Report: Elk River Watershed Regional Aquatic Effects Monitoring Program (RAEMP) Report, 2015-2016

Overview: This report presents the results of monitoring undertaken in 2015-2016 to support the evaluation of aquatic ecosystems, per the Regional Aquatic Effects Monitoring Program (RAEMP). The objectives of the RAEMP are to assess effects of mine operations, separately and cumulatively, on the aquatic ecosystems within the Elk River watershed, monitor change over time, and assist in understanding whether management and mitigation actions are working as predicted.

This report was prepared for Teck by Minnow Environmental Inc.

Jennifer Ings, Ph.D.
Aquatic Scientist

EXECUTIVE SUMMARY

The Elk River watershed is located in the southeastern corner of British Columbia (BC). From its headwaters at Elk Lakes near the continental divide, the Elk River flows in a southwesterly direction and into Koocanusa Reservoir about 20 kilometres (km) upstream from the Canada/United States border. Teck Resources Limited (Teck) operates five mines in the Elk River watershed to extract steel-making coal. The five mines are the Fording River Operation (FRO), Greenhills Operation (GHO), Line Creek Operation (LCO), Elkview Operation (EVO), and Coal Mountain Operation (CMO). In response to concerns of increasing water quality concentrations of selenium, cadmium, nitrate and sulphate, as well as calcite formation within watercourses in the Elk Valley, the BC Minister of Environment and Climate Change Strategy (ENV) issued a Minister's Order in April 2013 (Number [No.] M113). The Order outlined a framework to develop the Elk Valley Water Quality Plan (EVWQP) to allow for continued mine development in the Elk Valley while protecting aquatic ecosystem and human health, managing bioaccumulation of contaminants in the receiving environment (including fish tissue), and protecting groundwater. Teck submitted the EVWQP to ENV in July of 2014, and in November of 2014, ENV approved the EVWQP and issued Permit 107517 under the *Environmental Management Act.* The Regional Aquatic Effects Monitoring Program (RAEMP) is one of the requirements stipulated in Permit 107517 and is the subject of this report.

In general, the objectives of the RAEMP are to assess effects of mine operations, separately and cumulatively, on the aquatic ecosystems within the Elk River watershed, monitor change over time, and assist in understanding whether management and mitigation actions are working as predicted by the EVWQP and as intended by the Site Performance Objectives (SPOs) and Compliance Limits reflected in Permit 107517. Monitoring data are presented in an interpretive report every three years.

The first comprehensive cycle of field sampling occurred in 2015, with additional sampling in 2016 at a sub-set of areas. Monitoring data from other programs have been incorporated as applicable to support the evaluation of aquatic ecosystem conditions. This report presents data for water and sediment quality and toxicity, calcite conditions and effects on biota, periphyton and benthic invertebrate productivity, community structure, and tissue selenium concentrations, longnose sucker (LSU) population characteristics, and fish tissue chemistry (particularly selenium in westslope cutthroat trout [WCT], mountain whitefish (MW), and LSU). The outcome of the analysis of each of these components is summarized below, followed by a brief summary of the integrated analysis of conditions within the watershed on a Management Unit (MU) basis.

Water Quality

Water flows in the Elk River watershed vary annually, particularly during spring freshet, after which flows gradually decline toward winter minima. Peak spring water flows in 2012 to 2014 exceeded 10-year averages, especially in 2013 when record flows were observed in mid-June. In 2015, peak freshet flows were near the average, but declined more quickly in June and July. In 2016, freshet flows began earlier and peaked at below-average levels.

Water quality variability among stations downstream of mining relates mainly to variation in concentrations of Order constituents (nitrate, total selenium, and sulphate, and to a lesser degree cadmium), as well as alkalinity, conductivity, hardness, total dissolved solids (TDS), calcium, magnesium, nitrite, sodium, and potassium; and total and dissolved antimony, boron, calcium, chloride, lithium, magnesium, molybdenum, nickel, nitrite, potassium, strontium, and uranium. Water quality variability among mine-exposed stations was also associated with concentrations of total suspended solids (TSS) and turbidity, and substances often associated with particles in the water column (e.g., aluminum, iron, manganese) as well as total organic carbon (TOC) and phosphorus (which likely reflect the mobilization of organic matter during high flows).

Monthly mean concentrations of the key mine-related constituents (nitrate, selenium, and sulphate) tend to be lowest in the upper Elk River and highest in the Fording River. Most stations show a similar seasonal pattern of lowest concentrations in winter and highest concentrations during spring freshet, although there is variability that may relate to periodic precipitation events.

Strong negative correlations with water flow ($r>|0.6|$) were observed for concentrations of alkalinity, as well as total and dissolved lithium, molybdenum, and strontium among reference station samples, but specific conductivity ($r = 0.9$) and dissolved organic carbon ($r = -0.6$) were the only constituents that correlated strongly with water flow among samples collected at mine-exposed stations. Aqueous TSS and/or turbidity correlated strongly ($r>0.6$) with water flow at most individual reference stations, but only weakly when data for reference stations were combined ($r<0.4$), indicating that relationships between flow and TSS/turbidity vary naturally among stations, even among reference stations within close proximity in the watershed. The results suggest that prior to mining, water quality along main stem streams may have varied naturally from headwaters due to differences in water quality among tributary inputs.

A single normal (reference) range was defined for each water quality variable based on combining data for all reference water quality stations monitored by Teck (2012 to 2016) within each month. The upper limit of the normal range was defined as the 97.5th percentile of the combined reference station concentrations for each month (i.e., the upper limit of “normal” was

defined for each month, thereby partially accounting for natural seasonal variations in flow and water quality). This was deemed adequate for identifying areas of the watershed that are being affected by mining because concentrations at mine-exposed areas that are above the normal range for all reference stations combined provides strong evidence of mine-related influence. For aluminum, iron, manganese, and total phosphorus, which correlated strongly with TSS and/or turbidity among reference stations, normal ranges were also defined using a covariate approach. TSS or turbidity, whichever exhibited the strongest linear regression relationship, was used as the covariate.

Normal ranges for most total and dissolved metals were exceeded in more than 10% of samples collected at more than half of the monitoring stations downstream from mining. All samples collected in 2015 at the four monitoring stations in MU5, downstream from all mining, had selenium and nitrate concentrations greater than normal ranges indicating mine-related influence on water quality extends at least to the mouth of the Elk River. In addition to elevated selenium and nitrate concentrations, total and dissolved barium, chloride, and nitrite concentrations were above normal ranges in more than 50% of samples collected at the most downstream station on the Elk River (RG_ELKMOUTH), suggesting these six constituents are the ones most strongly indicative of mine influence on water quality (i.e., conservative tracers). Comparison of aluminum, iron, and manganese concentrations at individual mine-exposed stations to covariate-adjusted normal ranges typically identified a similar or lesser frequency of normal range exceedances than comparison to monthly normal ranges. However, the covariate-adjusted normal range for phosphorus identified more normal range exceedances than the monthly normal range approach at most stations. Results will be discussed with the EMC to determine the preferred approach for future evaluations of mine-related influence on water quality relative to reference station concentrations.

Although BC water guidelines for long-term exposure are based on 30-day mean concentrations, concentrations in individual samples were compared to the guidelines to conservatively identify constituents elevated above guidelines as a result of mining. Normal reference station ranges occasionally exceeded water quality guidelines for total beryllium, total chromium, total iron, and total mercury. Aqueous concentrations measured at mine-exposed stations in 2015 exceeded site-specific benchmarks (SSBMs) or BC guidelines, as well as reference area normal ranges in one or more samples collected at one or more mine-exposed stations for nitrate, sulphate, dissolved cadmium, selenium, TDS, total and dissolved iron, dissolved aluminum, total barium, total beryllium, chloride, total chromium, total cobalt, total mercury, total nickel, nitrite, ammonia, total silver, total thallium, total uranium, and total zinc. The constituents tending to be most elevated above both normal ranges and guidelines in the Elk River watershed as a result of mining were nitrate, total and dissolved selenium, sulphate,

TDS, total (but not dissolved) iron, dissolved aluminum, and total and dissolved uranium. Highest concentrations of all constituents were observed in tributaries closest to mine sources compared to main stem areas.

Concentrations of Order constituents were also evaluated based on maximum (calendar) monthly mean concentrations. Monthly means did not exceed EVWQP Level 1 effect benchmarks for cadmium, selenium, and sulphate among main stem stations, except in the Fording River (selenium and sulphate at FR_FRCP1; selenium at GH_PC2, FR_FRABCH, LC_LC6, and LC_LC5), and in lower Michel Creek (nitrate and selenium at EV_MC2).

Statistically significant increases in nitrate concentrations were observed at six mine-exposed water monitoring stations after 2014 (GH_COUGAR 377%; GH_MC1 1,539%) or 2015 (FR_CC1 99%, LC_DC3 83%, GH_ER1 28%, EV_MC3 65%). Significant increases in selenium were observed at four stations: Kilmarnock Creek (FR_KC1 22% after 2012), upper Dry Creek stations LC_DC3 (38% after 2015) and LC_DCDS (27% after 2015), and Mickelson Creek (GH_MC1 186% after 2014). Increasing sulphate concentrations were observed in Line Creek upstream from the AWTF (LC_LCUSWLC 15% after 2012), at the GHO Elk River Order station (GH_ER1 53% between 2012 and 2016), at Mickelson Creek (GH_MC1 407% after 2014), at Leask Creek (GH_LC2, 142% after 2013), and in Michel Creek upstream from Erickson Creek (EV_MC3; 18% after 2015).

Water quality performance was evaluated for nitrate, selenium, and sulphate at the 12 Order and Compliance Stations within the Elk River watershed, and at the Compliance Station in Koocanusa Reservoir. In most cases, observed concentrations were consistent with or less than modelled concentrations. Selenium and sulphate concentrations in water samples collected at the FRO Compliance Point (FR_FRCP1; MU1) in 2016 were greater than the modelled concentrations. The data indicated that water collected at this location during the winter low flow period is predominantly discharge from Cataract Creek, which explained the high concentrations of selenium and sulphate observed in winter samples.

