. subcapitata* cell yield in Q2.
- **LC_DCDS**—No adverse responses were observed in any quarter for 11 of 14 endpoints: *C. dubia* survival, *H. azteca* survival and all *O. mykiss* and *P. promelas* endpoints. Possible adverse responses were observed for 2 of 14 endpoints: *P. subcapitata* cell yield (Q1 and Q3) and *H. azteca* dry weight (Q4). A likely adverse response was observed for *C. dubia* reproduction (Q3 and Q4).
- **GH_ERC**—No adverse responses were observed in any quarter for 12 of 14 endpoints: all *C. dubia* endpoints, *H. azteca* survival and all *O. mykiss* and *P. promelas* endpoints. Possible adverse responses were observed for 2 of 14 endpoints: *P. subcapitata* cell yield (Q3 and Q4) and *H. azteca* dry weight (Q4).
- **CM_MC2**—No adverse responses were observed in any quarter for 10 of 14 endpoints: *C. dubia* survival and all *O. mykiss* and *P. promelas* endpoints. Possible adverse responses were observed for *P. subcapitata* cell yield in Q1 and Q4. Likely adverse responses were observed for 3 of 14 endpoints: *C. dubia* reproduction (Q1 and Q4) and *H. azteca* survival (Q2 and Q3) and dry weight (Q3).
- **RG_MIDAG**—No adverse responses were observed in any quarter for any endpoint.
- **EV_MC2**—No adverse responses were observed in any quarter for 13 of 14 test endpoints. Possible adverse responses were observed for *P. subcapitata* cell yield in Q1 and Q4.
- **EV_HC1**—No adverse responses were observed in any quarter for 13 of 14 test endpoints. Possible adverse responses were observed for *P. subcapitata* cell yield in Q3 and Q4.

- **LC_LC3**—No adverse responses were observed in any quarter for 12 of 14 endpoints: *C. dubia* survival and all *H. azteca*, *O. mykiss,* and *P. promelas* endpoints. Possible adverse responses were observed for 2 of 14 endpoints: *C. dubia* reproduction (Q4) and *P. subcapitata* cell yield (Q1). A likely adverse response was observed for *P. subcapitata* cell yield in Q2.
- **LC_LCDSSLCC**—No adverse responses were observed in any quarter for 13 of 14 test endpoints. A possible adverse response was observed for *P. subcapitata* cell yield in Q4.

The greatest number of adverse responses were observed at stations CM_MC2 (seven adverse responses summed across quarters) and FR_FRCP1 (seven adverse responses summed across quarters). These broad findings are similar to recent years in which CM_MC2 and FR_FRCP1 have been among the sites with greatest number of adverse responses.

Figure 3.3-30: Summary of test results by category for 2021 chronic toxicity stations.

Note: Test results are categorized in Section 3.3.1. Evidence of microbes were observed in *P. promelas* tests and *O. mykiss* tests for at least one replicate in all quarters (Section 3.1, 3.3.1.4 and 3.3.1.5).

3.4 Causation Assessment

Causation assessments were conducted for test endpoints for which possible or likely toxicity responses were observed for one or more test site waters in 2021. These endpoints included *C. dubia* reproduction, *H. azteca* growth and survival, *P. subcapitata* cell yield, *O. mykiss* survival, and *P. promelas* survival. The following appendices have supporting information for the causation assessment:

- Appendix B provides laboratory documentation of TIEs used to identify substances that explain patterns of toxicity.
- Appendix C provides water chemistry data screened against WQGs for all 2021 tests conducted with reference and test site waters. Sum of toxic units (∑TUs) and coefficients of variation (CVs) for multi-week tests are also provided in this appendix.
- Appendix D provides response data paired with water chemistry data and other explanatory variables (i.e., PCs and ∑TUs).
- Appendix E provides PCA component loadings and percent of variance explained by each component.
- Appendix F provides Spearman rank order correlations between constituent and explanatory variables.

Results of the causation assessment are provided in the following sections, organized by species and endpoint.

3.4.1 *Ceriodaphnia dubia* Reproduction

Eight tests conducted in 2021 were carried forward to the causation assessment, consisting of one test categorized as possible adverse response (Q4 LC_LC3) and seven tests categorized as likely adverse response (Q1 tests with FR_FRCP1 and CM_MC2; Q3 tests with FR_FRCP1 and LC_DCDS; and Q4 tests with FR_FRCP1, CM_MC2, LC_LCDS, and LC_LC3). Results are provided below for the *C. dubia* causation assessment.

Toxicity Identification Evaluation (C. dubia)

The following bullets summarize TIE results for quarterly tests categorized as a possible or likely adverse response:

- **FR_FRCP1** (Appendix B-6)—Reproduction was categorized as a likely adverse response in Q1, Q3, and Q4 (Section 3.3.1.1). In the Q1 and Q3 TIE tests, reproduction was improved in the EDTA-treated test compared to the untreated test, although not enough to return reproduction to reference levels. Effects on reproduction decreased from 41% in the untreated sample to 20% in the EDTA-treated test for Q1 and from 43% in the untreated sample to 16% in the EDTA-treated test for Q3. In the Q4 test, adverse effects on reproduction increased in the EDTA treatment (47%) compared to the untreated tests (30%). For Q1 and Q3, results indicate that divalent metals (likely nickel, see screening results below) may have contributed to adverse effects. As discussed in Appendix B-6, the EDTA controls in Q1, Q3, and Q4 had reduced reproduction relative to the negative laboratory controls; these results indicate that the EDTA treatment itself may have contributed to adverse effects, as was observed with the Q4 FR_FRCP1 test with EDTA.
- **CM_MC2** (Appendix B-7)—Reproduction was categorized as a likely adverse response in Q1 and Q4 (Section 3.3.1.1). In the Q1 and Q4 tests, reproduction was improved in the EDTA-treated test compared to the untreated test, although not enough to return reproduction to reference levels in Q4. Effects on reproduction decreased from 33% in the untreated sample to -1% in the EDTA-treated test for Q1 and from 36% in the untreated sample to 24% in the EDTA-treated test for Q4. These results indicate that divalent metals (likely nickel, see screening results below) may have contributed to adverse effects.

Water Quality Screening (C. dubia)

In the eight tests categorized as possible or likely adverse effects, concentrations of one or more constituents exceeded WQGs or lowest level 1 EVWQP benchmarks:

- **FR_FRCP1 (Q1)** — Concentrations of nitrate and selenium exceeded the lowest level 1 EVWQP benchmarks, the concentration of nickel exceeded the level 1 interim screening value, and the concentration of nitrite exceeded the chronic WQG.
- **FR_FRCP1 (Q3 and Q4)** — Concentrations of nitrate and selenium exceeded the lowest level 1 EVWQP benchmarks, the concentration of nickel exceeded the level 1 interim screening value, and the concentration of fluoride exceeded the chronic WQG.
- **LC_DCDS (Q3 and Q4)**— Concentrations of nitrate and selenium exceeded the lowest level 1 EVWQP benchmarks, and the concentration of nickel exceeded the level 1 interim screening value.
- **CM_MC2 (Q1 and Q4)**— The concentration of nickel exceeded the level 1 interim screening value.
- **LC_LC3 (Q4)**— The concentration of selenium exceeded the lowest level 1 EVWQP benchmark, the concentration of nickel exceeded the level 1 interim screening value, and the concentration of fluoride exceeded the chronic WQG.

The concentration of field measured dissolved oxygen was below the chronic WQGs for LC_DCDS (Q3); however, dissolved oxygen concentrations were maintained within protocol limits during the *C. dubia* tests (Appendix B) and therefore would not be expected to contribute to the observed responses in these tests.

Spearman Rank Correlation (C. dubia)

Constituents and explanatory variables with statistically significant Spearman rank correlations for *C. dubia* reproduction for the combined and 2021 datasets are summarized in Table 3.4-1. No strong negative correlations ($r_s \leq -0.6$) were identified in the combined dataset (Table F-1). For the 2021 dataset, strong negative correlations ($r_s \leq -0.6$) were identified for TDS, components of TDS (e.g., calcium, sulphate), lithium, uranium, and PC1 for the 2021 dataset.

The PC scores that had statistically significant Spearman rank correlations for reproduction are described below:

- PC1 (combined dataset): This component accounted for 27.4% of the variance (Table E-1). PC1 had strong positive loadings for TDS, components of TDS (e.g., calcium, magnesium), Order constituents (nitrate, selenium, sulphate), and several metals (lithium, nickel, uranium).
- PC2 (combined dataset): This component accounted for 14.7% of the variance (Table E-1). PC2 had strong positive loadings for arsenic, lead, and vanadium.
- PC1 (2021 dataset): This component accounted for 37.3% of the variance (Table E-1). As with the combined dataset, PC1 had strong positive loadings for TDS, components of TDS (e.g., calcium, magnesium), Order constituents (selenium, sulphate), and metals (lithium, uranium).

The component loadings for PC1, which appeared to be a strong signal of mine influence (i.e., strong loadings for TDS and Order constituents), exhibited similar patterns between the combined dataset and the 2021 dataset, with strong loadings for the same constituents (Table E-1). PC2 had strong loadings for various metals in both datasets; however, PC2 demonstrated different patterns between the combined and 2021 dataset.

Table 3.4-1: Constituents and Explanatory Variable with Significant Spearman Rank Correlations for *Ceriodaphnia dubia* Reproduction.

Constituent[a]	R_s Combined Dataset	R_s 2021 Dataset	Comparison to WQGs/EVWQP Benchmarks	Retained for Graphical Analysis?
Bicarbonate Alkalinity	-0.26	-0.50	No WQG	No - assessed as TDS/MIT
Carbonate Alkalinity	ns	-0.40	No WQG	No - assessed as TDS/MIT
Total Alkalinity	-0.31	-0.51	No WQG	No - assessed as TDS/MIT
Total Antimony	-0.36	-0.50	No	No
Total Barium	ns	-0.40	No	No
Total Boron	-0.26	-0.46	No	No
Dissolved Bromide	-0.20	-0.48	No WQG	No - low detection frequency[b]
Dissolved Cadmium	-0.27	-0.46	No	No

Major Anion Sum	-0.35	-0.62	No WQG	No - assessed as TDS/MIT
Major Cation Sum	-0.34	-0.63	No WQG	No - assessed as TDS/MIT
Total Manganese	-0.25	ns	No	No
Total Molybdenum	-0.30	-0.45	No	No
Total Nickel	-0.42	-0.44	Yes	Yes
Nitrate	-0.35	-0.53	Yes	Yes
Nitrite	-0.36	-0.51	Yes	Yes
Total Potassium	-0.40	-0.64	No WQG	No - assessed as TDS/MIT
Total Selenium	-0.31	-0.51	Yes	Yes
Total Sodium	-0.28	-0.39	No WQG	No - assessed as TDS/MIT
Dissolved Strontium	-0.25	-0.36	No	No
Sulphate	-0.39	-0.61	No	No
Total Thallium	-0.32	ns	No	No
Total Dissolved Solids	-0.39	-0.63	No WQG	Yes
Total Kjeldahl Nitrogen	-0.15	ns	No WQG	Yes
Total Uranium	-0.38	-0.64	No	No
Total Zinc	-0.21	ns	No	No
∑TUs−WQGs	-0.41	-0.58	No WQG	Yes
∑TU−WQGs/Benchmarks	-0.41	-0.47	No WQG	Yes
PC1 Combined	-0.42	ns	No WQG	Yes
PC2 Combined	-0.15	ns	No WQG	Yes
PC1 2021	ns	-0.65	No WQG	Yes

Notes: Values shown here were statistically significant at $\alpha < 0.005$, $r_s = -0.131$ for the combined dataset and $\alpha < 0.005$, $r_s = -0.286$ for the 2021 dataset. WQGs = water quality guidelines; EVWQP = Elk Valley Water Quality Program; MIT = multi-ion toxicity; ns = not significant; ∑TU = sum of toxicity units; TDS = total dissolved solids. Shaded values indicate a strong Spearman rank correlation at $r_s \leq -0.6$.

(a) Total concentrations are shown for metals that have a WQG for the total fraction or that lack a chronic WQG. Dissolved concentrations were used for metals with a WQG for the dissolved fraction.

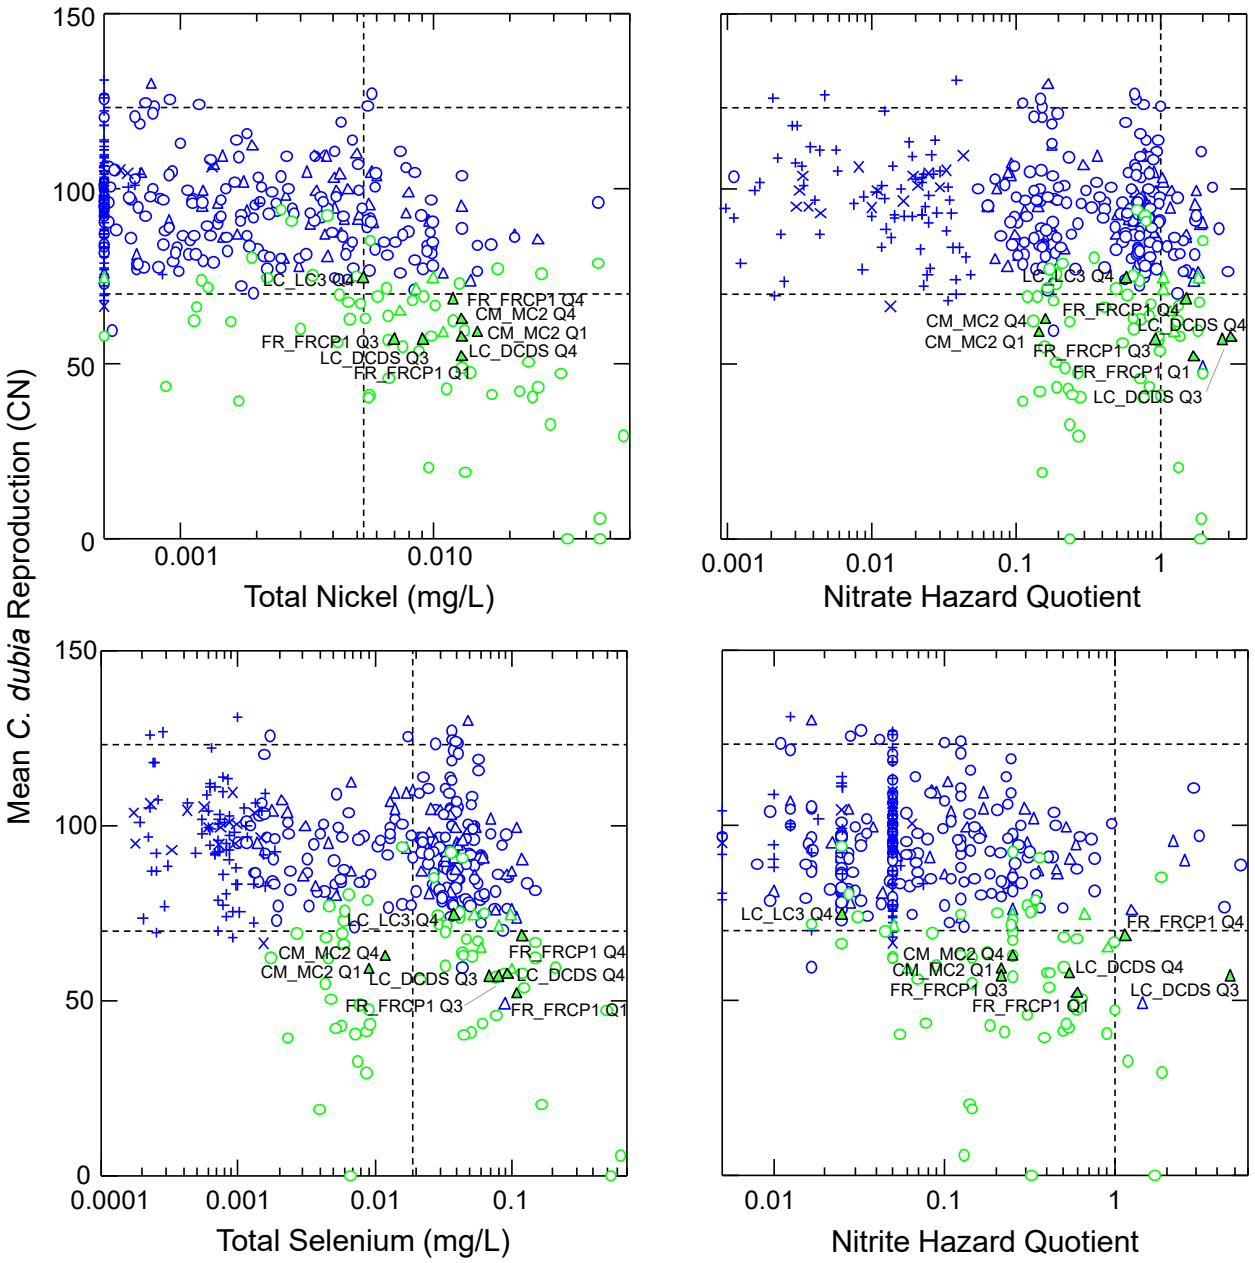
(b) Out of 80 *C. dubia* tests in 2021, bromide was only detected in five tests and was not detected in any test with possible or likely adverse effects.

Graphical Analysis (C. dubia)

Constituents and explanatory variables with significant Spearman rank correlations, and that were either above WQGs or did not have WQGs, were carried through to graphical analysis (Figures 3.4-1 to 3.4-4). Graphical analysis was conducted for two Order constituents (selenium, nitrate), total nickel, nitrite, TDS, MIT, total Kjeldahl nitrogen, ∑TU (calculated with WQGs only, and with WQGs and EVWQP benchmarks), PC1 (combined and 2021 datasets), and PC2 (combined dataset).

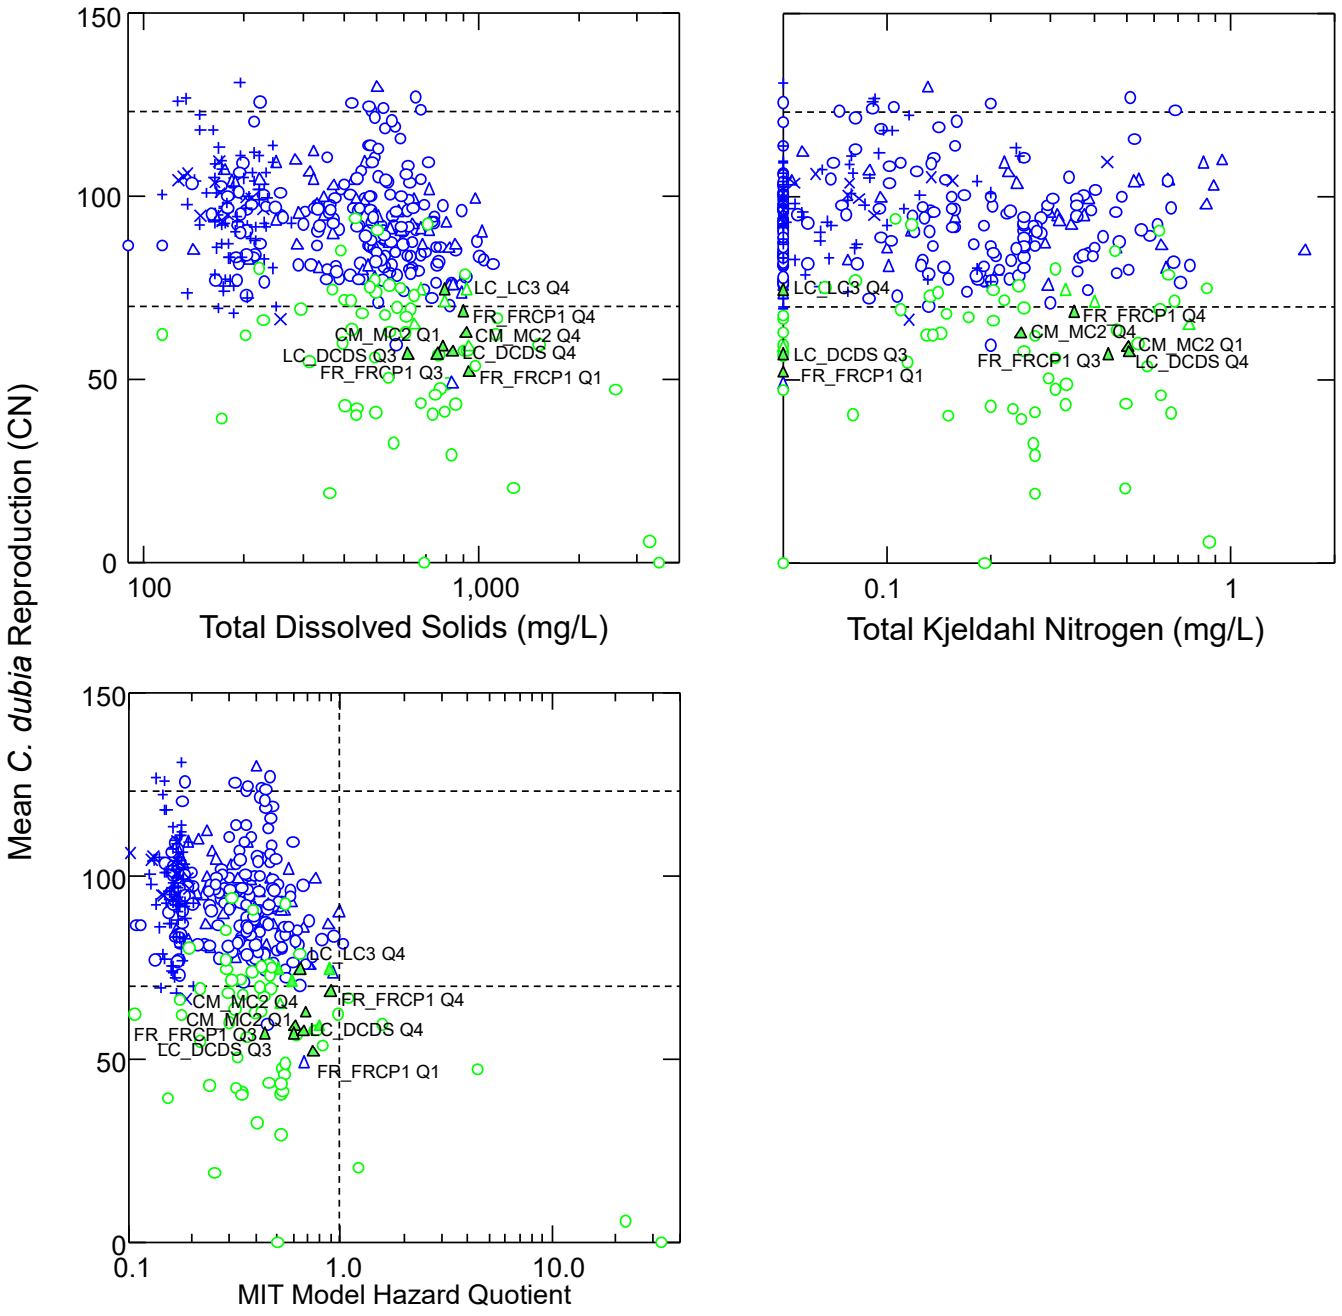
Most of the constituents and explanatory variables did not exhibit a consistent exposure-response relationship across all tests. For the PCs that were carried forward to graphical analysis, no consistent patterns were apparent between the PC scores and test responses. However, nickel exhibited a general relationship between concentrations and magnitude of adverse response. The potential for nickel to explain observed effects is discussed in the next section.

Figure 3.4-1: Mean *C. dubia* reproduction versus total nickel (top left), nitrate (top right), total selenium (bottom left), and nitrite (bottom right).



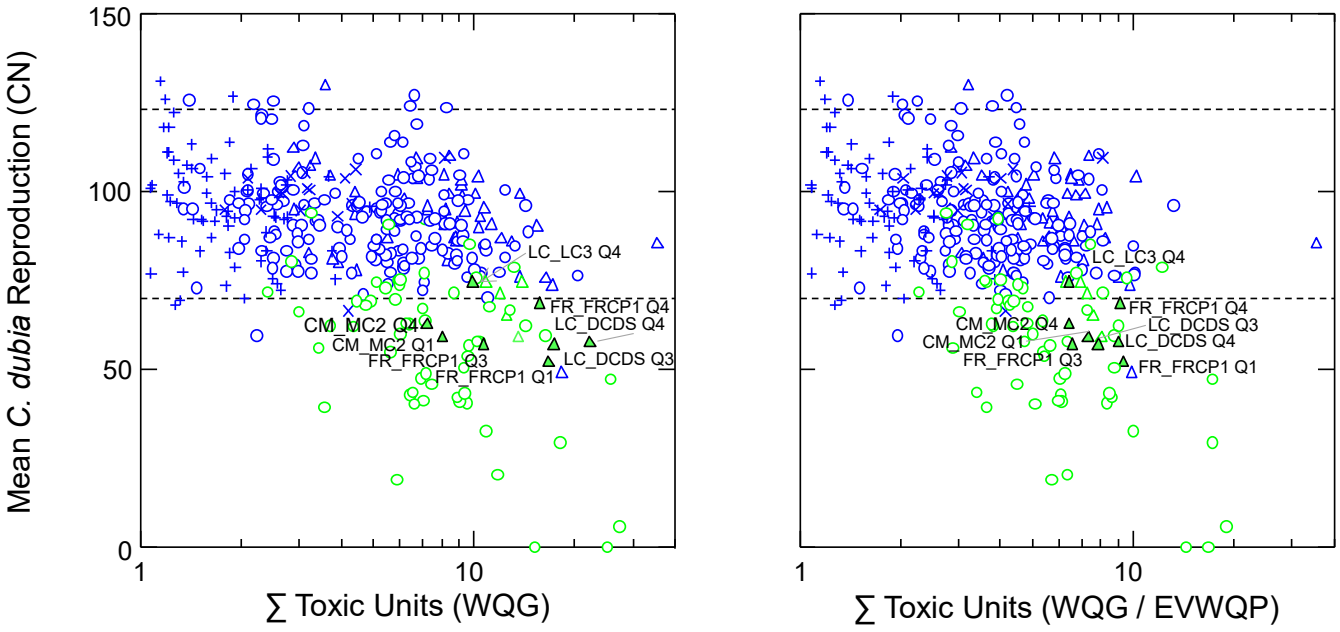
Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations; Δ = UFR stations). Regional chronic toxicity test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Nitrate hazard quotients are the ratio of nitrate concentrations to the lowest level 1 EVWQP benchmark for invertebrates. Nitrite hazard quotients are the ratio of nitrite concentrations to the chronic BC WQG. Vertical lines are screening values: for the nitrate and nitrite hazard quotients, the screening value is 1; for nickel the screening value is the level 1 interim screening value (5.3 µg/L), for selenium, the screening value is the level 1 EVWQP benchmark for invertebrates (104 µg/L). Horizontal lines are the regional normal range (see Figure 2.3-3 for description). CN = control normalized; EVWQP = Elk Valley Water Quality Plan; UFR= Upper Fording River; mg/L = milligrams per litre; WQG= water quality guideline.

Figure 3.4-2: Mean *C. dubia* reproduction versus total dissolved solids (top left), total Kjeldahl nitrogen (top right), and MIT model hazard quotient (bottom left).



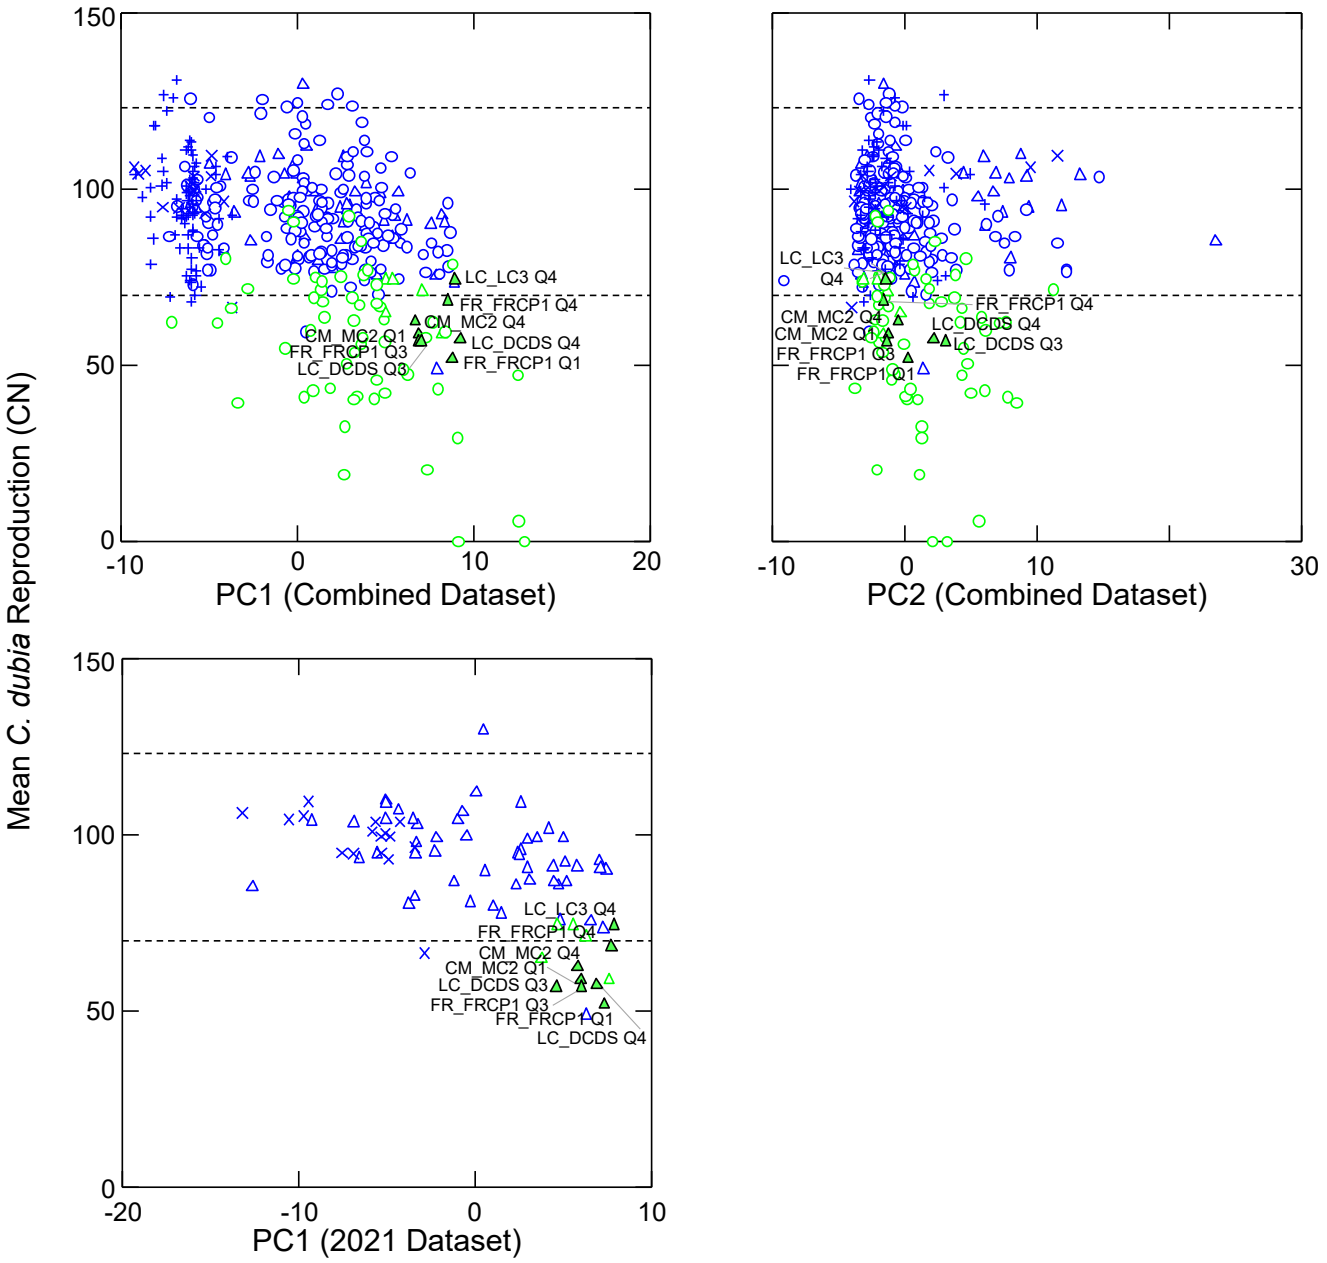
Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations; Δ = UFR stations). Test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. MIT hazard quotients are the ratio of MIT to the Mount et al. (2019) EC_{20}, i.e., a hazard quotient (HQ) of 1 indicates the tests had MIT equal to the EC_{20} (Mount et al. 2019). The vertical line for the MIT hazard quotient at 1 is the screening value. Horizontal lines are the regional normal range (see Figure 2.3-3 for description). CN = control normalized; HQ = hazard quotient; mg/L = milligrams per litre; MIT = Multi-Ion Toxicity; UFR = Upper Fording River.

Figure 3.4-3: Mean *C. dubia* reproduction versus sum of toxic units calculated using WQGs only (left) and WQGs and EVWQP benchmarks (right).



Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations; Δ = UFR stations). Test waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Horizontal lines are the regional normal range (see Figure 2.3-3 for description). CN = control normalized; EVWQP = Elk Valley Water Quality Plan; UFR = Upper Fording River; WQG = water quality guideline; Σ = sum.

Figure 3.4-4: Mean *C. dubia* reproduction versus PC1 for the combined dataset (top left), PC2 for the combined dataset (top right), and PC1 for the 2021 dataset (bottom left).



Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations; Δ = 2021 UFR stations). Test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Horizontal lines are regional normal range (see Figure 2.3-3 for description). CN = control normalized; PC = principal component; UFR = Upper Fording River

Identification of Potential Contributors to Toxicity (C. dubia)

In tests categorized as having a possible or likely adverse response, concentrations of most constituents were equal to or lower than concentrations in test site waters categorized as no adverse response (Table D-1), and/or were lower than chronic WQG or lowest level 1 EVWQP benchmark (Appendix C). Such constituents are not expected to contribute to toxicity in these tests. For the remaining constituents, published toxicity data were reviewed to evaluative their potential to contribute to observed effects. These constituents are discussed below.

- **FR_FRCP1 (Q1)**—Nickel showed the greatest evidence of causing the observed response in this test. The total nickel concentration in this test (13 µg/L) was higher than the reproduction EC_{25} for nickel in Michel Creek water (10.8 µg/L; Nautilus 2018), indicating that nickel may have contributed to toxicity in this test. This interpretation aligns with the 2021 *C. dubia* TIE testing conducted with Q1 FR_FRCP1 water, which showed decreased effects on reproduction upon addition of EDTA, and the graphical analysis of nickel, which demonstrated a concentration-response relationship for *C. dubia* reproduction (Figure 3.4-1). Other constituents exhibited weak to no evidence of potential for toxicity at this station in Q1 2021. The concentration of nitrate in this test (26 mg/L as N) was above the level 1 EVWQP benchmark but approximately two times lower than the updated, site-specific reproduction EC_{10} derived for the MQ2 project (Golder 2021b) using site water testing (57 mg/L as N, at the maximum hardness that the equation applies [709 mg/L]); these results indicate that nitrate did not contribute to the observed response. The concentration of nitrite in this test (0.024 mg/L as N) was above the chronic WQG but more than an order of magnitude below the reproduction EC_{10} (1.4 mg/L as N; US EPA 2010), indicating that nitrite did not contribute to the observed response.[25] The concentration of potassium in this test was higher than in tests categorized as no adverse response. There is no WQG or screening value for potassium, so potassium was assessed via TDS and MIT for which potassium is a component. The hazard quotient for the *C. dubia* EC_{20} MIT model was 0.75 (i.e., below the EC_{20}), and the concentration of TDS in this test (940 mg/L) was lower than the reproduction EC_{20} value for TDS in Fording River water (1,012 mg/L at hardness >500 mg/L as $CaCO_3$; Golder 2013); these results indicate that MIT did not contribute to the observed response.
- **FR_FRCP1 (Q3)** — Nickel showed the greatest evidence of causing the observed response in this test. The total nickel concentration in this test (7.0 µg/L) was higher than the reproduction EC_{10} for nickel in Michel Creek water (5.1 µg/L; Nautilus 2018), indicating that nickel may have contributed to toxicity in this test. This interpretation aligns with the 2021 *C. dubia* TIE testing conducted with Q3 FR_FRCP1 water, which showed decreased effects on reproduction upon addition of EDTA, and the graphical analysis of nickel, which demonstrated a concentration-response relationship for *C. dubia* reproduction (Figure 3.4-1). Other constituents exhibited weak to no evidence of potential for toxicity at this station in Q3 2021. The concentration of nitrate in this test (14 mg/L as N) was above the level 1 EVWQP benchmark but approximately three times lower than the updated, site-specific reproduction EC_{10} derived for the MQ2 project (Golder 2021b) using site water testing (46 mg/L as N at hardness 596 mg/L as $CaCO_3$), indicating that nitrate did not contribute to the observed response.