In MU2, aqueous nitrate concentrations at the LCO Compliance Point (LC_LCDSSLCC) in 2016 were greater than the modelled concentrations due to greater than anticipated loads from Line Creek upstream from West Line Creek. Observed concentrations were also greater than modelled concentrations for one or more constituents at each of the three Compliance Stations in MU4. In the case of EV_HC1, nitrate concentrations remained below water quality guidelines. Higher than expected concentrations at Michel Creek Compliance Stations (CM_MC2 and EV_MC2) may have been due to overestimation of water flows in the regional water quality model (RWQM; Golder 2017a). The RWQM was updated in 2017, so future comparisons of observed to modelled concentrations will be based on the updated model.

Water Toxicity

Teck routinely collects discharge water samples for acute toxicity testing, and surface water samples for chronic toxicity testing in accordance with requirements of Permit 107517. All acute tests completed in 2015 and 2016 using rainbow trout (n=176) were passes (≤50% mortality), as were most tests (169 of 179=94%) completed using *Daphnia magna*. Of the tests that failed, investigation suggested that mortality may have been due to a mineral precipitate (potentially calcite) that formed when the site water was warmed to the laboratory test temperature of 20 ± 2ºC. More than 97% of samples resulting in "passed" *D. magna* or rainbow trout tests had mortalities of 10% or less, which is within the accepted performance range for test control organisms based on the test methods.

In 2015 and 2016 a total of 70 *Ceriodaphnia dubia* (water flea), 70 *Pseudokirchneriella subcapitata* (green alga), 32 *Hyalella azteca* (amphipod), 16 *Pimephales promelas* (fathead minnow), and 36 *Oncorhynchus mykiss* (rainbow trout) chronic toxicity tests were conducted on surface water samples collected in the Elk Valley. Of tests for which a statistically significant response (relative to one or more reference waters) was identified, approximately one third showed a significant effect relative to one but not both reference waters and/or had mean responses within the typical range of test organism performance in reference waters. A review and statistical analysis of water chemistry did not identify any consistent relationships that could explain most of the significant responses, so there is uncertainty regarding whether the results represent an adverse response to toxicants in the test water or variance in test organism performance related to background water quality. Evaluation of whether temporal variation in test organism performance (batch sensitivity) was a potential confounding factor did not result in major differences in the data interpretation (i.e., most responses indicative of toxicity would be classified similarly either with or without control normalization). In 2016, eight tests exhibited a response that was significantly different from responses in reference water samples, below the reference envelope, and potentially attributable to water quality constituents in test waters. Effects to organisms observed in tests with first-quarter samples collected at the Fording River Compliance Point (FR_FRCP1) were attributed to water flowing from Cataract Creek, because the reach of the Fording River upstream of FR_FRCP1 goes dry during the winter low flow period. Additional investigations are underway to evaluate potential causes of the toxicity observed in a subset of the quarterly and semi-annual tests.

Calcite

In 2013, Teck initiated a regional calcite monitoring program to document calcite deposition in tributary and main stem areas of the Elk River watershed. Regional calcite monitoring results from 2015 and 2016 were generally similar to those reported in 2013 and 2014. All reference

streams assessed had calcite index (CI) values of 0.5 or less. Most of the mine-exposed stream kilometres that were assessed (in MUs 1-4 and a portion of MU5) also had a CI of 0.5 or less (≥75% of tributaries and ≥81% of main stem Fording and Elk Rivers). CI of 0.5 is a long-term (Year 2029) SPO specified in Permit 107517 for streams that provide or flow directly into fish habitat.

Analysis of temporal changes in calcite (using data collected from 2013 to 2016, as part of the regional calcite monitoring program) resulted in approximately half of all mine-exposed study areas (52 of 101) showing a significant increase or decrease over time, after accounting for mean trends among reference areas. More specifically, significant increasing trends in CI were identified in 27 reaches and significant decreasing trends were observed in 19 reaches, with most reaches showing significant temporal changes being in tributaries. Significant increases were only observed at two locations in the main stem Fording River: FORD4 (upstream from Line Creek) and FORD5 (vicinity of LCO Dry Creek). In both cases, the increase was due to a step change from 2014 to 2015. When temporal trends in CI were analyzed for main stem mine-exposed stations by MU, increasing average trends were only observed in MU1 (step from 2013 to 2014) and MU2 (step from 2015 to 2016). A decreasing trend was observed in MU5 after 2013, and no changes were identified in MU3 or MU4.

Calcite measurements made among the 40 reference areas sampled as part of the RAEMP in 2015 defined the upper limit (97.5th percentile) of the normal range for reference areas as CI = 1.0. Most (91%) of the mine-exposed areas sampled in the 2015 RAEMP cycle had CI>0.5 but 62% had CI within the upper limit of the normal range (i.e., ≤ 1.0). Areas that were sampled in some tributaries (Kilmarnock, Swift, Cataract, Greenhills, Wolfram, Thompson, and Corbin) and a portion of two areas in the upper Fording River (FOBSC and FOBCP) had CI greater than the upper normal range limit of 1.0. RAEMP data for calcite are based on proportions (%) of areas sampled whereas data for the regional program are based on stream kilometres. To guide interpretation of the regional monitoring results with respect to potential effects on aquatic biota, a separate supporting study was begun in 2014, focusing initially on assessing potential relationships between calcite deposition and both benthic invertebrate community structure and periphyton productivity. The study reported that periphyton chlorophyll-a and ash-free dry mass (AFDM) concentrations were weakly (i.e., r < 0.5) positively correlated with CI values among areas. The results suggested that calcite deposits may provide a surface favourable for periphyton growth, that periphyton growth alters water quality near the periphyton surface in a manner that favours calcite formation, and/or bioavailable nutrient concentrations may be elevated in areas with more calcite. The scientific literature also indicates that calcite formation is the product of complex interaction of abiotic habitat and periphyton community characteristics.

The supporting study did not indicate a specific CI value above which periphyton productivity would be expected to deviate from the normal range.

The same supporting study showed that benthic invertebrate community structure, and especially the proportion of Ephemeroptera, deviated from the reference area normal range when CI was greater than 1.0. However, the analysis also showed that there was strong correlation between CI and the concentrations of mine-related constituents in water among areas such that the effects of calcite could not be conclusively distinguished from potential effects associated with water quality.

Sediment

Sediment chemistry was evaluated at a total of 31 areas in 2013 and/or 2015, including 10 reference areas. Most of the areas chosen for sediment sampling have little or no surface water connection to the main channel flow for at least part of the year. Consequently, sediment samples collected among the 31 study areas were dominated by fine particles (silt and clay). These areas were expected to have the highest sediment accumulations of mine-related substances compared to lotic habitats that are regularly affected by seasonal high flows and associated scouring.

Mining influence on sediment chemistry was most evident as elevated concentrations of selenium and PAHs. Highest concentrations of selenium in sediment were observed at R5-1 (wetland adjacent to the Fording River, near GHO) and GO13 (Goddard Marsh). Highest PAH concentrations were observed in a sample collected at STPD (Stanford Pond near Fernie), but the pattern of PAHs suggested a source other than, or in addition to, coal mining. At areas closer to mining, 2-methylnaphthalene was the PAH found at highest concentrations relative to guidelines, particularly at OTTO (Otto Creek ponds), GO13, and reference area LOLA (Lost Lake). The upper limit of the reference area normal range exceeded the upper sediment quality guideline for selenium, fluorene, 2-methylnaphthalene, naphthalene, and phenanthrene.

Goddard Marsh (GO13) was the only mine-exposed area in which the change in sediment quality in 2015 compared to 2013 was significantly different from the change in reference area mean and each of the three reference areas sampled in both 2013 and 2015, individually. Concentrations of both selenium and PAHs (based on 2-methylnaphthalene) at GO13 were greater than the upper sediment quality guidelines (SQGs) in both years and increased significantly in 2015 relative to the reference areas.

The sediment toxicity supporting study completed in 2016 evaluated a variety of test species, test durations, and biological endpoints to decide which tests were the most appropriate for evaluating sediment toxicity in the Elk Valley. A subset of five mine-exposed areas was chosen

for the study based on having the highest concentrations of mine-related constituents of interest (e.g., selenium, cadmium, and PAHs). Three reference areas were also selected based on having a similar range of physical substrate characteristics (particle size distribution, sediment texture, and TOC content) to the sediments from mine-exposed areas, as well as a natural range of metal and PAH concentrations. The study found that toxicity was observed in samples having highest concentrations of selenium and/or PAHs. The 21-day *Hexagenia* survival and growth test and the 14-day *Hyalella* survival and growth test were recommended for future testing of potential mine-related sediment toxicity.

Periphyton

Periphyton represents an important component of aquatic food webs in the streams within the Elk River watershed and consists of a complex matrix of organisms that can include algae, fungi, bacteria, and protozoa. These organisms take up inorganic nutrients such as nitrogen (e.g., nitrate, nitrite) and phosphorus (e.g., ortho-phosphate), as well as other substances dissolved in water (e.g., selenate), to serve physiological functions and which thereby become available via dietary pathways to consumer organisms at higher trophic levels.

In the RAEMP and associated supporting studies, periphyton were used to evaluate primary productivity (based on chlorophyll-a and AFDM) in mine-exposed areas relative to reference and the BC guideline for chlorophyll-a, tissue selenium concentrations relative to the upper limit of the reference normal range, and differences in community characteristics among mine-exposed and reference areas.

Periphyton AFDM and chlorophyll-a concentrations were within the reference area normal range at ≥ 75% of 58 mine-exposed areas sampled in 2015. Chlorophyll-a concentrations were less than the guideline at 48 of 58 (83%) mine-exposed areas. There was no direct relationship between periphyton chlorophyll-a concentrations and aqueous total phosphorus or orthophosphate concentrations, even though phosphorus is the limiting nutrient within the watershed. Data from the literature suggest there is a threshold (P > 0.030 mg/L) above which periphyton growth may be related to nutrient concentrations, but concentrations in the Elk River watershed are typically less than this value. Instead, primary productivity in the Elk River watershed appears to be mostly related to other habitat factors. The strongest relationship between periphyton productivity endpoints and more than 50 habitat variables evaluated in this study was with calcite index ($p<0.001$, $r=0.55$). As noted above, periphyton potentially provides nucleation sites for calcite formation and/or calcite deposits serve as a suitable substrate for growth of some periphyton species.

Two supporting studies that evaluated periphyton communities in mine-exposed areas compared to reference areas concluded that periphyton communities in the Elk Valley are

sensitive to a variety of habitat factors that likely cannot be measured or effectively controlled in sampling designs or data analysis, and confound detection of mine-related effects.

Benthic Invertebrates

Benthic invertebrate communities were sampled in September 2015 at 40 reference and 59 mine-exposed lotic areas using the Canadian Aquatic Biomonitoring Network (CABIN) kick sampling method for evaluation of community structure (lowest practical level of taxonomy). Additional community samples were collected in 2016 to support the LCO Dry Creek, Line Creek and FRO local aquatic effects monitoring programs (LAEMPs), and to satisfy other data needs by Teck (total of 7 reference and 32 mine-exposed areas). Samples for tissue selenium analysis were also collected at all mine-exposed areas and a subset of reference areas in 2015. Additional tissue selenium samples were collected at a sub-set of areas in 2016.

Benthic invertebrate communities sampled in reference areas were composed mainly of Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies), collectively referred to as EPT. Of the 59 mine-exposed areas sampled in 2015, almost half (27 of 59) had proportions (%) of EPT and/or Ephemeroptera that were less than the reference area normal ranges for those endpoints. % EPT and % Ephemeroptera were inversely related to increasing gradients of mine-related influence on water quality and calcite.

More significant temporal changes were observed for % Ephemeroptera than the other benthic invertebrate community endpoints. Declines were observed in 2015 and 2016 relative to 2012 at main stem areas of the upper Fording River upstream from Ewin Creek (FOUKI, FOBKS, FOBCP, FODPO, and FOUEW) and at the Elk River mouth (ELH93). The other areas (Fording downstream from Greenhills [FODGH] and upstream [FRUL] and downstream [FO23] from Line Creek, as well as mid [MI3] and lower [MI2] Michel Creek) showed a pattern of decreased (lowest) % Ephemeroptera in 2013 compared to 2012, followed by increases in 2015 and 2016, with 2016 values being near the reference mean.

The pattern of lower % Ephemeroptera over a distance of about 12 km in the upper Fording River was identified in the FRO LAEMP report submitted in May 2017. The response appears to be chiefly attributable to declines in abundances of the mayfly families Ephemerellidae and Heptigeniidae. Several factors (e.g., elevated nitrate concentrations, increased temperature, variation in annual flow regimes, seasonal dewatering, and/or calcite deposition) may be influencing benthic invertebrate communities. In consideration of these findings, the FRO LAEMP design was adjusted to allow for further investigation of the cause(s) of benthic invertebrate community changes in September 2017.

Benthic invertebrate tissue selenium concentrations observed in lotic monitoring areas in 2015 and 2016 were compared to predictions that were derived from water modelling and tissue bioaccumulation models developed for the EVWQP. Tissue selenium concentrations were less than the upper prediction interval (i.e., within the range of model uncertainty for individual observations) at all areas except at Bodie Creek (BOCK), although additional areas reflected tissue selenium concentrations that were more than 20% greater than predicted mean concentrations in 2015 and/or 2016. Tissue selenium concentrations measured among mine-exposed areas in 2015 and 2016 were generally at the upper end of, or greater than, the normal range for reference areas (51 of 58 areas = 88%).

Benthic invertebrate tissue selenium concentrations measured in lotic habitats of the watershed since 2006 have typically been less than the EVWQP Level 1 benchmark for effects to invertebrates (13 mg/kg dw), as well as benchmarks for dietary effects to juvenile fish (11 mg/kg dw) and birds (15 mg/kg dw). Most (89%) of the areas sampled in 2015 had invertebrate tissue selenium concentrations less than the lowest benchmark. HQs > 1 occurred mainly in tributaries (e.g., Swift, Greenhills, Line, Wolfram, Thompson, and Bodie), as well as the most downstream Elk River area (ELH93). In 2016, 6 of 32 (19%) benthic invertebrate tissue samples collected in mine-exposed areas had concentrations greater than the benchmark of 11 mg/kg dw. By comparison, benthic invertebrate tissue selenium concentrations in lentic areas have frequently been greater than Level 1 benchmarks, and in 2015, at least one replicate sample exceeded the benchmark in 13 of 18 (72%) mine-exposed areas and one of five (20%) reference areas.

Potential changes in benthic invertebrate tissue selenium concentrations over time were evaluated for all areas having at least two years of data. Significant increases were identified at LILC3 (Line Creek downstream from the AWTF) and at BOCK (Bodie Creek) in 2015 and 2016 compared to 2012. The elevated tissue selenium concentration at LILC3 in 2016 was associated with discharge of selenium from the AWTF that was in a chemical form (i.e., predominantly selenite) that is more readily accumulated by aquatic organisms than the form that is normally found in other parts of the watershed (i.e., selenate). Teck is currently pilot testing an active oxidation process to convert most of the selenium discharged by the AWTF into selenate, which is expected to result in less tissue selenium accumulation in Line Creek after it becomes operational at full-scale. Increases at BOCK compared to predictions and past observations may be related to altered invertebrate communities due to exposure to mine-influenced water downstream of the sediment ponds, exposure to pit dewatering, or some other factor related to proximity to the point of discharge.

Decreasing step changes in benthic invertebrate tissue selenium concentration were observed at EL19 (Elk River downstream from Fording River) and MI2 (lower Michel Creek) after 2006. At all other areas, concentrations observed in 2015 were similar to those observed in one or more previous years.

Among lentic monitoring areas, a decreasing trend in tissue selenium was observed at the former Fording River Oxbow (FO10) in 2015 compared to previous years which is consistent with the transformation of that area from a stagnant lentic habitat to a flowing side-channel after the record storm event in June 2013. The invertebrate tissue selenium concentration at this area in 2015 was less than EVWQP Level 1 benchmarks.

A decreasing trend in invertebrate tissue selenium concentrations was also observed at Otto Ponds (OTTO), where the concentrations measured in 2015 ranged from less than the upper limit of the normal reference area range to greater than Level 1 benchmarks for effects to invertebrates and juvenile fish among the three replicate samples. This trend was supported by a decreasing trend for selenium in water at the Otto Creek monitoring station (EV_OC1). An increasing trend was observed for the Michel Creek wetland (MI16) downstream from CMO; however, no trends were found for aqueous selenium downstream from CMO (CM_MC2).

Longnose Sucker

Longnose sucker (LSU) populations are widespread in the Elk River watershed, being most abundant in small, cool, lentic water bodies that contain vegetative cover and few other fish species. Two reference and ten mine-exposed areas were sampled in May 2015 for evaluation of LSU density, population size, morphometrics, and tissue selenium concentrations. Although not stipulated in the study design, selected areas were revisited in September 2015, to determine if the timing of sampling affects catch success and population estimates.

LSU population estimates varied widely among the twelve study areas in May 2015. Largest population sizes were estimated for Goddard Marsh (GO13), Otto Ponds (OTTO) and Stanford Pond (STPD), where populations were greater than at the reference area. Confidence limits for the LSU population estimates were wide, especially in May.

Mean fork length and body weight were significantly lower for LSU captured at OTTO and STPD than at the reference areas. Based on input from the EMC, evaluation of potential changes over time focused on LSU condition. Increases in condition were observed at three of six areas in 2015 compared to earlier years but the changes were small (<10%) and comparable in magnitude between the reference area and the two mine-exposed areas where the increases were observed.

All LSU captured in six of eight mine-exposed areas where tissues were collected had tissue selenium concentrations greater than the tissue-specific reference normal ranges. The exceptions were the most northerly mine-exposed area, Elk River upper ponds (ERUP) and the unnamed wetland near Morrissey (UNWNMO), where ovary selenium concentrations (2 of 2 at ERUP and 1 of 1 at UNWNMO) and one muscle selenium concentration (of 3 at ERUP and 4 at UNWNMO) exceeded the normal range in each area, but not whole body selenium concentrations (n=5 in both areas). Ovary and muscle selenium concentrations were also above site-specific Level 1 benchmarks for all LSU captured at Goddard Marsh (GO13) and for some of the LSU captured at the Elk River wetland downstream from Grave Creek (ELWDGC) and at Stanford Pond (STPD).

Westslope Cutthroat Trout

Westslope cutthroat trout (WCT) are widely distributed throughout the Elk River watershed and are the only fish present in the Fording River upstream of Josephine Falls. A four-year study (2012 - 2015, inclusive) by Cope et al. (2016) characterized the fluvial population of WCT and their habitat within the upper Fording River watershed. The use of telemetric methods confirmed both resident and migratory life history forms of WCT within the upper Fording River population. The study concluded that the upper Fording River population metrics of sub-adult and adult abundance (2,552 to 3,874 fish > 200 mm fork length), habitat availability (57.5 km of main stem river plus approximately 59 km of tributary habitat), and genetic integrity (pure strain) represent a viable WCT population. Population characteristics such as condition factor (weight to length relationships), growth rates, von Bertalanffy growth model estimates, and population age structure indicate the population appears to be in good condition and robust compared to similar upper Kootenay River populations.

WCT muscle samples were collected non-lethally from main stem areas of the watershed in May and August 2015 to evaluate tissue selenium concentrations relative to predictions, normal ranges, and site-specific effect benchmarks developed in the EVWQP. Although all 90 fish had concentrations near or above the normal range for reference area fish, only one muscle sample (from one of the 10 fish collected in Henretta Lake), exceeded the Level 1 benchmark for reproductive effects. Tissue selenium concentrations were also within prediction intervals derived from water quality and tissue selenium bioaccumulation models developed in the EVWQP.

Mountain Whitefish

Mountain whitefish is a species native to the Elk River basin, where it is found mainly along the main stem of the Elk River and in lower reaches of larger tributaries such as the Fording River, Line Creek, Alexander Creek, and Michel Creek. Selenium concentrations in mountain

whitefish samples collected in 2015 were greater than the reference area normal range for 12 of 20 (60%) of muscle samples and 2 of 20 (15%) ovary samples collected in mine-exposed areas of the Elk River, lower Fording River, and lower Michel Creek. Ovary selenium concentrations were greater than the BC ovary selenium guideline among most reference and mine-exposed mountain whitefish, and 6 of the 20 (30%) individual mine-exposed whitefish captured (from lower Michel Creek and the lower Elk River) had ovary selenium concentrations greater than the estimated lower bound of the effect threshold (29.3 mg/kg dw).