[25] There is some uncertainty in this comparison because the chloride concentration in the Q1 FR_FRCP1 test (1.6 mg/L) was lower than that used in the US EPA (2013) toxicity test (2 mg/L). This uncertainty is offset by the nitrite concentration in the FR_FRCP1 test being more than an order of magnitude below the nitrite EC_{10}.

- **FR_FRCP1 (Q4)** — Nickel showed the greatest evidence of causing the observed response in this test. The total nickel concentration in this test (12 µg/L) was higher than the reproduction EC_{25} for nickel in Michel Creek water (10.8 µg/L; Nautilus 2018), indicating that nickel may have contributed to observed effects. Although the TIE results demonstrated comparable effects to reproduction between the EDTA treated sample and to the untreated sample, this appears to be related to EDTA-specific effects, which were also observed in the negative laboratory control. The nickel screening results align with the graphical analysis of nickel, which demonstrated a concentration-response relationship for *C. dubia* reproduction (Figure 3.4-1). Other constituents exhibited weak to no evidence of potential for toxicity at this station in Q4 2021. The concentration of nitrate in this test (23 mg/L as N) was above the level 1 EVWQP benchmark but approximately three times lower than the updated, site-specific reproduction EC_{10} derived for the MQ2 project (Golder 2021b) using site water testing (57 mg/L as N at hardness 701 mg/L as $CaCO_3$), indicating that nitrate did not contribute to the observed response.
- **LC_DCDS (Q3 and Q4)** — Nickel and nitrate showed the greatest evidence of causing the observed response in these tests. The total nickel concentration in the Q3 test (9.1 µg/L) was higher than the reproduction EC_{20} for nickel in Michel Creek water (8.6 µg/L) and the total nickel concentration in the Q4 test (13 µg/L) was higher than the reproduction EC_{25} for nickel in Michel Creek water (10.8 µg/L; Nautilus 2018). These results indicate that nickel may have contributed to the observed effects in both tests. The nickel screening results also align with the graphical analysis of nickel, which demonstrated a concentration-response relationship for *C. dubia* reproduction (Figure 3.4-1). Other constituents exhibited weak to no evidence of potential for toxicity at this station in Q3 or Q4 2021. Concentrations of potassium in these tests were higher than tests categorized as no adverse response. There is no WQG or screening value for potassium, so potassium was assessed via TDS and MIT for which potassium is a component. The hazard quotients for the *C. dubia* reproduction EC_{20} MIT model were 0.44 (Q3) and 0.68 (Q4; i.e., below the EC_{20}), and the concentrations of TDS in these tests (618 mg/L [Q3] and 838 mg/L [Q4]) were lower than the reproduction EC_{20} value for TDS in Fording River water (1,012 mg/L at hardness >500 mg/L as $CaCO_3$; Golder 2013). These results indicate that MIT did not contribute to the observed response. The concentration of nitrate in the Q4 test was higher than tests categorized as no adverse response and the concentrations of nitrate in both tests (36 mg/L as N [Q3] and 47 mg/L as N [Q4]) were above the level 1 EVWQP benchmark as well as than the updated, site-specific reproduction EC_{10} values derived for the MQ2 project (Golder 2021b) using site water testing (31 mg/L as N at hardness 438 mg/L as $CaCO_3$ [Q3] and 45 mg/L as N at hardness 590 mg/L as $CaCO_3$ [Q4]), indicating that nitrate may have contributed to observed effects.
- **CM_MC2 (Q1)** — Nickel showed the greatest evidence of causing the observed response in this test. The total nickel concentration in this test (15 µg/L) was higher than the reproduction EC_{25} for nickel in Michel Creek water (10.8 µg/L; Nautilus 2018), indicating that nickel may have contributed to toxicity in this test. This interpretation aligns with the 2021 *C. dubia* TIE testing conducted with Q1 CM_MC2 water, which showed decreased effects on reproduction upon addition of EDTA, and the graphical analysis of nickel, which demonstrated a concentration-response relationship for *C. dubia* reproduction (Figure 3.4-1). Other constituents exhibited weak to no evidence of potential for toxicity at this station in Q1 2021. The concentration of sodium in this test was higher than tests categorized as no adverse response. There is no WQG or screening value for sodium, so sodium was assessed via TDS and MIT for which sodium is a component. The hazard quotient for the *C. dubia* EC_{20} MIT model was 0.61 (i.e., below the EC_{20}), and the concentration of TDS in this test (785 mg/L) was lower than the reproduction EC_{20} value for TDS in Fording River water (1,012 mg/L at hardness >500 mg/L as $CaCO_3$; Golder 2013); these results indicate that MIT did not contribute to the observed response.

- **CM_MC2 (Q4)** — Nickel showed the greatest evidence of causing the observed response in this test. The total nickel concentration in this test (13 µg/L) was higher than the reproduction EC_{25} for nickel in Michel Creek water (10.8 µg/L; Nautilus 2018), indicating that nickel may have contributed to toxicity in this test. This interpretation aligns with the 2021 *C. dubia* TIE testing conducted with Q4 CM_MC2 water, which showed decreased effects on reproduction upon addition of EDTA, and the graphical analysis of nickel, which demonstrated a concentration-response relationship for *C. dubia* reproduction (Figure 3.4-1).
- **LC_LC3 (Q4)** — Nickel showed the greatest evidence of causing the observed response in this test. The total nickel concentration in this test (10 µg/L) was higher than the reproduction EC_{20} for nickel in Michel Creek water (8.6 µg/L; Nautilus 2018), indicating that nickel may have contributed to observed effects.

3.4.2 *Pseudokirchneriella subcapitata* Cell Yield

Nineteen tests conducted in 2021 were carried forward to the causation assessment, consisting of 16 tests categorized as possible adverse response (Q1 tests with FR_FRABCH, LC_LC5, LC_DCDS, CM_MC2, EV_MC2, and LC_LC3; Q2 test with GH_FR1; Q3 tests with LC_DCDS, GH_ERC, and EV_HC1; and Q4 tests with LC_LC5, LC_LCDSSLCC, GH_ERC, CM_MC2, EV_MC2, and EV_HC1) and 3 tests categorized as likely adverse response (Q1 test with FR_FRCP1 and Q2 tests with LC_LC5 and LC_LC3). Results are provided below for the *P. subcapitata* causation assessment.

Water Quality Screening (P. subcapitata)

In two of nineteen tests categorized as possible or likely (EV_MC2 [Q1 and Q3]), concentrations were below chronic WQGs or lowest level 1 EVWQP benchmarks. In the seventeen remaining tests categorized as possible or likely adverse effects, concentrations of one or more constituents exceeded chronic WQGs[26] or lowest level 1 EVWQP benchmarks for at least one constituent:

- **FR_FRCP1 (Q1)**—Concentrations of sulphate, nitrate and selenium exceeded the lowest level 1 EVWQP benchmarks, the concentration of nickel exceeded the level 1 interim screening value, and concentrations of fluoride and uranium exceeded chronic WQGs.
- **FR_FRABCH (Q1)**—Concentrations of nitrate and selenium exceeded the lowest level 1 EVWQP benchmarks.
- **LC_LC5 (Q2)**—The concentration of selenium exceeded the lowest level 1 EVWQP benchmark, and the concentration of fluoride and chromium exceeded the chronic WQGs.
- **LC_DCDS (Q1 and Q3)**—Concentrations of nitrate and selenium exceeded the lowest level 1 EVWQP benchmarks, the concentration of nickel exceeded the level 1 interim screening value.
- **GH_ERC (Q3 and Q4)**—The concentration of fluoride exceeded the chronic WQG.
- **CM_MC2 (Q1 and Q4)**—The concentration of nickel exceeded the level 1 interim screening value.
- **LC_LC3 (Q1)**—Concentrations of sulphate, and selenium exceeded the lowest level 1 EVWQP benchmarks, and the concentration of nickel exceeded the level 1 interim screening value.

[26] Per Section 2.3.4, nickel was compared to the interim level 1 screening value (5.3 µg/L), which is based on potential effects to invertebrates.

- **LC_LC3 (Q2)**—The concentration of selenium exceeded the lowest level 1 EVWQP benchmarks, the concentration of nickel exceeded the level 1 interim screening value, and the concentration of fluoride exceeded the chronic WQG.
- **LC_LC5 (Q1 and Q4), GH_FR1 (Q2), EV_HC1 (Q3 and Q4), LC_LCDSSLCC (Q4)**—The concentration of selenium exceeded the lowest level 1 EVWQP benchmark, and the concentration of fluoride exceeded the chronic WQG.

Concentrations of field measured dissolved oxygen were below the minimum chronic WQGs in several tests[27] and below the minimum acute WQG for GH_ERC (Q3). However, dissolved oxygen concentrations were maintained within protocol limits during the test duration (Appendix B) and therefore are not considered to be a causal factor in the observed response.

Spearman Rank Correlation (P. subcapitata)

Constituents and explanatory variables with a statistically significant Spearman rank correlation for *P. subcapitata* cell yield for the combined and 2021 datasets are summarized in Table 3.4-2. Strong negative statistical correlations (i.e., $r_s \leq -0.4$) were observed in the combined dataset for total acidity, and in the 2021 dataset for TOC, TSS, turbidity, several metals (e.g., cobalt, mercury, zinc), and PC2 (Table F-1).

The PC score that had a statistically significant Spearman rank correlation is described below:

- **PC2 (2021 dataset)**—This component accounted for 23.3% of the variance (Table E-2). PC2 had strong positive loadings for TSS and turbidity, one Order constituent (cadmium), and several metals (e.g., cobalt, mercury, zinc).

The component loadings for PC2 exhibited similar patterns between the combined dataset and the 2021 dataset. PC2 in both datasets had strong positive loadings for TSS and turbidity and several metals; however, loadings tended to be stronger in the 2021 dataset compared to the combined dataset.

[27] FR_FRABCH (Q1), GH_FR1 (Q1), LC_LC5 (Q2), LC_DCDS (Q3), GH_ERC (Q4), EV_MC2 (Q4), EV_HC1 (Q3), LC_LC3 (Q2), and LC_LCDSSLCC (Q4)

Table 3.4-2: Constituents and Explanatory Variables with Significant Spearman Rank Correlations for *Pseudokirchneriella subcapitata* Cell Yield.

Constituent[(a)]	R_s Combined Dataset	R_s 2021 Dataset	Comparison to WQGs/ EVWQP Benchmarks	Retained for Graphical Analysis?
Total Acidity	-0.45	ns	No WQG	Yes
Bicarbonate Alkalinity	-0.36	ns	No WQG	No - assessed as TDS
Total Alkalinity	-0.16	ns	No	No
Total Antimony	ns	-0.34	No	No
Total Arsenic	ns	-0.33	No	No
Total Boron	-0.16	ns	No	No
Dissolved Cadmium	ns	-0.33	No	No
Total Calcium	-0.18	ns	No WQG	No - assessed as TDS
Dissolved Organic Carbon	ns	-0.38	No WQG	Yes
Total Cobalt	-0.14	-0.43	No	No
Conductivity	-0.16	ns	No WQG	No - assessed as TDS
Dissolved Copper	ns	-0.33	No	No
Hardness	-0.15	ns	No WQG	No - assessed as TDS
Total Iron	ns	-0.59	No	No
Total Lead	ns	-0.43	No	No
Total Lithium	-0.19	ns	No	No
Total Magnesium	-0.17	ns	No WQG	No - assessed as TDS
Total Manganese	ns	-0.57	No	No
Total Mercury	ns	-0.53	No	No
Total Nickel	-0.15	-0.47	Yes	Yes
Nitrate	-0.15	ns	Yes	Yes
Total Ammonia	-0.15	ns	No	No
Oxidation-Reduction Potential	-0.40	ns	No WQG	No – not a direct toxicant[28]
Total Potassium	-0.17	ns	No WQG	No - assessed as TDS
Total Selenium	-0.15	ns	Yes	Yes
Total Silicon	-0.32	ns	No WQG	Yes
Total Thallium	ns	-0.40	No	No
Total Dissolved Solids	-0.16	ns	No WQG	Yes
Total Organic Carbon	ns	-0.44	No WQG	Yes
Total Suspended Solids	ns	-0.51	No WQG	Yes
Turbidity	ns	-0.52	No WQG	Yes
Total Uranium	-0.19	ns	Yes	Yes
Total Vanadium	ns	-0.41	No	No
Zinc−Total	-0.20	-0.51	No	No
∑TUs−WQGs	-0.30	ns	No WQG	Yes
∑TU−WQGs/Benchmarks	-0.25	-0.36	No WQG	Yes
PC1 Combined	-0.22	ns	No WQG	Yes
PC2 2021	ns	-0.56	No WQG	Yes

Notes: Values shown here were statistically significant at $\alpha < 0.005$, $r_s = -0.137$ for the combined dataset and $\alpha < 0.005$, $r_s = -0.33$ for the 2021 dataset. WQGs = British Columbia water quality guidelines; EVWQP = Elk Valley Water Quality Program; ns = not significant; ∑TU = sum of toxicity units; TDS = total dissolved solids. Shaded values indicate a strong Spearman rank correlation at $r_s \leq -0.4$.

(a) Total concentrations are shown for metals that have a WQG for the total fraction or that lack a chronic WQG. Dissolved concentrations were used for metals with a WQG for the dissolved fraction.

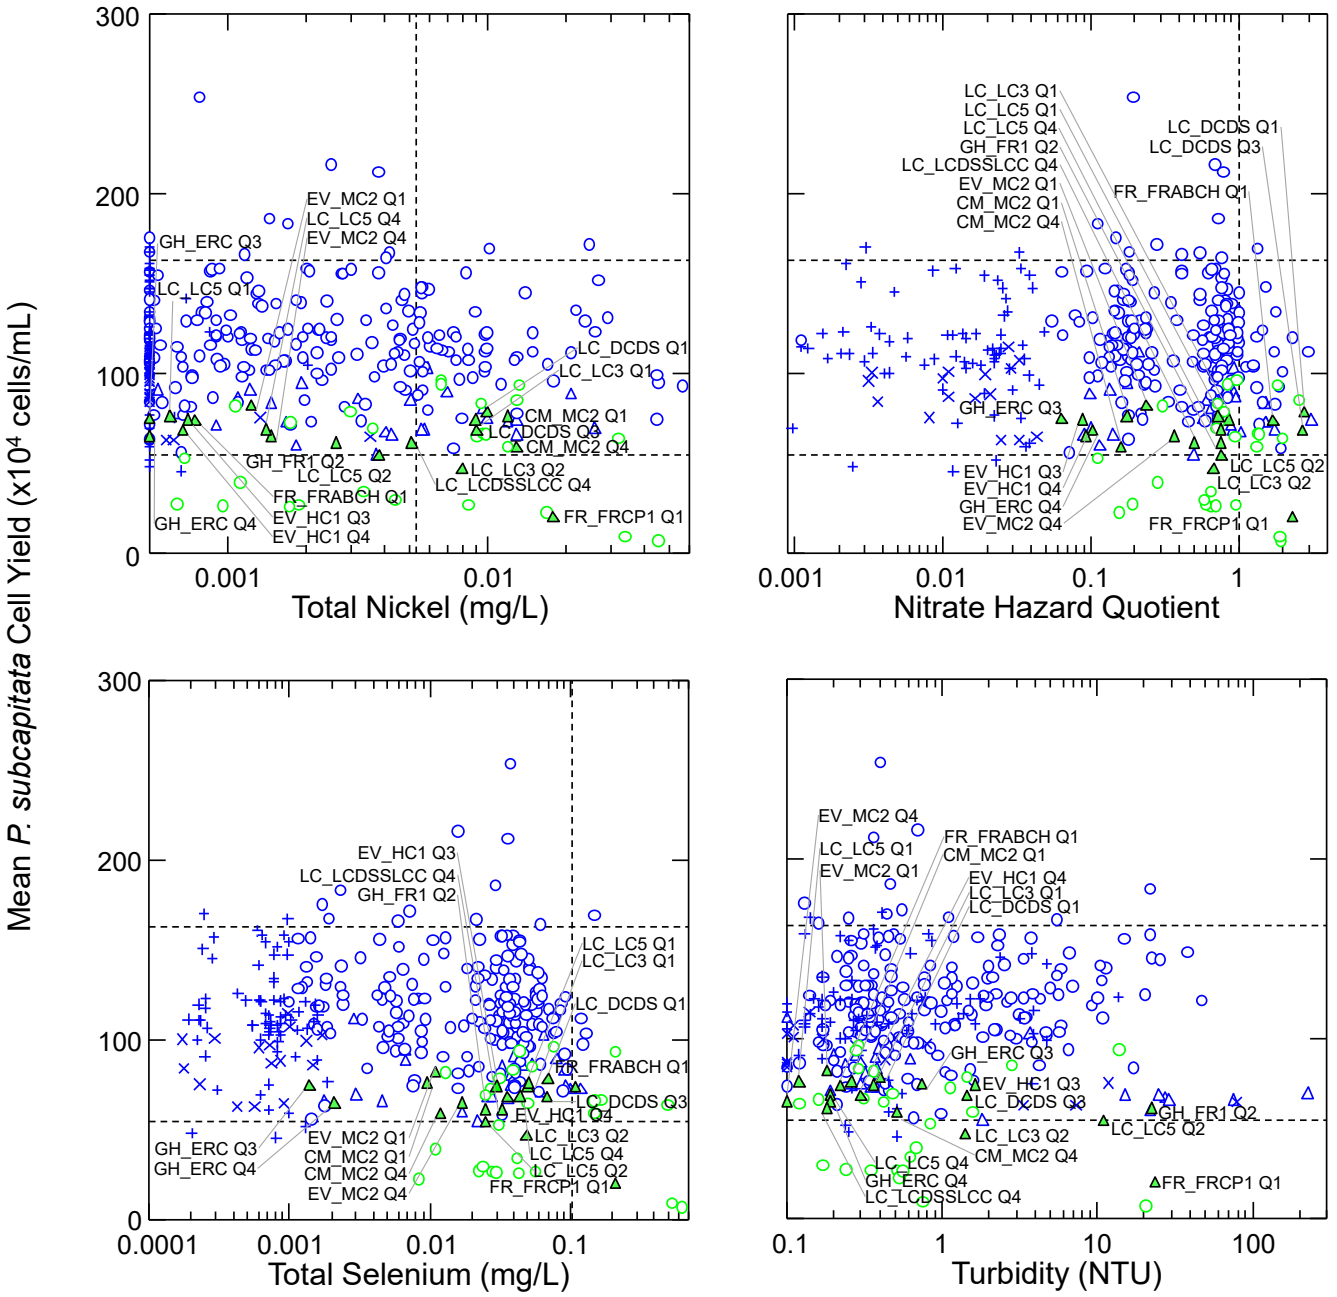
[28] Oxidation-reduction potential is not a direct toxicant to aquatic life but refers to the tendency of a water body to undergo oxidizing or reducing process upon introduction of a new substance (US EPA 2017b), and therefore was not expected to explain observed toxicity.

Graphical Analysis (P. subcapitata)

Constituents and explanatory variables with significant Spearman rank correlations, and that were either above WQGs or did not have WQGs, were carried through to graphical analysis (Figures 3.4-5 to 3.4-8). Graphical analysis was conducted for two Order constituents (total selenium, nitrate), total nickel, turbidity, TDS, TSS, total organic carbon, DOC, uranium, silicon, total acidity, ∑TU (calculated with WQGs only and WQGs and EVWQP benchmarks), PC1 (combined), and PC2 (2021 dataset).

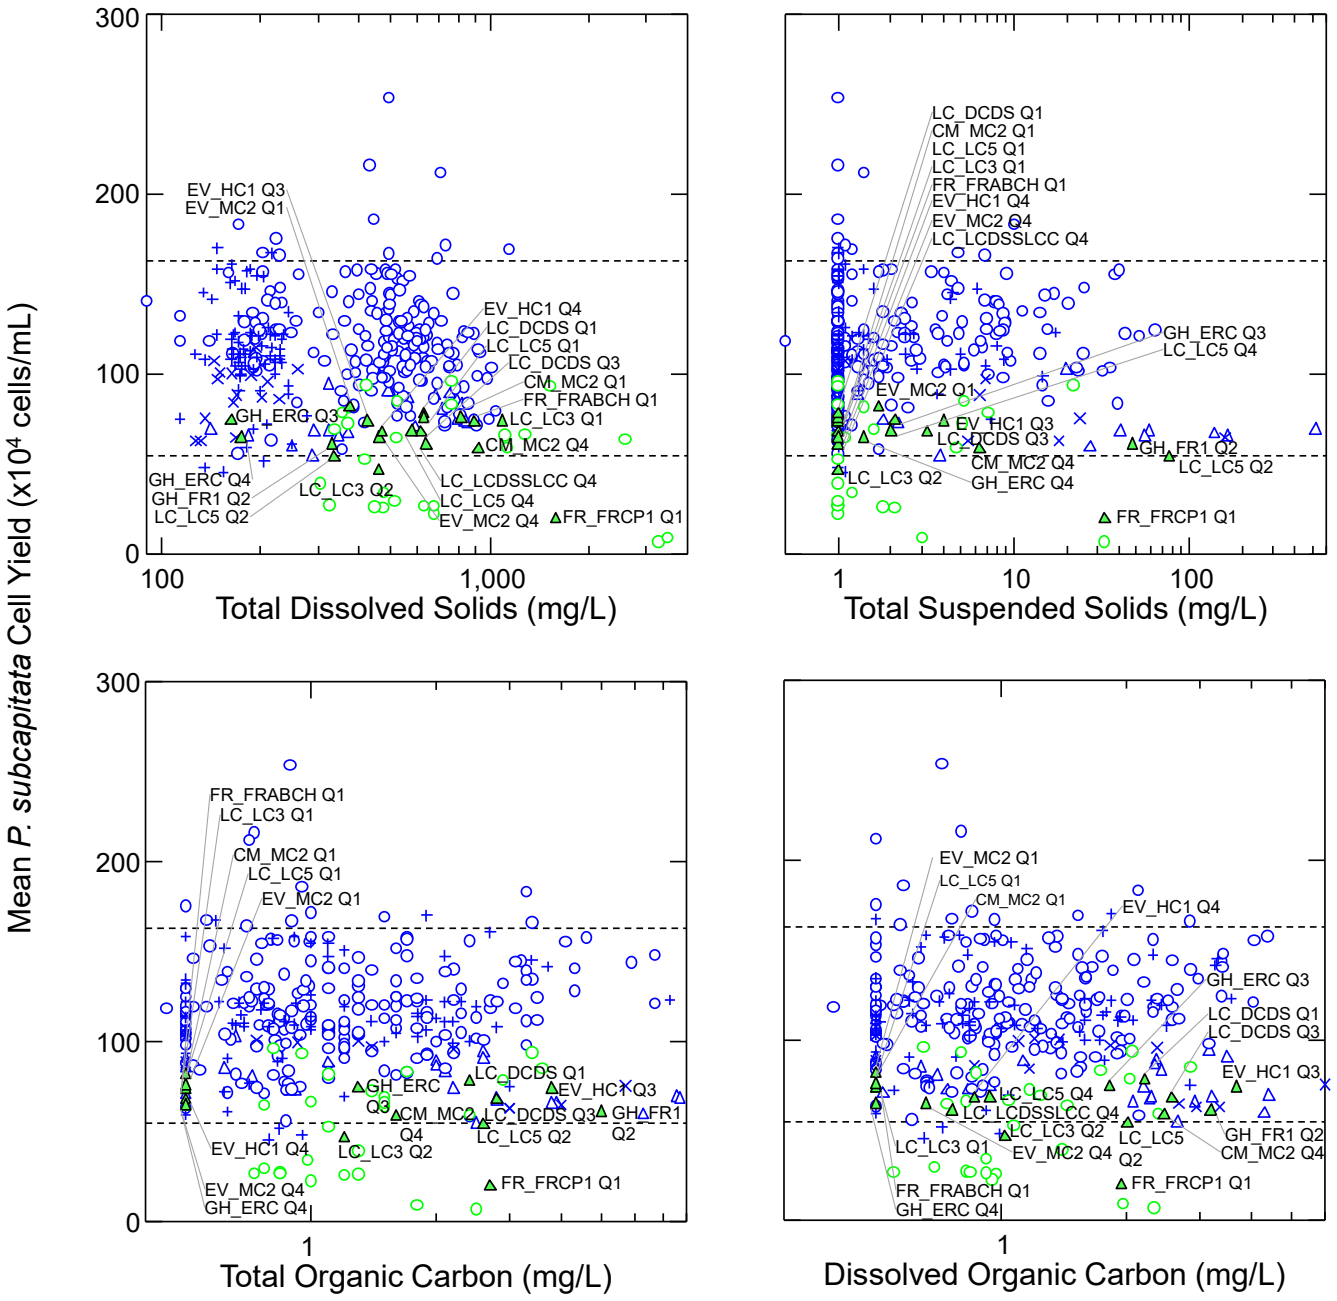
None of the evaluated explanatory variables exhibited a consistent exposure-response relationship across *P. subcapitata* tests. The lack of relationship was not surprising, given that many of the 2021 tests categorized as possible or likely had similar magnitude responses, despite the sites having different chemistry profiles (Section 3.3.1.2). Because no strong or consistent relationships were observed for concentrations versus responses, the water quality screening (next subsection) was relied upon for identification of potential causes of observed effects.

Figure 3.4-5: Mean *P. subcapitata* cell yield versus total nickel (top left), nitrate (top right), total selenium (bottom left), and turbidity (bottom right).



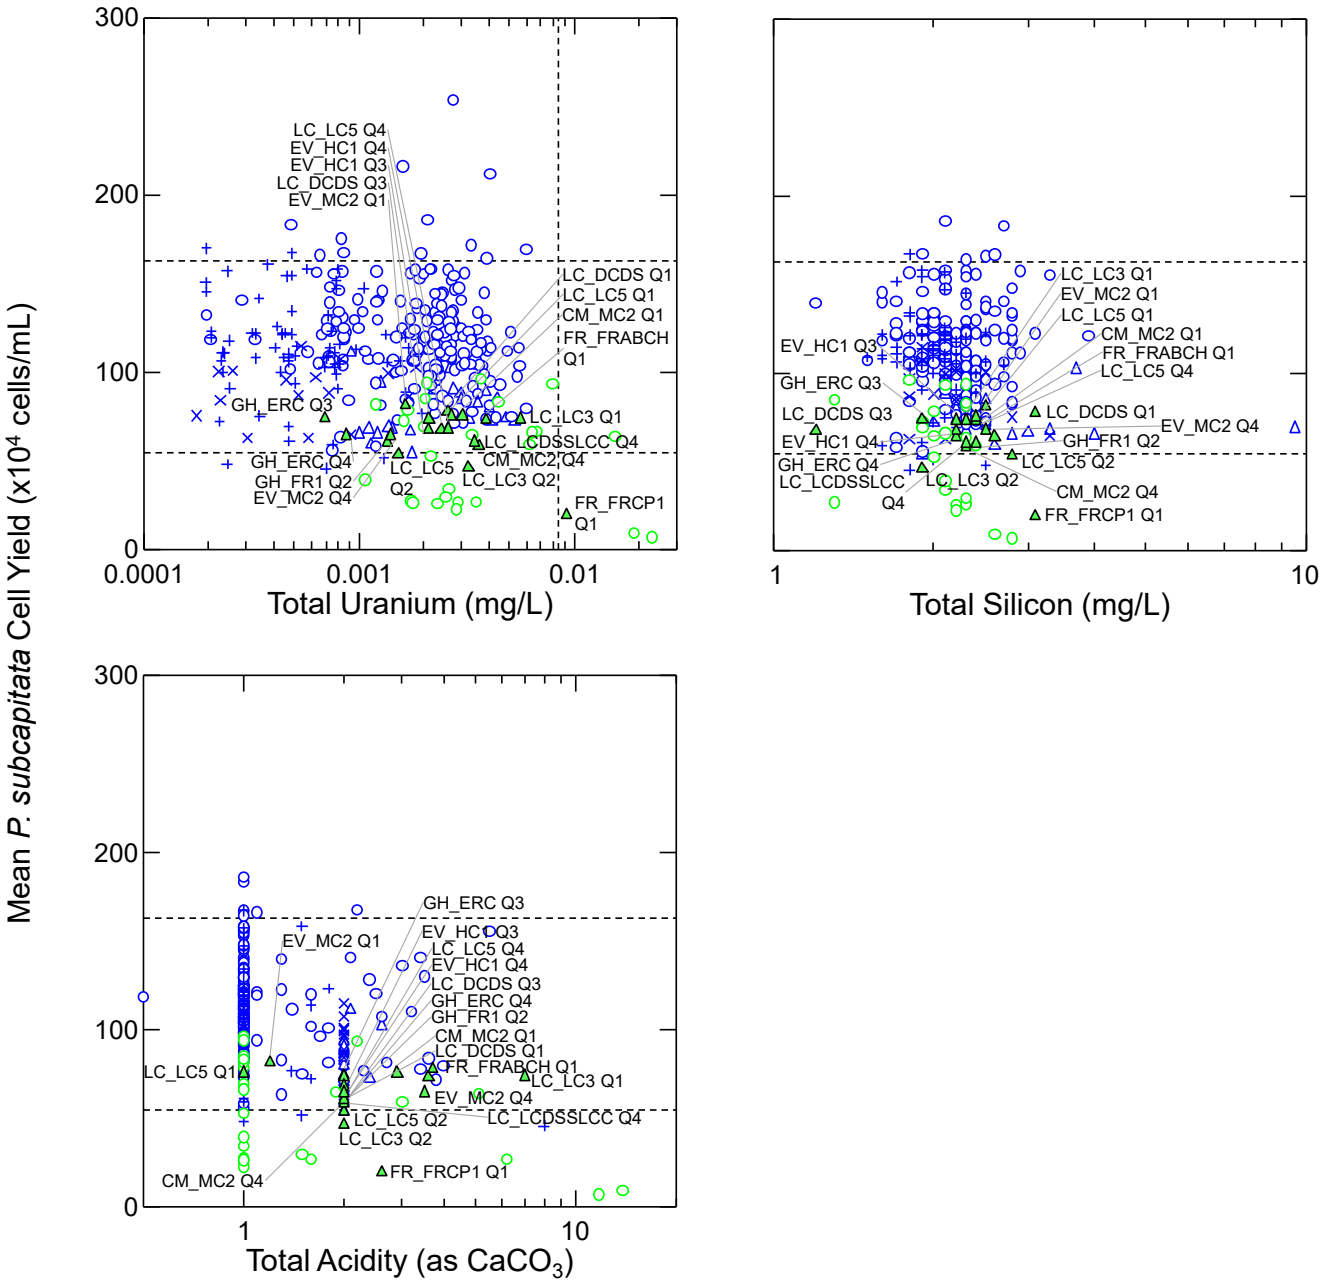
Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations). Regional chronic toxicity test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Nitrate hazard quotients are the ratio of nitrate concentrations to the lowest level 1 EVWQP benchmark for invertebrates. Nitrite hazard quotients are the ratio of nitrite concentrations to the chronic BC WQG. Vertical lines are screening values: for the nitrate hazard quotients, the screening value is 1; for nickel the screening value is the level 1 interim screening value (5.3 µg/L), for selenium, the screening value is the level 1 EVWQP benchmark for invertebrates (104 µg/L). Horizontal lines are the regional normal range (see Figure 2.3-3 for description). Cells/mL = cells per milliliter; EVWQP = Elk Valley Water Quality Plan; HQ = hazard quotient; mg/L = milligrams per litre; NTU = nephelometric turbidity units; WQG= water quality guideline.

Figure 3.4-6: Mean *P. subcapitata* cell yield versus total dissolved solids (top left), total suspended solids (top right), total organic carbon (bottom left), and dissolved organic carbon (bottom right).



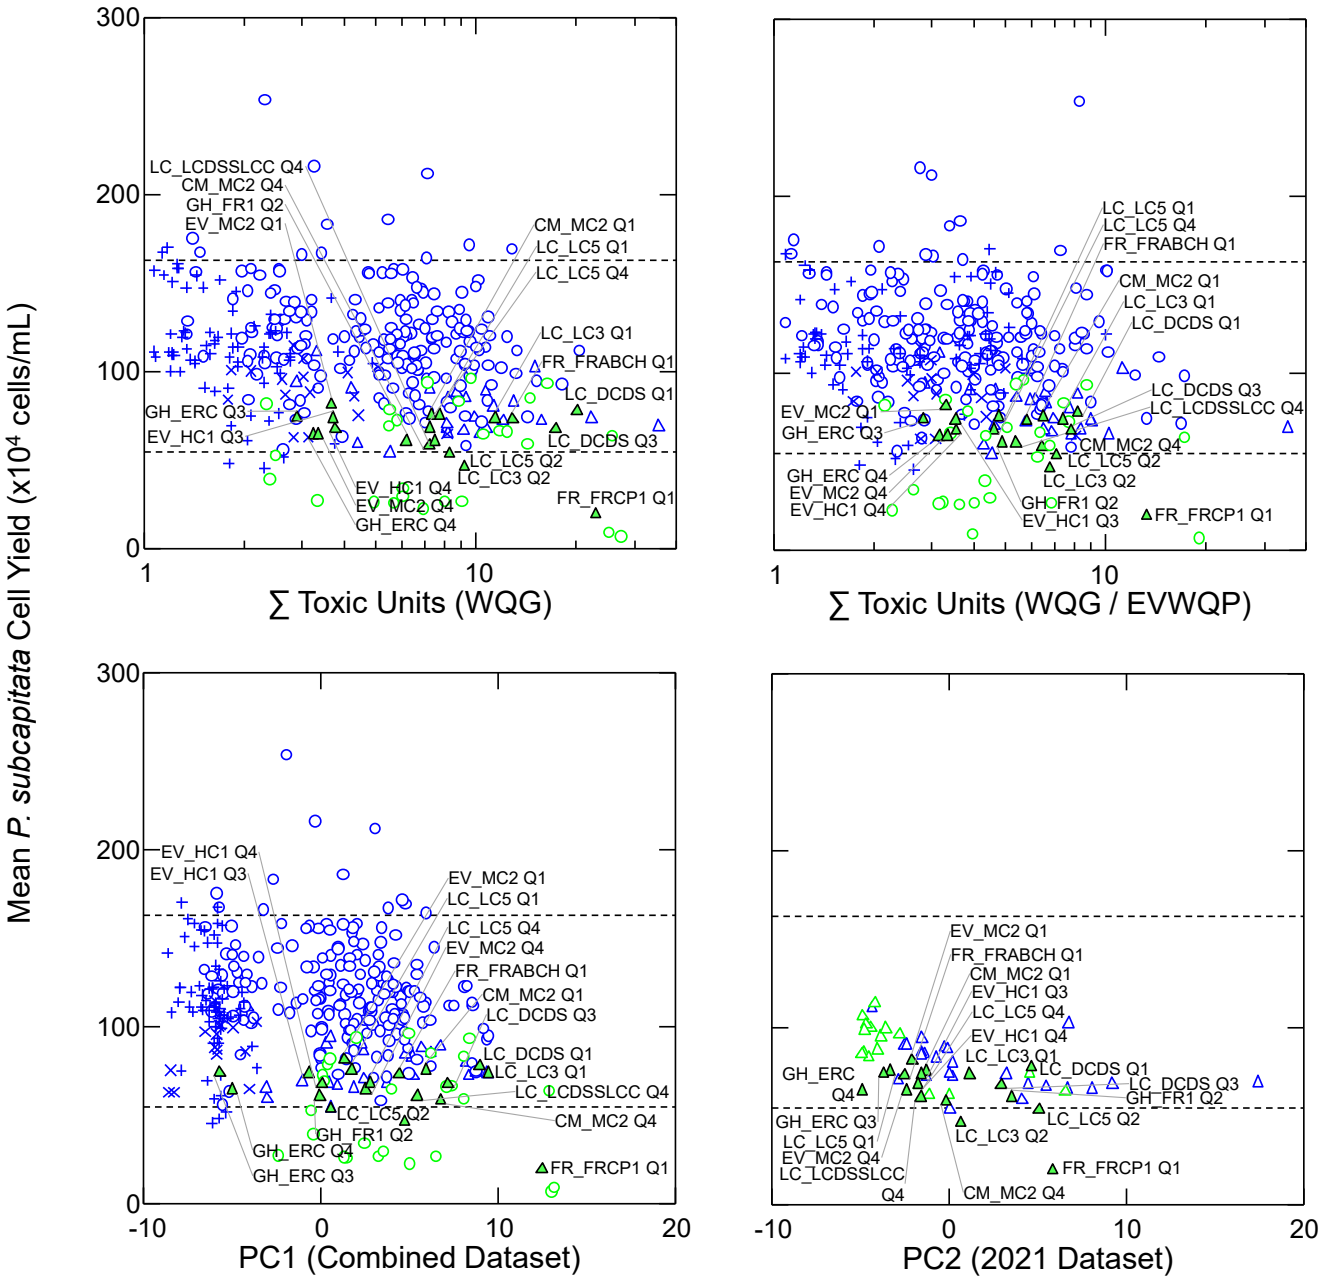
Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations). Test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Horizontal lines are the regional normal range (see Figure 2.3-3 for description). Cells/mL = cells per milliliter; mg/L = milligrams per litre.

Figure 3.4-7: Mean *P. subcapitata* cell yield versus total uranium (top left), total silicon (top right), and total acidity (bottom left).



Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations). Test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Horizontal lines are the regional normal range (see Figure 2.3-3 for description). $CaCO_3$ = calcium carbonate; cells/mL = cells per milliliter; mg/L = milligrams per litre.

Figure 3.4-8: Mean *P. subcapitata* cell yield versus sum of toxic units calculated using WQGs only (top left), sum of toxic units calculated using WQGs and EVWQP benchmarks (top right), PC1 for the combined dataset (bottom left), and PC2 for the 2021 dataset (bottom right).



Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations). Test waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Horizontal lines are the regional normal range (see Figure 2.3-3 for description). Cells/mL = cells per milliliter; EVWQP = Elk Valley Water Quality Plan; PC = principal component; WQG = water quality guideline; Σ = sum.

Identification of Potential Contributors to Toxicity (P. subcapitata)

In tests categorized as having a possible or likely adverse response to *P. subcapitata*, concentrations of most constituents were equal to or lower than concentrations in reference waters and/or test site waters categorized as no adverse response (Table D-2), and/or were lower than the chronic WQG (Appendix C). Such constituents are not expected to contribute to toxicity in these tests. For the remaining constituents, published toxicity data were reviewed to evaluate their potential to contribute to observed effects. These constituents are discussed below.

- **FR_FRCP1 (Q1)**—No water quality constituent was identified as the potential cause of the observed response in this test. Several constituents were above WQGs and/or concentrations measured in tests categorized as no adverse response; however, as described in the following bullets, these constituents were identified to be unlikely to have contributed to the response.
  - The ∑TUs (calculated with WQGs) for this test was higher than test sites categorized as no adverse response. The ∑TUs for this test was largely driven by nitrate, which accounted for 51% of the ∑TUs, and nickel, which accounted for 15% of the ∑TUs. As discussed below, neither of these constituents are expected to have contributed to the observed response in this test.
  - Concentrations of nitrate (35 mg/L as N at hardness 1,300 mg/L as $CaCO_3$) and sulphate (811 mg/L) in this test were above the level 1 EVWQP benchmarks but below the highest concentrations tested in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (nitrate = 50 mg/L as N at hardness 702 mg/L as $CaCO_3$; sulphate = 931 mg/L). These results indicate that nitrate and sulphate did not contribute to the observed response.
  - The concentration of nickel in this test (18 µg/L) was above the level 1 interim screening value for invertebrates[29] but below the lowest effect concentration estimated by European Union (EU 2008) of 61 µg/L for pH of 8.1, DOC of 1 mg/L, and hardness of 6 mg/L (i.e., conditions that would result in similar toxicity [pH and DOC] or much higher toxicity [hardness] relative to test conditions), indicating that nickel did not contribute to the observed response.[30]
  - The concentration of dissolved silicon in this test (3.0 mg/L) was higher than tests categorized as no adverse response but was below the EC_{10} of 3.4 mg/L for *P. subcapitata* growth (3.4 mg/L; Van Hoecke et al. 2008), indicating that silicon did not contribute to the observed response.
  - The concentration of total uranium in this test (9.2 µg/L) was above the chronic WQG and higher than tests categorized as no adverse response but was below the EC_{10} of 40 µg/L for *P. subcapitata* growth (CCME 2011), indicating that uranium did not contribute to the observed response.

[29] Per Section 2.3.4, nickel was compared to the interim level 1 screening value for (5.3 µg/L), which is based on potential effects to invertebrates.

[30] EU 2008 generated EC10 estimates for various combinations of pH (7, 7.5, 8.1), hardness (6 to 320 mg/L), and DOC (1 to 25 mg/L). Nickel EC10 estimates for *P. subcapitata* ranged from 61 to 297 µg/L. The lowest value (61 µg/L) was used for screening.

  - Concentrations of TDS and components of TDS (e.g., calcium) in this test were higher than tests categorized as no adverse response. In absence of WQGs or screening values, these constituents were assessed collectively via TDS. The concentration of TDS in this test (1,590 mg/L) was greater than the highest concentration in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (1,498 mg/L), so it cannot be ruled out that TDS may have contributed to the observed response in this test based on toxicity testing data alone. However, Figure 3.4-6 indicates a lack of concentration-response relationship between the observed effects on cell yield and TDS, where cell yield was 20×10^4 cells/mL in the Q1 FR_FRCP1 test with 1,590 mg/L TDS, and 64×10^4 cells/mL in the Q1 2015 FR_FRCP1 test at a greater TDS concentration (2,580 mg/L). The marginal (6%) difference in TDS between toxicity tests and the lack of relationship between TDS and response in cell yield indicates that TDS was unlikely to have contributed to the observed response.
  - The concentration of selenium in this test (210 µg/L) was greater than the lowest level 1 EVWQP invertebrate benchmark and concentrations observed in tests categorized as no adverse response but was two orders of magnitude below the 72-h EC_{50} of 99,000 µg/L for *P. subcapitata* growth (Ibrahim and Spacie 1990), indicating that selenium did not contribute to the observed response.

- **FR_FRABCH (Q1)**—No water quality constituent was identified as the potential cause of the observed response in this test. The concentration of dissolved calcium in this test was higher than tests categorized as no adverse response. In absence of a WQG or screening value, calcium was assessed via TDS of which calcium is a component. The concentration of TDS in this test (898 mg/L) was lower than the highest concentration tested in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (1,498 mg/L), indicating that TDS did not contribute to the observed response. The concentration of nitrate in this test (26 mg/L as N at hardness 756 mg/L as $CaCO_3$) was above the level 1 EVWQP benchmark but was below the highest concentration tested in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (50 mg/L as N at hardness 702 mg/L as $CaCO_3$), indicating that nitrate did not contribute to the observed response. As discussed in Section 3.3.1.2 and illustrated on Figures 3.5-4 to 3.5-8, adverse effects were observed across most tests in Q1 and Q4, despite dissimilar water chemistries.
- **LC_DCDS (Q1)**—No water quality constituent was identified as the potential cause of the observed response in this test. Several constituents were above WQGs and/or concentrations measured in tests categorized as no adverse response; however, as described in the following bullets, these constituents were identified to be unlikely to have contributed to the response.
  - The concentration of potassium in this test was higher than tests categorized as no adverse response. In absence of a WQG or screening value, potassium was assessed via TDS of which potassium is a component. The concentration of TDS in this test (627 mg/L) was lower than the highest concentration tested in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (1,498 mg/L), indicating that TDS did not contribute to the observed response.
  - The concentration of nitrate in this test (42 mg/L as N at hardness 530 mg/L as $CaCO_3$) was above the level 1 EVWQP benchmark but was below the highest concentration tested in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (nitrate = 50 mg/L as N at hardness 702 mg/L as $CaCO_3$), indicating that nitrate did not contribute to the observed response.

- The concentration of nickel in this test (10 µg/L) was above the level 1 interim screening value but below the lowest effect concentration estimated by European Union (EU 2008) of 61 µg/L for pH of 8.1, DOC of 1 mg/L, and hardness of 6 mg/L (i.e., conditions that would result in similar toxicity [pH and DOC] or much higher toxicity [hardness] relative to test conditions), indicating that nickel did not contribute to the observed response.[30]
- The concentration of dissolved silicon in this test (2.9 mg/L) was higher than tests categorized as no adverse response but was below the EC_{10} of 3.4 mg/L for *P. subcapitata* growth (Van Hoecke et al. 2008), indicating that silicon did not contribute to the observed response.

As discussed in Section 3.3.1.2 and illustrated on Figures 3.5-4 to 3.5-8, adverse effects were observed across most tests in Q1 and Q4, despite dissimilar water chemistries.

- **LC_DCDS (Q3)**—No water quality constituent was identified as the potential cause of the observed response in this test. The concentration of nitrate in this test (36 mg/L as N at hardness 438 mg/L as $CaCO_3$) was above the level 1 EVWQP benchmark but was below the highest concentration tested in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (50 mg/L as N at hardness 702 mg/L as $CaCO_3$), indicating that nitrate did not contribute to the observed response. The concentration of nickel in this test (9.1 µg/L) was above the level 1 interim screening value but below the lowest effect concentration estimated by European Union (EU 2008) of 61 µg/L for pH of 8.1, DOC of 1 mg/L, and hardness of 6 mg/L (i.e., conditions that would result in similar toxicity [pH and DOC] or much higher toxicity [hardness] relative to test conditions), indicating that nickel did not contribute to the observed response.[30]
- **LC_LC3 (Q1)**—No water quality constituent was identified as the potential cause of the observed response in this test. Concentrations of components of TDS (e.g., calcium) in this test were higher than categorized as no adverse response. In absence of WQGs or screening values, these constituents were assessed via TDS. The concentration of TDS in this test (1,090 mg/L) was lower than the highest concentration tested in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (1,498 mg/L) indicating that TDS did not contribute to the observed response. The concentration of sulphate in this test (483 mg/L) was above the level 1 EVWQP benchmark but was below the highest concentration tested in the Golder (2013) mixture toxicity test that resulted in no significant adverse effects to *P. subcapitata* cell yield (931 mg/L) indicating that sulphate did not contribute to the observed response. The concentration of nickel in this test (9.0 µg/L) was above the level 1 interim screening value but was below the lowest effect concentration estimated by European Union (EU 2008) of 61 µg/L for pH of 8.1, DOC of 1 mg/L, and hardness of 6 mg/L (i.e., conditions that would result in similar toxicity [pH and DOC] or much higher toxicity [hardness] relative to test conditions), indicating that nickel did not contribute to the observed response.[30] As discussed in Section 3.3.1.2 and illustrated on Figures 3.5-4 to 3.5-8, adverse effects were observed across most tests in Q1 and Q4, despite dissimilar water chemistries.
- **CM_MC2 (Q1 and Q4), and LC_LC3 (Q2)**—No water quality constituent was identified as the potential cause of the observed response in this test. The concentrations of nickel in these tests (12 µg/L [CM_MC2 Q1], 13 µg/L [CM_MC2 Q4], and 8.0 µg/L [LC_LC3 Q2]) were above the level 1 interim screening value but were below the lowest effect concentration estimated by European Union (EU 2008) of 61 µg/L for pH of 8.1, DOC of 1 mg/L, and hardness of 6 mg/L (i.e., conditions that would result in similar toxicity [pH and DOC] or much higher toxicity [hardness] relative to test conditions), indicating that nickel did not contribute to the observed response.[30] As discussed in Section 3.3.1.2 and illustrated on Figures 3.5-4 to 3.5-8, adverse effects were observed across most tests in Q1 and Q4, despite dissimilar water chemistries.

- **LC_LC5 (Q1, Q2 and Q4), GH_FR1 (Q2), GH_ERC (Q3 and Q4), EV_MC2 (Q1 and Q4, EV_HC1 (Q3 and Q4), and LC_LCDSSLCC (Q4)**—No water quality constituent was identified as the potential cause of the observed response in this test. Concentrations of constituents were equal to or lower than concentrations in other test waters categorized as no adverse response (Table D-2), and/or were lower than the chronic WQG and lowest level 1 EVWQP benchmarks (Appendix C). As discussed in Section 3.3.1.2 and illustrated on Figures 3.5-4 to 3.5-8, adverse effects were observed across most tests in Q1 and Q4, despite dissimilar water chemistries.

3.4.3 *Hyalella azteca* Survival and Growth

Eight tests conducted in 2021 were carried forward to the causation assessment, consisting of six tests categorized as possible adverse response (Q3 tests with FR_FRCP1, FR_FRABCH, GH_FR1, and LC_LC5; Q4 tests with LC_DCDS and GH_ERC) and two tests categorized as likely adverse response (Q2 and Q3 tests with CM_MC2). As discussed in Section 3.3.1.3, there is elevated uncertainty in the Q3 categories, due to high inter- reference variability.

Toxicity Identification Evaluation (H. azteca)

The following bullets summarize TIE results for quarterly tests categorized as a possible or likely adverse response.

- **FR_FRCP1**—Dry weight was categorized as a possible adverse response in Q3 (Section 3.3.1.3). In the Q3 test, effects to dry weight worsened in the EDTA treatment (43%) compared to untreated tests (27%). As discussed in Appendix B-6, the EDTA controls in Q3 had reduced dry weight relative to the negative laboratory controls indicating that the EDTA treatment itself may have contributed to adverse effects, as was observed with the Q3 FR_FRCP1 test with EDTA.

- **CM_MC2**—Survival (Q2 and Q3) and dry weight (Q3) were categorized as likely adverse responses. In both quarters, survival was improved in the EDTA-treated test compared to the untreated test. Effects on survival decreased from 28% in the untreated sample to 1% in the EDTA-treated test for Q2, and from 60% in the untreated samples to 8% in the EDTA-treated sample for Q3. These results indicate that divalent metals (likely nickel, see screening results below) may have contributed to the adverse effects. In Q3, effects on dry weight worsened in the EDTA treatment (61%) compared to the untreated test (48%). As discussed in Appendix B-7, the EDTA control in Q3 had reduced growth relative to the negative laboratory control, indicating that the EDTA treatment itself may have contributed to adverse effects, as was observed with the Q3 CM_MC2 test with EDTA.

Water Quality Screening (H. azteca)

In the eight tests categorized as possible or likely adverse effects for the *H. azteca* survival and/or dry weight endpoints, concentrations exceeded chronic WQGs or lowest level 1 EVWQP benchmarks for one or more constituent:

- **FR_FRCP1 (Q3)**—The average concentration of selenium exceeded the lowest level 1 EVWQP benchmark, the average concentration of nickel exceeded the level 1 interim screening value, and the average concentration of fluoride exceeded the chronic WQG.

- **FR_FRABCH (Q3)**—The average concentrations of selenium and nitrate exceeded lowest level 1 EVWQP benchmarks, and the average concentration of fluoride exceeded the chronic WQG.

- **GH_FR1 (Q3) and LC_LC5 (Q3)**—The average concentration of selenium exceeded the lowest level 1 EVWQP benchmark, and average concentration of fluoride exceeded the chronic WQG.
- **LC_DCDS (Q4)**—The average concentrations of selenium and nitrate exceeded lowest level 1 EVWQP benchmarks, and the average concentration of nickel exceeded the level 1 interim screening value.
- **GH_ERC (Q4)**—The average concentration of fluoride exceeded the chronic WQG.
- **CM_MC2 (Q2)**—The average concentration of nickel exceeded the level 1 interim screening value, and the average concentration of chromium exceeded the chronic WQG.
- **CM_MC2 (Q3)**—The average concentration of nickel exceeded the level 1 interim screening value, and the average concentration of fluoride exceeded the chronic WQG.

The concentration of field measured dissolved oxygen was below the chronic WQG for GH_ERC (Q4); however, dissolved oxygen concentrations were maintained within protocol limits during the test duration (Appendix B) and therefore are not considered to be a causal factor in the observed response.

Spearman Rank Correlation (H. azteca)

Constituents and explanatory variables with a statistically significant Spearman rank correlation for *H. azteca* survival and dry weight for the combined and 2021 datasets are summarized in Table 3.4-3.

Survival—No strong negative correlations ($r_s \leq -0.4$) were identified in the combined or 2021 datasets for survival (Table F-2).

Dry Weight—No strong negative correlations ($r_s \leq -0.4$) were observed in the combined dataset (Table F-3). For the 2021 dataset, strong correlations were identified for several metals (mercury, lead, silver, vanadium), DOC, TOC, TSS, turbidity, and PC2 for the 2021 dataset.

PC scores were generated separately for the survival and dry weight endpoints because a subset of tests in Q2 2021 had only survival data and no dry weight data; therefore, the analysis differed between the two endpoints. The PC scores that had statistically significant Spearman rank correlations for survival and dry weight are described below:

- Survival
  - PC3 (combined dataset)—This component accounted for 10.3% of the variance (Table E-3). PC3 had strong negative loadings for iron, lead, and TSS.
- Dry weight
  - PC1 (combined dataset)—This component accounted for 25.4% of the variance (Table E-3). PC1 had strong positive loadings for TDS, components of TDS (e.g., calcium, magnesium), three Order constituents (nitrate, selenium, sulphate), and metals (lithium, uranium).
  - PC2 (combined dataset)—This component accounted for 22.8% of the variance (Table E-3). PC2 had strong positive loadings for several metals (beryllium, bismuth, lead, mercury, silver, tin, vanadium).
  - PC4 (combined dataset)—This component accounted for 6.9% of the variance (Table E-3). PC4 had strong negative loadings for bicarbonate alkalinity, oxidation-reduction potential, and silicon.

- PC2 (2021 dataset)—This component accounted for 13.2% of the variance (Table E-3). PC2 had strong positive loadings for turbidity and several metals (aluminium, lead, titanium).

The factor loading scores from the combined datasets and the respective 2021 datasets showed similar patterns for PC1 and dissimilar patterns for PC2 and PC3. The component loadings for PC1 for dry weight, which appeared to be a strong signal of mine influence (i.e., strong loadings for TDS and Order constituents), exhibited similar patterns between the combined dataset and the 2021 dataset. PC1 in both datasets had strong loadings for the same constituents (Table E-3). PC2 for dry weight and PC3 for survival showed no clear consistency in loadings between the two datasets.

Table 3.4-3: Constituents and Explanatory Variables with Significant Spearman Rank Correlations for *Hyalella azteca* Survival and Dry Weight.

Notes: Values shown here were statistically significant for survival at $\alpha < 0.005$, $r_s = -0.177$ for the combined dataset and $\alpha < 0.005$, $r_s = -0.317$ for the 2021 dataset; and, for dry weight at $\alpha < 0.005$, $r_s = -0.185$ for the combined dataset and $\alpha < 0.005$, $r_s = -0.338$ for the 2021 dataset.
DOC = dissolved organic carbon; EVWQP = Elk Valley Water Quality Program; ns = not significant; WQGs = water quality guidelines; ∑TU = sum of toxicity units; TDS = total dissolved solids. Shaded values indicate a strong Spearman rank correlation at $r_s \leq -0.6$.

(a) Total concentrations are shown for metals that have a WQG for the total fraction or that lack a chronic WQG. Dissolved concentrations were used for metals with a WQG for the dissolved fraction.

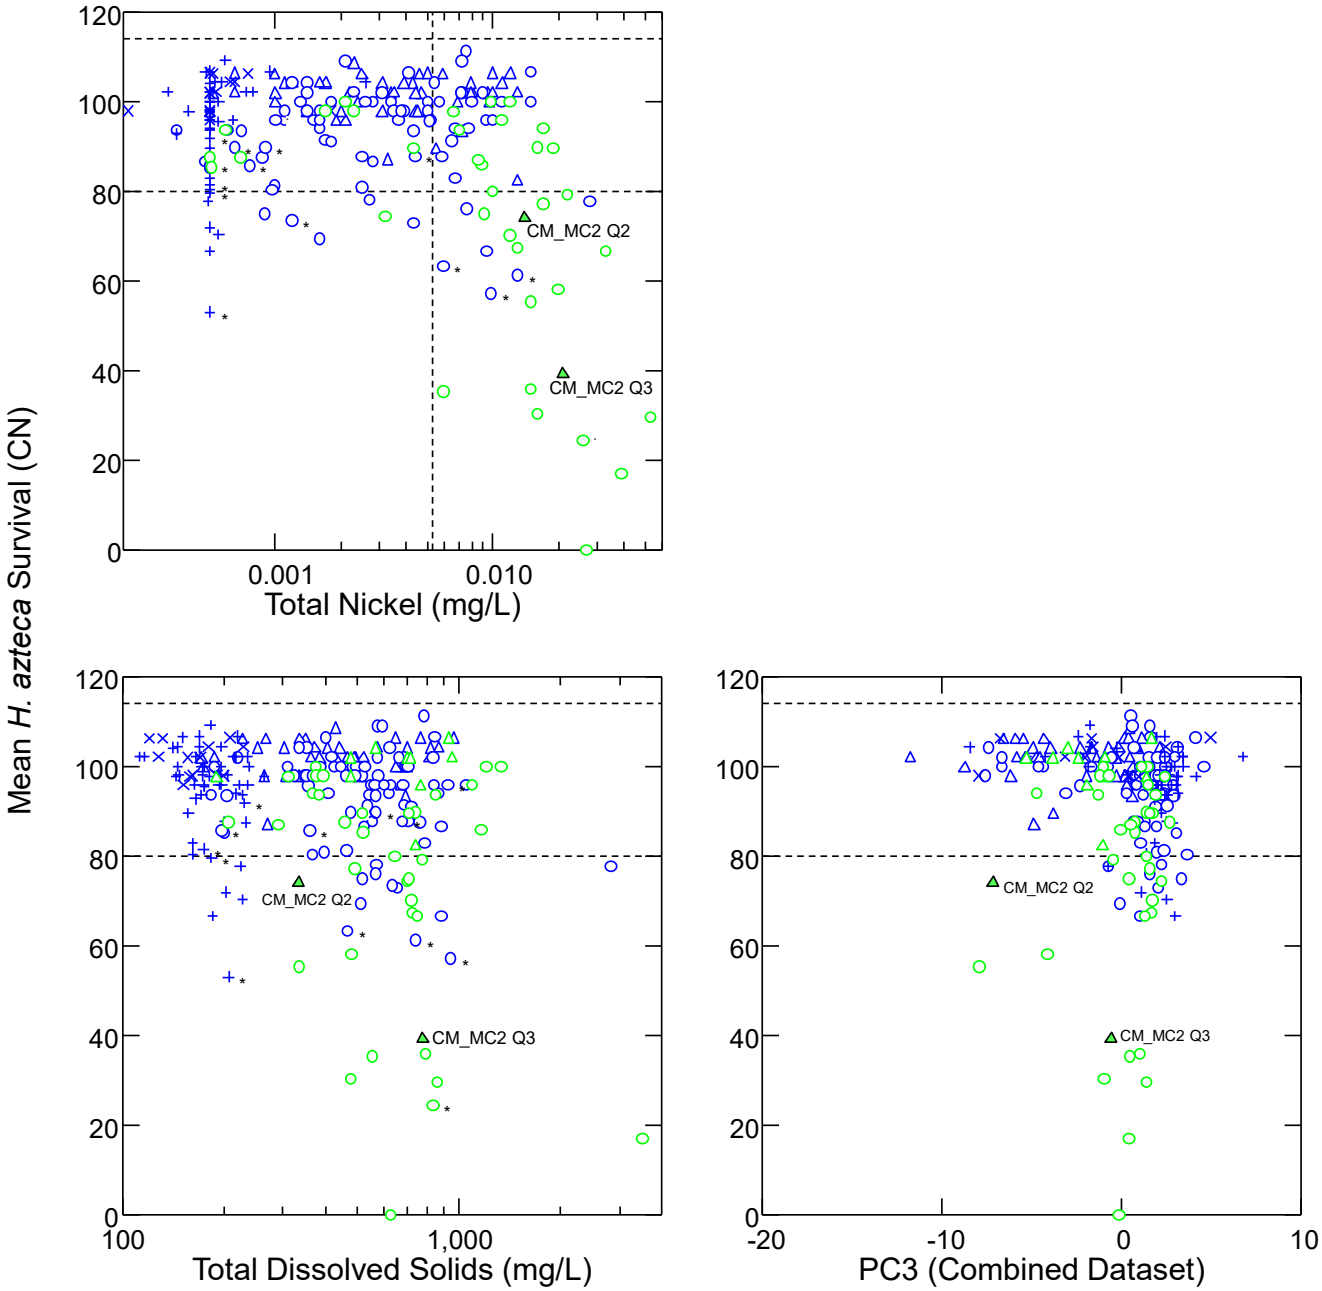
Graphical Analysis (H. azteca)

Constituents and explanatory variables with significant Spearman rank correlations, and that were either above WQGs or did not have WQGs, were carried through to graphical analysis (Figures 3.4-9 to 3.4-13). Graphical analysis for survival was conducted for nickel[31], total dissolved solids, and PC3 (combined dataset). Graphical analysis for dry weight was conducted for one Order constituent (nitrate), total nickel, nitrite, turbidity, dissolved and total organic carbon, dissolved and total suspended solids, ∑TU (calculated with WQGs only, and with WQGs and EVWQP benchmarks), PC1 (combined dataset), PC2 (combined and 2021 datasets), and PC4 (combined dataset).

Most of the constituents and explanatory variables did not exhibit a consistent exposure-response relationship across all tests for survival and dry weight. For the PCs that were carried forward to graphical analysis, no consistent patterns were apparent between the PC scores and test responses. However, nickel exhibited a general relationship between concentrations and magnitude of adverse response for both survival and dry weight. The potential for nickel to explain observed effects on dry weight is discussed in the next section.

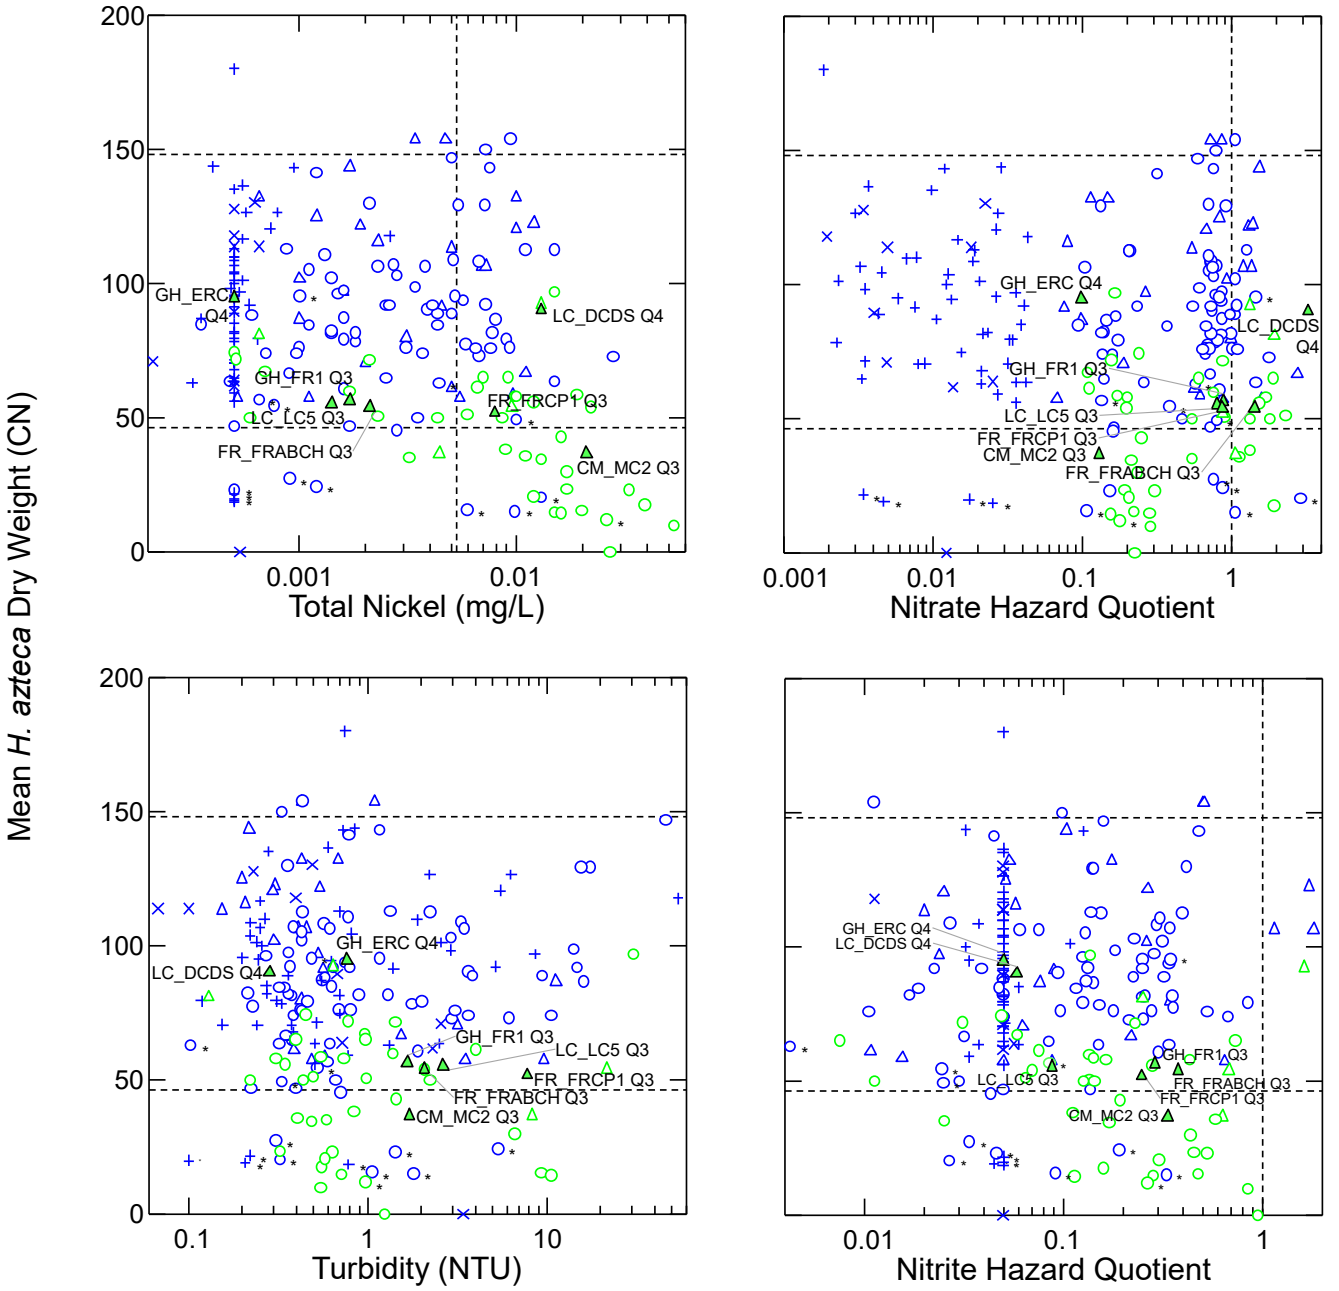
[31] Although survival was not significantly correlated with nickel, nickel was retained because it has been commonly identified as a possible or likely cause of observed responses in CM_MC2 tests.

Figure 3.4-9: Mean *H. azteca* survival versus total nickel (top left), total dissolved solids (bottom left), and PC3 for the combined dataset (bottom right).



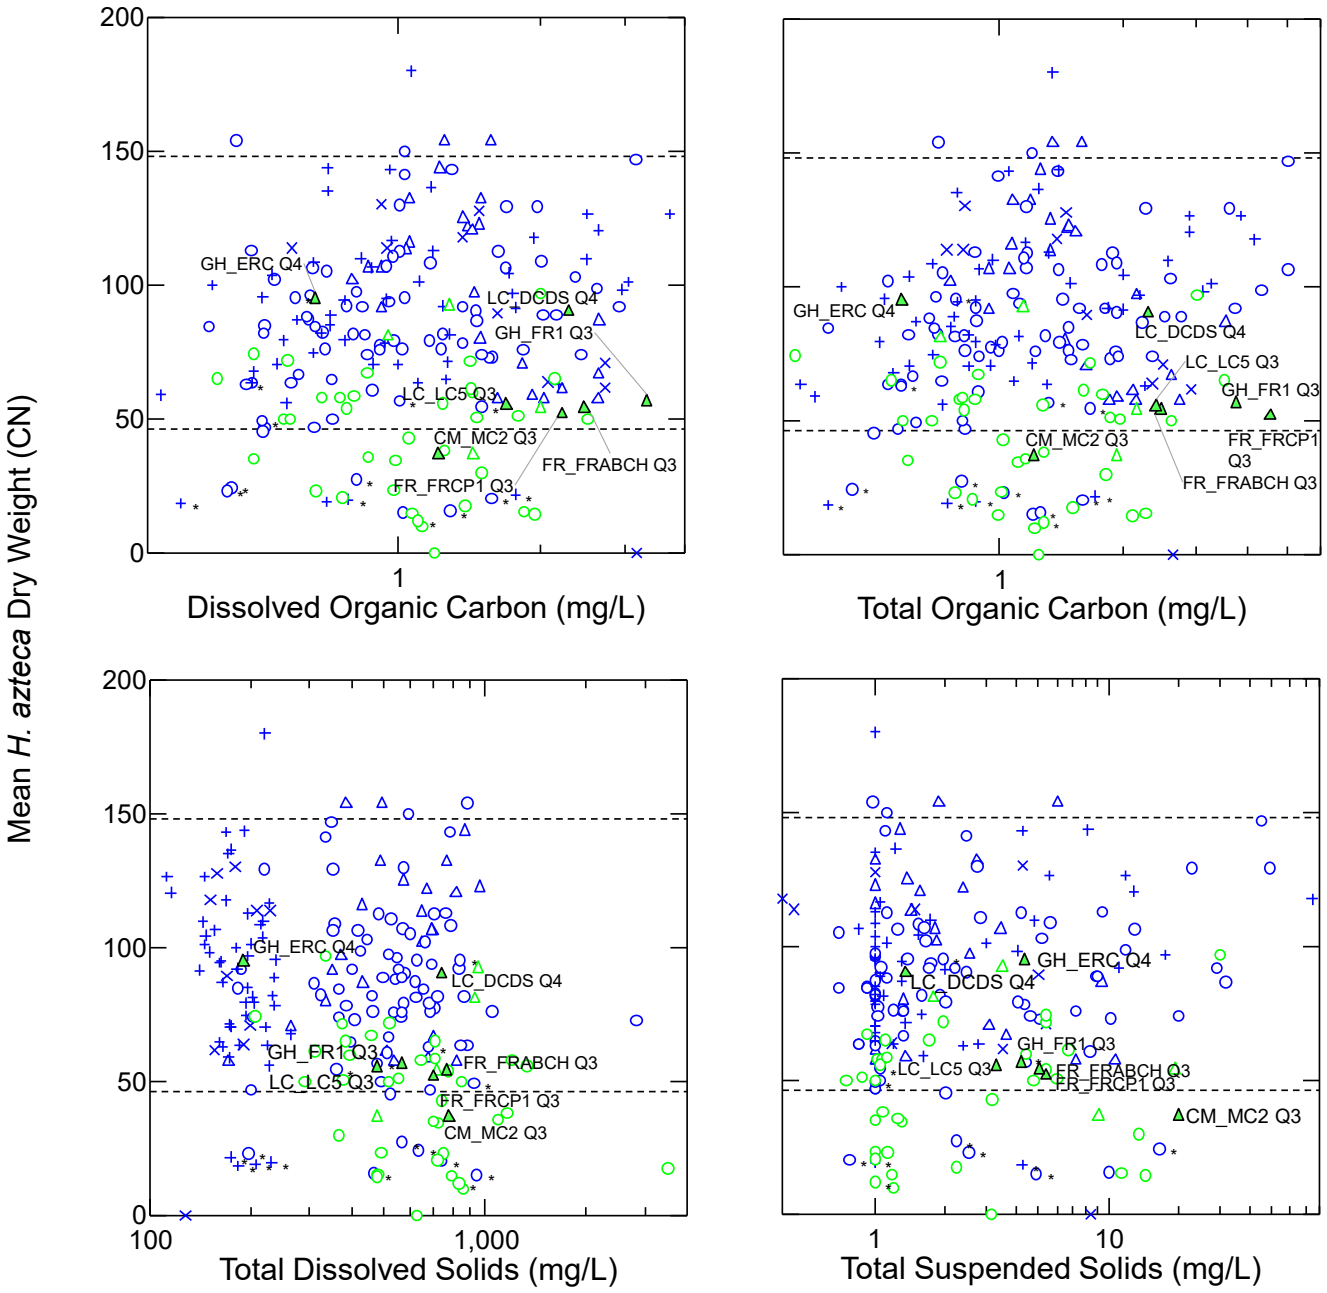
Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 UFR stations; △ = 2021 non-UFR stations). UFR test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. The vertical line is the level 1 interim screening value for nickel (5.3 µg/L). Horizontal lines are regional normal range (see Figure 2.3-3 for description). Asterisks indicate tests that were excluded from statistical analysis (i.e., Q4 2020). CN = control normalized; mg/L = milligrams per litre; PC = principal component; UFR = Upper Fording River.