Mountain whitefish have unusually high egg/ovary selenium concentrations relative to muscle compared to other fish species. On average, mountain whitefish ovary selenium concentrations are about 7 times those in muscle, whereas in most other fish species, ovary selenium concentrations are 1 to 2 times those in muscle. Monitoring data since 2006 show that whitefish ovary selenium concentrations tend to be higher in late August or early September than in October, closer to spawning. Therefore, the timing of monitoring was shifted from August-September (2006, 2009) to October (2012, 2015). Ovary samples collected in October 2015 had similar selenium concentrations to those collected in October 2012.

Management Unit 1 (Upper Fording River) Integrated Summary

MU1 includes areas along the main stem Fording River, as well as numerous tributaries as far downstream as Josephine Falls.

Conditions in MU1 in 2015-2016 were largely as expected based on the long history of mining, projections from the EVWQP and monitoring results. Most tributaries in MU1 have been both physically and chemically altered by mining (Minnow 2016e). The upper Fording River WCT population study (Cope et al. 2016) indicated that the fish are in good condition and the population is viable. This is an important finding because it suggests that mine-related effects on WCT are unlikely in lotic habitats of other MUs where main stem concentrations of mine-related stressors are lower, and there is greater access to main stem and tributary habitats with minimal or no disturbance from mining. Teck continues to work with the Regional Fish and Fish Habitat Committee to identify, prioritize, and implement aquatic habitat improvements, with particular focus on MU1 where historical mining has had more effect on the amount and quality of tributary habitat than in other MUs. A Tributary Management Plan is also under development to protect or rehabilitate aquatic ecosystems in tributaries that flow into the Fording River, Michel Creek, and the Elk River.

The main, unexpected observation for MU1 was a reduction in the proportion of Ephemeroptera relative to normal reference area values over a distance of about 12 km of the Fording River main stem since 2012. Several factors were identified as potential causes (e.g., elevated nitrate concentrations increased temperature, variation in annual flow regimes, seasonal dewatering,

and/or calcite deposition) and the FRO LAEMP design was adjusted to allow for further investigation of the cause(s) of benthic invertebrate community changes in September 2017.

Reduced % EPT at lower Swift Creek (GH_SC1 and GH_SC2), and reduced invertebrate abundance at lower Cataract Creek (GH_CC1) have no long-term ecological consequence, because water from these streams will be directed to the future FRO AWTF. Increasing selenium concentrations at Kilmarnock Creek (FR_KC1) will also be addressed by directing a portion of the flow to the future AWTF. Increasing concentrations of nitrate at Clode Ponds decant [FR_CC1] warrant on-going monitoring since concentrations of nitrate already exceed Level 1 benchmarks in much of the Fording River.

Twenty two of 25 mine-exposed tributary and main stem monitoring areas in MU had benthic invertebrate community total abundance and taxa richness within normal reference area ranges. Of 19 and 10 WCT muscle samples collected in lotic and lentic areas of MU1 in 2015, only one fish from the lentic area (Henretta Lake) had a tissue selenium concentration slightly over the EVWQP Level 1 benchmark (HQ > 1) (=3%).

Increasing nitrate and selenium concentrations in upper LCO Dry Creek [LC_DCDS, LC_DC3]) are the expected consequence of advancement of mining into that catchment based on the approved plan for LCOII. The concentrations of mine-related constituents in LCO Dry Creek remain well below levels of concern at the present time.

Management Unit 2 (Lower Fording River) Integrated Summary

MU2 includes areas on the main stem Fording River downstream from Josephine Falls and in two tributaries to the Fording River (Grace Creek [reference] and Line Creek [reference and mine-exposed portions]).

Concentrations of mine-related constituents in water and tissues in MU2 were generally consistent with expectations based on models developed in support of the EVWQP. Exceptions included higher than anticipated aqueous nitrate concentrations due to greater loading than anticipated from Line Creek upstream from West Line Creek, which will be taken into account in the next update of the RWQM. Also, despite significant reductions in total aqueous selenium concentrations, tissue selenium concentrations were elevated in Line Creek immediately downstream from the AWTF in 2016 (compared to predictions and values observed in 2015). This was the result of discharge of selenium from the AWTF that was in a chemical form (i.e., predominantly selenite) that is more readily accumulated by aquatic organisms than the form that is normally found in other parts of the watershed (i.e., selenate). Teck is currently pilot testing an active oxidation process to convert most of the selenium discharged by the AWTF

back to selenate, which is expected to result in less tissue selenium accumulation in Line Creek after it becomes operational at full-scale.

All six mine-exposed tributary and main stem monitoring areas in MU2 had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges. All 10 WCT captured in MU2 in 2015 had muscle selenium concentrations less than the Level 1 benchmark for reproductive effects.

A significant temporal reduction of % Ephemeroptera in the lower Fording River (FO23) occurred after 2012 and then showed consecutive increases in 2013, 2015, and 2016. The 2016 value was within the reference area normal range.

Management Unit 3 (Upper Elk River) Integrated Summary

MU 3 includes the main stem Elk River and its east-side tributaries located to the west of GHO, extending downstream to the mouth of the Fording River. Conditions in MU3 in 2015 to 2016 were generally consistent with expectations based on comparisons of observed conditions to EVWQP predictions and past monitoring results. The exceptions were reduced % EPT and % Ephemeroptera at the monitoring area on the Elk River upstream from the Fording River (ELUFO). No benthic invertebrate community effects were observed at EL20, ELDEL, and ELUEL, closer to GHO sources and HQs for mine-related stressors were also less than one at all four Elk River areas downstream from GHO, suggesting the cause of effects at ELUFO was not mine-related.

Cougar Creek (GH_COUGAR), for which an increasing trend in nitrate concentrations was observed, flows only intermittently. As it is dry much of the year, it has low habitat value within the broader spatial context of MU3.

Step increases in concentrations of nitrate, selenium, and sulphate were observed at Mickelson Creek (GH_ MC1) in all years after 2012, but especially after 2014. Maximum monthly mean concentrations of both nitrate and sulphate were greater than EVWQP Level 1 benchmarks in 2015. Calcite deposition also increased over time, particularly after 2015. It is not considered to be fish bearing, but western toads have been observed within the catchment (Minnow 2016e). The area around Mickelson Creek has been extensively deforested in recent years. This information bears consideration in future cycles of RAEMP or GHO LAEMP study design development.

Sulphate concentrations increased at Leask Creek (GH_LC2) in all years, particularly after 2013 and were above the Level 1 benchmark in 2013. The stream is considered to be non-fish-bearing and the catchment has also been disturbed by logging.

All six mine-exposed tributary and main stem monitoring areas in MU3 had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges. All 10 WCT captured in MU3 in 2015 had muscle selenium concentrations less than the Level 1 benchmark for reproductive effects.

MU3 is very large and includes the Elk River up to its headwaters. The mine-disturbed tributaries have small catchments relative to other mine-disturbed and undisturbed tributaries in MU1-MU4. Therefore the mine-disturbed tributaries represent a small proportion of the total tributary habitat in MU3 and in the watershed as a whole.

Management Unit 4 (Michel Creek and Middle Elk River) Integrated Summary

MU4 is large and encompasses Michel Creek and its tributaries as well as the middle portion of the Elk River and its tributaries. Aqueous concentrations of selenium, nitrate, and sulphate agreed with predictions from EVWQP models at the Order Station in the Elk River downstream from the Fording River (EV_ER1) in 2016. At the CMO Michel Creek Compliance Point (CM_MC2), observed values corresponded reasonably well to modelled values for sulphate; however, selenium and nitrate concentrations were greater than modelled concentrations, which also occurred during the EVWQP model calibration period and may relate to overestimation of flows at that location. Future adjustments to the RWQM are expected to address the few discrepancies noted between observed and modelled concentrations of nitrate, selenium, or sulphate at some water monitoring stations in MU4.

Tissue selenium concentrations in benthic invertebrates were consistent with predicted values, except at Bodie Creek, where observed values were outside of the predicted range in both 2015 and 2016. Increases in tissue selenium concentrations compared to predictions and past observations (2012) may be related to one or more of a number of factors, such as altered invertebrate communities due to exposure to mine-influenced water downstream of the sediment ponds, exposure to pit dewatering, or some other factor related to proximity to the point of discharge.

The reduction in % Ephemeroptera observed in Michel Creek upstream from EVO occurred after 2012 and was followed by consecutive increases in 2015 and 2016, with all values being within the reference area normal range. In spite of significant increases observed after 2015, concentrations of nitrate and sulphate in water remain near or within normal ranges for reference areas (depending on the month) and well below Level 1 benchmarks. Therefore, no further action is warranted other than on-going monitoring.

Another concern that has emerged from the monitoring data for MU4 is elevated concentrations of selenium and PAHs in sediment at Goddard Marsh (GO13) and Otto Creek ponds (OTTO),

and the toxicity response that was observed in laboratory tests of sediment samples from these areas that used standard invertebrate species. There were no significant differences in condition of LSU from GO13 relative to reference, and only a minor increase in condition of LSU from OTTO (6%) but, based on very large differences in area size, habitat characteristics, and LSU population sizes among reference and mine-exposed areas, the relative health of the populations in Goddard Marsh and Otto Ponds is uncertain.

The other monitoring observations for MU4 were consistent with expectations based on past monitoring results. All 15 mine-exposed tributary and main stem monitoring areas in MU4 had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges.

Management Unit 5 – Lower Elk River

MU5 represents the portion of the Elk River downstream from Michel Creek to its mouth at Koocanusa Reservoir. There are no tributaries affected by mining within this MU. Aqueous concentrations of selenium, nitrate, and sulphate agreed with EVWQP model predictions at the Order stations in the Elk River downstream from Michel Creek (EV_ER1) and at the Elko Reservoir (EV_ELKORES) in 2016. Three reference tributaries had water quality, calcite, and benthic invertebrate tissue selenium concentrations within normal ranges, except for elevated sulphate at McCool Creek. Water quality in the Elk River reflected the influence of mining based on NRQs > 1 for nitrate, selenium, and sulphate. Benthic invertebrates collected between Sparwood and ELDFE (Elk River immediately downstream from Fernie) had selenium concentrations within normal ranges, but selenium concentrations were greater than the normal range in invertebrates collected farther downstream near Elko (ELELKO) and near the mouth of the Elk River (ELH93). The most notable finding was temporal reduction in % EPT and % Ephemeroptera immediately upstream the Elk River mouth (ELH93), where values of these endpoints were well below reference area normal ranges. There were no significant changes detected for mine-related stressors, so the cause of the benthic invertebrate community changes is uncertain. Additional samples were collected in 2017 to further investigate conditions at this location. All monitoring areas in MU5 had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges.