Figure 3.4-10: Mean *H. azteca* dry weight versus total nickel (top left), nitrate (top right), turbidity (bottom left), and nitrite (bottom left).



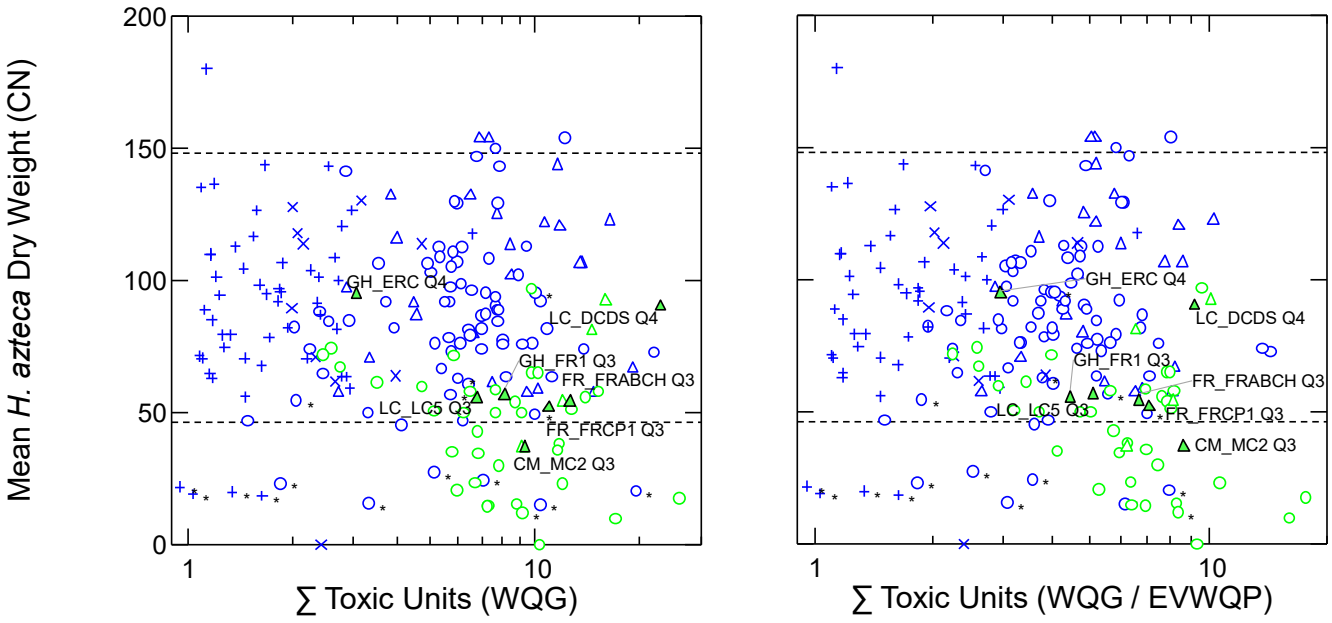
Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations; Δ = UFR stations). Regional chronic toxicity test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Nitrate hazard quotients are the ratio of nitrate concentrations to the lowest level 1 EVWQP benchmark for invertebrates. Nitrite hazard quotients are the ratio of nitrite concentrations to the chronic BC WQG. Vertical lines are screening values: for the nitrate and nitrite hazard quotients, the screening value is 1; and, for nickel the screening value is the level 1 interim screening value (5.3 µg/L). Horizontal lines are the regional normal range (see Figure 2.3-3 for description). Asterisks indicate tests that were excluded from statistical analysis (i.e., Q4 2020). CN = control normalized; EVWQP = Elk Valley Water Quality Plan; mg/L = milligrams per litre; UFR= Upper Fording River; WQG= water quality guideline.

Figure 3.4-11: Mean *H. azteca* dry weight versus dissolved organic carbon (top left), total organic carbon (top right), total dissolved solids (bottom left), and total suspended solids (bottom right).



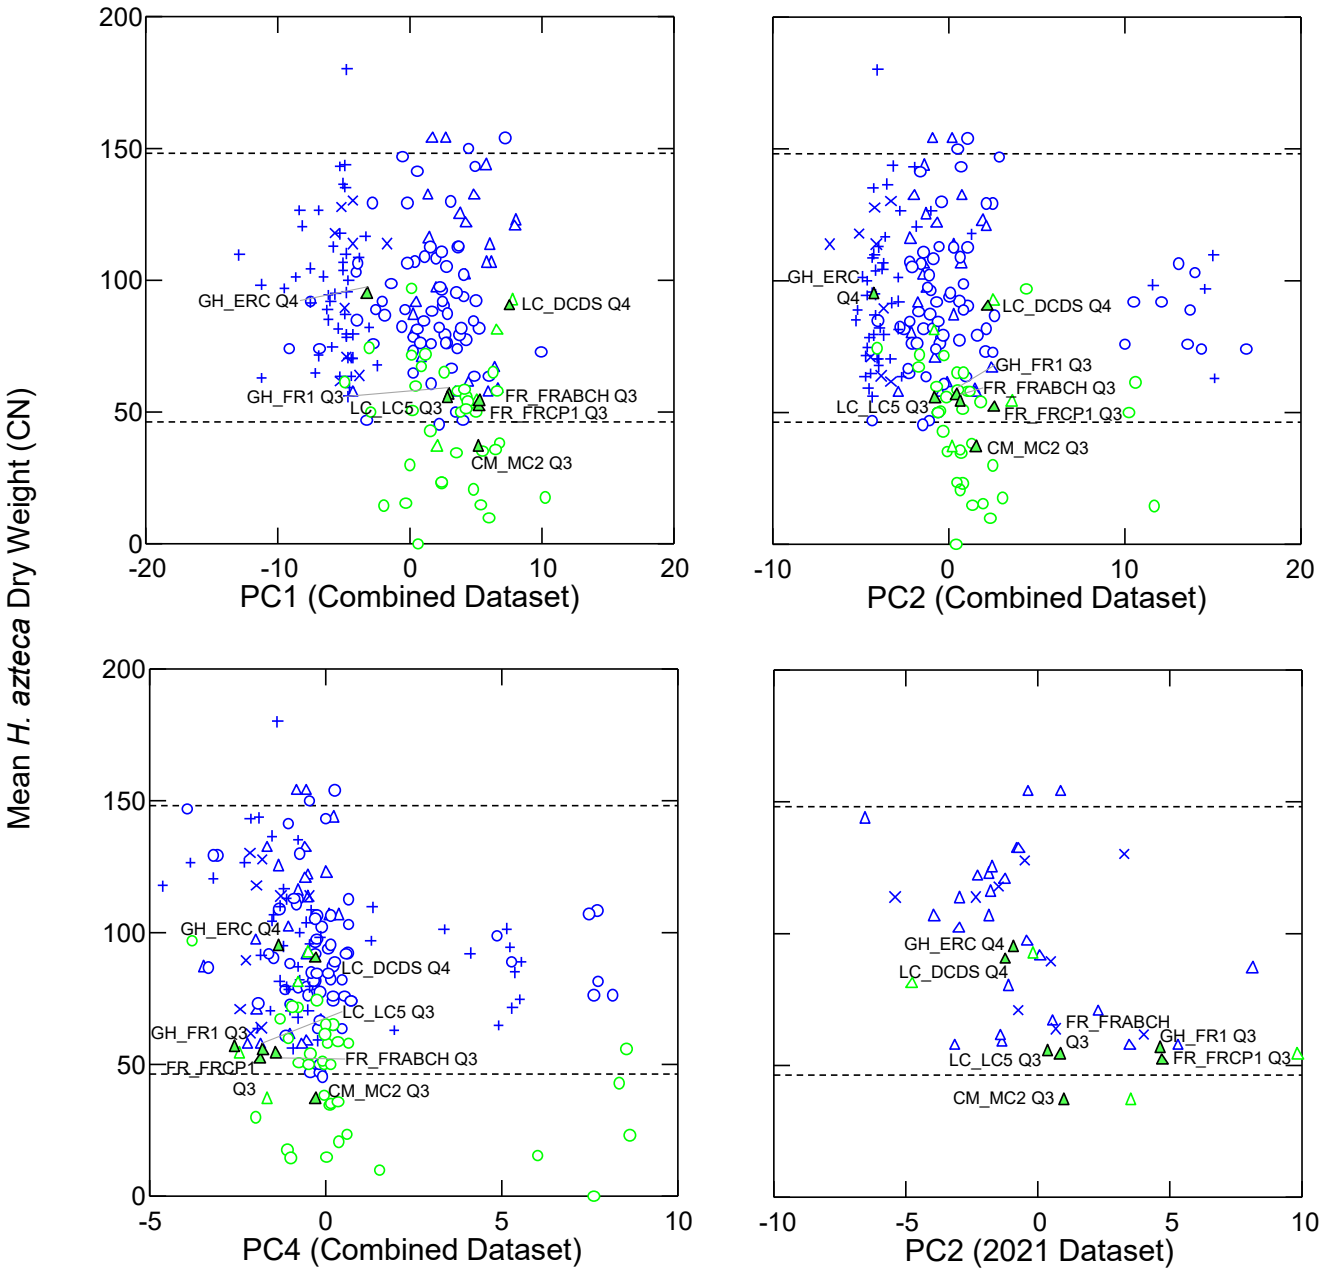
Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations; Δ = UFR stations). Test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Asterisks indicate tests that were excluded from statistical analysis (i.e., Q4 2020). Horizontal lines are the regional normal range (see Figure 2.3-3 for description). CN = control normalized; mg/L = milligrams per litre; = Upper Fording River.

Figure 3.4-12: Mean *H. azteca* dry weight versus sum of toxic units calculated using WQGs only (left) and WQGs and EVWQP benchmarks (right).



Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations; Δ = UFR stations). Test waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Horizontal lines are the regional normal range (see Figure 2.3-3 for description). Asterisks indicate tests that were excluded from statistical analysis (i.e., Q4 2020). CN = control normalized; EVWQP = Elk Valley Water Quality Plan; UFR = Upper Fording River; WQG = water quality guideline; Σ = sum.

Figure 3.4-13: Mean *H. azteca* dry weight versus PC1 (top left), PC2 (top right), and PC4 (bottom left) for the combined dataset and PC2 for the 2021 dataset (bottom right).



Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 stations; Δ = 2021 UFR stations). Test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Horizontal lines are regional normal range (see Figure 2.3-3 for description). CN = control normalized; PC = principal component; UFR = Upper Fording River.

Identification of Potential Contributors to Toxicity (H. azteca)

In tests categorized as having a possible or likely adverse response, concentrations of most constituents were equal to or lower than concentrations in reference waters and/or test site waters categorized as no adverse response (Table D-3), and/or were lower than the chronic WQG (Appendix C). Such constituents are not expected to contribute to toxicity in these tests. For the remaining constituents, published toxicity data were reviewed to evaluate the potential for these constituents to contribute to observed effects. These constituents are discussed below.

- **FR_FRCP1 (Q3)**—Nickel showed the strongest evidence of causing the observed effect on dry weight in this test. The nickel concentration in this test (7.9 µg/L) exceeded the dry weight EC_{10} in Michel Creek water (6.8 µg/L; Nautilus 2020c). Although the TIE results demonstrated worsened effects to production in the EDTA treated sample compared to the untreated sample, this appears to be related to EDTA-specific effects, which were also observed in the negative laboratory control. The nickel screening results align with the graphical analysis of nickel, which demonstrated a concentration-response relationship for *H. azteca* dry weight (Figure 3.4-10).

- **FR_FRABCH (Q3)**—No water quality constituent was identified as the potential cause of the observed response in this test. On one occasion, the concentration of fluoride in a weekly refresh sample (0.42 mg/L) exceeded the concentration observed in tests previously categorized as no adverse response; however, this concentration was approximately four times below the chronic effects benchmark for the protection of aquatic life (1.94 mg/L; MacPherson et al 2014), indicating that fluoride did not contribute to the observed response. The average nitrate concentration in this test (22 mg/L as N at hardness 582 mg/L as $CaCO_3$) was above the lowest level 1 EVWQP benchmark but was below the 14-day EC_{10} of 36 mg/L as N for *H. azteca* dry weight in Elk Valley water (Teck 2014; hardness 500 mg/L as $CaCO_3$)[32], indicating that nitrate did not contribute to the observed response[33]. As discussed in Section 3.3.1.2, the narrative category for this test (possible adverse response) has elevated uncertainty due to high inter-reference variability in Q3. This interpretation is supported by the observation that: (1) dry weight in this test was statistically similar to three of four references tested in Q3, including the local reference for FR_FRABCH (Fording River); and (2) no water quality constituent was identified as a potential cause of the observed response.

- **LC_DCDS (Q4)**—Nitrate and nickel showed the strongest evidence of causing the observed effect on dry weight in this test. The nitrate concentration in this test (49 mg/L as N at hardness 582 mg/L as $CaCO_3$) was above the 14-day EC_{10} of 36 mg/L as N for *H. azteca* dry weight in Elk Valley water (Teck 2014; hardness 500 mg/L as $CaCO_3$)[32], indicating that nitrate may have contributed to the observed response. The nickel concentration in this test (13 µg/L) was above the dry weight EC_{20} in Michel Creek water (9.4 µg/L; Nautilus 2020c), indicating that nickel may have contributed to the observed response. The nickel screening results align with the graphical analysis of nickel, which demonstrated a concentration-response relationship for *H. azteca* dry weight (Figure 3.4-10). The ∑TUs (calculated with WQGs) for this test was higher than test sites categorized as no adverse response. The ∑TUs for this test was largely driven by nitrate, which accounted for 71% of the ∑TU, and nickel, which accounted for 10% of the ∑TUs, both of which were identified as potential contributors to the observed response through the water quality screening.

[32] EC_{10} is the geometric mean of two Elk River tests and two Fording River tests normalized to test hardness or the highest hardness that the equation applies (500 mg/L as $CaCO_3$).

[33] There is some uncertainty in this comparison because the EC_{10} is based on a 14-day test, whereas tests conducted for this study consisted of 28 days. The uncertainty is offset by the magnitude of the difference between the test concentration and the EC_{10}, i.e., the EC_{10} is almost two times greater than the FR_FRABCH Q3 test concentration.

- **CM_MC2 (Q2)** — Nickel may have contributed to the observed effect on survival in this test. The nickel concentration in this test (14 µg/L) was above the level 1 interim screening value. Although the concentration in this test was below the LC_{10} in Michel Creek water (17.5 µg/L; Nautilus 2020c), the results of the graphical analysis which demonstrated a concentration-response relationship for *H. azteca* survival (Figure 3.4-9) and the TIE results showed decreased effects to survival upon addition of EDTA, supporting nickel as a potential causal factor in this test.
- **CM_MC2 (Q3)** — Nickel showed the strongest evidence of causing the observed effects on dry weight and survival in this test. The nickel concentration in this test (22 µg/L) was above the dry weight EC_{50} (15.1 µg/L) and comparable to the LC_{20} (21 µg/L) in Michel Creek water; Nautilus 2020c), indicating that nickel may have contributed to the observed response. This interpretation aligns with the 2021 *H. azteca* TIE testing conducted with Q3 CM_MC2 water, which showed decreased effects on survival upon addition of EDTA. Although the TIE results in Q3 demonstrated worsened effects to dry weight upon addition of EDTA, this may be related to an EDTA-specific effect on growth, which was also observed in the laboratory control. This uncertainty is offset by the results of the graphical analysis which demonstrated a concentration-response relationship for both *H. azteca* dry weight and survival (Figure 3.4-10). Other constituents exhibited weak to no evidence of potential for toxicity at this station in Q3 2021. The concentration of sodium in this test was higher than tests categorized as no adverse response. In absence of a WQG or screening value, sodium was assessed via TDS. The concentration of TDS in this test (779 mg/L) was below the highest concentrations tested in two Elk River tests (1,431 mg/L and 1,455 mg/L) and two Fording River tests (1,788 mg/L and 1,829 mg/L) that resulted in no significant adverse effects on *H. azteca* dry weight or survival (Teck 2014)[34]. This result indicates that TDS did not contribute to the observed response.
- **GH_FR1 (Q3) and LC_LC5 (Q3) —** No water quality constituent was identified as the potential cause of the observed response in this test. Concentrations of all constituents in this test were lower than concentrations in reference waters and/or test site waters categorized as no adverse response and/or were lower than the chronic WQG. As discussed in Section 3.3.1.2, the narrative categories for these tests have elevated uncertainty due to high inter-reference variability in Q3. This interpretation is supported by the observation that: (1) dry weight in this test was statistically similar to three of four references tested in Q3; and (2) no water quality constituent was identified as a potential cause of the observed response.
- **GH_ERC (Q4) —** No water quality constituent was identified as the potential cause of the observed response in this test. Concentrations of all constituents in this test were lower than concentrations in reference waters and/or test site waters categorized as no adverse response and/or were lower than the chronic WQG.

[34] There is some uncertainty in this comparison because the Teck (2014) toxicity tests were conducted over 14 days, whereas tests conducted for this study were conducted over 28 days. The uncertainty is offset by the magnitude of difference between the test concentration and the Teck (2014) test concentrations: the highest tested concentrations across the two Elk River and two Fording River tests were 1.8 to 2.3 times greater than the CM_MC2 Q3 test concentration.

3.4.4 *Oncorhynchus mykiss* Survival

As discussed in Section 3.3.1.4, survival in the Q4 FR_FRCP1 test was the only test categorized as a possible adverse response. However, survival in this test (83%) was within the local NR for the Fording River reference (79%–114%) and the regional NR (80%–113%). This test was carried forward to the causation assessment and results are provided below.

Water Quality Screening (O. mykiss)

In the Q4 FR_FRCP1 test, concentrations of nitrate and selenium exceeded the lowest level 1 EVWQP benchmarks, the concentration of nickel exceeded the level 1 interim screening value[35], and the concentration of fluoride exceeded the chronic WQG. Concentrations of nitrite exceeded the chronic WQG for two test collection dates; however, the average concentration was below the guideline. Concentrations of field measured dissolved oxygen were below the chronic WQGs during one sample collection. However, dissolved oxygen concentrations were maintained within protocol limits during the test duration (Appendix B) and therefore are not considered to be a causal factor in the observed response.

Spearman Rank Correlation (O. mykiss)

Constituents and explanatory variables with statistically significant Spearman rank correlations for *O. mykiss* survival for the combined and 2021 datasets are summarized in Table 3.4-4. Strong negative statistical correlations ($r_s \leq -0.4$) were identified for calcium and conductivity in the combined dataset, and for total ammonia and total Kjeldahl nitrogen in the 2021 dataset. Total ammonia and total Kjeldahl nitrogen were also the only constituents with statistically significant Spearman rank correlations for survival in the 2021 dataset.

The PC score that had a statistically significant Spearman rank correlation for survival is described below:

- PC1 (combined dataset): This component accounted for 30.3% of the variance (Table E-3). PC1 had strong positive loadings for TDS, components of TDS (e.g., calcium, magnesium), three Order constituents (nitrate, selenium, sulphate), and metals (lithium, uranium).

When compared, the factor loading scores from the combined dataset and the 2021 dataset showed the similar patterns. The component loadings for PC1, which appeared to be a strong signal of mine influence (i.e., strong loadings for TDS and Order constituents; Table E-3).

[35] Per Section 2.3.4, nickel was compared to the interim level 1 screening value (5.3 µg/L) , which is based on potential effects to invertebrates.

Table 3.4-4: Constituents and Explanatory Variables with Significant Spearman Rank Correlations for *Oncorhynchus mykiss* Survival.

Constituent[(a)]	R_s Combined Dataset	R_s 2021 Dataset	Comparison to WQGs/EVWQP Benchmarks	Retained for Graphical Analysis?

Nitrate	-0.345	ns	Yes	Yes
Nitrite	-0.382	ns	No	No
Total Ammonia	ns	-0.515	No	No
Total Potassium	-0.294	ns	No WQG	No - assessed as TDS
Total Selenium	-0.358	ns	Yes	Yes
Sulphate	-0.385	ns	No	No
Total Titanium	-0.324	ns	No	No
Total Dissolved Solids	-0.391	ns	No WQG	Yes
Total Kjeldahl Nitrogen	ns	-0.540	No WQG	Yes
Total Uranium	-0.331	ns	No	No
PC1 Combined	-0.324	ns	No WQG	Yes

Notes: Values shown here were statistically significant at $\alpha < 0.005$ where $r_s = -0.202$ for the combined dataset; $r = -0.272$ and $r_s = -0.413$ for the 2021 dataset. WQGs = British Columbia water quality guidelines; EVWQP = Elk Valley Water Quality Plan; MIT: ns = not significant; ∑TU = sum of toxicity units; TDS = total dissolved solids. Shaded values indicate a strong Spearman rank correlation at $r_s \leq -0.4$.

(a) Total concentrations are shown for metals that have a WQG for the total fraction or that lack a chronic WQG. Dissolved concentrations were used for metals with a WQG for the dissolved fraction.

(b) Out of 38 *O. mykiss* tests in 2021, bromide was only detected once and was not detected in any test with possible or likely adverse effects.

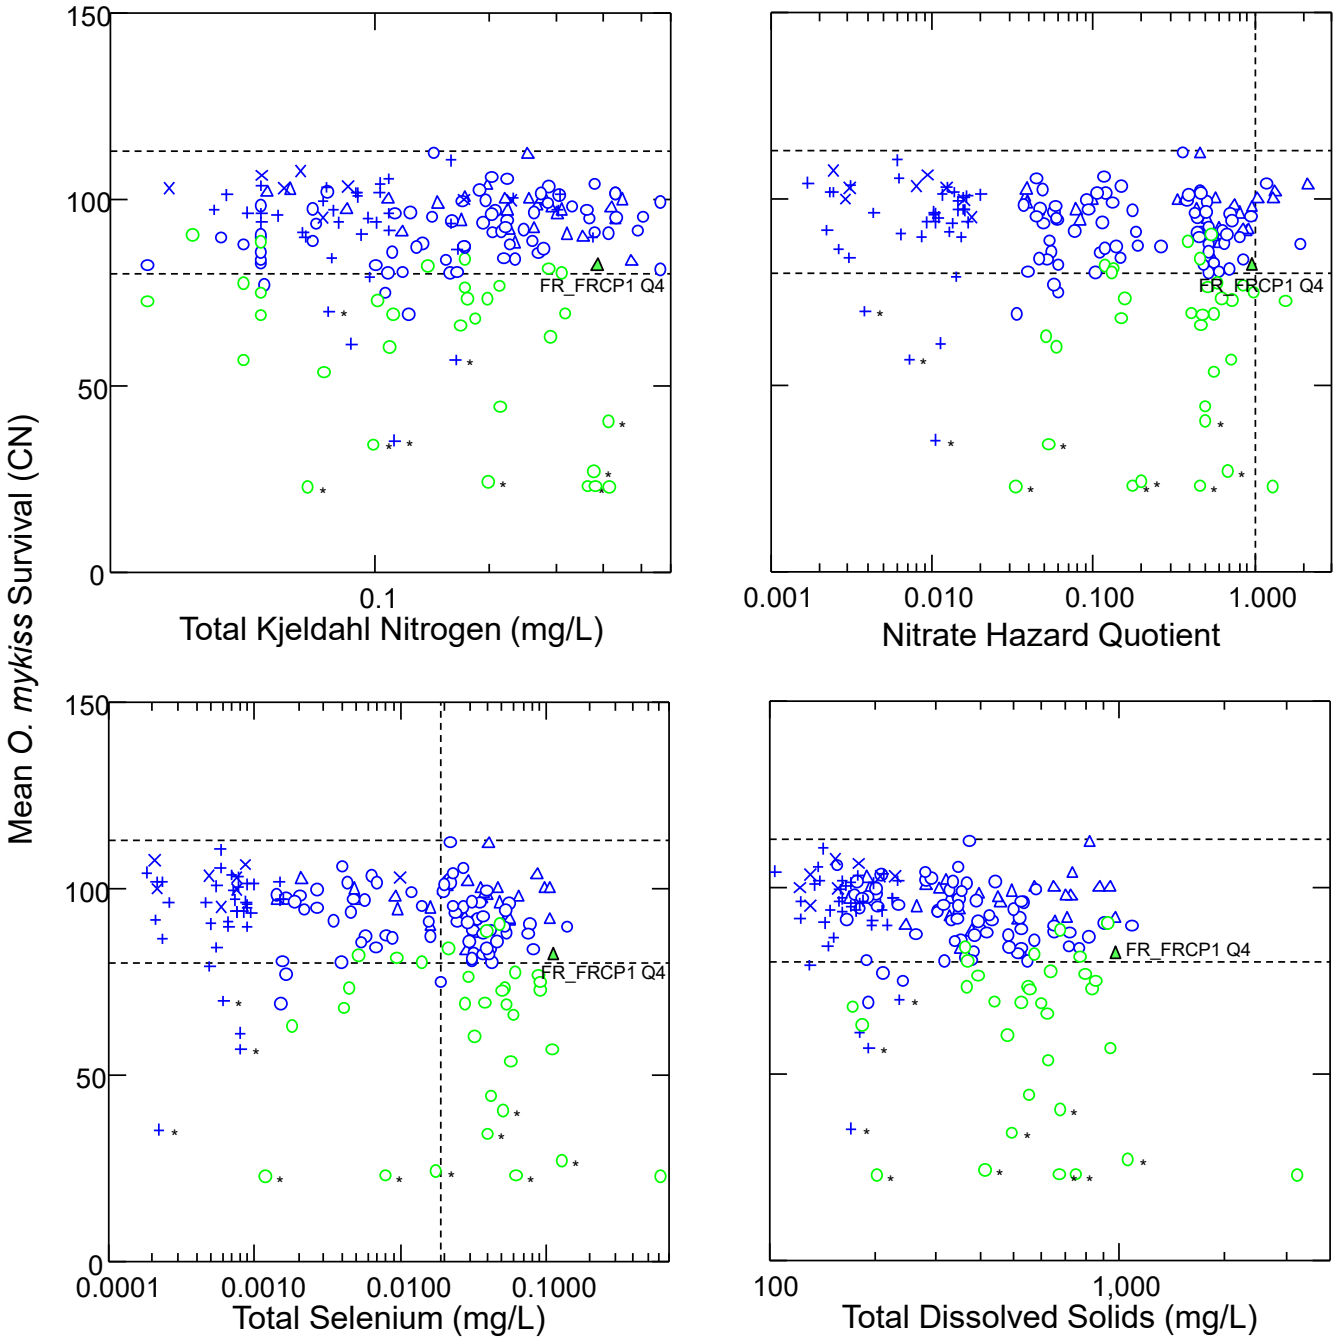
Graphical Analysis (O. mykiss)

Constituents and explanatory variables with significant Spearman rank correlations, and that were either above WQGs or did not have WQGs, were carried through to graphical analysis (Figures 3.4-14; Figure 3.4-15). Graphical analysis was conducted for two Order constituents (nitrate, selenium), TDS, total Kjeldahl nitrogen, and PC1 (combined dataset). Although bromide exhibited significant negative correlations, it was not included in graphical analysis because of low detection frequency[36].

None of the evaluated explanatory variables exhibited a consistent exposure-response relationship across *O. mykiss* tests. Because no strong or consistent relationships were observed for concentrations versus responses, the water quality screening (next subsection) was relied upon for identification of potential causes of observed effects.

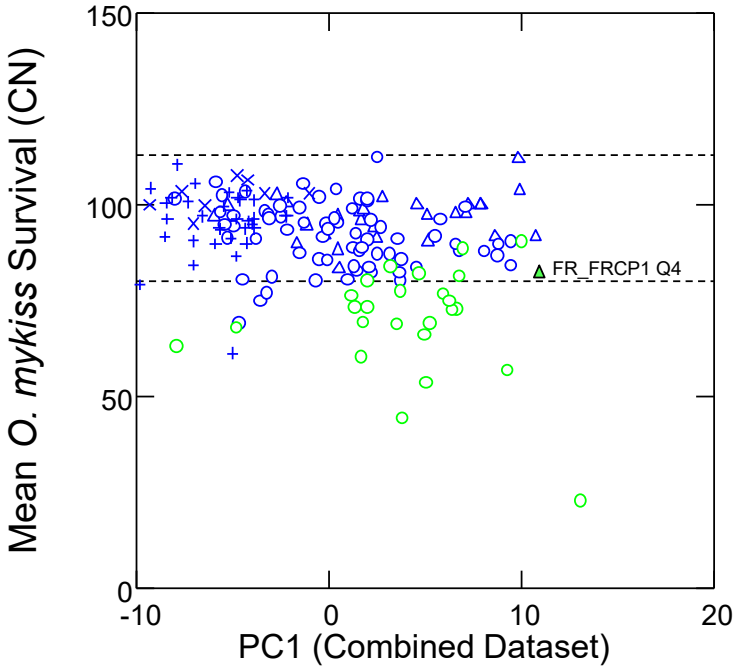
[36] Out of 38 *O. mykiss* tests in 2021, bromide was only detected once and was not detected in any test with possible or likely adverse effects.

Figure 3.4-14: Mean *O. mykiss* survival versus total Kjeldahl nitrogen (top left), nitrate hazard quotient (top right), total selenium (bottom left), and total dissolved solids (bottom right).



Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 UFR stations; Δ = 2021 non-UFR stations). UFR test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Nitrate hazard quotients are the ratio of nitrate concentrations to the lowest level 1 benchmark for fish. Vertical lines are screening values: for the nitrate hazard quotient, the screening value is 1; and, for selenium, the screening value is the level 1 benchmark for fish (19 µg/L). Horizontal lines are regional normal range (see Figure 2.3-3 for description). Asterisks indicate tests that were excluded from statistical analysis (i.e., Q4 2017 tests that had no copper amendments and evidence of microbes). CN = control normalized; EVWQP = Elk Valley Water Quality Plan; mg/L = milligrams per litre; UFR = Upper Fording River, WQG = water quality guideline.

Figure 3.4-15: Mean *O. mykiss* survival versus PC1 for the combined dataset.



Notes: Symbols indicate reference waters (× = 2015 to 2020; + = 2021), test site waters with mean results categorized as no adverse response (○ = 2015 to 2020; Δ = 2021), and test site waters with mean results categorized as possible or likely adverse response (○ = 2015 to 2020; ▲ = 2021 UFR stations; Δ = 2021 non-UFR stations). UFR test site waters categorized as possible or likely in 2021 (▲) are labelled with the test site and quarter. Horizontal lines are regional normal range (see Figure 2.3-3 for description). CN = control normalized; PC = principal component; UFR = Upper Fording River.

Identification of Potential Contributors to Toxicity (O. mykiss)

In the Q4 FR_FRCP1 test, of the chemical and biological stressors evaluated, the strongest evidence for causation was identified for nitrate and microbes. The average nitrate concentration in this test (22 mg/L as N) was approximately equal to the 30-d survival/viability EC_{10} of 20 mg/L as N, at hardness >448 mg/L as $CaCO_3$ (Golder 2021b), indicating that nitrate may have contributed to the observed response in this test. Early life stages of fish are much more sensitive to nitrate compared to other life stages (CCME 2012), so the identification of nitrate in this Q4 test would not be expected to be translate to older life stages of WCT that are present under winter low-flow conditions. As discussed in Section 3.3.1.3, microbes were observed in two of four test replicates. One of the two replicates with microbes had the lowest survival, whereas the response in the other replicate with was equal to the minimum response in replicates with no observed microbes. This suggests that, at a minimum, the replicates with observed microbes may have depressed the average response in this test.

Other constituents exhibited weak to no evidence of potential for toxicity to *O. mykiss* in 2021. Concentrations of most constituents were equal to or lower than concentrations in reference waters and/or test site waters categorized as no adverse response (Table D-5), and/or were lower than chronic WQGs (Appendix C). Such constituents are not expected to contribute to toxicity in these tests. The average nickel concentration in this test (12 µg/L) was above the level 1 interim screening value for invertebrates[37] but was an order of magnitude lower than the lowest effect concentration for *O. mykiss* estimated by European Union (EU 2008) of 105 µg/L for

[37] Per Section 2.3.4, nickel was compared to the interim level 1 screening value (5.3 µg/L), which is based on potential effects to invertebrates.

pH of 8.1, DOC of 1 mg/L, and hardness of 6 mg/L (i.e., conditions that would result in similar toxicity [pH and DOC] or much higher toxicity [hardness] relative to FR_FRCP1 conditions), indicating that nickel did not contribute to the observed response. The concentration of nitrite in this test was above the chronic WQG for two test collection dates; however, the average nitrite concentration in this test (0.035 mg/L as N; test chloride of 2.1 mg/L) was below the chronic WQG and was approximately seven times lower than the 30-d *O. mykiss* survival NOEC of 0.27 mg/L (Kroupová et al. 2006; Golder 2020a[38]), indicating that nitrite did not contribute to the observed response.

3.4.5 *Pimephales promelas* Survival

One test conducted in 2021 (Q1 FR_FRCP1) was carried forward to the causation assessment, for which results are provided below. As discussed in Section 3.3.1.3, the Q1 Elk and Michel references were excluded from normal range and effect size calculations, thereby increasing the likelihood of categorizing this test as a likely adverse response. Survival in this test was higher than both the excluded references. Results are provided below for the *P. promelas* causation assessment.

Water Quality Screening (P. promelas)

In the Q1 FR_FRCP1 test, concentrations of nitrate and selenium exceeded the lowest level 1 EVWQP benchmarks, the concentration of nickel exceeded the level 1 interim screening value[39], and the concentration of fluoride exceeded the chronic WQG.

Spearman Rank Correlation (P. promelas)

Constituents and explanatory variables with a statistically significant Spearman rank correlation for *P. promelas* survival were reviewed for the combined and 2021 datasets.

No strong correlations (i.e., r_s >-0.4) or significant Spearman rank correlations with survival were observed for any constituents in the combined or 2021 datasets (Table F-4).

No significant correlations were observed for the PCs. When compared, PC1 in the combined dataset showed strong positive loadings for several metals (e.g., beryllium, bismuth, silver) whereas PC1 in the 2021 dataset showed strong positive loadings for TDS, components of TDS (e.g., calcium), Order constituents (nitrate, selenium, sulphate), and a different suite of metals (e.g., cadmium, lithium, nickel) (Table E-4).

Graphical Analysis (P. promelas)

No constituents and explanatory variables had significant Spearman rank correlations and therefore no constituents were carried through to graphical analysis.

Identification of Potential Contributors to Toxicity (P. promelas)

In the Q1 FR_FRCP1 test, no water quality constituent was identified as a potential cause of the observed response in this test. As discussed in Section 3.3.1.4, the narrative category for this test has elevated uncertainty due to high inter-reference variability in Q1. This interpretation is supported by the observation that: (1) responses in two reference waters were depressed to a similar magnitude as observed in this test; and (2) no water quality constituent was identified as a potential cause of the observed response (as follows). The concentration of potassium in this test was higher than reference waters and tests categorized as no adverse response. In the absence of a WQG or screening value, potassium was assessed via TDS of which potassium is a component.

[38] Normalized for chloride using the slope derived by Golder (2020)

[39] Per Section 2.3.4, nickel was compared to the interim level 1 screening value (5.3 µg/L), which is based on potential effects to invertebrates.