Management Unit 6 – Koocanusa Reservoir

Management Unit 6 (MU6) consists of the Canadian portion of Koocanusa Reservoir, which was created when the Libby Dam (Montana) was constructed in 1972. As required under Permit 107517, a three-year study characterizing and comparing chemical and biological conditions downstream from the Elk River relative to upstream was implemented from 2014 to 2016.

Most of the water column within the reservoir was oxygenated with slightly alkaline pH. In situ water quality profiles showed only limited gradients in temperature, oxygen, pH, and conductivity with depth. Findings were consistent with a study completed by Hamilton et al. (1990) which concluded that waters in the Canadian portion of the reservoir remain relatively well-mixed, even during periods of maximum water elevation (May-November), as a result of basin morphometry, continual movement of water from river inputs and reservoir operations, and exposure to strong prevailing winds.

The evaluation of water quality focused on key substances associated with coal mining: nitrate, selenium, and sulphate. Concentrations of these substances were generally similar in water samples collected at middle and bottom depths at all sample locations downstream of the Elk River, but were higher than concentrations measured in samples collected at the surface. Differences between upstream and downstream concentrations were greater in 2016 than 2015 for both nitrate and selenium, but mean concentrations at the downstream areas in 2016 were similar to or less than those observed in 2015. Sulphate concentrations did not differ significantly between downstream and upstream. Site performance objectives for nitrate, selenium, sulphate, and dissolved cadmium were consistently met at the Order station (RG_DSELK).

Sediment samples collected in the reservoir both downstream and upstream from the Elk River were mostly silt (≥60%), with sand and clay comprising smaller fractions. Sediments collected upstream from the Elk River (T2/TN) were significantly sandier (annual means of 2-10%) with less clay (means of 17-19%) than those collected downstream (T4; means of <1% for sand and 26-30% for clay). This may be related to the shallower depths and more fluvial nature of the reservoir upstream of the Elk River (i.e., greater seasonal scour resulting in finer particles accumulating in sediments farther downstream). Total organic carbon content was similar at both areas, ranging from 0.9 to 1.7%.

Concentrations of most metals and polycyclic aromatic hydrocarbons (PAHs) in sediment were higher in sediments collected downstream from the Elk River compared to upstream, but did not increase over the three year study. Concentrations of some metals (upstream and downstream) and PAHs (downstream only) in sediments were above the lower provincial sediment quality guidelines, but none exceeded the higher guidelines. The general pattern of higher concentrations in sediment downstream from the Elk River compared to upstream may be related to a greater proportion of fine sediment particles in the downstream area, providing more surface area for adsorption than larger particles.

The reservoir is considered to be phosphorus limited. Low concentrations of phosphorus and chlorophyll-a, along with low seston and zooplankton biomass, all indicated that the reservoir is

oligotrophic. Phytoplankton communities in the reservoir were numerically dominated by diatoms, and to a lesser extent with Chrysophytes. There were no significant differences in overall phytoplankton density, biomass, or richness between downstream and upstream areas over the three years. Community structure was similar between upstream and downstream areas, except for greater Cyanophyte (biomass at the downstream area, which was considered to have low ecological significance because this group represented <1% of the community.

The zooplankton community was numerically dominated by rotifers and copepods, with relatively low numbers of cladocerans. With the exception of abundance and biomass of cladocerans (tended to be lower downstream from the Elk River compared to upstream), no consistent differences were observed between downstream and upstream areas in overall zooplankton community structure (i.e., density, biomass, richness, and absolute or relative density or biomass of copepods or rotifers), over the three year study. Selenium concentrations in zooplankton were also similar between downstream and upstream areas in all three years.

Benthic invertebrate communities upstream (T2/TN) and downstream (T4) from the Elk River were primarily composed of oligochaetes (mostly immature Tubificinae), insects (various species of chironomids), and ostracods in all three study years. Overall community density and richness did not differ significantly between upstream and downstream areas in any of the three study years. However, the densities of ostracods and oligochaetes were higher at the downstream area compared to upstream. Greater abundance of these organisms may be associated with preference for greater depths and finer sediment texture present at the downstream area, and/or avoidance of coarser, compacted sediments that may dry out during low pool in the upstream area.

Mean benthic invertebrate tissue selenium concentrations were significantly higher at the downstream area (6.9 µg/g dw) than the upstream area (5.0 µg/g dw), and were greater than the BC interim chronic dietary guideline of 4 µg/g dw, but were consistently less than the Level 1 EVWQP benchmarks (based on <10% effect) for growth and reproductive effects to benthic invertebrates (13 mg/kg dw) and for dietary effects to fish (11 mg/kg dw).

Largescale sucker, northern pikeminnow, peamouth chub, redside shiner, and yellow perch were consistently captured in highest numbers at all three fish study areas (i.e., areas within the reservoir in the vicinity of the mouths of Sand Creek, Elk River, and Gold Creek). Other species that were captured included bull trout, burbot, kokanee, longnose sucker, mountain whitefish, pumpkinseed, rainbow trout, slimy sculpin, and westslope cutthroat trout.

Following technical guidance developed by Environment Canada, fish surveys were conducted in April of each study year at each of the three study areas, to assess endpoints indicative of

fish survival (mean age), growth (body size-at-age), reproduction (relative gonad weight) and energy storage (relative liver weight and overall condition). Peamouth chub were targeted in 2014 but additional species (northern pikeminnow, redside shiner, yellow perch, and largescale sucker) were also evaluated in subsequent years. Results were statistically compared between the downstream areas (Elk River and Gold Creek) and the upstream area (Sand Creek). No consistent patterns were observed among fish species, sexes, or sampling years that were indicative of influence from the Elk River.

Tissue samples were collected for analysis of metals from all fish species collected over the three-year study. Some fish had concentrations of selenium in muscle or whole body that were greater than the BC guidelines of 4 µg/g dw for both tissue types. All muscle and whole body samples were less than the USEPA criterion of 11.3 µg/g dw in muscle and 8.5 µg/g dw in whole bodies, except for a single yellow perch with a muscle selenium concentration of 15.0 µg/g dw. Similarly, ovary selenium concentrations were frequently greater than the BC chronic guideline of 11 µg/g dw (particularly in peamouth chub, redside shiner, and northern pikeminnow). All species except redside shiner and northern pikeminnow had mean ovary selenium concentrations less than the EVWQP Level 1 benchmark for reproductive effects to fish (18 mg/kg dw), and the 2016 USEPA guideline of 15.1 µg/g dw. Northern pikeminnow had mean ovary selenium concentrations above the Level 1 benchmark at the Elk River area in only one of the three years they were sampled (2014), when ovaries were relatively undeveloped. Mean redside shiner ovary selenium concentrations were above the Level 1 benchmark at both the Elk River and the Sand Creek areas in both years sampled.

Data obtained during the 2014 to 2016 sampling program are being used to design the next phase (2018 to 2020) of chemical and biological monitoring in the Canadian portion of Koocanusa reservoir. Results of all monitoring will be considered in the weight of evidence evaluation of MU6, which is currently under development in consultation with the EMC.

LIST OF TABLES

ACRONYMS AND ABBREVIATIONS

ABMP – Area-based management plan (refers to Elk Valley Water Quality Plan)

AFDM – Ash-free dry mass (in this project, refers to periphyton)

AMP – Adaptive Management Plan

ANOVA – Analysis of Variance

ANCOVA – Analysis of Covariance

APHA – American Public Health Association

AWTF – Active Water Treatment Facility

BACI – Before-After Control-Impact

CABIN – Canadian Aquatic Biomonitoring Network (Environment Canada 2012a,b).

CI – Calcite Index

CIp – Calcite Presence Score (Number of particles with calcite)/(Number of particles counted)

CIc – Calcite Concretion Score (Sum of particle concretion score)/(Number of particles counted)

CMO – Coal Mountain Operation

CSM – Conceptual Site Model

CV – Coefficients of Variation

CPUE – Catch-per-unit-effort

CRC ICP-MS – Collision Reaction Cell Inductively Coupled Plasma-Mass Spectrophotometry

CRFD – Cumulative Relative Frequency Distributions

CVAFS – Cold Vapour Atomic Fluorescence Spectrophotometry

CV – Coefficient of Variation

DO – Dissolved Oxygen

DOC – Dissolved Organic Carbon

DQA – Data Quality Assessment

DQO – Data Quality Objective

dw – Dry Weight

EA – Environmental Assessment

EF – Enrichment Function

EMC – Environmental Monitoring Committee

ENV – British Columbia Ministry of Environment and Climate Change Strategy (formerly BCMOE)

EPA – Environmental Protection Agency

EPT – Ephemeroptera (mayflies), Plecoptera (stoneflies), Trichoptera (caddisflies)

EVO – Elkview Operation

EVWQP – Elk Valley Water Quality Plan

FRO – Fording River Operation

GIS – Geographic Information System

GHO – Greenhills Operation

GPS – Global Positioning System

HR – High Resolution

HQ – Hazard Quotient, computed by dividing an measured value by a value that represents a threshold for potential effects

HSD – Honestly Significant Differences

ICP-MS – Inductively Coupled Plasma Mass Spectrometry

IQR – Interquartile Range

KNC – Ktunaxa Nation Council

KS – Kolmogorov-Smirnov statistical test

km – Kilometres

LAEMP – Local Aquatic Effects Monitoring Program

LCO – Line Creek Operation

LPL – Lowest Practical Level, referring to taxonomic identification of benthic invertebrates

LRL – Laboratory Reporting Limit

LSU – Longnose Sucker

m – Metres

MW – Mountain Whitefish

MU – Management Unit

MURR – University if Missouri's Research Reactor Center

NAA – Neutron Activation Analysis

NMDS – Nonmetric Multidimensional Scaling Ordination

N:P – Total Nitrogen to Total Phosphorus

NRQ – Normal Range Quotient. Computed by dividing a measured value by the upper limit of the normal reference area range (97.5th percentile) for a given sample type and measurement endpoint

PAH – Polycyclic Aromatic Hydrocarbon

PCA – Principal Components Analysis

PC-x – (as in PC-1) referring to one of the summary variables resulting from a Principal Components Analysis