The concentration of TDS in this test (1,008 mg/L) was lower than the survival NOEC value for TDS in Fording River water (2,000 mg/L; Golder 2013), indicating that TDS did not contribute to the observed response. The average nitrate concentration in this test (25 mg/L as N; hardness 783 mg/L as $CaCO_3$) was above the lowest level 1 EVWQP benchmark but approximately two times lower than the 30-d *P. promelas* survival NOEC of 58 mg/L (Adelman et al. 2009; hardness of ~220 mg/L), indicating that nitrate did not contribute to the observe response. The average nickel concentration in this test (13 µg/L) was above the level 1 interim screening value but was less than the 32-day *P. promelas* survival EC_{10} of 151 µg/L (normalized to test conditions[31]; Birge et al. 1984), indicating that nickel did not contribute to the observe response. Therefore, there is negligible evidence that the response observed at FR_FRCP1 in Q1 was a result of mine-influenced water quality. Given the elevated uncertainty due to the anomalous responses observed in reference waters, leading to inter-reference variations, factors unrelated to water quality are likely responsible for the observed responses. Therefore, responses in these tests are not expected to be indicative of adverse effects to other life stages of WCT that are present in the UFR in Q1.

3.5 Comparison of 2021 Results to Previous Years

Mean results for 2015 through 2021 were plotted by species and are in Appendix G. Effect categories for 2015 through 2021 were plotted by station and are presented in Sections 3.5.1 to 3.5.12. Plots were visually examined to identify potential seasonal or inter-annual changes in responses and the following sections discuss 2021 test results compared to previous years (i.e., 2015 to 2020) for each test site.

3.5.1 FR_FRCP1

Results for FR_FRCP1 (Fording River downstream of Cataract Creek) in 2015–2021 are summarized in Figure 3.5-1. An overview of the results is provided below:

- ***C. dubia***—All tests except one (Q1 2019) were categorized as no adverse response for survival (Figure G-1). Mean reproduction has consistently been the most sensitive endpoint for this test. FR_FRCP1 has exhibited the greatest frequency of adverse responses to reproduction of any test site, with mean reproduction below the local and regional NRs over much of the period of monitoring (Figure G-2). In 2021, reproduction was generally below the local and regional NRs, although the magnitude of response was not as large as in 2017 to 2019. Constituents that have been identified as potentially contributing to observed responses over time are nickel (10 tests, including Q1, Q3, and Q4 2021), nitrate (eight tests), and sulphate/TDS (seven tests).
- ***P. subcapitata***— FR_FRCP1 has exhibited the greatest frequency of adverse responses to cell yield of any test site. The responses to green algae cell yield have been variable over the period of record, with large differences observed among consecutive quarters and among years. Although approximately 40% of tests were categorized as possible or likely adverse response, mean cell yield was within the local and regional NRs in most quarterly tests (Figure G-3). Cell yield fell outside the local and regional NRs in Q4 2018, Q1 and Q3 in 2019, Q1 2020 and Q1 2021. In Q3 2019, most tests including reference tests exhibited adverse responses on cell yield and results for that batch of tests were considered anomalous (Golder 2020b). For all tests with depressed cell yield relative to reference except Q4 2018, the cause of adverse responses is unknown. In the Q4 2018 tests, sulphate and TDS were identified as potentially contributing to the observed response.
- ***H. azteca***—All but two tests (Q4 in 2018 and 2020) were categorized as no adverse response to survival (Figure G-4). As expected, the sublethal endpoint (growth in dry weight) was the most sensitive endpoint for this species. Adverse responses to dry weight were observed in approximately a third of all tests. Historically,

FR_FRCP1 has exhibited the greatest frequency of adverse responses to amphipod growth of any test site and the largest magnitude responses across the period of record. Mean dry weight was generally within the local and regional NRs, but the wide range of the NRs reflects the high variability in results across batches (Figure G-5). In 2021, responses were within the local and regional NRs. Constituents that have been identified as potentially contributing to observed responses over time are primarily nickel (two tests, including Q3 2021) and nitrate (four tests), although uranium and sulphate/TDS were also identified for Q4 2018.

- ***O. mykiss***—All Q2 tests were categorized as no adverse response. This finding has high ecological relevance to field conditions because the timing of early life stages of WCT in the UFR best aligns with the Q2 testing; therefore, the Q2 results are considered the most relevant for evaluating potential effects on early life stages of the congenic WCT (Section 1.2.3). In Q4 tests, mean length and weight were usually within the local and regional NRs (Figure G-8; Figure G-9). Most responses for these endpoints were categorized as no adverse response, except for Q4 2018 which was categorized as a likely adverse response. The trout growth endpoints have not typically been a sensitive indicator of responses for this species. Instead, mean survival and viability have historically been the most sensitive endpoints, typically resulting in similar temporal response trends (Figure G-6; Figure G-7). Within Q4 tests, there was a pattern towards more frequent and larger responses through 2018, but responses improved starting in 2019. This pattern continued in 2021, where all tests were within the local and regional NRs for both endpoints. The Q4 temporal trend analysis for survival and viability is complicated by the presence of microbes in all Q4 tests categorized as possible or likely. Nitrate and/or sulphate/TDS were identified as potentially contributing factors in four of the six Q4 tests with adverse responses.
- ***P. promelas***—There were no adverse responses on hatch or development in *P. promelas* tests (Figures G-10 and G-14) *P. promelas* endpoints were usually within local and regional NRs, but with exceptions occurring for one or more endpoints between Q3 2018 and Q1 2019 and for survival in Q1 2021 (Figures G-10 to G-14). As discussed in Section 3.4.4, the narrative category for the Q1 2021 test has elevated uncertainty due to high inter-reference variability in Q1. This interpretation is supported by the observations that: (1) responses in two reference waters were depressed to a similar magnitude as observed in this test; and (2) no water quality constituent was identified as a potential cause of the observed response. Sulphate/TDS were identified as potentially contributing to observed adverse responses in Q4 2018 and Q1 2019, and microbes were identified in Q3 2018 and 2019.

Overall, FR_FRCP1 has shown relatively consistent patterns of response over time, with toxicity indicated in several test endpoints, particularly under base flow conditions. The response to several endpoints were greatest in Q4 2018, associated with elevated concentrations of several mine-related constituents including sulphate, TDS, nitrate, and nickel. A broad trend towards more frequent and larger responses for *C. dubia* was observed until Q2 of 2019. However, that trend did not continue into or beyond 2020; magnitudes of response in *C. dubia* in 2020 and 2021 tests were similar to those observed at the beginning of the monitoring program (2015 and 2016), indicating environmental improvement in recent years. Several constituents have been identified as potential causes of toxicity in previous testing, including nitrate, TDS and/or sulphate, and nickel. Concentrations of TDS appear to have peaked in Q4 2018 and Q1 2019, when concentrations were ~3,300 mg/L, but have decreased in 2020 and continued to show reduced concentrations in 2021 (~320 to ~1,000 mg/L). The peak in TDS concentrations corresponded with higher frequencies of responses and higher magnitudes of response in several test species.

As discussed in Section 2.2.2.1, water quality under winter low flow conditions at FR_FRCP1 may not be representative of conditions in the Fording River, such that this station does provide a reliable indicator of broader aquatic health responses to evaluate cumulative discharges from Fording River Operations in the receiving environment (Teck 2019). During low flow conditions, water quality at FR_FRCP1 historically has been predominantly discharge from upstream mine-impacted Cataract Creek. Commissioning of the Cataract Creek diversion in August 2019 improved water quality and associated test responses in subsequent quarters.

Figure 3.5-1: Summary of test results by category at FR_FRCP1.

Note: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. Ref Var = high inter-reference variability; HI-RV = high inter-replicate variability; Ni = nickel; NO_3 = nitrate; SO4 = sulphate; TDS = total dissolved solids; U = uranium; UN = unknown: no water quality constituent was identified. Toxicity Identification Evaluations were conducted to support the causation assessment for *C. dubia* tests in 2018 (Q4), 2019 (Q1 to Q4), 2020 (Q1 to Q4) and 2021 (Q1 to Q4), *H. azteca* tests in 2019 (Q1, Q3, and Q4), 2020 (Q1 to Q4) and 2021 (Q1 to Q4).

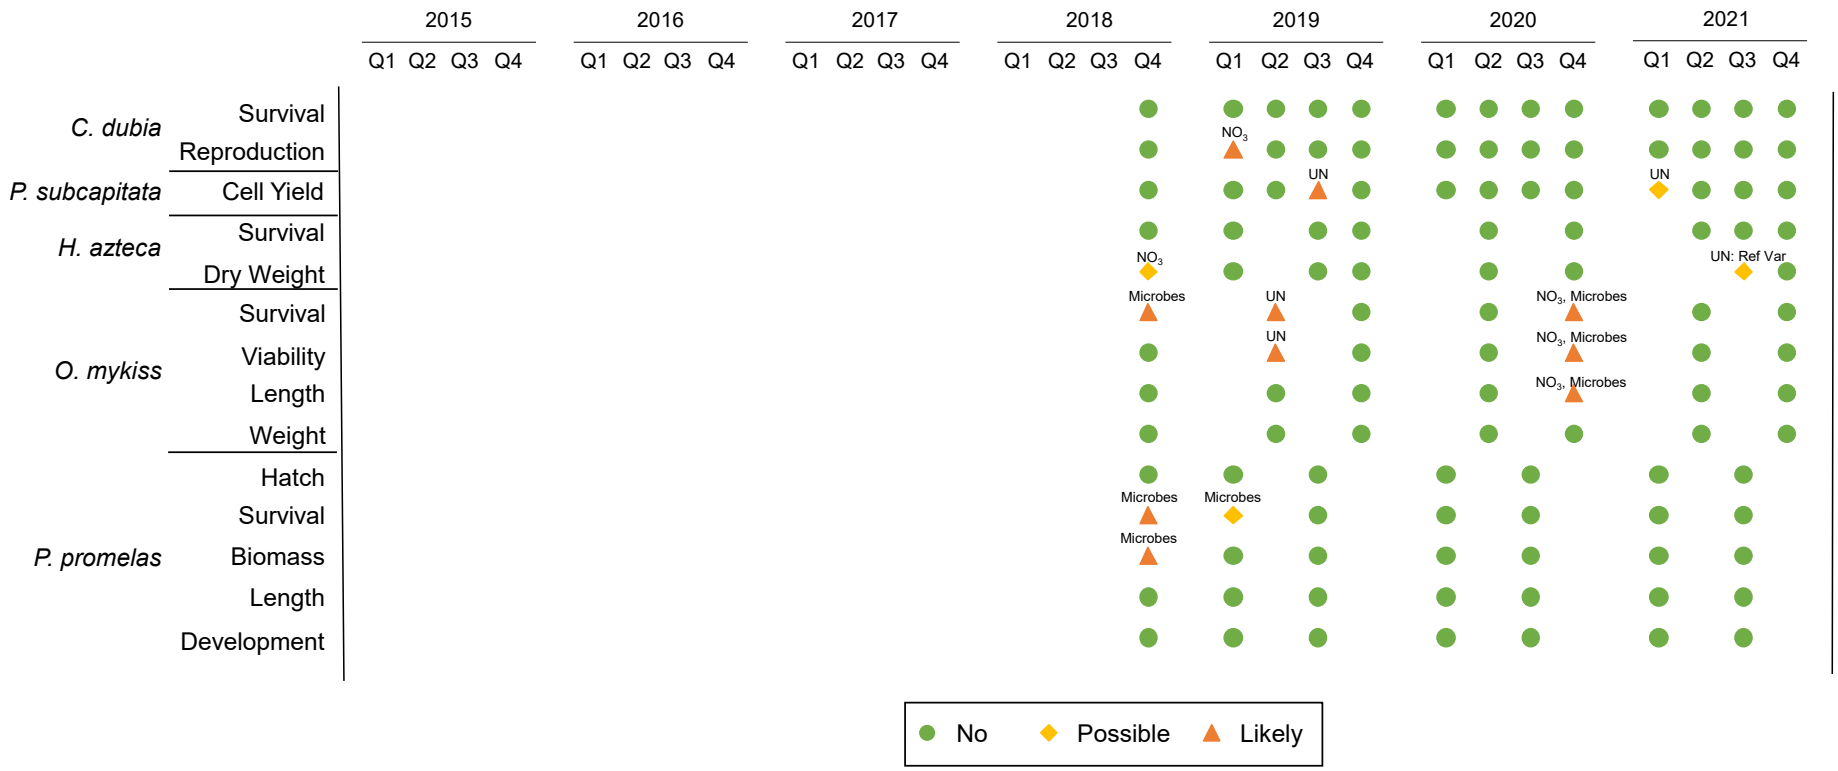
3.5.2 FR_FRABCH

FR_FRABCH is approximately 5 km downstream of FR_FRCP1 and is intended to represent mixed Fording River water quality, capture more completely constituent loadings from upstream mining, and reduce the confounding influence of mid-winter Cataract Creek flows at FR_FRCP1 (see Section 2.2.2). In 2021, the Fording River Operations compliance location was moved from FR_FRCP1 to FR_FRABCH. Results are summarized in Figure 3.5-2. An overview of the results is provided below:

- ***C. dubia***—No effects were observed on survival in any test (Figure G-1). All but one test (Q1 2019) was categorized as no adverse response for reproduction (Figure G-2). A potential contributor to the observed response in this test was nitrate.
- ***P. subcapitata***—All but two tests (Q3 2019, Q1 2021) were categorized as no adverse response. In Q3 2019, most tests, including reference tests, exhibited adverse responses on cell yield and results for that batch of tests were considered anomalous (Golder 2020b). In Q1 2021, many test sites had mean cell yield that was systematically depressed across test sites despite variability in water chemistries; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). No water quality constituent was identified as potentially contributing to observed responses in either test.
- ***H. azteca***— No effects were observed on survival in any test (Figure G-3). All but two tests (Q4 2018 and Q3 2021) were categorized as no adverse response for dry weight (Figure G-4). A potential contributor to the observed response in Q4 2018 was nitrate. No water quality constituent was identified as potentially contributing to the observed response in Q3 2021; however, as discussed in Section 3.4.2, high inter-reference variability increased the uncertainty associated with the assigned narrative category (possible adverse response) for the Q3 2021 test.
- ***O. mykiss***—All but three tests (Q4 2018, Q2 2019 and Q4 2020) were categorized as no adverse response (Figure G-6 to Figure G-9). Nitrate was identified as a possible contributor in Q4 2018, and microbes were identified as a possible contributor in Q4 2018 and 2020. As discussed in the Section 1.2.3, spring (Q2) results are considered the most relevant for evaluating potential effects on early life stages of the congenic WCT. All but one Q2 test (Q2 2019) were categorized as no adverse response. In Q2 2019, responses appeared factors unrelated to water quality because concentrations of all constituents were below chronic WQGs and EVWQP benchmarks and were below concentrations measured in tests categorized as no adverse response. Results that show poor correspondence with water quality (as in Q2 2019) are best distinguished from true toxicity responses through validation and trend assessment over time. In the case of Q2 FR_FRABCH tests, no adverse responses have been observed in subsequent tests, indicating no trend over time.
- ***P. promelas***—All but two tests (Q4 2018 and Q1 2019) were categorized as no adverse response (Figures G-10 to G-14). Responses observed in both tests were consistent with responses associated with microbial growth.

Overall, FR_FRABCH showed fewer and lower magnitude responses relative to FR_FRCP1. This downstream improvement in water quality was apparent in 2021, where only two endpoints were categorized as a possible adverse response compared to seven adverse responses identified at FR_FRCP1 across quarters.

Figure 3.5-2: Summary of test results by category at FR_FRABCH.



Notes: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. Ref Var = high inter-reference variability; NO_3 = nitrate; UN = unknown: no water quality constituent was identified.

3.5.3 GH_FR1

Results for GH_FR1 (Fording River downstream of Greenhills Creek) in 2015–2021 are summarized in Figure 3.5-3. An overview of the results is provided below:

- ***C. dubia***—No effects were observed on survival in any test (Figure G-1). All but four tests (Q2 2016 and 2018, Q3 2017, Q1 2020) were categorized as no adverse response for reproduction (Figure G-2). Nitrite was identified as a potential contributor in the Q2 2016 test. In other tests with adverse responses, responses appeared unrelated to water quality because concentrations of all constituents were below chronic WQGs and EVWQP benchmarks, and/or were below concentrations measured in tests categorized as no adverse response.
- ***P. subcapitata***—All but two tests (Q3 2019 and Q2 2021) were categorized as no adverse response. In Q3 2019, most tests including reference tests exhibited adverse responses on cell yield and results for that batch of tests were considered anomalous (Golder 2020b). No water quality constituent was identified as potentially contributing to observed responses in either test.
- ***H. azteca***——No effects were observed on survival in any test (Figure G-4). All but two tests (Q2 2016, Q3 2021) were categorized as no adverse response for dry weight (Figure G-4; Figure G-5). As discussed in Section 3.4.2, high inter-reference variability increased the uncertainty associated with the assigned narrative category (possible adverse response) for the Q3 2021 test. No water quality constituent was identified as potentially contributing to observed responses.
- ***O. mykiss***—All 2021 tests were categorized as no adverse response, representing an improvement compared with previous years in which 67% of tests were categorized as adverse response for at least one endpoint (Figures G-6 to G-9) Microbes were identified as a potential contributor in approximately half of the tests with adverse responses. As discussed in the Section 1.2.3, Q2 results are considered the most relevant for evaluating potential effects on early life stages of the congenic WCT. In all but two Q2 tests (Q2 2016 and 2019), tests were categorized as no adverse response. In both tests, responses appeared unrelated to water quality because concentrations of all constituents were below chronic WQGs and EVWQP benchmarks, and/or were below concentrations measured in tests categorized as no adverse response. Results that show poor correspondence with water quality (as in Q2 2016 and 2019) are best distinguished from true toxicity responses through validation and trend assessment over time. In the case of Q2 GH_FR1 tests, no adverse responses have been observed in adjacent years tests or since 2019, indicating a lack of Q2 trend over time.
- ***P. promelas***—All tests except one (Q2 2017) were categorized as no adverse response, and responses for all endpoints have generally been within local and regional NRs (Figure G-10 to Figure G-14). Responses observed in Q2 2017 were consistent with responses associated with microbial growth.

Overall, GH_FR1 has shown a lack of responses for all test species except *O. mykiss*, with no apparent consistent pattern of responses over time and no clear evidence of causal factors. For *O. mykiss*, approximately half of adverse responses were consistent with responses associated with microbes. In the other half of tests with adverse responses, no water quality constituent has been identified because concentrations of all constituents were below chronic WQGs and EVWQP benchmarks, and/or were below concentrations measured in tests categorized as no adverse response. In aggregate, there is a lack of correspondence between *O. mykiss* responses and water quality variables. Furthermore, the *O. mykiss* results do not align with GH_FR1 results for other test species, which have shown a lack of adverse responses over time.

Figure 3.5-3: Summary of test results by category at GH_FR1.

Notes: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. NO_3 = nitrate; Ref Var = high inter-reference variability; UN = unknown: no water quality constituent was identified.

3.5.4 LC_LC5

Results for LC_LC5 (Fording River downstream of Line Creek) in 2015–2021 are summarized in Figure 3.5-4. An overview of the results is provided below:

- ***C. dubia***—No effects were observed on survival in any test (Figure G-1). All but two tests (Q2 2018 and Q4 2018) were categorized as no adverse response for reproduction, and mean responses were generally within the local and regional NRs (Figure G-2). No water quality constituent was identified as potentially contributing to observed responses.
- ***P. subcapitata***—Mean cell yield was generally within the local and regional NRs except for Q3 2019 and Q2 2021 (Figure G-3). Prior to 2021, all but two tests (Q3 2019 and Q2 2015) were categorized as no adverse response. In 2021, three tests (Q1, Q2, and Q4) exhibited adverse responses. In Q3 2019, most tests including reference tests exhibited adverse responses on cell yield and results for that batch of tests were considered anomalous (Golder 2020b). In Q1 and Q4 2021, many test sites had mean cell yield that was systematically depressed across test sites despite variability in water chemistries; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). No water quality constituent was identified as potentially contributing to observed responses in these tests.
- ***H. azteca***—All but three tests (Q3 and Q4 2019 and Q3 2021) were categorized as no adverse response. (Figure G-4; Figure G-5). In tests with adverse responses, there was elevated uncertainty associated with the test result due to high inter-replicate variability (Q3 and Q4 2019) or high inter-reference variability (Q3 2021). No water quality constituent was identified as potentially contributing to observed responses.
- ***O. mykiss***—All tests except one (Q4 2019) were categorized as no adverse response (Figures G-6 to Figure G-9). No water quality constituent was identified as potentially contributing to the observed response.
- ***P. promelas***—There were no adverse responses observed for any endpoint, and mean responses were generally within the local and regional NRs (Figure G-9 to Figure G-13).

Overall, LC_LC5 has shown few adverse responses over time, with no apparent consistent pattern of responses and no clear evidence of causal factors. Over the period of record, no responses have been identified that can be plausibly linked to mine-influenced chemical parameters.

Figure 3.5-4: Summary of test results by category at LC_LC5.

Notes: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. RV = high inter-replicate variability; Ref Var = high inter-reference variability; UN = unknown: no water quality constituent was identified.

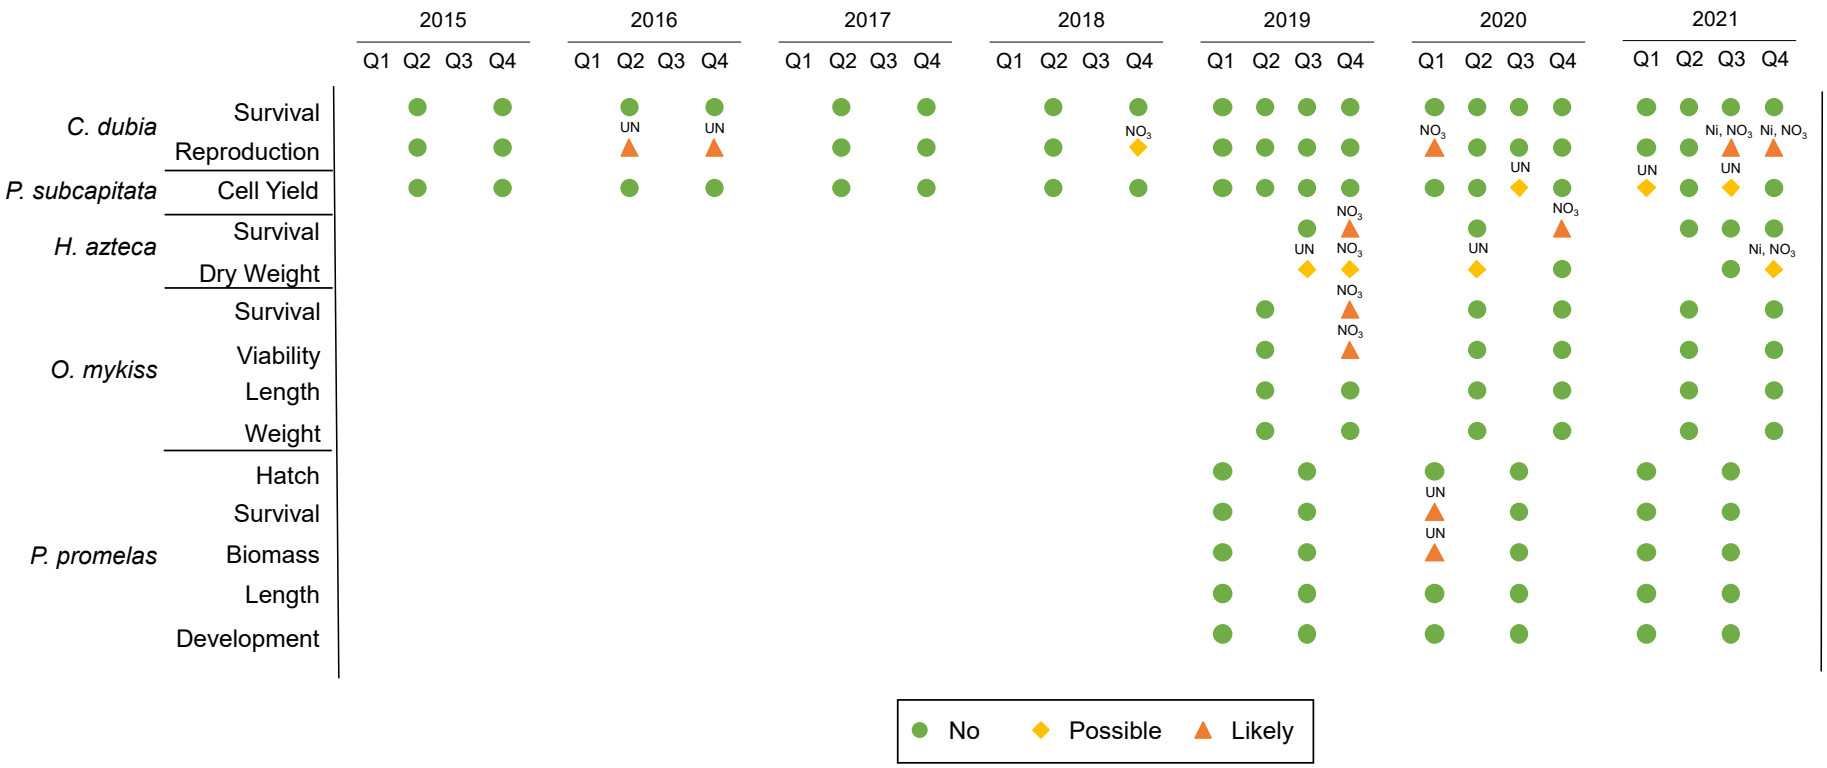
3.5.5 LC_DCDS

Station LC_DCDS (Dry Creek downstream of sedimentation ponds) was added to the regional chronic toxicity testing program after the 2019 integration of the Line Creek toxicity testing and regional toxicity testing permits. Results are summarized in Figure 3.5-5. An overview of the results is provided below:

- ***C. dubia***—No effects were observed on survival in any test (Figure G-1). Approximately 30% of tests were categorized as an adverse response for reproduction (Figure G-2). Nitrate was identified as potentially contributing to observed responses in the Q1 2018, Q1 2020, and Q3 and Q4 tests in 2021. Nickel was identified as a potential contributor to responses in Q3 and Q4 2021 tests. No water quality constituent was identified as potentially contributing to observed responses in the 2016 tests.
- ***P. subcapitata***—All but three tests (Q3 2020, and Q1 and Q3 2021) were categorized as no adverse response. In Q1 2021, many test sites had mean cell yield that was systematically depressed across test sites despite variability in water chemistries; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). No water quality constituent was identified as potentially contributing to observed responses in these tests.
- ***H. azteca***—Five tests (2019 tests, 2020 tests and Q4 2021) were categorized as a possible or likely adverse response, although most tests fell within the local and regional NRs (Figure G-5; Figure G-6). Nitrate was identified as potentially contributing to observed responses in Q4 2019, Q4 2020, and Q4 2021. Nickel was also identified as a potential contributor to responses observed in Q4 2021. No water quality constituent was identified as potentially contributing to observed responses in other tests.
- ***O. mykiss***—All tests except Q4 2019 were categorized as no adverse response (Figure G-6 to Figure G-9). Nitrate was identified as potentially contributing to the observed response in this test. As discussed in the Section 1.2.3, spring (Q2) results are considered the most relevant for evaluating potential effects on early life stages of the congenic WCT, and all Q2 tests were categorized as no adverse response.
- ***P. promelas***—All tests except Q1 2020 were categorized as no adverse response. No water quality constituent was identified as potentially contributing to the observed response; however, this test had high inter-replicate variability (Golder 2021a).

Overall, LC_DCDS has exhibited a low proportion of adverse responses with no apparent consistent pattern of responses over time. Nitrate was identified as a potential cause of observed responses in 8 of 16 tests with possible or likely adverse responses, half of which were *C. dubia* tests between Q4 2018 and 2021. This is likely due to the observed increase in nitrate in these years (12 to 47 mg/L as N for *C. dubia* tests) compared to concentrations in previous quarters and years (<9.0 mg/L as N for *C. dubia* tests). Nickel was also identified as a plausible cause of observed responses in Q3 and Q4 2021 tests; nickel concentrations in 2021 (0.003 to 0.015 mg/L for *C. dubia* tests) were increased compared to previous years (0.001 to 0.007 mg/L for *C. dubia* tests). The slightly increased frequency of adverse responses in LC_DCDS relative to several stations on the mainstem upper Fording River (FR_FRABCH, GH_FR1, and LC_LC5) may be attributable to differences in nitrate and nickel concentrations.

Figure 3.5-5: Summary of test results by category at LC_DCDS.



Notes: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. NO_3 = nitrate; Ni = nickel; UN = unknown: no water quality constituent was identified.

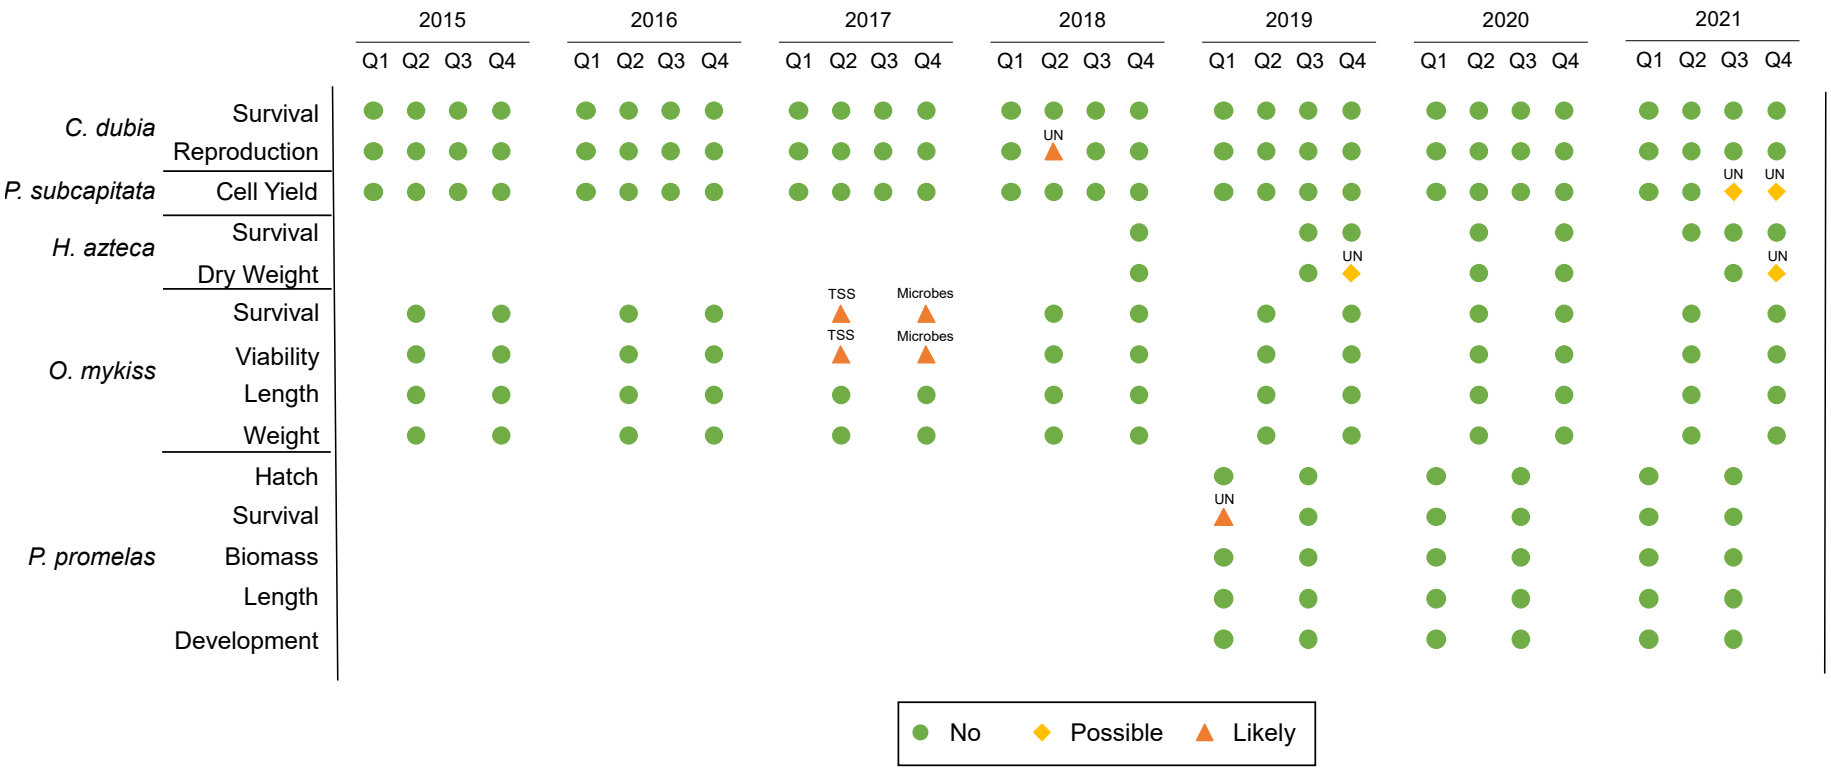
3.5.6 GH_ERC

Results for GH_ERC (Elk River upstream of Fording River confluence) in 2015–2021 are summarized in Figure 3.5-6. An overview of the results is provided below:

- ***C. dubia***— No effects were observed on survival in any test (Figure G-1). All tests except Q2 2018 were categorized as no adverse response on reproduction (Figures G-2). No water quality constituent was identified as potentially contributing to the observed response.
- ***P. subcapitata***—All but two tests (Q3 and Q4 2021) were categorized as no adverse response (Figure G-3). In Q4 2021, many test sites had mean cell yield that was systematically depressed across test sites despite variability in water chemistries; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). The observed responses in both quarters appeared unrelated to water quality because concentrations of all constituents were below chronic WQGs and EVWQP benchmarks, and/or were below concentrations measured in tests categorized as no adverse response.
- ***H.* azteca**— No effects were observed on survival in any test (Figure G-4). All but two tests (Q4 2019 and 2021) were categorized as no adverse response for dry weight (Figure G-5). Both tests with adverse responses were within the local and regional normal ranges. No water quality constituent was identified as potentially contributing to the observed responses.
- ***O. mykiss***—All but two tests (Q2 and Q4 2017) were categorized as no adverse response (Figure G-6 to G-9). TSS was identified as potentially contributing to observed responses in Q2 2017 and responses in Q4 2017 were consistent with responses associated with microbial growth (Golder 2018).
- ***P. promelas***—All tests except Q1 2019 were categorized as no adverse response (Figures G-10 to G-14). No water quality constituent was identified as potentially contributing to the observed response.

Overall, GH_ERC has shown few adverse responses, with no apparent consistent pattern of responses over time and no clear evidence of causal factors. The results for GH_ERC in recent years of monitoring are also consistent with findings from the closest upstream station on the mainstem Fording River (LC_LC5), with both stations exhibiting no adverse responses for all endpoints in 2020, and a few (three to four) adverse responses in 2021.

Figure 3.5-6: Summary of test results by category at GH_ERC.



Notes: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. TSS = total suspended solids; UN = unknown: no water quality constituent was identified.

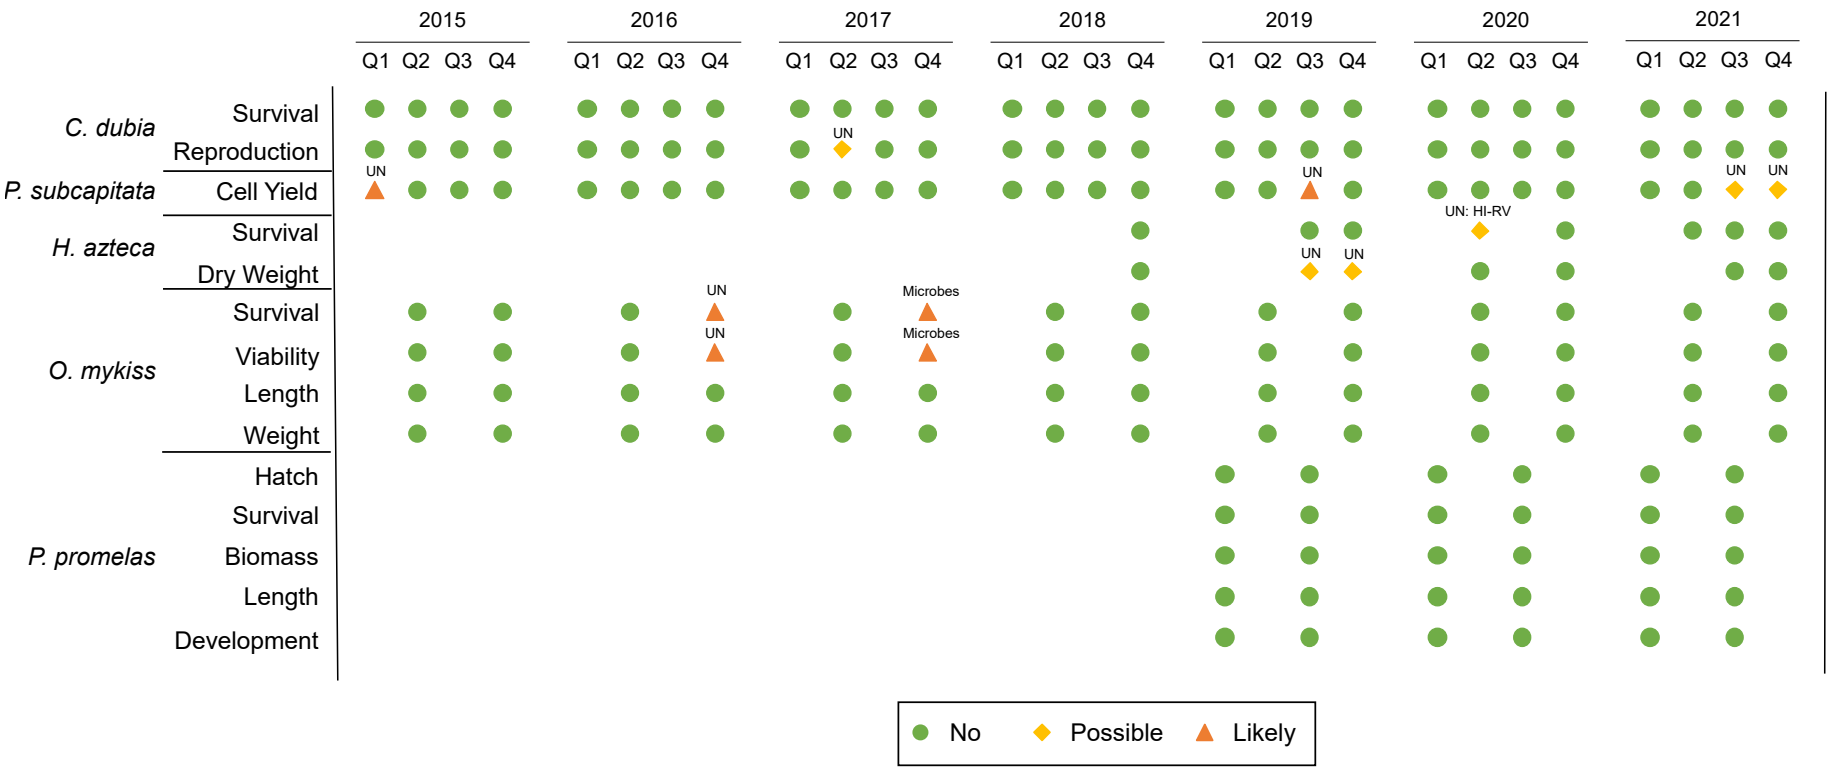
3.5.7 EV_HC1

Results for EV_HC1 (Harmer Creek) in 2015–2021 are summarized in Figure 3.5-7. An overview of the results is provided below:

- ***C. dubia***— No effects were observed on survival in any test (Figure G-1). All tests except Q2 2017 were categorized as no adverse response on reproduction (Figure G-1). Mean reproduction was within local and regional NRs except Q1 2018. No water quality constituent was identified as potentially contributing to observed response.
- ***P. subcapitata***—All but four tests (Q1 2015, Q3 2019 and Q3 and Q4 2021) were categorized as no adverse response (Figure G-3). In Q3 2019, most tests including reference tests exhibited adverse responses on cell yield and results for that batch of tests were considered anomalous (Golder 2020b). In Q4 2021, many test sites had mean cell yield that was systematically depressed across test sites despite variability in water chemistries; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). No water quality constituent was identified as potentially contributing to observed responses.
- ***H.* azteca**—All but three tests (Q3 2019, Q4 2019, and Q2 2020) were categorized as no adverse response (Figure G-3; Figure G-4). No water quality constituent was identified as potentially contributing to the observed response; however, high inter-replicate variability was observed in Q2 2020 and may have contributed to observed effects.
- ***O. mykiss***—All tests but two tests (Q4 2016 and 2017) were categorized as no adverse response (Figure G-6 to Figure G-9). As discussed in the Section 1.2.3, spring (Q2) results are considered the most relevant for evaluating potential effects on early life stages of the congenic WCT, and all Q2 tests were categorized as no adverse response. Responses observed in Q4 2017 were consistent with responses associated with microbial growth (Golder 2018). No water quality constituent was identified as potentially contributing to observed responses in the Q4 2016 test.
- ***P. promelas***—All tests were categorized as no adverse response and response were generally within the local and regional NRs (Figures G-10 to G-14).

Overall, EV_HC1 has shown few adverse responses over time, with no apparent consistent pattern of responses and no clear evidence of causal factors. Adverse responses on *O. mykiss* survival and viability have not been observed since Q4 2017. In 2021, all but two test results were categorized as no adverse response, with one adverse response (Q4) having high uncertainty. Over the period of record, no responses have been identified that can be plausibly linked to mine-influenced chemical parameters.

Figure 3.5-7: Summary of test results by category at EV_HC1.



Notes: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. RV = high inter-replicate variability; UN = unknown: no water quality constituent was identified.

3.5.8 CM_MC2

Results for CM_MC2 (Michel Creek downstream of Corbin Creek) in 2015–2021 are summarized in Figure 3.5-8. An overview of the results is provided below:

- ***C. dubia***— No effects were observed on survival in any test (Figure G-1). Mean reproduction was generally below the local and regional NRs and 66% of tests were categorized as a possible or likely response (Figure G-2). A lower frequency and magnitude of adverse responses was observed between 2019 and 2021 compared to 2017 and 2018, in which all quarters were categorized as likely adverse responses. Nickel was identified as potentially contributing to observed responses in tests conducted between 2017 and 2021. No water quality constituent was identified as potentially contributing to observed responses in 2015 and 2016 tests.
- ***P. subcapitata***—All but three tests (Q3 2019 and Q1 and Q4 2021) were categorized as no adverse response (Figure G-3). In Q3 2019, most tests including reference tests exhibited adverse responses on cell yield and results for that batch of tests were considered anomalous (Golder 2020b). In Q1 and Q4 2021, many test sites had mean cell yield that was systematically depressed across test sites despite variability in water chemistries; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). No water quality constituent was identified as potentially contributing to observed responses.
- ***H.* azteca**—Seventeen tests (approximately 70% of all tests) were categorized as a possible or likely adverse response (Figure G-4; Figure G-5). Responses were trending towards an increase in frequency and magnitude in responses over time until Q4 2018. Nickel has been identified as potentially contributing to observed responses in most tests. There was increased uncertainty for the Q4 2020 dry weight results (where responses were unusually low across most tests, including reference) and the Q2 and Q4 2020 survival results (which demonstrated high levels of inter-replicate variability).
- ***O. mykiss***—All but five tests (Q2 test in 2016 and Q4 tests in 2015, 2016, 2017 and 2019) were categorized as no adverse response (Figures G-6 to Figure G-9). Responses observed in Q4 2017 were consistent with responses associated with microbial growth (Golder 2018). No water quality constituent was identified as potentially contributing to observed responses in the remainder of tests.
- ***P. promelas***—All but four tests (Q3 2016, 2018, 2019, and 2020) were categorized as no adverse response (G 3.5-10 to G-14). No water quality constituent was identified as potentially contributing to observed responses, but responses observed in Q3 2018, 2019, and 2020 were consistent with responses associated with microbial growth.

Overall, CM_MC2 has shown similar patterns of response over time for *C. dubia* reproduction and *H. azteca* survival and dry weight. These two crustacean species are known to be sensitive to dissolved nickel exposure, and multiple lines of evidence have implicated nickel as driving adverse responses at this sampling location. A trend towards more frequent and larger responses for *C. dubia* and *H. azteca* was observed until Q4 2018. For *C. dubia,* mean responses from 2019 to 2021 have generally been within local and regional NRs, indicating that response sizes have decreased since 2018.

The pattern in responses for both species between 2015 and 2018 corresponds with an increase in aqueous nickel concentrations from 2015 (generally ranged from 5 to 15 µg/L) to 2018 (generally ranged from 10 to 60 µg/L). Compared to the 2018 peak, nickel concentrations decreased through 2021, ranging from 8 to 25 µg/L except for two samples at 45 µg/L in Q1 and Q3 2020. The pattern in nickel concentrations may help explain the fewer and lower-magnitude responses observed between 2019 and 2021 relative to 2018, particularly for crustaceans.

Aside from the responses to nickel-sensitive crustaceans discussed above, adverse effects to other species (trout, minnows, and algae) in recent years of testing have been rare at CM_MC2, and where observed, appear linked to confounding factors (microbes or atypical batch-wide test results). This finding is also consistent with the water quality composition of Michel Creek test waters because the concentrations of major ions (sulphate, nitrate, and total dissolved solids) are lower in Michel Creek relative to portions of the upper Fording River. As such, nickel has been the only constituent identified in Michel Creek that would introduce incremental potential for toxicity relative to other stations in the regional program. The concentrations of nickel observed in Michel Creek are not predicted to cause effects to fish or algae, and the chronic tests in this program confirm this expectation.

Figure 3.5-8: Summary of test results by category at CM_MC2.

Note: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. HI-RV = high inter-replicate variability; Ni = nickel; UN = unknown: no water quality constituent was identified; Recat = category was previously assigned as "no adverse response." Toxicity Identification Evaluations were conducted to support the causation assessment for *C. dubia* tests in 2017 (Q3 and Q4), 2018 (Q1 to Q4), 2019 (Q1 to Q4), 2020 (Q1 to Q4), and 2021 (Q1 to Q4); and. *H. azteca* tests in 2018 (Q1 to Q4), 2019 (Q1, Q3, and Q4), 2020 (Q2 and Q4), and 2021 (Q2 and Q4).

3.5.9 RG_MIDAG

In 2018, non-permit station CM_MC3 was added to the program in 2018 as part of the AMP response framework to characterize the spatial extent of effects observed in previous CM_MC2 testing. Station CM_MC3 was replaced with station RG_MIDAG in 2019, which is approximately 2 km downstream of CM_MC2. As discussed at the June 2019 EMC meeting, the replacement occurred because there was uncertainty in the amount of flow along Michel Creek at CM_MC3 due to an ice dam in winter conditions. Michel Creek flows were consolidated in one channel throughout the year at RG_MIDAG, making this station a better candidate to evaluate the spatial extent of observed effects.

Results are summarized in Figure 3.5-9. An overview of the RG_MIDAG results is provided below:

- ***C. dubia***— No effects were observed on survival or reproduction in any test (Figure G-1; Figure G-2). All responses were within local and regional NRs.
- ***H.* azteca**—All but two tests (Q2 and Q4 2020) were categorized as no adverse response (Figure G-4 and G- 5). Nickel was identified as potentially contributing to observed responses in Q2 2020, and high variability across replicates was observed in the Q4 2020 test (Golder 2021a).
- ***P. promelas***— All test were categorized as no adverse response on survival and reproduction and responses were within local and regional NRs (Figure G-10 to G-14).

Overall, RG_MIDAG showed fewer and lower magnitude responses relative to CM_MC2. Between 2019 and 2021, the only results categorized as adverse response were *H. azteca* results with high uncertainty. Furthermore, the temporal improvement in crustacean responses observed at CM_MC2 since 2018 were also observed at RG_MIDAG.

Figure 3.5-9: Summary of test results by category at RG_MIDAG.

Note: 2018 test results are for CM_MC3. In 2019, CM_MC3 was replaced by RG_MIDAG, the station located 2 km downstream of CM_MC3. Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. High inter-reference variability was observed for Q3 *H. azteca* and Q1 *P. promelas*, see Section 3.3.1. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. HI-RV = high inter-replicate variability; Ni = nickel; UN = unknown: no water quality constituent was identified.

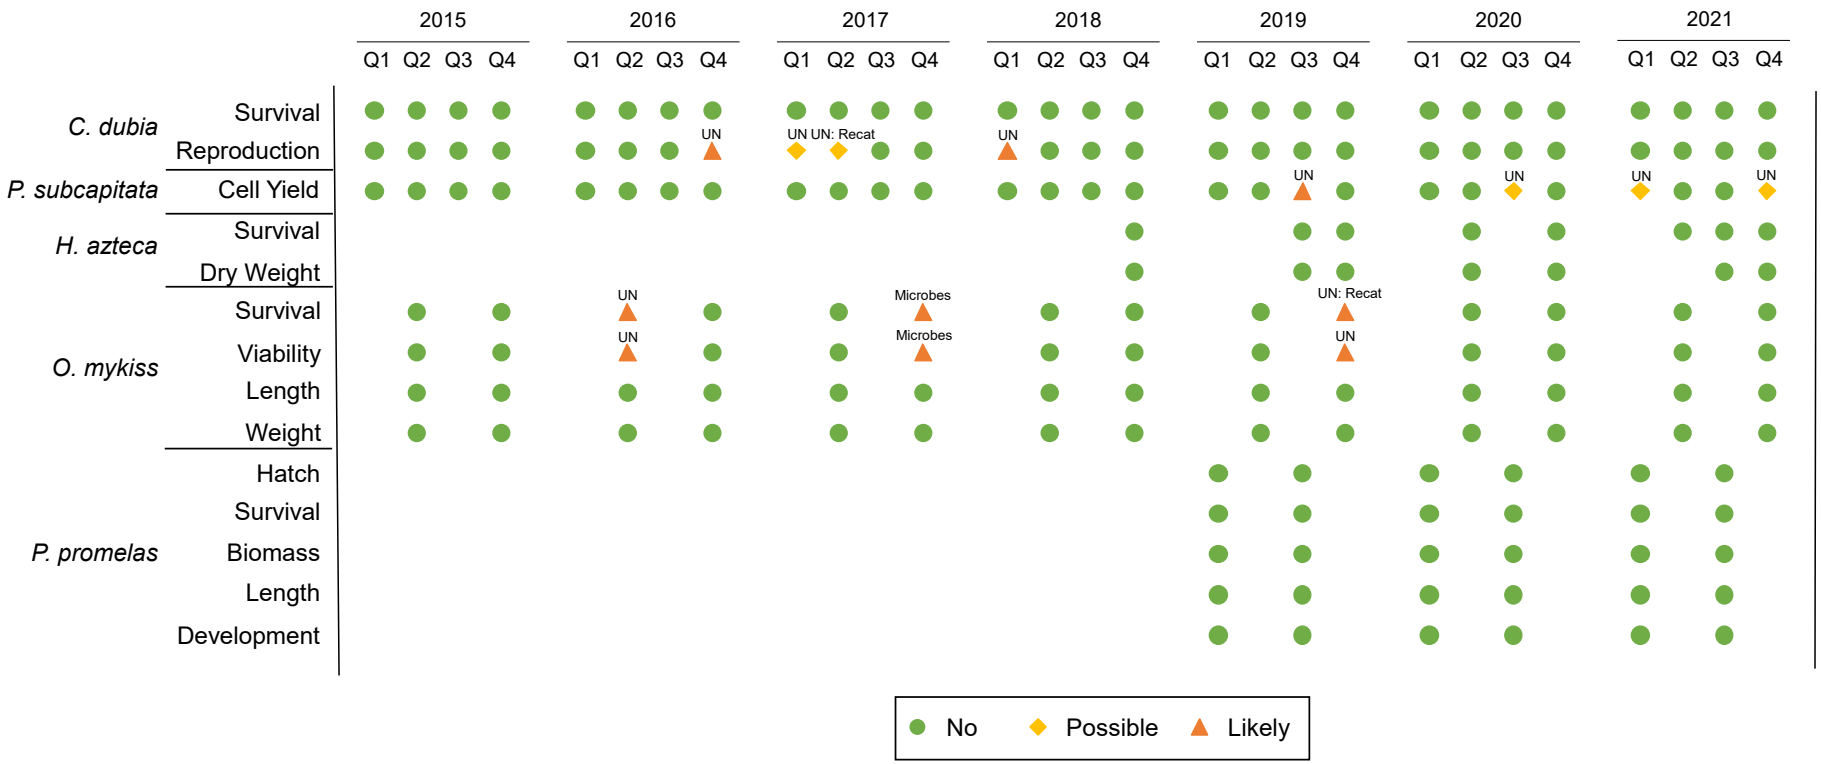
3.5.10 EV_MC2

Results for EV_MC2 (Michel Creek downstream of Bodie Creek) in 2015–2021 are summarized in Figure 3.5-10. An overview of the results is provided below:

- ***C. dubia***— No effects were observed on survival in any test (Figure G-1). All but three tests (Q4 2016, Q1 and Q2 2017 and Q1 2018) were categorized as no adverse response for reproduction (Figure G-2). No water quality constituent was identified as potentially contributing to observed responses.
- ***P. subcapitata***—All but four tests (Q3 2019, Q3 2020 and Q1 and Q4 2021) were categorized as no adverse response (Figure G-3). In Q3 2019, most tests including reference tests exhibited adverse responses on cell yield and results for that batch of tests were considered anomalous (Golder 2020b). In Q1 and Q4 2021, many test sites had mean cell yield that was systematically depressed across test sites despite variability in water chemistries; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). No water quality constituent was identified as potentially contributing to observed responses.
- ***H.* azteca**— All tests were categorized as no adverse response, and responses were within local and/or regional NRs (Figure G-4 and G-6).
- ***O. mykiss***—All but three tests (Q2 2016 and Q4 2017 and 2019) were categorized as no adverse response (Figures G-6 to G9). No water quality constituent was identified as potentially contributing to observed responses, although responses observed in 2017 were consistent with responses associated with microbial growth (Golder 2018).
- ***P. promelas***— All tests were categorized as no adverse response and mean results were generally within local and/or regional NRs (Figure G-10 to G-14).

Overall, EV_MC2 has shown few adverse responses over time, with no apparent consistent pattern of responses and no clear evidence of causal factors. Over the period of record, no responses have been identified that can be plausibly linked to mine-influenced chemical parameters.

Figure 3.5-10: Summary of test results by category at EV_MC2.



Note: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. UN = unknown: no water quality constituent was identified; Recat = category was previously assigned as “no adverse response.

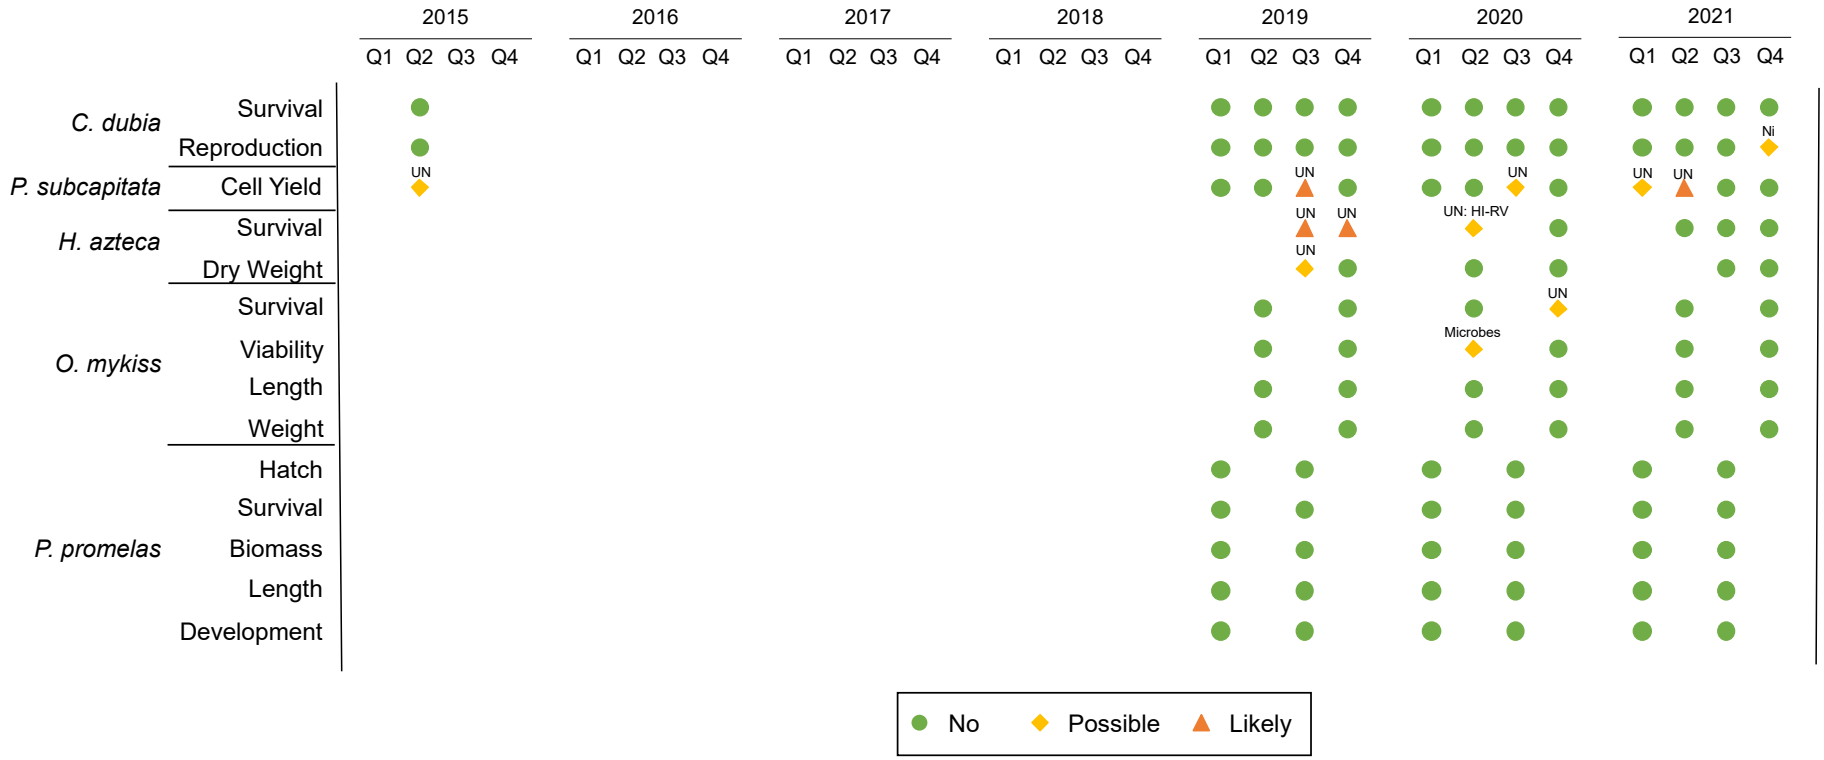
3.5.11 LC_LC3

Station LC_LC3 (Line Creek downstream of West Line Creek) was added to the regional chronic toxicity testing program after 2019 integration of the Line Creek toxicity testing and regional toxicity testing permits. Results are summarized in Figure 3.5-11. An overview of the results is provided below:

- ***C. dubia***—No effects were observed on survival in any test (Figure G-1). All test except one (Q4 2021) were categorized as no adverse response for reproduction (Figures G-1 and G-2). Nickel was identified as potentially contributing to the observed effect in Q4 2021.
- ***P. subcapitata***—Mean cell yield was within the local and regional NRs (Figure G-3) except for Q3 2019 and Q2 2021. Approximately 40% of tests were categorized as possible or likely adverse response, including Q3 2019 for which the batch test results were considered anomalous (Golder 2020b), and Q1 2021, which was associated with elevated uncertainty due to the systematic depression of cell yield despite variability across water chemistries (Section 3.4.2). No water quality constituent was identified as potentially contributing to observed responses.
- ***H.* azteca**—All but three tests (Q3 and Q4 2019 and Q1 2020) were categorized as no adverse response (Figure G-4 and G-5). No water quality constituent was identified as potentially contributing to the observed responses, although high replicate variability was observed for survival in Q2 2020 (Golder 2021a).
- ***O. mykiss***—All but two tests (Q2 2020 and Q4 2020) were categorized as no adverse response (Figures G-6 to Figure G-9). No water quality constituent was identified as potentially contributing to the observed response, although responses in the Q2 2020 test were consistent with microbial influence (Golder 2021a).
- ***P. promelas***—All tests were categorized as no adverse response across all endpoints, and response were generally within local and normal NRs (Figures G-10 to G-14).

Overall, LC_LC3 has shown few adverse responses over time, with no apparent consistent pattern of responses and no clear evidence of causal factors.

Figure 3.5-11: Summary of test results by category at LC_LC3.



Note: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. HI-RV = high inter-replicate variability; Ni = nickel; UN = unknown: no water quality constituent was identified.

3.5.12 LC_LCDSSLCC

Results for LC_LCDSSLCC (Line Creek downstream of South Line Creek) in 2015 to 2021 are summarized in Figure 3.5-12. An overview of the results is provided below:

- ***C. dubia***—No effects were observed on survival in any test (Figure G-1). All but four tests (Q1 2017, Q2 and Q4 2018, and Q3 2020) were categorized as no adverse response for reproduction (Figure G-2). No water quality constituent was identified as potentially contributing to observed responses in these tests.
- ***P. subcapitata***—All but three tests (Q2 2015, Q3 2019, and Q4 2021) were categorized as no adverse response (Figure G-3). In Q3 2019, most tests including reference tests exhibited adverse responses on cell yield and results for that batch of tests were considered anomalous (Golder 2020b). In Q4 2021, many test sites had mean cell yield that was systematically depressed across test sites despite variability in water chemistries; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). No water quality constituent was identified as potentially contributing to observed responses.
- ***H.* azteca**—All but three tests (Q4 2018, Q3 2019, and Q4 2019) were categorized as no adverse response (Figures G-4 and G-5). No water quality constituent was identified as potentially contributing to the observed responses.
- ***O. mykiss***—All but four tests (Q2 and Q4 2016, Q4 2017, and Q4 2020) were categorized as no adverse response (Figures G-8 and G-9). No water quality constituent was identified as potentially contributing to observed responses, although responses observed in 2017 were consistent with responses associated with microbial growth (Golder 2018).
- ***P. promelas***—All tests except one (Q1 2020) were categorized as no adverse response (Figures G-10 to G-14). These responses were consistent with responses associated with microbial growth and no water quality constituent was identified as potentially contributing to observed responses.

Overall, LC_LCDSSLCC has shown few adverse responses over time, with no apparent consistent pattern of responses and no clear evidence of causal factors. Over the period of record, no responses have been identified that can be plausibly linked to mine-influenced chemical parameters.

Figure 3.5-12: Summary of test results by category at LC_LCDSSLCC.

Note: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. UN = unknown: no water quality constituent was identified.

4.0 SUMMARY

The following bullets summarize results from the 2021 interpretive report.

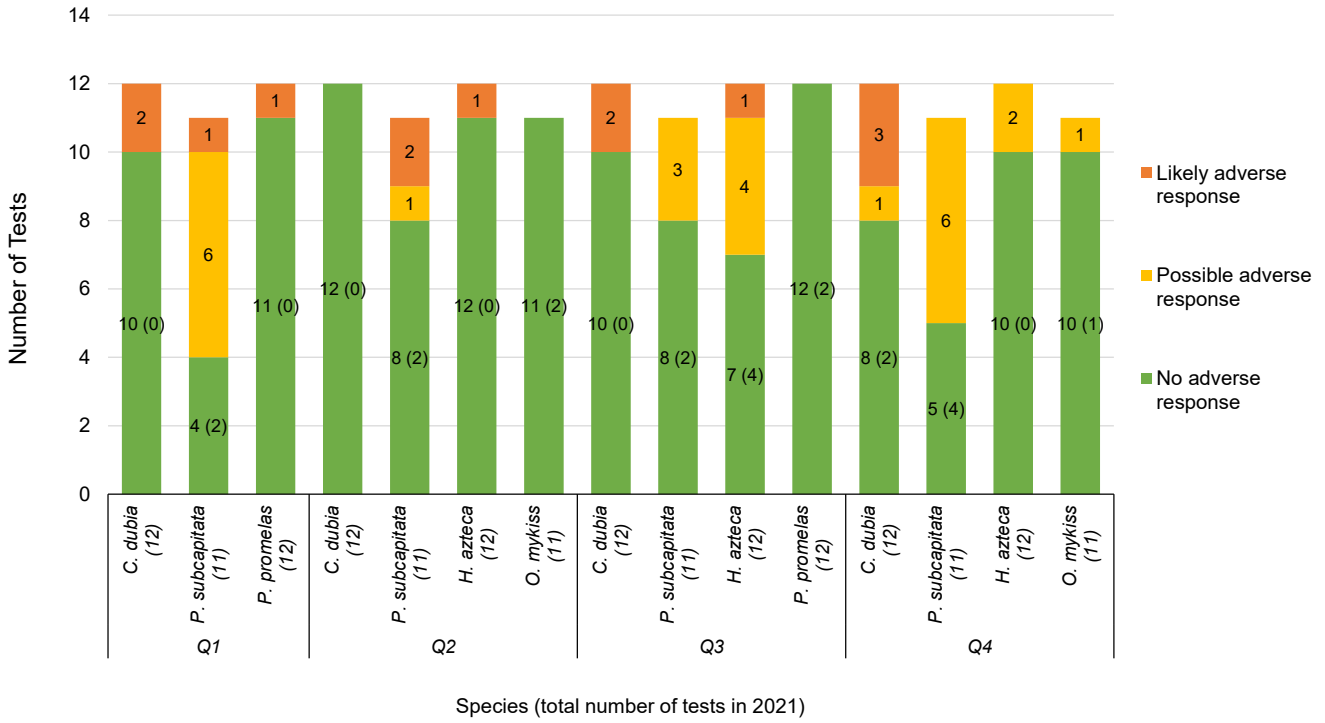
- **Quality Assurance/Quality Control**—QA/QC results indicated that organism performance in the laboratory control water generally met acceptability criteria for health histories and sensitivity of the organisms (Section 3.1). Where deviations occurred that could influence the reliability of the data, actions for data processing were taken to address this influence:
  - *P. subcapitata* in Q1 and Q4—many of the test sites had mean cell yield that was affected systematically (reduced growth) across the batch, despite the tested sites having different water quality profiles; this resulted in poor correspondence between water chemistry and responses (Section 3.4.2). This finding did not warrant outright rejection as invalid test outcomes, but instead indicated higher uncertainty for this endpoint relative to previous years.
  - *H. azteca* dry weight in Q3—the high inter-reference variability resulted in the identification of possible adverse responses for several test sites. For many of the possible responses for this endpoint, the responses did not match previous tests nor did any findings associate strongly with water quality. These unusual findings did not warrant outright rejection as invalid test outcomes, but instead indicated higher uncertainty for this endpoint relative to previous years.
  - Q1 *P. promelas* tests with Elk River and Michel Creek reference waters—results from these waters were excluded from statistical analyses, and the results from the remaining two references were used to categorize site water responses. As described for Q3 *H. azteca* results in the preceding bullet, adverse responses in Q1 tests did not match previous tests or water quality; these unusual findings did not warrant outright rejection as invalid test site outcomes, but instead indicate higher uncertainty than in previous years for these endpoints. Exclusion of these references made the identification of adverse responses more likely in test site waters, but was adopted as a conservative screening approach.
  - Microbes were observed in a subset of test treatments for both fish species. The potential for confounding of test endpoints was partially controlled through administration of copper, which prevented large disruptions to the test endpoint performance, but did not eliminate the presence of microbes entirely. Comparisons of results for replicates with and without evidence of microbe presence indicated potential for a small downward bias in survival and viability of tested fish.
- **Sources of Variance**—Key sources of variance that could affect responses observed in test waters were addressed herein, including variation in test organism performance (addressed by control normalization), variation in test organism sensitivity to toxicants (addressed by reviewing reference toxicant results), variation in background water quality characteristics (addressed by developing regional and local NRs), and variation in concentrations of toxicants in test waters (addressed by reviewing CVs; Section 3.2). Addressing these sources of variance is expected to improve the ability to identify a true toxicological response.
- **Evaluation of 2021 Test Results**—The 2021 test results categorized as “no adverse response”, “possible adverse response”, or “likely adverse response” are illustrated on Figure 4-1 and Figure 4-2. Historical (i.e., 2015 to 2020) test results were re-categorized using normal ranges developed in this year’s report. Key findings were:

- For all species, most tests were categorized as exhibiting no adverse response. Likely adverse responses were most common for *C. dubia* reproduction and least common for *O. mykiss* and *P. promelas*; the latter two species had only one adverse response each for survival.
- The frequency of likely adverse responses was similar across quarters, with three likely adverse responses in Q2 and Q4 and four in Q1 and Q3. A high frequency of possible adverse effects was observed in Q1, Q3, and Q4, although most of these tests were linked to atypical results for *P. subcapitata* (Q1 and Q4) and *H. azteca* (Q3), as mentioned above.
- The frequency of adverse effects was highest at FR_FRCP1 (seven tests), LC_DCDS (five tests), and CM_MC2 (six tests), a finding consistent with spatial patterns from previous years of monitoring. Other stations have fewer adverse responses, ranging from no adverse responses observed at RG_MIDAG to four adverse responses observed at LC_LC5.
- The proportion of samples exhibiting adverse effects to fish endpoints was low for fathead minnow (1 of 32 tests) and rainbow trout (1 of 30 tests)—the introduction of low copper concentrations to control the prevalence and confounding effects of microbes has greatly improved the reliability of that test endpoint relative to early rounds of testing. As discussed in Section 1.2.3, chronic toxicity results for early life stages of fish can be conservatively relied upon to infer potential effects to other fish life stages; if no adverse response is observed in early life stage tests, then no adverse response would be expected for older life stages.
- The addition of FR_FRABCH and integration of the Line Creek and regional monitoring programs has improved the spatial characterization of sampling in the mainstem Fording and Elk rivers. The results from 2021 provide evidence that several stations of the mainstem Fording River downstream of FR_FRCP1 (i.e., FR_FRABCH, GH_FR1, and LC_LC5) have lower frequency and magnitude of chronic toxicity.

- **Causation Assessment**—Constituents identified as potential causes of toxicity in 2021 tests categorized as possible or likely (Section 3.4) are summarized in Figure 4-3. Key findings were:
  - In the Fording River (FR_FRCP1) and its tributary Dry Creek (LC_DCDS), nickel and/or nitrate showed the greatest evidence of causing the observed effects to *C. dubia* and *H. azteca* in one or more tests:
    - Nickel was identified in the largest number of tests at FR_FRCP1 and LC_DCDS as a potential causal factor for the observed effects to crustaceans (i.e., *C. dubia* reproduction and *H. azteca* dry weight). The interpretation of nickel as potentially contributing to effects at FR_FRCP1 aligned with TIE findings and graphical analysis. The magnitude of toxicity observed at FR_FRCP1 in 2021 was lower than in other recent years, possibly reflecting the lower concentrations of major ions (i.e., TDS components) measured in site water.
    - Nitrate was identified as potentially contributing to effects on *O. mykiss* survival at FR_FRCP1, although the influence of microbes cannot be discounted in this test. Adverse responses in this test would not be expected to translate to other life stages of WCT, given that responses were attributed to a testing artifact (microbes) and to a stressor (nitrate) for which older life stages of fish are less sensitive (CCME 2012). Nitrate was also identified as potentially contributing to observed effects on *C. dubia* reproduction and *H. azteca* dry weight at LC_DCDS.