Qx – referring to calendar quarters

QA/QC – Quality Assurance / Quality Control

r – Correlation Coefficient

RAEMP – Regional Aquatic Effects Monitoring Program

RM – Repeated Measures

SPO – Site Performance Objective

SQG - Sediment Quality Guideline

SRC – Saskatchewan Research Council

SSBM – Site-Specific Benchmarks

TDS – Total Dissolved Solids

TIE – Toxicity Identification Evaluation

TKN – Total Kjeldahl Nitrogen

TOC – Total Organic Carbon

TSS – Total Suspended Solids

TTF – Trophic Transfer Factors or Functions

USEPA – U.S. Environmental Protection Agency

UTM – Universal Transverse Mercator system

VIE – Visible Implant Elastomer

WCT – Westslope Cutthroat Trout

DEFINITIONS

algae – simple rootless, unicellular plants containing chlorophyll that grow in sunlit waters in proportion to the amount of available nutrients.

allochthonous – material that is imported into an ecosystem (in this report referring to organic material and nutrients in the aquatic ecosystem that have terrestrial origin)

ANOVA – analysis of variance

autochthonous – native to or produced within an ecosystem (e.g., algae are autochthonous sources of energy in the aquatic ecosystem)

bacteria – single-celled microorganisms that lack chlorophyll.

basin – the area drained by a river and its tributaries.

benthic – pertaining to the bottom substrates of aquatic environments.

benthic invertebrates – animals (without backbones) living in or on the bottom of a water body. Also referred to as benthic macroinvertebrates, infauna, or macrobenthos.

bioaccumulation – the accumulation of substances in an organism, which occurs when the rate of absorption exceeds the rate of loss by catabolism or excretion.

bioavailable – when a substance is in a form that can be absorbed into the body/tissues of an organism.

biota – referring to plant or animal life

calcite – a precipitate created by the reaction of dissolved calcium (Ca2+) and carbonate (CO_3^2) ions under conditions of saturated carbonate and/or increasing water pH or calcium concentrations.

community – an assemblage of populations of different species living together in space and time.

conceptual site model – a picture and/or written description used to describe sources of environmental stressors and the physical-chemical processes that control fate and exposure pathways relevant to evaluating environmental conditions and potential effects to receptors

consumer – any organism which consumes other organisms (living or dead) to satisfy its energy needs.

detritus – suspended or deposited organic matter resulting from the decomposition of plants and animal tissues or waste products.

emergent vegetation – aquatic plants (macrophytes), the greater part of which, including the leaves, protrudes from the surface of the water, although its roots are under water (e.g., cattails, bulrushes).

enrichment – in ecology, enrichment usually refers to the addition of nitrogen, phosphorus and carbon compounds or other nutrients into a lake or other waterway that greatly increases the growth potential for algae and other aquatic plants. In contaminant ecology, it can refer to the relative concentrations of a contaminant in organisms relative to their environment (e.g., water or sediment concentrations).

Ephemeroptera – mayflies

family – Biological classification between genus and order.

food chain – series of organisms, each eating or decomposing the preceding one (with the exception of food producers, which obtain their food by assimilation of inorganic nutrients). The succession of trophic levels through which energy flows.

food web – complex network of many interconnected food chains and feeding interactions.

genus – biological classification between family and species

habitat – a place where the physical and biological elements of ecosystems provide a suitable environment including the food, cover, and space resources needed for plant and animal livelihood.

in situ – in the natural or original place

lentic – traditionally refers to standing or still water bodies. In this study, the definition has been broadened to include relatively slow-flowing habitats (see also lotic).

lotic – traditionally refers to any flowing aquatic system, such as streams or rivers. In this study, the definition has been more narrowly applied to relatively fast-flowing habitats typical of much of the Elk River watershed (see also lentic).

macrophyte – large, rooted or floating aquatic plants that may bear flowers and seeds. Some plants, like duckweed and coontail, are free-floating and are not attached to the bottom.

macroinvertebrate – organisms without backbones that are visible to the eye without the aid of a microscope.

nutrient – materials that are considered essential to the support of biological life; in freshwater systems, nitrogen and phosphorus are particularly important for supporting plant life at the base of the food web

organic matter – the components of live or dead plant or animal matter possessing a carbon-hydrogen structure.

Order – biological classification between class and family

otolith – An ear stone (or calcareous concretion) in the inner ear of a bony fish. Each year, a new concretion (layer of bone) is added, which can be used to measure age.

periphyton – the aggregation of algae and other organisms that form on stones and other substrates on streambeds and the lake bottom (see also epilithon and epipelon).

Plecoptera – stoneflies

post hoc – in this study referring to statistical procedures to test for differences in sample values between or among sample means following ANOVA

receiving environment/water – the waterbody inhabited by aquatic biota (receptors) into which an anthropogenically-affected discharge (e.g., effluent) flows

receptor – an organism that could be adversely affected by environmental stressors

RM ANOVA – repeated measures analysis of variance

stressor – a chemical or biological agent, environmental condition, external stimulus or an event that causes stress to an organism.

substrate – "supporting surface" on which an organism grows. The substrate may simply provide structural support, or may provide water and nutrients. A substrate may be inorganic, such as rock or soil, or it may be organic, such as wood.

taxa – Plural of taxon, representing any group or rank in a biological classification into which related organisms are classified.

Trichoptera – caddisflies

taxonomy – the classification of organisms into groups on the basis of shared characteristics.

trophic level – the position occupied by an organism within a food web.

trophic transfer – transfer of food energy through levels of a food web; dietary uptake.

watershed – the natural geographic region drained by one or more watercourses and their tributaries.

wetland – areas of vegetation that are transitional between land and water bodies and range from being permanently wet to intermittently water covered.

1 INTRODUCTION

1.1 Background

1.1.1 Setting

The Elk River watershed is located in the southeastern corner of British Columbia (BC) in the rugged terrain of the Front and Border Ranges of the Rocky Mountains, with peaks up to 3,300 metres (m) in the north and 2,200 m in the south. From its headwaters at Elk Lakes near the continental divide, the Elk River flows in a southwesterly direction and into Koocanusa Reservoir about 20 kilometres (km) upstream from the Canada/United States (U.S.) border (Swain 2007; Kennedy et al. 2000). Koocanusa Reservoir was created by the damming of the Kootenay[1] River at Libby, Montana, U.S., in 1972 (HydroQual 1990).

The Ktunaxa First Nation has occupied lands in the region for more than 10,000 years (KNC 2005). Rivers and streams of the region provide culturally important sources of fish and plants. The Ktunaxa Territory is divided into traditional land districts historically associated with key actors in the Ktunaxa creation story, but also with specific key resources and with specific Ktunaxa individuals or lineages that held particular authority and responsibility for stewardship of resources in those areas (Robertson 2010).

Teck Coal Limited (Teck) operates five mines in the Elk River watershed to extract steel-making coal. The five mines are the Fording River Operation (FRO), Greenhills Operation (GHO), Line Creek Operation (LCO), Elkview Operation (EVO), and Coal Mountain Operation (CMO; Figure 1.1).

1.1.2 Elk Valley Water Quality Plan and Permit 107517

In response to concerns of increasing water quality concentrations of selenium, cadmium, nitrate and sulphate[2], as well as calcite formation within watercourses in the Elk Valley, the BC Minister of Environment and Climate Change Strategy (ENV) issued a Minister's Order in April 2013 (Number [No.] M113). The Order outlined a framework to develop an area-based management plan (ABMP), the Elk Valley Water Quality Plan (EVWQP), to allow for continued mining development in the Elk Valley while achieving the following outcomes:

- protection of aquatic ecosystem health;

[1] Spelled "Kootenai" in U.S.

[2] Collectively referred to as "Order constituents" because they are specifically named in Provincial Order M113.

- management of bioaccumulation of contaminants in the receiving environment (including fish tissue);
- protection of human health; and
- protection of groundwater.

In 2013 and 2014, Teck worked with First Nations, governments, other stakeholders and scientists to develop the EVWQP (Teck 2014). The EVWQP was designed for the Elk River watershed and the Canadian portion of Koocanusa Reservoir, which represents the Designated Area referred to in Order M113. The EVWQP divided the Designated Area into six management units (MUs) based on geographic features, major tributaries and hydrodynamic characteristics (Figure 1.2), five of which are in the Elk River watershed, while the Canadian portion of Koocanusa Reservoir represents the sixth MU[3].

The process of developing the EVWQP incorporated water, sediment, and biological monitoring data to characterize baseline conditions, assess current conditions with respect to aquatic ecosystem and human health, and project future water quality. The water quality assessment identified that selenium and nitrate concentrations in the Elk River were routinely greater than water quality guidelines, and were increasing in many areas (Windward et al. 2014, Teck 2014). Selenium bioaccumulation was evident in fish and other biota, and localized effects on biota were observed near some mine sources. Results from Teck's research and technology development program revealed that active water treatment was the most effective option for stabilizing selenium and nitrate concentrations in the near-term (Teck 2014).

Short-, medium-, and long-term targets were derived for specific ("Order") stations in the EVWQP to protect aquatic ecosystem health at an MU scale (Teck 2014). The EVWQP also outlined the initial implementation plan for achieving targets including phased commissioning of active water treatment facilities in relevant areas of the watershed.

Teck submitted the EVWQP to ENV in July of 2014. In November of 2014, ENV approved the EVWQP and issued Permit 107517[4] under the *Environmental Management Act.* Permit 107517 regulates discharges from Teck's five Elk Valley mine operations in a manner consistent with the EVWQP, and is periodically amended in response to new learnings. The Permit specifies water quality limits and site performance objectives (SPOs) for monitoring stations downstream from the mines, and outlines requirements for commissioning and operating active water

[3] Conditions in Koocanusa Reservoir have been studied separately (Minnow 2018) and results of that monitoring program are summarized in this report.

[4] Permit 107517 was most recently amended in March 1, 2017.

treatment facilities (AWTFs), tributary evaluation and management, calcite management, toxicity testing, monitoring of water quality, flow and aquatic effects, and adaptive management and reporting.