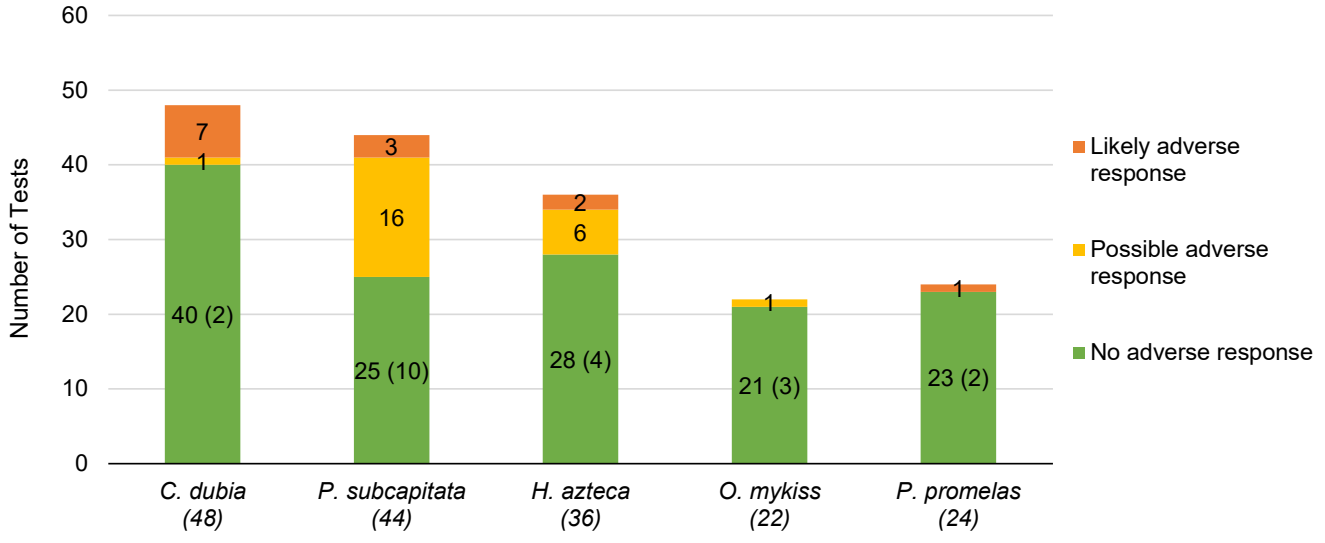
- Nickel was the only constituent identified as a causal factor for adverse responses observed in Michel Creek station CM_MC2, potentially contributing to observed effects on *C. dubia* reproduction and *H. azteca* survival and dry weight. This finding aligned with TIE results for these species and is consistent with previous years of water quality and toxicity monitoring. The influence of nickel in Michel Creek is limited spatially, as the tests of sensitive crustaceans at RG_MIDAG showed improvement relative to CM_MC2.
- Nickel was identified as a potential causal factor in for the possible adverse response to *C. dubia* reproduction observed for Line Creek station LC_LC3 in Q4. In previous years, no water quality constituent had been identified at this station.
- Potential explanatory factors other than water quality were identified in some tests, including microbial interference (Q4 *O. mykiss*; discussed above), high inter-reference variability (discussed below), and unusually similar magnitude of responses across varying water chemistries (discussed below).
  - High inter-reference variability was identified in Q3 for *H. azteca* and Q1 for *P. promelas*. The variability observed in references for both species (see Section 3.3.1) created elevated uncertainty to whether tests categorized as possible or likely represented an adverse response to toxicants in the test water. These results indicate the presence of variance in test organism performance due to factors other than water quality. This is further supported by the observation that all Q3 *H. azteca* tests (with the exception of CM_MC2) were statistically similar to three of the four references tested concurrently. In the case of Q1 *P. promelas*, survival in this test (with a conservatively-assigned category of likely adverse response) was higher than Elk and Michel references. The removal of the anomalous references introduces potential for a false positive designation; site waters with similar results to these Elk and Michel references were retained for statistical analysis.
  - For Q1 and Q4 *P. subcapitata* tests, many test sites had mean cell yields that were systematically depressed across test sites despite variability across water chemistries, resulting in poor correspondence between water chemistry and responses (Section 3.4.2).
- For other tests categorized as possible or likely adverse response, no explanatory factor was identified as causing the observed response.

Figure 4-1: Summary of 2021 Test Results by Species and Quarter.



Note: Values in parentheses are the number of tests with endpoint(s) significantly lower than one or more reference but categorized as no adverse response according to the decision framework in Figure 2.3-1.

Figure 4-2: Summary of 2021 Test Results by Species.



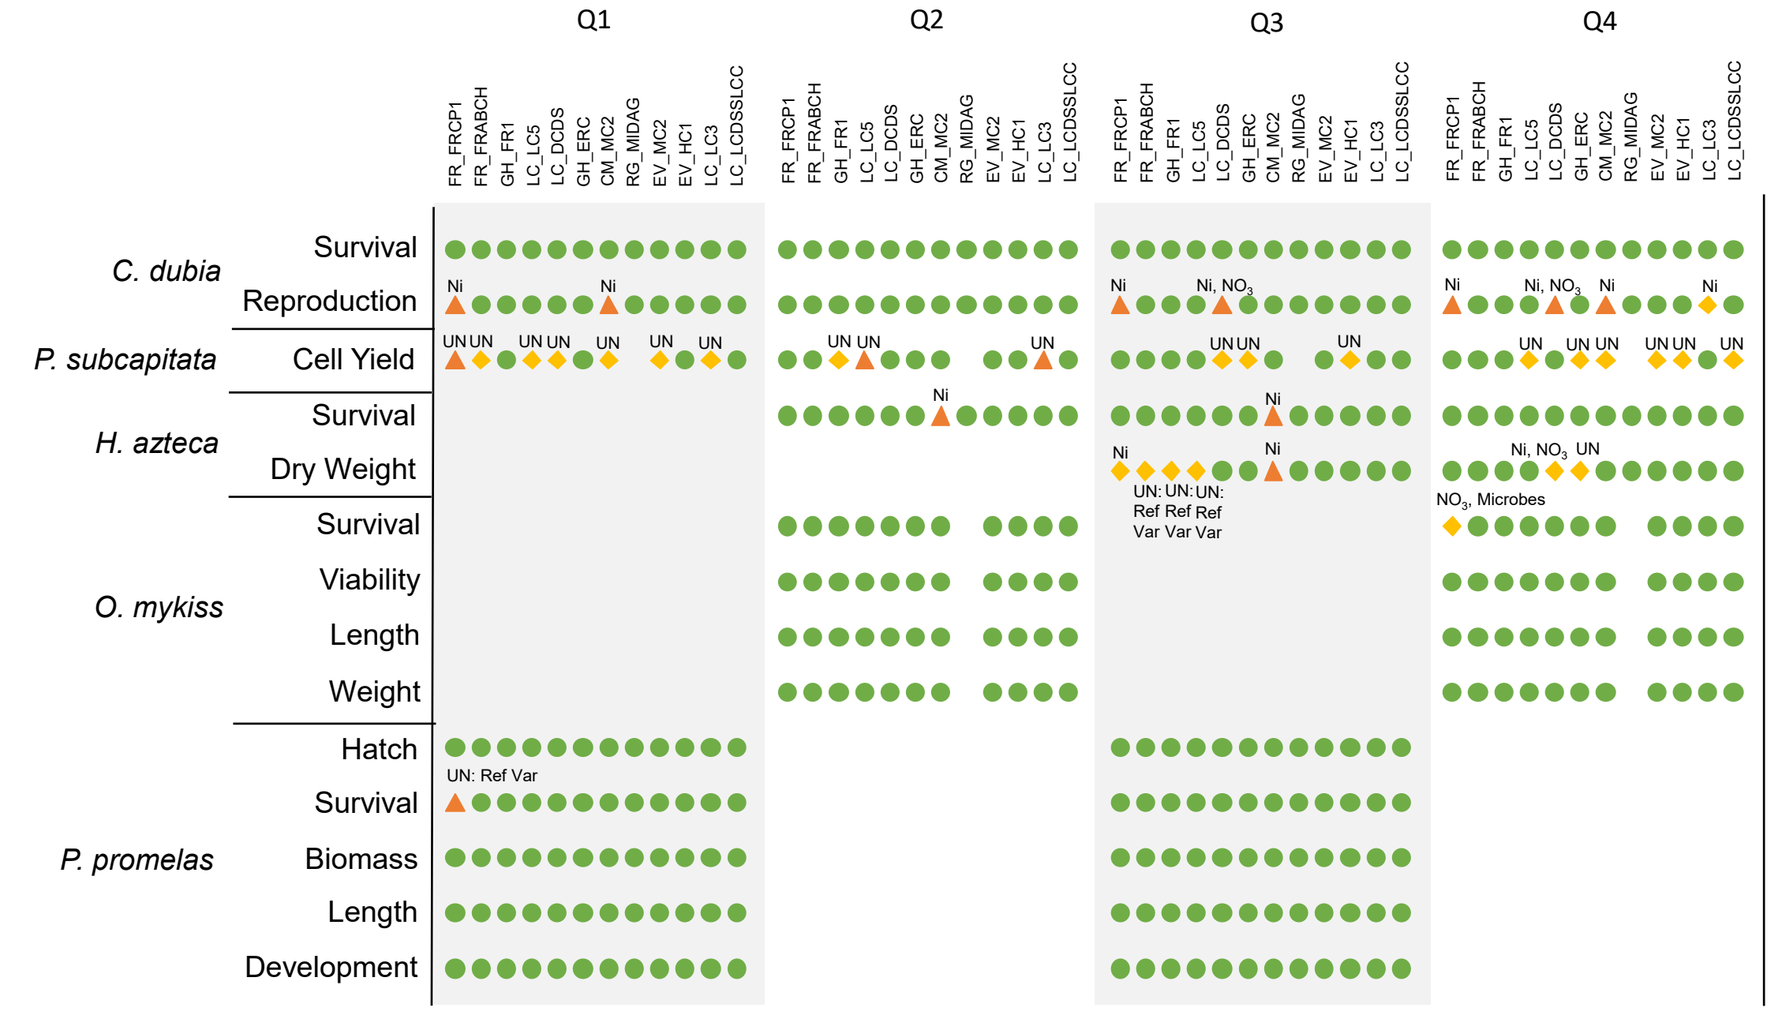
Note: Values in parentheses are the number of tests with endpoint(s) significantly lower than one or more reference but categorized as no adverse response according to the decision framework in Figure 2.3-1.

- **Comparison of 2021 Results to Previous Years**—Similarities and differences were summarized between test results in the 2021 program and previous programs (2015 to 2020), focusing on the incidence of adverse responses by season and station (Section 3.5). The broad findings of the program were similar to 2020, with most stations exhibiting a low proportion of significant toxicity outcomes, *C. dubia* remaining a sensitive indicator for influence of mine-related constituents, and the greatest frequency of mine-related responses observed for FR_FRCP1 in the upper Fording River, LC_DCDS in Dry Creek, and CM_MC2 in Michel Creek. The remaining stations have exhibited possible or likely adverse effects in a minority of sampling events, but these cases were typically associated with elevated uncertainty in the toxicity tests (i.e., anomalous responses in site and reference waters, or high inter-reference variations) and/or had weak to negligible evidence for influence of mine-influenced water quality. Other key findings were:
  - The strength of toxicity at FR_FRCP1 has decreased in recent years. At FR_FRCP1, there was a pattern of more frequent and larger responses for *C. dubia* until Q2 of 2019, when mean reproduction recovered to lie within local and regional NRs. Although 2021 results indicate adverse responses are still occurring, the magnitude of response was lower than in 2017 and 2018 and was similar to results observed in 2015 and 2016. In 2021, the adverse responses observed for *C. dubia* (Q1, Q3, and Q4), *H. azteca* (Q3), and *O. mykiss* (Q4) were attributed to nickel and nitrate. Teck has initiated several actions in response to these results (see Section 2.2.2), including diverting Cataract Creek through Swift Creek Ponds for eventual treatment at the FRO South AWTF, which avoids discharging into the seasonally dry reach of the Fording River; the water quality measured at FR_FRCP1 under base flow conditions suggests at least partial improvement in water quality and toxicity. Teck also applied to relocate the Fording River Operations compliance location from FR_FRCP1 to FR_FRABCH to better capture all upstream mine influence, and early indications from FR_FRABCH are that chronic toxicity is reduced relative to FR_FRCP1. Approval to move the compliance location was received in March 2021. Commissioning of the FRO South AWTF is expected to further improve water quality at FR_FRCP1, FR_FRABCH, and all downstream reaches.
  - At LC_DCDS, the overall frequency and magnitude of responses has remained stable (and mostly limited to invertebrate endpoints), but recently there has been improved understanding of causation. Nitrate was identified as potentially causing observed effects in some tests with *C. dubia* (Q4 2018, Q1 2020, and Q3 and Q4 2021), *H. azteca* (Q4 2019 and Q4 2021), and *O. mykiss* (Q4 2019), which corresponded with an observed increase in nitrate in these quarters (~20 to ~47 mg/L as N) compared to concentrations in previous quarters and years (5 to 10 mg/L as N). In addition to nitrate, nickel was identified as potentially causing observed effects in some tests with *C. dubia* (Q3 and Q4) and *H. azteca* (Q4) in 2021 but had not been identified as such in previous years. Teck has initiated several actions under the AMP Response framework and submitted the Nitrogen Source Control Plan Annual Report which encompasses water management and blasting practices at LCO related to nitrogen management. In addition, Teck also has initiated the conveyance and supplementation project in LCO Dry Creek, which is intended to improve water quality in Dry Creek in the earliest timeframe possible (pending approval, scheduled to be operational in Q1 2023). Longer-term mitigation to manage water quality in Dry Creek, incorporating water treatment, is being developed by Teck for operation in 2026.

- At CM_MC2, responses to nickel-sensitive crustaceans have been observed in historical testing, and this continued in 2021. However, the frequency and magnitude of toxicity has reduced in recent years (2019 to 2021) relative to 2017 and 2018. There has been a consistent pattern of nickel being identified as a potential or likely cause of observed effects in most of these tests. Spatially, nickel concentrations decrease from upstream to downstream on Michel Creek. At the station further downstream on Michel Creek (RG_MIDAG), nickel concentrations were lower relative to CM_MC2 (e.g., average nickel concentration of 5 µg/L at RG_MIDAG compared to 17 µg/L at CM_MC2, for *H. azteca* tests in 2021) and adverse test responses to crustaceans were reduced. As discussed in Section 2.2.2.2, Teck has initiated several actions under the AMP response framework to address water quality in Michel Creek. These actions include:
  - Expanding monitoring at CMm (including the addition of CM_MC3 [2018 only] and RG_MIDAG to characterize spatial extent of effects at CM_MC2)
  - Initiating laboratory and desktop studies to support the development of site-specific effects benchmarks for nickel in the Elk Valley. This work includes an ongoing series of laboratory-based toxicity studies and desktop data analyses to better understand the toxicity of nickel in Elk Valley waters, the influence of water chemistry factors on toxicity, and to what extent nickel may be contributing to observed effects in the chronic toxicity and biological monitoring programs. The outcome of this work is expected to be a set of site-specific benchmarks that will support evaluation and management of nickel at CMm and throughout the Elk Valley,
  - Modifying pit dewatering activities at CMm to minimize the effect of 34 pit pumping on downstream concentrations of nickel and other mine-influenced constituents. The changes in pit dewatering have reduced peak concentrations of nickel since 2019. This has been associated with a reduction in the frequency and magnitude of chronic toxicity test results in 2019, 2020 and 2021 as compared to 2017 and 2018.
  - Developing nickel tank and non-tank-based removal technology.
  - Evaluating mitigation options for nickel at CMm.

At other stations, there was no apparent consistent pattern of responses and no clear evidence of causal factors. The elevated incidence of adverse effects to *H. azteca* in Q3 and *P. subcapitata* in Q1 and Q4 did not occur in a concentration-dependent manner, are inconsistent with previous patterns, and appear to be related to high inter- reference variability (*H. azteca)* or the systematic depression responses across varying water chemistries (*P. subcapitata*).

Figure 4-3: Summary of Constituents Identified as Potentially Contributing to Observed Responses in 2021.



Note: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Due to a lab technician error in the Q2 amphipod test, the Fording River reference was re-tested in Q2 resulting in two sets of survival results for this station (see Section 3.3.1.2). Both results for the Fording River reference in Q2 were categorized as no adverse response and have been combined in this figure. All stations were re-tested in Q3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. Ref Var = high inter-reference variability; Ni = nickel; NO3 = nitrate; UN = unknown: no water quality constituent was identified. Toxicity Identification Evaluations were conducted to support the causation assessment for *C. dubia* and *H. azteca* tests.

5.0 UNCERTAINTY

Sources of uncertainty associated with the interpretation of the quarterly and semi-annual toxicity testing program were:

- **Pairing of water quality and response data**—For the *H. azteca*, *P. promelas*, and *O. mykiss* tests, where test durations extended over multiple weeks, refresh water samples were collected on a weekly basis for the duration of the test. Refresh water samples, as well as the mean concentration over the test, were compared to chronic WQGs. In the causation assessment, effects data for these tests were paired with the mean concentration of the weekly samples to conduct correlations. If concentrations of water quality constituents were higher (or lower) in one of the weekly samples, then examination of weekly samples may have resulted in different conclusions regarding constituents retained for graphical analysis. This uncertainty is not expected to affect the overall interpretation of the quarterly and semi-annual toxicity testing program because weekly refresh samples were screened against chronic WQGs and EVWQP benchmarks, so constituents potentially contributing to observed effects were captured in the overall causation assessment. In addition, results of other testing of Elk Valley waters confirmed that variations over the span of a few weeks tend to be low (Golder 2018).
- **Mixture effects**—The causation assessment presented in Section 3.4 evaluated individual water quality constituents potentially contributing to observed test responses. Although ∑TUs were used in the causation assessment as an exposure metric for mixtures, it cannot be ruled out that some constituents may act in combination in such a way that is not captured by the ∑TU calculations. A qualitative multiple-stressor analysis was conducted in Chapter 8 of the EVWQP to assess potential interactions among the four EVWQP constituents. Although mechanisms of action have not been definitively determined, the available information indicates that these constituents likely have different mechanisms of action:
  - Selenium produces adverse effects following dietary accumulation of seleno-amino acids into protein-rich tissues.
  - Although the specific mechanism of action is uncertain, nitrate may exhibit toxicity following uptake and conversion to nitrite, which can then impair oxygen transport. In the Elk Valley, nitrate is not likely to contribute meaningfully to the osmotic pressure that may be important for sulphate toxicity, because it is present at low concentrations relative to the total ionic content of mine-influenced water.
  - Sulphate appears to act primarily on the iono-regulatory organs of freshwater organisms and may exert stress because of general osmoregulatory pressure or disruption of cellular membrane function in conjunction with other components of TDS.

  In addition to those constituents discussed in the EVWQP, nickel was also identified herein as a likely cause of toxicity in some tests. Potential mechanisms for nickel toxicity on aquatic organisms include disruption of trace element and ion homeostasis (e.g., calcium, magnesium, and iron), allergic reactions at respiratory epithelia, disruption of energy metabolism, and oxidative stress (Brix et al. 2017).

  Notwithstanding the different mechanisms of action, conceptually it is possible that effects from multiple constituents could operate in an additive manner where they ultimately affect the same toxicological endpoint (e.g., nitrate and TDS could separately influence *O. mykiss* survival via different toxicological pathways).

Most water quality constituents evaluated in the causation assessment had concentrations below water quality guidelines or orders of magnitude below effect concentrations. Based on the information above (i.e., different mechanisms of action and most concentrations below water quality guidelines or toxicological benchmarks), there is a low potential for additive effects of multiple constituents. It is unlikely that combined effects among the constituents would occur, and the approach taken in the assessment of evaluating each substance independently is expected to provide a reliable assessment of the overall potential for adverse effects from water quality.

- **Microbial Influence (Fathead Minnows)**—The uncertainty related to microbial activity (i.e., sporadic mortality phenomenon) has been substantially reduced through use of up to 20 µg/L copper amendment (Appendix B). In 2021, no tests with microbial presence had adverse effects on any endpoint.
  The implementation of copper amendment has greatly reduced this source of variance (that is unrelated to mining activity) and thereby reduced the incidence of false positive toxicity findings. As a result, the incidence of toxicity to fathead minnows decreased substantially from 2015 to 2021, to the extent that fathead minnows currently yield one of the lowest rates of significant results among the five species tested in quarterly or semi-annual chronic testing.

- **Microbial Influence (Rainbow Trout)**—The frequency of microbial observations was high, particularly in Q2; however, survival was affected in only one of seventeen tests with evidence of microbe presence. Similar to fathead minnows, the timing of mortalities in the affected test indicated that microbial interference can influence the survival endpoint but, as demonstrated in these results, the use of copper amendment was effective in preventing large magnitude effects to survival. Although many of the rainbow trout tests (80%) had some evidence of microbes in one or more replicates, adverse effects were not observed in most tests, suggesting that rainbow trout are often tolerant of at least some level of microbe presence. Where microbes were observed, the survival endpoint in that replicate was often, but not always, reduced relative to replicates without documentation of microbes.

- **High Inter-Reference Variability**—There were atypical findings observed for *H. azteca* dry weight (Q3) and *P. promelas* survival (Q1), where high variability was observed among references tested in the same quarter. This variability introduces elevated uncertainty associated with the assigned narrative category. For many of the adverse responses associated with these references, the responses did not match previous tests or water quality. These tests did not warrant outright rejection as invalid test outcomes, but instead indicate higher uncertainty than in previous testing for these endpoints.

- **Atypical Endpoint Results**—There were atypical findings for *P. subcapitata* (Q1 and Q4) where many test sites had mean cell yield that was systematically depressed, despite the variability in water quality profiles. This resulted in poor correspondence between water chemistry and responses. The causation analysis was also unable to identify an explanation for these test results based on water quality composition. These unusual findings did not warrant outright rejection as invalid test outcomes, but instead indicate higher uncertainty than in previous years for this endpoint. These results were retained in the toxicity summaries for each location; testing in 2022 will help to confirm whether the findings are anomalous (i.e., not repeated through testing under similar exposure conditions).

6.0 RECOMMENDATIONS

Recommendations for future quarterly and semi-annual toxicity testing programs are:

- **Revisit the potential contribution of nickel in historical test results for invertebrates**—For the 2022 reporting, we recommend that the potential contribution of nickel in historical invertebrate results be re- evaluated using the final nickel benchmark, which is expected in 2022. This will improve interpretation of historical comparisons and potentially amend adverse responses that currently have "no constituent identified".
- **Return to standard *C. dubia* Environment Canada protocol tests**—In 2021, the test durations for *C. dubia* were run according to protocol methods (i.e., 7 ± 1 day), with the test being terminated on the day that at least 60% of control organisms have produced three broods. A parallel set of results was obtained by extending the test to 8 days, regardless of when the control organisms produced a third brood, and the output was counted from the first three broods only. As discussed in Section 3.3.1.1, the 2021 tests did not identify a meaningful difference between procedures (i.e., influence test significance decisions). Therefore, as recommended in the 2020 Chronic Toxicity Report (Golder 2021a), testing may return to the Environment Canada protocol in subsequent years, beginning in 2022.
- **Revise *H. azteca* refresh rate from twice-daily to once-daily**—Historical testing has used twice-daily water refreshes to be consistent with sediment test methods. Nautilus has successfully implemented *H. azteca* tests with thrice-weekly water refreshes, as is recommended in the Environment Canada method for the water-only 14-d exposure for other testing programs. Per the February 2022 EMC meeting, we propose to use once-daily water refreshes which will reduce organism handling and may help to address high inter-replicate variability observed in recent rounds of testing.
- **Conduct *P. promelas* tests using US EPA 2016 method starting in Q1 2023**—Historical testing for *P. promelas* used US EPA 1996 and ASTM 2013 test methods, as specified in Permit 107517. As discussed at the February 2022 EMC meeting, we propose to use the updated test method, US EPA 2016, starting in Q1 2023. Key differences between the methods include 20 fish per replicate as opposed to 15, increased volume per exposure vessel, and thrice-daily feeding as opposed to twice-daily. There is a potential for raw growth metrics to be affected (i.e., absolute dry weight in individual measurements); however, this is not expected to affect control-normalized metrics or comparisons to reference. This will be supported by paired control tests conducted by Nautilus in 2022, to compare control performance using the two methods.
- **Maintain modified *P. promelas* test procedures**—Nautilus conducted *P. promelas* quarterly tests with reference and test site water treated with 10 µg/L to 30 µg/L of copper amendment (Appendix B). Due to the efficacy and minimal impact on control performance, copper treatment is recommended as a method to effectively mitigate toxicity due to microbial/fungal interference, while still allowing a relevant measure of the presence of other toxicants in the samples. In most testing conducted to date, a copper amendment of 15 to 30 µg/L has effectively mitigated toxicity due to microbial effects. Copper additions up to 20 µg/L are approved for standard quarterly testing with fathead minnow; testing with higher copper doses (e.g., 40 µg/L) remains an option for Teck to consider as part of test refinement but would require ENV approval for formal amendment of the study design. Given the cost and complexity of additional studies conducted over multiple copper concentrations, we recommend keeping the 10–20 µg/L amendment range specified in the January 2018 amendment to Permit 107517 and continuing to evaluate frequency and intensity of microbial interference. Ameliorating factors that influence copper toxicity (e.g., hardness, DOC) will be considered when determining the base copper amendment within the range of 10 µg/L to 20 µg/L. We also recommend that, where the optimal copper concentration is unclear, a concentration toward the upper end of this range be applied.

- **Maintain *O. mykiss* test procedures**—Nautilus conducted *O. mykiss* semi-annual tests with reference and test site water treated with 20 µg/L of copper amendment (Appendix B). Due to the efficacy and minimal impact on control performance, copper treatment is recommended as a method to effectively mitigate toxicity due to microbial/fungal interference, while still allowing a relevant measure of the presence of other toxicants in the samples. Results of the 2021 testing indicated that amendments of 20 µg/L copper were not always effective. Copper additions up to 20 µg/L copper are approved by ENV for testing with rainbow trout; therefore, it is recommended to continue testing with this dose and to continue monitoring the frequency of microbial observations. Similar to fathead minnow testing, we recommend that, where the optimal copper concentration is unclear, a concentration toward the upper end the range of 10 µg/L to 20 µg/L be applied, particularly as rainbow trout are predicted to be less sensitive to copper relative to fathead minnows[40]. If the frequency of microbes increases in 2022, or the evidence for interference by microbes increases, we will recommend that the concentrations of copper be increased to a maximum of 40 µg/L.
- **Continue toxicity testing with Elk River, Fording River, Michel Creek, and South Line Creek reference waters**—Test organism responses references were usually comparable within a given season. However, in some quarterly tests, responses were significantly different in reference waters. Inclusion of all four references provided useful information about the natural variability in reference responses and important context for the interpretation of test site results. The 2021 data confirmed findings from previous years that, although individual references can vary within a single batch of testing, the long-term performance of reference waters is generally equivalent across all four reference sites. The strength of including multiple reference stations appears to come from increased sample size used to develop reliable reference normal ranges, rather than a need to characterize references in specific watersheds within the Elk Valley. The additional references provide a contingency for an anomalous response in one reference water (as occurred in 2021 for the *P. promelas* tests with Elk River and Michel Creek references). Furthermore, the increase in sample sizes for recently-added reference stations (Michel Creek and South Line Creek) has improved the confidence in the local NRs calculated for these waters.
- **Continue RG_MIDAG testing with invertebrates in 2022**—Testing at RG_MIDAG has been primarily conducted with *C. dubia* and *H. azteca* to characterize the spatial extent of potential nickel effects to invertebrates. Testing conducted to date indicates a lack of adverse responses at RG_MIDAG. Moving forward, it is recommended that if 2022 testing also shows a lack of adverse responses, RG_MIDAG testing with *C. dubia* and *H. azteca* can be discontinued and aqueous nickel concentrations can be used to evaluate the spatial extent of potential effects. Nickel concentrations in Michel Creek are well below effect concentrations for *O. mykiss*, *P. promelas*, and *P. subcapitata*, as demonstrated by the lack of adverse responses for these test species at both CM_MC2 and RG_MIDAG and screening against reported effect concentrations; therefore, testing at RG_MIDAG for these species is not recommended.

[40] This prediction is based on the output of the model developed by Kevin Brix that calculates the estimated low-effect benchmark for chronic toxicity to fish based on concentrations of toxicity modifying factors.

7.0 CLOSURE

We trust the above meets your present requirements. If you have questions or require additional details, please contact the undersigned.

Yours very truly,

APPENDIX A

Legal Requirements

Permit #107517 issued under the Environmental Management Act (Elk Valley EMA Permit) – Section 8.9

8.9 CHRONIC TOXICITY TESTING PROGRAM

The permittee must develop and implement a toxicity testing program for receiving environments affected by coal mining operations. The purpose of the program is to evaluate chronic toxicity at the compliance points and other locations throughout the Elk Valley.

The program shall be planned and implemented by qualified professionals using methods that have documented test procedures, reliability, and quality assurance.

The toxicity testing program must include, at a minimum, the following elements:

i. Once every three years beginning in 2015, bioassays must be conducted to evaluate the survival and development (incidence of deformities) of targeted aquatic species using gametes obtained from species using habitats in the Elk River, the Fording River, their tributaries, and associated lentic habitats, and the Koocanusa Reservoir. The concentrations of selenium in the eggs of each female spawned must be measured.

ii. For the purposes of the following requirements the listed mine-influenced stations must include:

- FR_FRCP1 (EMS E300071),
- FR_FRABCH (EMS 223753),
- GH_FR1 (EMS 0200378),
- LC_LC5 (EMS E200028),
- GH_ERC (E300090),
- CM_MC2 (EMS E258937),
- EV_MC2 (EMS E300091),
- EV_HC1 (EMSE102682),
- LC_LCDSSLCC (EMS E297110),
- LC_LC3 (EMS 200337), and

- LC_DCDS (EMS E295210).

Appropriate reference stations must be determined in consultation with the Environmental Monitoring Committee.

The following toxicity test must be conducted during each semi-annual (spring and fall) sampling event at all listed mine-influenced stations plus multiple reference stations:

- 30-day early life-stage test with the rainbow trout (*Oncorhynchus mykiss*; EPS1/RM/28) using <24-hour post-fertilization eggs; endpoints: survival, viability, length, wet weight (plus documentation of observed deformities or behavioral changes); and
- 28-day water-only test with amphipod, *Hyalella azteca* (adapted from USEPA 2000, with appropriate supplementation of halides); endpoints: survival, growth.

The following toxicity tests must be conducted during each semi-annual (summer and winter) sampling event at all listed mine-influenced stations plus multiple reference stations:

- 30-day early life-stage test with the fathead minnow, *Pimephales promelas* (USEPA 1996) using <24-hour post-fertilization eggs; endpoints: survival, normal development, length, biomass (plus documentation of observed deformities or behavioral changes).

The following toxicity tests must be conducted during each quarterly sampling event at all listed mine-influenced stations plus multiple reference stations:

- 7-day water-only test with the cladoceran, *Ceriodaphnia dubia* (EPS1/RM/21); endpoints: survival, reproduction; and
- 72-hour test with the alga, *Pseudokirchneriella subcapitata* (EPS1/RM/25); endpoints: growth inhibition.

iii. Toxicity testing methods must be consistent with Environment Canada's, U.S. Environmental Protection Agency's, or ASTM's approved biological test methods. Waters used for fathead minnow (Pimephales promelas) and rainbow trout (Oncorhynchus mykiss) 30-day early life-stage tests may be augmented with up to, and not exceeding, 20 ug/L copper to control for fungi and microbial pathogens. Ameliorating factors that influence copper toxicity (e.g., water hardness, dissolved organic carbon, and major ions) must be considered when determining the lowest and most effective dose below this limit.

iv. A Quality Assurance/Quality Control component.

v. A proposed schedule of dates that coincide with water quality sampling and that target predicted worst-case times such as low flow, during flocculant use, or when discharge quality is expected to be reduced.

The suite of toxicity tests will be reviewed on an annual basis by the EMC and recommendations provided to the director for consideration.

8.9.1 SULPHATE TOXICITY AT HIGH HARDNESS CONCENTRATIONS

The permittee must develop with input from the EMC and implement a toxicity testing program specifically to assess sulphate toxicity at high hardness concentrations. Results will be used to support finalization of long-term sulphate site performance objectives.

The following toxicity test shall be conducted as a component of the Sulphate toxicity testing program.

- 30-day early life-stage test with the fathead minnow, *Pimephales promelas* (USEPA 1996) using <24-hour post-fertilization eggs; endpoints: survival, hatching, growth, deformity.
- Other sensitive species (amphibian, trout, water flea, etc.) shall be included.

Monitoring results and interpretation must be compiled into a written report and submitted to the satisfaction of the director by December 31, 2017.

8.9.2 SUBLETHAL TOXICITY STUDY

The permittee must develop with input from the EMC and implement a sublethal toxicity study to confirm that surface waters meeting the Site Performance Objectives for the order stations are not toxic to sensitive aquatic receptors. The permittee must submit the study design to the director by April 30, 2015.

1.0 INTRODUCTION

Nautilus Environmental (Nautilus) conducted toxicity tests for Teck Coal Ltd. (Teck) on samples collected from various locations in the Elk Valley as part of a quarterly toxicity testing program required under the BC Ministry of Environment and Climate Change Strategy permit number 107517.

Stations sampled in the first quarter of 2021 are shown in Figure 1 and align with the integrated chronic toxicity testing program, which was designed to eliminate redundancy between Permit 107517 Section 9.8 (ii) and Permit 106970 toxicity testing programs. The integrated program was approved by BC Ministry of Environment and Climate Change Strategy on March 4, 2019 (BC ENV 2019). Four new sites from the Upper Fording River location were added to the testing program for *Ceriodaphnia dubia* testing. Test species required to be tested quarterly include a cladoceran (*Ceriodaphnia dubia*) and a unicellular green alga (*Pseudokirchneriella subcapitata*). Tests are also required on a semi-annual basis using rainbow trout (*Oncorhynchus mykiss*; Q2 and Q4), an amphipod (*Hyalella azteca*; Q2 and Q4), and fathead minnows (*Pimephales promelas*; Q1 and Q3).

Water samples used for testing were transported in 20-L plastic containers in coolers containing ice packs. Samples were received at temperatures ranging from -0.7 to 8.4°C and were stored in the dark at 4 ± 2°C prior to testing. Table 1 summarizes the toxicity tests that were conducted on each sample as well as sample collection dates. Samples were collected weekly on the dates shown in Table 1 for the duration of the *P. promelas* test. The *C. dubia* and *P. promelas* test was conducted at the Nautilus Environmental laboratory in Calgary, AB; the *P. subcapitata* test was conducted at the Burnaby, BC location.

This report presents the results of the toxicity tests. Copies of laboratory data sheets and printouts of statistical analyses are provided in Appendices A through C. The chain-of-custody forms are provided in Appendix D. Results of analytical chemistry that was performed on the samples tested in this program are uploaded by Teck to the Environmental Management System database. Analytical chemistry samples were collected by Teck personnel at the same time the samples were collected for toxicity testing.

2.0 METHODS

Methods for the toxicity tests using *C. dubia* (test initiated on April 15th, 2021), *P. subcapitata* (test initiated on February 25th, 2021), and *P. promelas subcapitata* (test initiated on March 6th, 2021) are summarized in Tables 2 through 4. Laboratory control water was 20% Perrier water prepared with deionized water for *C. dubia*; deionized water with supplemented nutrients for *P. subcapitata*; and dechlorinated City of Calgary municipal tap water with the addition of 4 mg/L potassium chloride (KCl) for *P. promelas*.

For *C. dubia*, the test protocol specifies that test duration must be 7 ± 1 day, with the test being terminated on the day that at least 60% of control organisms have produced three broods. To provide additional information on reproduction patterns in the samples, and as requested by Teck, the tests were extended to 8 days, regardless of when 60% of controls had produced three broods. However, the results reported below were calculated based on the specifications of the test method, which in this case was based on the reproduction that had been observed up to Day 7 of exposure. The additional information on reproduction up to Day 8 of exposure is available in Appendix A.

As requested by Teck, site water used in the tests with *P. promelas* were amended with either 10, 15, or 20 µg/L of copper, depending on the hardness of each sample, to reduce the potential for confounding effects from microbial growth. Fathead minnows are known to be susceptible to adverse effects caused by fungi and microbes (Grothe and Johnson, 1996; Kszos et al., 1997; Downey et al., 2000). Results of toxicity tests and Toxicity Identification Evaluation efforts conducted in 2015 indicated that artefactual toxicity (*i.e.*, adverse effects that were not associated with toxicants in the sample) had occurred in fathead minnow tests using ambient water samples from the Elk Valley and amendment of the samples with a low dose of copper appeared to counteract the adverse effect. Consequently, samples were amended with copper for the *P. promelas* tests in order to reduce the potential adverse effects caused by fungi and microbes.

The fathead minnows were evaluated for potential microbial growth during daily replenishments and test termination (Nautilus, 2020). Microbial growth is noted on the bench sheets at every instance of visual confirmation of a superficial fungus-like growth around the gill region and/or surrounding the surfaces of the test organisms, and high mortality that is not consistent across replicates, as described in Downey et al. (2000).

Statistical analyses were performed using CETIS (Tidepool Scientific Software, 2013), and involved comparison of results to both the laboratory and site water controls.

Table 2. Test conditions: *Ceriodaphnia dubia* survival and reproduction test.

Test species	*Ceriodaphnia dubia*
Organism source	In-house culture
Organism age	<24 hour old neonates, produced within a 12 hour window
Test type	Static-renewal
Test duration	8 days*
Test vessel	20-mL glass test tube
Test volume	15 mL
Test solution depth	10 cm
Test concentrations	100% (undiluted) sample, plus laboratory control
Test replicates	10 per treatment
Number of organisms	1 per replicate
Control water	20% Perrier water and 80% deionized water + 5 µg/L Se and 2 µg/L vitamin B12
Test solution renewal	Daily (100% renewal)
Test temperature	25 ± 1°C
Feeding	Daily with *Pseudokirchneriella subcapitata* and TCC[1] (3:1 ratio)
Light intensity	100 to 600 lux at water surface
Photoperiod	16 hours light / 8 hours dark
Aeration	None
Test measurements	Temperature, dissolved oxygen, pH and conductivity measured daily; hardness and alkalinity of undiluted sample measured at test initiation; survival and reproduction checked daily
Test protocol	Environment Canada (2007a), EPS 1/RM/21
Statistical software	CETIS Version 1.9.4
Test endpoints	Survival and reproduction
Test acceptability criteria for controls	≥80% survival; ≥15 young per surviving control producing three broods; ≥60% of controls producing three or more broods; no ephippia present
Reference toxicant	Sodium chloride (NaCl)

* Test duration was extended to 8 days to provide additional information on patterns of reproduction. Summarized data and calculated endpoints are based on results from Day 6, according to the standard test procedure; however, all of the data through 8 days are provided in Appendix A.

[1] TCC = Trout Chow + cerophyl

Table 3. Test conditions: *Pseudokirchneriella subcapitata* growth inhibition test.

Test species	*Pseudokirchneriella subcapitata*, strain CPCC# 37
Organism source	In-house axenic culture, obtained from Canadian Phycological Culture Center, and originally isolated from Nivelta River, Norway.
Organism age	3-to 7-day old culture in logarithmic growth phase
Test type	Static
Test duration	72 hours
Test vessel	Microplate
Test volume	220 µL
Test concentrations	Full strength sample diluted to 95.2% (v/v) by addition of nutrients, plus laboratory control
Test replicates	4 per treatment; 8 for laboratory control and site controls
Number of organisms	10,000 cells/mL
Control water	Deionized water supplemented with nutrients
Test solution renewal	None
Test temperature	24 ± 2°C
Feeding	None
Light intensity	3600 to 4400 lux
Photoperiod	24 hours light
Aeration	None
Test measurements	Test area temperature measured daily; temperature and pH measured at test initiation; pH of two control wells measured at test termination
Test protocol	Environment Canada (2007b), EPS 1/RM/25
Statistical software	CETIS Version 1.9.4
Test endpoints	Algal cell growth inhibition
Test acceptability criteria for controls	>16-fold increase in number of algal cells; CV ≤ 20%; no trend when analyzed using Mann-Kendall test
Reference toxicant	Zinc (added as $ZnSO_4$)

Table 4. Test conditions: 32-day fathead minnow *(Pimephales promelas)* survival and growth test.

Test species	*Pimephales promelas*
Organism source	Aquatic Biosystems, CO
Organism age	<24 hours
Test type	Static-renewal
Test duration	From egg stage until 28 days post hatch
Test vessel	1-L glass jar
Test volume	1 L
Test concentrations	100% (undiluted) sample amended with 10, 15, or 20 µg/L Cu, plus laboratory control and control amended with 10, 15, or 20 µg/L Cu
Test replicates	4 per treatment
Number of organisms	10 per replicate
Control water	Dechlorinated City of Calgary municipal tapwater amended with 4 mg/L KCl.
Test solution renewal	Daily (80% renewal)
Test temperature	25 ± 1°C
Feeding	Twice a day, after hatch, with newly hatched brine shrimp (*Artemia* nauplii)
Light intensity	100 to 500 lux
Photoperiod	16 hours light / 8 hours dark
Aeration	None unless dissolved oxygen fell to less than 60% saturation
Test measurements	Temperature, dissolved oxygen, pH and conductivity measured daily; hardness and alkalinity measured upon arrival; survival and any incidence of fungal growth on the test organisms recorded daily
Test protocol	US EPA (1996) and ASTM (2013)
Statistical software	CETIS Version 1.9.4
Test endpoints	Hatch, survival, length, biomass, normal development (which assesses incidence of deformities)
Test acceptability criteria for controls	>66% hatch, ≥70% post-hatch survival
Reference toxicant	Sodium chloride (NaCl)

3.0 RESULTS

3.1 *Ceriodaphnia dubia*

Results of the toxicity tests using *C. dubia* are provided in Table 5. The site water control samples from FR_UFR1, GH_ER2, CM_MC1 and LC_SLC performed similarly to the laboratory control, indicating that there were no adverse effects associated with the upstream stations.

There were no adverse effects on survival in any of the samples tested; survival ranged between 80 and 100%. Significantly lower reproduction relative to the laboratory control or one or more of the site controls was observed in FR_FRCP1, CM_MC2 and FR_FR4.

3.2 *Pseudokirchneriella subcapitata*

Results of the toxicity tests using *P. subcapitata* are provided in Table 6. The site water controls FR_UFR1, GH_ER2, CM_MC1 and LC_SLC produced 3.0- to 3.4-fold greater growth than the laboratory control. This finding is not unusual, since the higher ionic strength associated with the site water controls would be expected to stimulate cell growth of this species relative to the very low ionic strength associated with the laboratory control water.

There were no adverse effects on cell yield in any of the samples tested relative to the laboratory control except in sample FR_FRCP1. Stimulation of growth was observed in all samples tested compared to the laboratory control with the exception of FR_FRCP1; percent stimulation ranged between 121.7 and 243.4%. With the exception of GH_FR1 and GH_ERC, all samples had reduced cell yield to one or more site controls.

3.3 *Pimephales promelas*

Results of the toxicity tests using *P. promelas* are provided in Table 7. Relative to the laboratory control, there were no adverse effects observed in the copper-amended controls for hatch rate, survival, biomass, or length or normal development. Adverse effects were observed in site controls GH_ER2 and CM_MC1 relative to the respective copper controls in three endpoints.

There were no adverse effects observed in hatch rate for any samples with the exception of LC_DCDS, which was significantly lower compared to the laboratory control. Adverse effects on survival in downstream stations relative to one or more controls were observed in samples FR_FRCP1, RG_MIDAG, FR_FR2 and FR_FR4. Decreased biomass relative to one or more controls

was observed in FR_FRCP1 and FR_FR2. No adverse effects on length or normal development were observed in downstream samples.

Microbial growth was observed on test organisms in one or more replicates of samples CM_MC2 (replicate d), FR_FR4 (replicate d), FR_FR2 (all replicates), and F4_FRRD (replicate c), suggesting that the copper dose employed in these samples was not sufficient to curtail microbial effects. In the case of FR_FR2, observations of microbial growth were noted every day in at least one replicate in between day 9 and 15 of the test. Observed patterns are consistent with previous observations regarding mortalities caused by microbial growth.

Table 5. Results: *Ceriodaphnia dubia* survival and reproduction test.

4.0 QA/QC

The health histories of the test organisms used in the exposures were acceptable and met the requirements of the test protocols. Tests met all control acceptability criteria and water quality parameters remained within ranges specified in the protocol throughout the tests. There were no other deviations from the test methodologies, other than the planned addition of copper in the *P. promelas* tests, as described in Section 2.0. Uncertainty associated with the test is best described by the standard deviation around the mean.

Results of the reference toxicant tests conducted during the testing program are summarized in Table 8. Results fell within the acceptable range for organism performance of two standard deviations around the mean, based on historical results obtained by the laboratory with these tests. Thus, the sensitivity of the organisms used in these tests was appropriate.

Table 8. Reference toxicant test results.

Test species	Endpoint	Historical mean (2 SD Range)	CV (%)	Test date
C. dubia	Survival (LC50): 1.7 g/L NaCl	1.8 (1.6 – 2.1)	4	April 5, 2021
	Reproduction (IC50): 1.6 g/L NaCl	1.5 (1.2 – 1.8)	6	
P. subcapitata	Growth (IC50): 27.6 µg/L Zn	31.5 (25.7 – 38.6)	10	February 12, 2021
P. promelas	Survival (LC50): 5.3 g/L NaCl	7.2 (4.8 – 10.8)	13	March 11, 2021
	Biomass (IC25): 3.2 g/L NaCl	3.9 (2.1 – 7.4)	21	

SD = Standard Deviation, CV = Coefficient of Variation, LC = Lethal Concentration, IC = Inhibition Concentration

Sample Information:

Sample ID: Various - See Below
Sample Date: 2021/02/23
Date Received: 2021/02/24
Sample Volume: Various

Test Validity Criteria:

1) Mean survival of first generation controls is ≥80 %
2) At least 60% of controls have produced three broods within 8 days
3) An average of ≥15 live young produced per surviving female in the control solutions during the first three broods.
4) Invalid if ephippia observed in any control solution at any time.

WQ Ranges:

T (°C) = 25 ± 1; DO (mg/L) = 3.3 to 8.4 ; pH = 6.0 to 8.5

Test Organism Information:

Broodstock No.: Tuesday B2; Thursday A1
Age of young (Day 0): <24-h (within 12-h)
Avg No. young in first 3 broods of previous 7 d: 27
Mortality (%) in previous 7 d: 1
Individual female # used ≥8 young on test day: A1, A2, A3, A4, B1, B2, B3, B4, B5, D1, D2, D3, D4, C1, C2, C4, C5, E3, E5; A4, B2, B5, C1, D1, C3, C4, C5, D2

Test Organism Information

Client: TECHeq

Culture history for adults used in the test for sample reference: LAB CTL + 2021-0970 – 2021-0979

Day Used: 2021/04/15

Test organisms appeared healthy before use: (Yes) No

Number of young produced per brood adult within first three broods:

Brood	row/replicate	A1	A2	A3	A4	B1	B2	B3	B4	SL B5	D1	D2
	number of young	3	3	3	2	3	5	5	5	3	5	3

	number of young	9	9	12	9	9	9	9	8	11	10	8

Culture(s) Used for Testing: TUES B2

Number of Adults Alive in Culture	7 days prior: 50	day used: 47

Notes: all cups have 1 adult

Average No. of young in first 3 broods: 23
(must be ≥15)

Culture % mortality (7-days prior to testing): 6%
(must be ≤20%)

Number of young produced by each brood organism in last complete brood is ≥8: Y
Yes (Y) or No (N)

Test Organism Information

Client: TECHeq

Culture history for adults used in the test for sample reference: LAB CTL + 2021-0970 – 2021-0979

Day Used: 2021/04/15

Test organisms appeared healthy before use: (Yes) No

Number of young produced per brood adult within first three broods:

Brood	row/replicate	A1	A2	A3	A4	B1	B2	B3	B4	SL B5	D1	D2
	number of young	3	3	3	2	3	5	5	5	3	5	3

	number of young	9	9	12	9	9	9	9	8	11	10	8

Culture(s) Used for Testing: TUES B2

Number of Adults Alive in Culture	7 days prior: 50	day used: 47

Notes: all cups have 1 adult

Average No. of young in first 3 broods: 23
(must be ≥15)

Culture % mortality (7-days prior to testing): 6%
(must be ≤20%)

Number of young produced by each brood organism in last complete brood is ≥8: Y
Yes (Y) or No (N)

APPENDIX B – *Pseudokirchneriella subcapitata* Toxicity Test Data

Pseudokirchneriella subcapitata Summary Sheet

Client: TECK
Work Order No.: 210288

Start Date: Feb. 25/21 @1530h
Set up by: SAK

Sample Information:

Sample ID: Various - see below
Sample Date: Feb. 23/21
Date Received: Feb. 24/21
Sample Volume: 1 × 20L

Test Organism Information:

Culture Date: Feb. 19/21
Age of culture (Day 0): 6d

Zinc Reference Toxicant Results:

Reference Toxicant ID: SC211
Stock Solution ID: 21ZN01
Date Initiated: Feb. 12/21

72-h IC50 (95% CL): 27.6 (24.1 - 31.3)

72-h IC50 Reference Toxicant Mean and Range: 31.5 (25.7 - 38.6) CV (%): 10

Test Results:

	Cell Yield (Mean± SD)
Negative Control	33.4 ± 1.4
FR_UFRI	114.6 ± 7.3 a,d,e
GH_ER2	107.2 ± 6.8 a,d,e
CM_MCI	100.9 ± 13.0 a,g
LC_SLC	102.8 ± 7.8 a,g
FR_FRABCH	74 ± 2.2 a,g,h,i,j
FR_FRCPI	20.2 ± 2.1 f,g,h,i,j
GH_FRI	103.2 ± 14.4 a
GH_ERC	111.8 ± 16.7 a

Results that are significantly greater than:
a = Lab Control
~~b = FR_UFRI~~ SAK
c = GH_ER2
d = CM_MCI
e = LC_SLC

Results that are significantly lower than:
f = Lab Control
g = FR_UFRI
h = GH_ER2
i = CM_MCI
j = LC_SLC

72-h Algal Growth Inhibition Toxicity Test
Water Quality Measurements

Client: TELK | Setup by: SAH

Sample ID: Various | Test Date/Time: Feb. 25/21 @ 1530h

Work Order No.: 210288 | CER #: 4

Test Species: *Pseudokirchneriella subcapitata*

Culture Date: 021921C | Age of Culture: 6d | Culture Health: Good

Culture Count: 1 255 2 240 | Average: 247.5 | Culture Cell Density (c1): 247.5×10^4 cells/mL

v1 = 220,000 cells/ml x 70 ml / (c1) 247.5×10^4 cells/ml = 6.2 mL

Time Zero Counts: 1 20 2 21 | Average: 20.5×10^4 cells/mL

No. of Cells/mL: 20.5×10^4 cells/mL | Initial Density: # cells/mL + 220 µL x 10 µL = 9318 cells/mL

Concentration %(v/v)	Water Quality		Incubator Temperature (°C)				Microplates rotated 2X per day?

APPENDIX C – *Pimephales promelas* Toxicity Test Data

32-d Fathead Minnow Survival and Growth Test

Client: Teck
Work Order No.: NA
Test Date: 06-Mar-21
Test Species: *Pimephales promelas*

Sample Information:

Sample ID: Various - see table below
Sample Date: Tuesday, March 2nd
Date Received: Wednesday, March 3rd

Dilution Water:

Type: Dechlorinated Tap Water (amended with 4 mg/L KCl)
Temperature (°C): 24°C
pH: 8
Conductivity: 524
Dissolved Oxygen (mg/L): 7.3
Hardness (mg/L CaCO3): 237
Alkalinity (mg/L CaCO3): 200

Test Organism Information:

Batch No: 20210306FM-ELS
Source: Aquatox
Age: <24 hours post fertilization
Receipt temperature: 21.1 & 24.1°C
Acclimation Rate: N/A
Swim bladder inflated at test initiation? (Y/N): N/A
Breeding stock mortality during the week prior to test initiation (%): N/A
Breeding stock mortality on weekly basis: N/A
Incidence of disease: No

NaCl Reference Toxicant Results:

Reference Toxicant ID: QA70
Stock Solution ID: NA
Date Initiated: March 11, 2021
7-d LC50 (95% CL): 5.3 (4.6 - 6.1) g/L NaCl
7-d IC25 (95% CL): 3.2 (2.6 - 4.5) g/L NaCl

Survival

Reference Toxicant Mean and Range: 7.2 (4.8 - 10.8) g/L NaCl (13.4 % CV)

Biomass

Reference Toxicant Mean and Range: 3.9 (2.1 - 7.4) g/L NaCl (21.3% CV)

Test Results:

Sample ID	Hatch (%) (Mean ± SD)	Biomass (mg) (Mean ± SD)	Length (mm) (Mean ± SD)	Normality (%) (Mean ± SD)	32 day survival (%) (Mean ± SD)

Final Weight (mg):	dried pan + organisms	2021/04/14	KL	Mettler 1

* same balance must be used for initial and final weights
* for FM/HA/CT, must use scale with 0.01 mg accuracy

Balance Calibration Check:

	Initial	Final
first pan weighed:	2021-0979A	LAB CTLA
weight of first pan:	804.11	813.22
first pan after all other pans weighed:	804.08	813.67

% difference <5%: (Yes)/No Yes/No

% difference = (initial weight - reweight) / (initial weight + reweight) / 2) × 100%

Test Validity Met: Yes/No/NA

Results are Logical:** Yes/No

** no negative numbers, consistent values across replicates

If "no" is circled for any parameter, notify Lab Supervisor/ QA Group to determine appropriate action

This report has been prepared by Nautilus Environmental Company Inc. based on data and/or samples provided by our client and the results of this study are for their sole benefit. Any reliance on the data by a third party is at the sole and exclusive risk of that party. The results presented here relate only to the samples tested.

1.0 INTRODUCTION

Nautilus Environmental conducted toxicity tests for Teck Coal Ltd. (Teck) on samples collected from various locations in the Elk Valley as part of a quarterly toxicity testing program required under the BC Ministry of Environment and Climate Change Strategy permit number 107517.

Stations sampled in the second quarter of 2021 are shown in Figure 1; stations shown as green symbols align with the integrated chronic toxicity testing program, which was designed to eliminate redundancy between Permit 107517 Section 9.8 (ii) and Permit 106970 toxicity testing programs. The integrated program was approved by the BC Ministry of Environment and Climate Change Strategy on March 4, 2019 (BC ENV 2019). Species requiring quarterly testing include a cladoceran (*Ceriodaphnia dubia*) and a unicellular green alga (*Pseudokirchneriella subcapitata*). On a semi-annual basis, tests using rainbow trout (*Oncorhynchus mykiss*; Q2 and Q4), an amphipod (*Hyalella azteca*; Q2 and Q4), and fathead minnows (*Pimephales promelas*; Q1 and Q3) are also required. Figure 1 stations shown as orange symbols align with the upper Fording River chronic toxicity testing program, which is a supplemental study for 2021 to satisfy Section 4D3.6 of Permit 107517. The upper Fording River program includes the same test species and testing frequency as the regional program, except that green alga is not tested.

Water samples used for testing were transported in 20-L plastic containers in coolers containing ice packs. Samples were received at temperatures ranging from 0.0 to 20.6°C and were stored in the dark at 4 ± 2°C prior to testing. Table 1 summarizes the toxicity tests that were conducted on each sample as well as weekly sample collection dates for the duration of the *H. azteca* and *O. mykiss* tests. All toxicity tests were conducted at the Nautilus Environmental laboratory in Burnaby, BC.

This report presents the results of the toxicity tests. Copies of laboratory data sheets and printouts of statistical analyses are provided in Appendices A through D. The chain-of-custody forms are provided in Appendix E. Results of analytical chemistry that was performed on the samples tested in this program are uploaded by Teck to the Environmental Management System database. Analytical chemistry samples were collected by Teck personnel at the same time the samples were collected for toxicity testing.

***** Site water controls

[#] upper Fording River samples from the supplemental study for 2021.

[†] June 29th to July 20th, 2021 sample collections were for the *H. azteca* re-test.

2.0 METHODS

Methods for the toxicity tests using *C. dubia*, *P. subcapitata*, *H. azteca,* and *O. mykiss* are summarized in Tables 2-5. Laboratory control water was prepared using deionized water with 20% Perrier for *C. dubia*; deionized water with supplemented nutrients for *P. subcapitata*; reconstituted water prepared by addition of reagent grade salts to dechlorinated Metro Vancouver municipal tap water for *H. azteca* according to a recipe provided in Environment Canada (2013); and dechlorinated Metro Vancouver municipal tap water for *O. mykiss*.

For *C. dubia*, the test protocol specifies that test duration must be 7 ± 1 day, with the test terminated on the day that at least 60% of control organisms have produced three broods. To provide additional information on reproduction patterns in the samples, and as requested by Teck, the tests were extended to 8 days, regardless of when 60% of controls had produced three broods. However, the results reported below were calculated based on the specifications of the test method, which in this case was based on the reproduction that had been observed up to Day 6 of exposure. The additional information on reproduction up to Day 8 of exposure is available in Appendix A.

For the *H. azteca* tests, all site waters were supplemented with 25 mg/L chloride and 0.02 mg/L bromide using NaCl and NaBr, respectively, in accordance with recommendations by the *Hyalella* Advisory Group (chaired by Chris Ingersoll, USGS; Norberg-King et al., 2014). Insufficient concentrations of these halides are known to impair growth of this species. The laboratory control water contained approximately 75 mg/L chloride and 0.8 mg/L bromide.

As requested by Teck, site waters used in tests with *O. mykiss* were amended with 20 µg/L copper to reduce the potentially confounding effects of microbial growth (Nautilus 2020).

Rainbow trout embryo-alevin tests were performed using a blocked design (i.e., eggs from one fish were used for replicate A of each test concentration, eggs from a second fish for replicate B, etc.). The blocked design approach was a planned deviation from the Environment Canada test method, which indicates that the eggs should be pooled prior to testing. However, this modification is considered appropriate because it reduces the risk of non-viable eggs from a single fish affecting the results of the entire test.

Statistical analyses were performed using CETIS (Tidepool Scientific Software, 2013), and involved comparison of results to both the laboratory and site water controls.

Table 2. Test conditions: *Ceriodaphnia dubia* survival and reproduction test.

Test species	*Ceriodaphnia dubia*
Organism source	In-house culture
Organism age	<24-hour old neonates, produced within a 12-hour window
Test type	Static-renewal
Test duration	8 days[1]
Test vessel	20-mL glass test tube
Test volume	15 mL
Test solution depth	10 cm
Test concentrations	100% (undiluted) sample, plus laboratory control
Test replicates	10 per treatment
Number of organisms	1 per replicate
Control water	20% Perrier water and 80% deionized water + 5 µg/L Se and 2 µg/L vitamin B12
Test solution renewal	Daily (100% renewal)
Test temperature	25 ± 1°C
Feeding	Daily with *Pseudokirchneriella subcapitata* and TCC[2] (3:1 ratio)
Light intensity	100 to 600 lux at water surface
Photoperiod	16 hours light / 8 hours dark
Aeration	None
Test measurements	Temperature, dissolved oxygen, pH and conductivity measured daily; hardness and alkalinity of undiluted sample measured at test initiation; survival and reproduction checked daily
Test protocol	Environment Canada (2007a), EPS 1/RM/21
Statistical software	CETIS Version 1.9.4
Test endpoints	Survival and reproduction
Test acceptability criteria for controls	≥80% survival; ≥15 young per surviving control producing three broods; ≥60% of controls producing three or more broods; no ephippia present
Reference toxicant	Sodium chloride (NaCl)

[1] Test duration was extended to 8 days to provide additional information on patterns of reproduction. Summarized data and calculated means are based on results from Day 6, according to the standard test procedure; however, all of the data through 8 days are provided in Appendix A.

[2] TCC = Trout chow + cerophyl

Table 3. Test conditions: *Pseudokirchneriella subcapitata* growth inhibition test.

Test species	*Pseudokirchneriella subcapitata*, strain CPCC# 37
Organism source	In-house axenic culture, obtained from Canadian Phycological Culture Center, and originally isolated from Nivelta River, Norway.
Organism age	3-to 7-day old culture in logarithmic growth phase
Test type	Static
Test duration	72 hours
Test vessel	Microplate
Test volume	220 µL
Test concentrations	Full strength sample diluted to 95.2% (v/v) by addition of nutrients, plus laboratory control
Test replicates	4 per treatment; 8 for laboratory control and site control
Number of organisms	10,000 cells/mL
Control water	Deionized water supplemented with nutrients
Test solution renewal	None
Test temperature	24 ± 2°C
Feeding	None
Light intensity	3600 to 4400 lux
Photoperiod	24 hours light
Aeration	None
Test measurements	Test area temperature measured daily; temperature and pH measured at test initiation; pH of two control wells measured at test termination
Test protocol	Environment Canada (2007b), EPS 1/RM/25
Statistical software	CETIS Version 1.9.4
Test endpoints	Algal cell growth inhibition
Test acceptability criteria for controls	>16-fold increase in number of algal cells; CV ≤20%; no trend when analyzed using Mann-Kendall test
Reference toxicant	Zinc (added as $ZnSO_4$)

Table 4. Test conditions: *Hyalella azteca* survival and growth test.

Test species	*Hyalella azteca*
Organism source	Aquatic Biosystems, CO
Organism age	7- to 8-days old
Test type	Static-renewal
Test duration	28 days
Test vessel	375-mL glass container
Test volume	300 mL
Test concentrations	100% (undiluted) samples amended with 25 mg/L Cl and 0.02 mg/L Br, plus laboratory control
Test replicates	5 per treatment
Number of organisms	10 per replicate
Control water	Reconstituted water containing ~75 mg/L Cl and 0.8 mg/L Br (Environment Canada 2013). Samples were supplemented with 25 mg/L Cl and 0.02 mg/L Br.
Test solution renewal	Twice daily (~80% renewal)
Test temperature	23 ± 1°C
Feeding	1 mL of YCT daily to each container. Tetramin daily, with amounts increasing weekly; Week 1: 0.25 mg, Week 2: 0.5 mg, Week 3: 1 mg, Week 4: 1.5 mg in each test container.
Light intensity	500 to 1000 lux at water surface
Photoperiod	16 hours light / 8 hours dark
Aeration	None
Test measurements	Temperature, dissolved oxygen, pH and conductivity measured daily; hardness and alkalinity measured upon arrival; hardness and alkalinity measured at test termination; total ammonia measured at test initiation and termination
Test protocol	Modified from US EPA (2000), as described in Norberg-King et al. (2014)
Statistical software	CETIS Version 1.9.4
Test endpoints	Survival and dry weight
Test acceptability criteria for controls	Mean control survival of ≥80%, dry weight ≥0.10 mg
Reference toxicant	Sodium chloride (NaCl)

Table 5. Test conditions: *Oncorhynchus mykiss* embryo-alevin development test.

Test species	*Oncorhynchus mykiss*
Organism source	Ted's Trout, BC
Gamete quality	Small amount of water added to milt on a dry glass slide; verification of vigorous sperm motility using a compound microscope (100 X magnification)
Organism age	<30 minutes post fertilization, <24-hour old gametes
Test type	Static-renewal
Test duration	Test terminated 7 days after ≥50% of controls hatch
Test vessel	4-L plastic containers
Test volume	2 L
Test solution depth	17 cm
Test concentrations	100% (undiluted sample) amended with 20 µg/L Cu, plus laboratory control
Test replicates	6 per treatment
Number of organisms	30 per replicate
Control water	Dechlorinated Metro Vancouver municipal tap water
Test solution renewal	Daily (80% renewal)
Test temperature	14 ± 1°C
Feeding	None
Light intensity	Dark
Photoperiod	24 hours dark; low intensity light used during solution renewals
Aeration	Continuous gentle aeration
Test measurements	Temperature, dissolved oxygen, pH and conductivity measured daily; hardness and alkalinity of undiluted sample measured upon arrival; survival checked daily
Test protocol	Environment Canada (1998), EPS 1/RM/28
Statistical software	CETIS Version 1.9.4
Test endpoint	Survival, viability (which assesses incidence of deformities), length, wet weight
Test acceptability criteria for controls	≥65% normally developed hatched fish
Reference toxicant	Sodium dodecyl sulphate (SDS)

3.0 RESULTS

3.1 *Ceriodaphnia dubia*

Results of the toxicity tests using *C. dubia* are provided in Table 6. Survival and reproduction in the site controls (FR_UFR1, GH_ER2, CM_MC1 and LC_SLC) performed similarly to the laboratory control, indicating that there were no adverse effects associated with the upstream stations.

There were no adverse effects on survival in any of the samples tested; survival ranged between 90 and 100%. Additionally, there were no adverse effects on reproduction in any of the samples tested.

3.2 *Pseudokirchneriella subcapitata*

Results of the toxicity tests using *P. subcapitata* are provided in Table 7. The cell yield in site controls FR_UFR1, GH_ER2, CM_MC1 and LC_SLC was 2.0- to 2.4-fold greater than the laboratory control. This finding is not unusual. The higher ionic strength associated with the site water controls would be expected to stimulate cell growth of this species relative to the very low ionic strength associated with the laboratory control water.

Significantly lower cell yield relative to one or more controls was observed in GH_FR1, EV_HC1, LC_LC3, LC_LC5, and LC_LCDSSLC. Percent stimulation of growth, compared to laboratory control, ranged from 47.7 – 135.6% across samples.

3.3 *Hyalella azteca*

Results of the *H. azteca* toxicity tests are provided in Table 8. Tests were originally initiated with samples from all stations and were successfully terminated. However, a technical laboratory error rendered the organisms collected at termination unusable and final dry weight measurements could not be collected. Survival results from the original test of all stations will be provided in a separate memo. The results included here are derived from a subset of the samples originally intended for testing. Testing for stations associated with the UFR program were re-initiated right away (including the upstream reference station on the Fording), which is why they are shown in this quarterly report. Re-testing for stations associated with the regional program occurred in the third quarter and will therefore be reported in the next quarterly report.

The survival and dry weight of the site control did not differ from those of the laboratory control. Additionally, there were no adverse effects on survival or dry weight in any of the samples tested.

3.4 *Oncorhynchus mykiss*

Results of the toxicity tests using *O. mykiss* are provided in Table 9. The site water controls FR_UFR1, CM_MC1, GH_ER2 and LC_SLC performed similarly to the laboratory control for all endpoints (survival, viability, length, and wet weight), indicating that there were no adverse effects associated with the upstream site waters. Adverse effects on survival were observed in the copper control relative to the laboratory control. The viability, length, and wet weight of the copper control, however, were not affected.

Adverse effects on survival were observed in GH_FR1 and LC_LC5 when compared to one or more controls. Viability of the eggs were also significantly decreased in GH_FR1, LC_LC5 and FR_MULTIPLATE when compared to one or more controls. Survival ranged from 75.6 – 95.4% and embryo viability ranged from 71.1 – 94.3%. No adverse effects on growth endpoints (length and wet weight) were observed in any of the samples tested.

There were no observations of unusual behavior in fish exposed to any of the samples. A new protocol for microbial growth observations was implemented wherein daily observations of the number of fish with microbial growth were divided by whether the affected fish was alive or dead. This quarter, all observations of microbial growth were associated with dead fish. Microbial growth was observed following hatch in one or more replicates of all controls and samples, except the laboratory control. Observations of microbial growth were made as early as day 6 of exposure (FR_FRRD); however, the majority of observations were made when eggs were hatching (on days 26 through 29 of exposure), and this is not an uncommon occurrence in this toxicity test because of the organic material associated with the egg that is released into the test containers during hatch. The sample with the most fish observed to have microbial growth was GH_FR1.

Table 6. Results: *Ceriodaphnia dubia* survival and reproduction test.

Sample ID	Survival (%)	Reproduction (Mean ± SD)

4.0 QA/QC

The health histories of the test organisms used in the exposures were acceptable and met the requirements of the test protocols. All tests met control acceptability criteria. Water quality parameters remained within the ranges specified in the protocols throughout the tests and uncertainty associated with these tests is best described by the standard deviations around the means.

There were no deviations from test methodologies with the exception of planned modifications to the *C. dubia, H. azteca* and *O. mykiss* methods described in Section 2.0. In the *O. mykiss* test, eggs in one of the four replicates were considered non-viable, producing poor results (near complete mortality across all treatments within the first two weeks of exposure). Since the blocked design of the test isolated eggs from individual females into individual replicates across the test, the effect of this non-viable batch of eggs was removed by excluding this replicate from statistical analyses, thereby leaving three replicates with viable eggs for analysis.

Results of the reference toxicant tests conducted during the testing program are summarized in Table 10. Results for these tests fell within the acceptable range for organism performance of two standard deviations around the mean, based on historical results obtained by the laboratory. Thus, the sensitivity of the organisms used in these tests was appropriate. The reference toxicant tests were performed under the same conditions as those used for the samples.

Table 10. Reference toxicant test results.

Test species	Endpoint	Historical mean (2 SD Range)	CV (%)	Test date
C. dubia	Survival (LC50): 2.1 g/L NaCl	2.0 (1.8 – 2.2)	5	May 21, 2021
	Reproduction (IC50): 1.9 g/L NaCl	1.9 (1.5 – 2.3)	11	
P. subcapitata	Growth (IC50): 32.7 µg/L Zn	31.7 (26.0 – 38.5)	10	May 6, 2021
H. azteca	Survival (LC50): 6.9 g/L NaCl	6.1 (3.8-9.8)	24	July 1, 2021
O. mykiss	Viability (EC50): 5.3 mg/L SDS	4.8 (2.2 – 10.4)	41	May 19, 2021

SD = Standard Deviation, CV = Coefficient of Variation, LC = Lethal Concentration, IC = Inhibition Concentration, EC = Effective Concentration

APPENDIX A – *Ceriodaphnia dubia* toxicity test data

Ceriodaphnia dubia Summary Sheet

Client: TECK
Work Order No.: 210962

Start Date/Time: May. 19/21 @ 1400h
Set up by: JZL/GJU

Sample Information:

Sample ID: Various - see below
Sample Date: May. 18/21
Date Received: May. 19/21
Sample Volume: Various

Test Validity Criteria:

1) Mean survival of first generation controls is ≥80 %
2) At least 60% of controls have produced three broods within 8 days
3) An average of ≥15 live young produced per surviving female in the control solutions during the first three broods.
4) Invalid if ephippia observed in any control solution at any time.

WQ Ranges:

T (°C) = 25 ± 1; DO (mg/L) = 3.3 to 8.4 ; pH = 6.0 to 8.5

Test Organism Information:

Broodstock No.: BBO50621A+B ; BBO511218, BB 051321
Age of young (Day 0): <24-h (within 12-h)
Avg No. young in first 3 broods of previous 7 d: 23
Mortality (%) in previous 7 d: 5 %
Individual female # used ≥8 young on test day: ± 4, 6, 9, 12, 37, 38 ; # 71-74, 76, 79, 80 ; 1-10, 12-15, 17-20

NaCl Reference Toxicant Results:

Reference Toxicant ID: Cd284
Stock Solution ID: 21NaCl
Date Initiated: ~~Jun~~ May. 21/21

7-d LC50 (95% CL): 2.1 (2.0-2.2) g/L NaCL
7-d IC50 (95% CL): 1.9 (1.8-2.0) g/L NaCL

7-d LC50 Reference Toxicant Mean and Historical Range: 2.0 (1.8-2.2) g/L NaCL CV (%): 5
7-d IC50 Reference Toxicant Mean and Historical Range: 1.9 (1.5-2.3) g/L NaCL CV (%): 11

Test Results:

APPENDIX B – *Pseudokirchneriella subcapitata* toxicity test data

Pseudokirchneriella subcapitata Summary Sheet

Client: TECK
Work Order No.: 210961

Start Date: May. 20/21
Set up by: SAK

Sample Information:

Sample ID: Various - see below
Sample Date: May. 18/21
Date Received: May. 19/21
Sample Volume: various

Test Organism Information:

Culture Date: May. 14/21
Age of culture (Day 0): 6d

Zinc Reference Toxicant Results:

Reference Toxicant ID: SC214
Stock Solution ID: 21Zn01
Date Initiated: May. 6/21
72-h IC50 (95% CL): 32.7 (31.2 - 33.9) ~~35.0 (32.5 - 36.7)~~ mg/L Zn

72-h IC50 Reference Toxicant Mean and Range: 31.7 (26.0 - 38.5) mg/L ^{Zn} CV (%): 10

Test Results:

All samples are significantly greater than the lab control.
Results that are significantly lower than*:
a = FR_UFR1
b = GH_ER2
c = CM_MC1
d = LC_SLC

	Cell Yield (Mean± SD)
Negative Control	32.0 ± 2.9
FR_UFR1	62.8 ± 7.8 [c]
GH_ER2	64.9 ± 5.5 [c]
CM_MC1	75.4 ± 4.3 [GH_ER2]
LC_SLC	63.1 ± 4.5 [c]
FR_FRABCH	67.5 ± 6.6
FR_FRCP1	68.8 ± 10.5
GH_ERC	66.2 ~~61.5~~ [CM] ± ~~3.4~~ [CM] 6.2
CM_MC2	66.2 ± ~~6.2~~ [CM] 6.8

EC Alga Growth Inhibition Test — **Nautilus Environmental**

Batch ID:	17-9854-5282	**Test Type:**	Cell Growth	**Analyst:**	Sierra Klueppel
Start Date:	20 May-21 16:30	**Protocol:**	EC/EPS 1/RM/25	**Diluent:**	Deionized Water + nutrients
Ending Date:	23 May-21 16:30	**Species:**	Pseudokirchneriella subcapitata	**Brine:**	
Test Length:	72h	**Taxon:**	Chlorophyta	**Source:**	In-House Culture **Age:** 6d

Sample Code	Sample ID	Sample Date	Receipt Date	Sample Age	Client Name	Project