Teck's Regional Aquatic Effects Monitoring Program (RAEMP) is also one of the requirements stipulated in Permit 107517 and is the subject of this report. The requirement for RAEMP reporting and submission is as follows:

> *(Section 10.6) "The RAEMP report for the first approved cycle under the ABMP must be submitted to the Director by September 30, 2017 and by September 30 of the final year of each subsequent three year monitoring cycle. The Permittee shall submit a report that contains a detailed rationalization of the overall RAEMP including reasons why specific monitoring areas are/are not being monitored in a given year. The report may include a discussion and analysis of the results of the previous cycle of monitoring of the following components:*
>
> 1. *Water quality*
> 2. *Sediment quality and calcite*
> 3. *Water and sediment toxicity testing*
> 4. *Periphyton productivity and community structure*
> 5. *Benthic invertebrate community structure and tissue contaminants*
> 6. *Fish population metrics and tissue contaminants*
> 7. *Amphibian and bird egg tissue contaminants*
> 8. *QA/QC*
>
> *Each report will also discuss cumulative effects by providing an integrated interpretation of conditions in the Elk River Watershed. Each report will, on a three year cycle, verify and calibrate the selenium bioaccumulation model using the most recent three years of water quality, aquatic effects and other data from any special studies undertaken."*

1.2 Regional Aquatic Effects Monitoring

1.2.1 Overview

The RAEMP provides spatially comprehensive monitoring and assessment of potential mine-related effects on the aquatic environment downstream from Teck's coal mines in the Elk Valley. Although implementation of the RAEMP is the responsibility of Teck, the program was designed with input and advice from ENV and the Ktunaxa Nation Council (KNC). The RAEMP study

design was submitted to ENV by Teck in November, 2014, updated in response to approval conditions from ENV (BCMOE 2014), re-submitted in March 2015 (Minnow 2015a), and approved by ENV in October 2015 (BCMOE 2015). The RAEMP involves completion of a sampling program and interpretive report every three years, as well as annual sampling for selected components. The first comprehensive cycle of field sampling occurred in 2015, with additional sampling in 2016 at a sub-set of areas in accordance with the approved study design. This report presents the results of the 2015-2016 monitoring cycle.

Permit 107517 also required Teck to develop local aquatic effects monitoring programs (LAEMPs) at LCO, FRO, and GHO to assess localized concerns on a more frequent and/or spatially intensive basis. A LAEMP is also in place for LCO Dry Creek under a separate permit. LAEMPs are required at specific areas until sufficient data have been collected, concerns no longer exist, or relevant monitoring can be incorporated into the RAEMP. Data from these programs have been included, as applicable, in this report.

Teck conducts a variety of additional programs to monitor, evaluate, and/or manage the aquatic effects of mining operations within the Elk Valley at local and regional scales:

- Water Quality Monitoring Program
- Flow Monitoring Plan
- Calcite Monitoring Program
- Chronic Toxicity Testing Program
- Fish and Fish Habitat Management Program
- Tributary Evaluation and Management Plan

Some of these programs are still under development. Relevant data from these programs are summarized in this report to describe and support assessment of conditions in the aquatic habitats of the Elk River watershed downstream from Teck's mines.

After the RAEMP design was approved and implemented in 2015, Teck established an Environmental Monitoring Committee (EMC), consisting of representatives from Teck, ENV, the Ministry of Energy and Mines, the KNC, Interior Health Authority, and an Independent Scientist[5]. The EMC reviews submissions and provides technical advice and input to Teck and the ENV Director, as stipulated in Section 12.2 of Permit 107517. Throughout 2016 and early 2017, draft

[5] Environment Canada has also agreed to provide its perspectives on matters related to Permit 107517 and the Committee's activities, on a case-by-case basis when requested by the Committee. To-date, the Committee has not called on Environment Canada to participate.

results from the 2015 to 2016 RAEMP cycle (and LAEMPs) were presented to, and discussed with the EMC. The input provided by the EMC was incorporated into this report.

The RAEMP report was submitted September 30, 2017, in draft, for EMC review and has been updated for submission January 31, 2018, based on input received.

1.2.2 Conceptual Site Models

A conceptual site model (CSM) provides the framework to summarize and illustrate the chemical, physical, and biological processes and interactions relevant to evaluating potential effects on environmental receptors. Chemical and physical CSMs (Figures 1.3 and 1.4) were developed and ultimately integrated (Figure 1.5) to assist with understanding and evaluating potential cumulative effects associated with coal mining, and were the basis on which the study design for the RAEMP was developed (Minnow 2015a).

1.2.3 Objectives

The general objectives of the RAEMP are to:

- Assess effects of mine operations on the aquatic ecosystem of the Elk River watershed, and monitor changes over time, relative to expectations established in approved plans for mine development and in Permit 107517; and
- Assist in understanding whether management and mitigation actions are working as predicted by the EVWQP (Teck 2014) and as intended by the Site Performance Objectives (SPOs) and Compliance Limits reflected in Permit 107517.

Specific objectives of the RAEMP cycle were framed as questions to guide data analysis and interpretation, and were developed collaboratively among Teck, ENV, and KNC representatives (Minnow 2015a):

1. What are the mine-related chemical and physical changes to aquatic ecosystems and where do they occur?
2. Are mine-related chemical and physical changes to the aquatic environment resulting in unacceptable biological effects and where do they occur?
3. What are the specific mine-related sources of any unacceptable changes to chemical, physical, or biological conditions?
4. How are chemical, physical, and biological conditions changing over time?
5. What are the consequences of observed biological effects to the aquatic ecosystem?

6. Are the mine-related chemical and physical changes and/or biological effects impacting water and aquatic ecosystem uses?

The monitoring results presented in this report have been evaluated relative to the questions presented above; however, the questions are being updated for the 2018-2020 cycle of the RAEMP, so that data analysis and interpretation will lead to improved understanding of the influences of mining on the aquatic ecosystem of the Elk River watershed and Koocanusa Reservoir and feed more clearly and directly into Teck's Adaptive Management Plan (AMP).

1.3 Linkages to Teck's Adaptive Management Plan

As required by Section 11 of Permit 107517, Teck has also developed an AMP to support implementation of the EVWQP, achieve water quality and calcite targets, ensure human health and the environment are protected (and where necessary, restored), and facilitate continuous improvement of water quality in the Elk Valley (Teck 2016b). The AMP is structured around a set of six overarching environmental Management Questions that collectively address the environmental management objectives of the AMP and the EVWQP. In addition, the AMP identifies Key Uncertainties underlying each Management Question, which if reduced, either help confirm that Teck's current management actions are appropriate, or lead to refinements or changes that would better achievement of the EVWQP objectives. Monitoring data and evaluations conducted within the RAEMP are designed to support answering AMP Management Question #5, (currently worded as "Does monitoring for mine-related effects indicate that the aquatic ecosystem is healthy?") and Key Uncertainty 5.1 (currently worded as "How will monitoring data be used to identify potentially important mine-related effects on aquatic ecosystem health at a management unit scale?"). The RAEMP evaluates data to address these AMP questions. Should management response be required associated with findings from this analysis, additional investigations or adjustments would likely occur within the AMP itself.

Data, and to a lesser extent, analysis conducted under the RAEMP, will also contribute to answering AMP Management Question #2 (currently worded as "Will aquatic ecosystem health be protected by meeting the long-term site performance objectives?"), by assessing the aquatic ecosystem under a range of current conditions and identifying areas where biological effects may be occurring due to one or more mine-related constituents. The RAEMP will also contribute information to help reduce Key Uncertainty 2.1 (currently worded as "How will the science-based benchmarks be validated and updated?") and Key Uncertainty 2.2 (currently worded as "How will the integrated assessment methodology used to derive area-based SPOs be validated and updated?"). Assessments associated with these AMP components will primarily be conducted separately from the RAEMP.

Specific information collected under the RAEMP will also be used to help reduce Key Uncertainty 4.1 (currently worded as “Are the calcite SPOs ecologically relevant and protective of fish and aquatic life?”) and provide data required for Management Question 6 (currently worded as “Is water quality being managed to be protective of human health?”). Assessments associated with these AMP components will be conducted outside the RAEMP.

The above context related to Teck’s AMP also guides the evaluation of monitoring data presented in this report.

The AMP was submitted to ENV on February 29, 2016, as required by the Permit. Following this, the EMC reviewed the AMP and provided substantial technical advice. Teck considered this advice and submitted a revised AMP to the EMC on July 31, 2016. The EMC reviewed the revised submission and provided additional technical advice, concluding in September 2016. Teck then re-submitted the revised AMP to ENV. In October 2016, after review of the resubmitted AMP, KNC wrote a letter that outlined key concerns with the submission. KNC, Teck, and ENV continue to work towards addressing the concerns about the AMP identified by the KNC.

1.4 Aquatic Ecosystem Health

As noted above in Section 1.1.2, one of the environmental management goals of the EVWQP is to protect aquatic ecosystem health, from which arose Management Question #5 in the AMP: “Does monitoring for mine-related effects indicate that the aquatic ecosystem is healthy?” Permit 107517 also refers to ecosystem health (Sections 5 and 11). However, the term “health” is not defined in the EVWQP or in Permit 107517. Teck received input from the EMC on the definition of the term “aquatic ecosystem health” to facilitate development of a framework for analyzing and interpreting monitoring data to decide if the aquatic ecosystem is healthy or if further management action is needed.

Following discussions with the EMC, Teck proposed the following definition for aquatic ecosystem health, which is similar to that used by Environment Canada (Kilgour et al. 2005, 2007),

> “A healthy aquatic ecosystem is one in which the chemical and physical conditions support a biological community that is diverse and functioning, with normal assemblages and abundances of organisms.”

There was support but not complete consensus for this definition within the EMC. In part, this is because the term “health” originated as a property of organisms and is an unsuitable metaphor for ecosystems (Suter 1993). Most importantly, ecosystem health is not an objective scientific concept and instead is defined by specific societal values and goals (Costanza 1992,

Suter 1993, Lancaster 2000, Lu et al. 2015), which are not necessarily shared equally among stakeholders. Although it is relatively straightforward to measure aquatic ecosystem properties, integrated interpretation of data to judge overall "health" or "quality" of the ecosystem necessitates human value judgements (Costanza 1992, Rapport et al. 1998, Pollard and Huxam 1998).

The tentative definition of ecosystem health presented above is consistent with the approach and values underlying the EVWQP and the need for interpreting monitoring data at spatial scales relevant to the home ranges of relevant indigenous biota (e.g., fish). However, Teck will continue to work with the EMC to determine if a more suitable, consensus term or description can be developed for future reports to articulate aquatic ecosystem conditions in a manner that is consistent with the objectives of the EVWQP.

2 METHODS

2.1 Overview

The RAEMP was implemented according to the design described by Minnow (2015a), which was approved by ENV in October, 2015 (BCMOE 2015). As outlined by the design, sampling was comprehensive in 2015, and repeated for a subset of areas, sample types, and endpoints in 2016. Deviations from the approved design were few, and are discussed in the following sections where applicable.

Sampling areas are shown on maps in each section where data are presented.

2.2 Water

2.2.1 Routine Water Monitoring by Teck

Data from Teck's water quality monitoring program are stored in Teck's EQuIS™ database. Data for the 2012-2016 monitoring period were downloaded and provided to Minnow in an Excel workbook for data analyses.

2.2.2 Water Sampling Associated with the RAEMP

Water samples were collected at areas sampled for periphyton productivity and tissue selenium analysis, benthic invertebrate community assessment and tissue selenium analysis, and longnose sucker population monitoring areas in 2015.

In lotic areas, water samples were collected by wading into mid-channel (or as far into the channel as was practical and safe to do so), moving from downstream to upstream, to avoid collecting water downstream of disturbed substrates. In lentic areas, water samples were collected by wading from downstream to upstream in an area where some flow was present, from shore or from a boat. All samples were collected at arm's length below the water surface or, in shallower waters, at mid-depth. Sample bottles were not pre-rinsed.

Samples requiring preservatives were preserved on shore. Bottles were filled to minimize the amount of air in the container. Once re-capped, bottles were inverted two or three times to mix the preservative with the water sample. Water samples being analyzed for dissolved organic carbon (DOC) and dissolved metals were filtered in the field using a clean syringe affixed with a 0.45 µm membrane. Following filtering, the samples were preserved immediately as specified by the analytical laboratory. Water samples were stored in a cooler with ice or freezer packs during the day and then transferred to a refrigerator at the end of the day. Water samples were re-packed in coolers with ice and/or freezer packs for shipment to the analytical laboratory each

day or every other day. Samples were shipped to ALS Environmental in Calgary, Alberta, for analysis.

At the laboratory, samples were analyzed for the following analytes using the methods indicated in parentheses:

- total organic carbon (TOC) and DOC (combustion method; American Public Health Association [APHA] 5310 for TOC);
- total suspended solids (TSS) and total dissolved solids (TDS) (gravimetric method; APHA 2540 D and C for TSS and TDS, respectively);
- alkalinity (potentiometric titration; APHA 2320);
- turbidity (nephelometric method; APHA 2130 Turbidity);
- hardness, as $CaCO_3$ (by calculation; APHA 2340 B);
- total and dissolved metals[6], (collision cell inductively coupled plasma - mass spectrometry and inductively coupled plasma - optical emission spectrophotometry; APHA 3030 B&E / Environmental Protection Agency (EPA) SW-846 6020A, and EPA 3005A/6010B, respectively);
- bromide, chloride, fluoride, and sulphate (ion chromatography; APHA 4110 B);
- ammonia, as N (fluorescence; J. Env. Monit., 2005, 7:37-42);
- nitrate and nitrite, as N (ion chromatography; EPA 300.0);
- total Kjeldahl nitrogen (TKN) (fluorescence; APHA 4500-NORG D.); and
- orthophosphate and total phosphorus (colourimetric method; APHA 4500-P Phosphorus).

Temperature, dissolved oxygen (DO), pH, and specific conductance/conductivity were measured in each sampling area using a YSI ProPlus meter (or equivalent) that was calibrated daily (or multiple times per day for DO, if moving among high- and low-elevation areas). Water velocity was measured at all lotic benthic invertebrate sampling areas using a Marsh-McBirney Flowmate. Sampling area locations were marked using a hand-held global positioning system (GPS) unit. All field measurements were recorded on standardized field data collection forms copied on waterproof paper.

[6] Here and elsewhere in this document, “metals” includes metalloids, such as selenium.

2.2.3 Data Analysis

To support evaluation of potential mine-related effects on productivity, ratios of aqueous total nitrogen to total phosphorus (N:P mass/volume) for reference and mine-exposed stations were plotted using a boxplot for samples collected in September 2015. The boxplots were defined using the minimum, first quartile (Q1), median, third quartile (Q3), and maximum values. When extreme values were present [values above Q3 + 1.5(IQR) or below Q1 – 1.5(IQR); IQR = Q3 – Q1] then the extreme values were plotted as individual points and the whiskers of the plot were truncated to the next value in the data set (Figure 2.1). N:P ratios of < 7 were used to indicate nitrogen limitation and N:P ratios > 15 were used to indicate phosphorus limitation (McDowell et al. 2009).

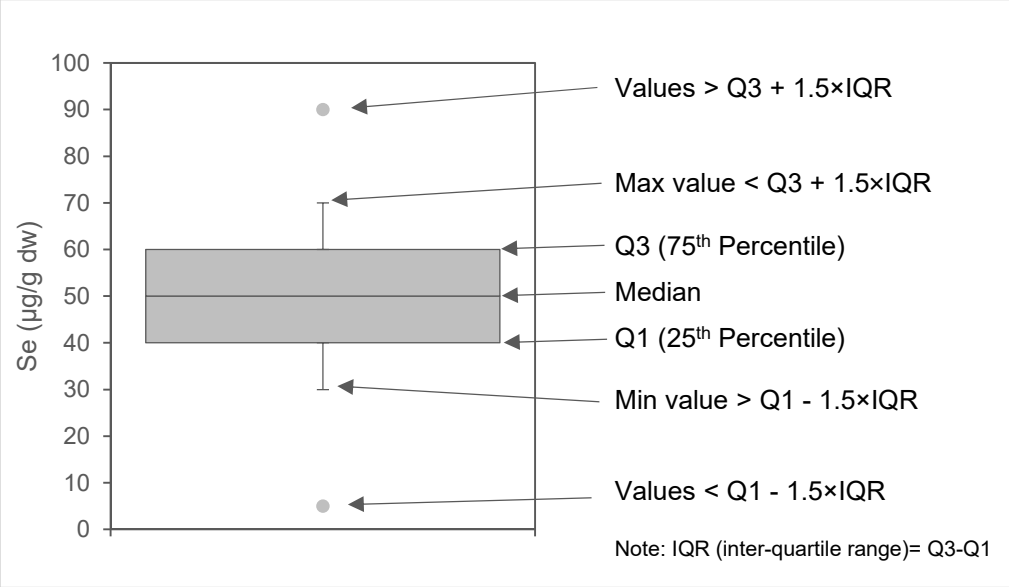

Figure 2.1: Description of Boxplot

Reference station normal ranges were defined for all analytes separately by month to account for seasonal variability in concentrations of constituents in water. The normal ranges were defined as the 2.5th and 97.5th percentiles of monthly mean concentrations for each reference station for each year between 2012 and 2016. The percentiles were estimated using the *quantile* function in R (R Core Team, 2017) using the default Type 7 method. The percentiles were estimated based on a survival curve for censored data generated using the *survfit* function in R (*survival* package; Therneau 2017) to accommodate values below the laboratory reporting limit (LRL) (i.e., the Kaplan-Meier method). Outliers in the reference station datasets were defined as values that exceeded Q3 + 1.5(IQR) on the untransformed and $\log_{10}$-transformed scales and were removed from estimation of the normal ranges. In additional to the 2.5th and

97.5th percentiles, the following summary statistics were calculated for each reference station data set by month: sample size, minimum value, 25th percentile, median, 75th percentile, maximum value, mean, and standard deviation.

Spearman rank correlations were conducted to evaluate monotonic trends between all parameters and potential covariates known to influence water quality: flow rates, total suspended solids, and turbidity. Correlations were performed using the Hmisc package (version 4.1-1; Harrell 2017) in R. Instantaneous flow rates were converted to daily flow rates and used for the correlations. Flow rates reported as zero were not included in the correlation analyses. Data reported as below the LRL were substituted with the LRL for the correlation analysis. For total phosphorus, samples at the poor LRL (i.e., reported as <0.3 mg/L) were excluded. Correlations were performed separately for the reference (2012-2016) and mine-exposed (2015) stations. Spearman rank correlations were also conducted between total suspended solids, turbidity, and flow rates for individual reference stations for data collected in all years. Correlations with a correlation coefficient (r) with magnitude greater than 0.6 were considered strong (Milton and Arnold 2002), and significance was tested at $\alpha = 0.05$.

For parameters with strong monotonic correlations with turbidity or total suspended solids (total aluminum, iron, manganese, and phosphorus), covariate adjusted normal ranges were defined to account for the influence of suspended particles on water quality. The relationships were approximately linear, so linear regression models were developed for these parameters with data for all reference stations (2012 to 2016) using turbidity and total suspended solids as predictor variables. Outliers were defined as observations with residuals beyond Q3 + 1.5 (IQR) or Q1 - 1.5 (IQR) and were removed from the regression. The predictor variable with the highest r^2 was chosen as the covariate for the adjusted normal ranges. The 97.5th percentile of the residuals of the regression model was added to the regression model equation to produce an equation for the upper limit of the normal range. For individual samples, concurrent predictor variable concentrations (i.e., total suspended solids or turbidity) and the adjusted model equation were used to define a sample-specific covariate-adjusted normal range. Since mine-exposure could cause elevated covariate concentrations, data for individual samples were screened against the covariate-adjusted normal range using either the individual sample covariate concentration or the upper limit of the monthly normal range for the covariate, whichever was smaller.

In order to evaluate the potential proximity to mine-exposure, individual sample data at all mine-exposed stations (2015) were screened against upper monthly normal ranges (e.g., parameters for a sample collected in January would be screened against the upper normal range determined for January). In addition, data collected at reference stations in 2015 were screened

against monthly normal ranges in order to assess how frequently reference stations sampled in 2015 naturally exceeded the normal range determined for 2012 to 2016. Only stations with data collected in at least 8 months in 2015 were included in the analysis in ensure sufficient annual coverage. One exception with 7 months was included, LC_LC1, in order to include more reference stations in the analysis.

Normal range quotients (NRQs) for individual samples for all reference and all mine-exposed stations sampled in 2015 were calculated as the ratio of the sample concentration to the upper limit of the normal range for a given month. For analytes with covariate-adjusted normal ranges, the NRQ was determined using either the individual sample covariate-adjusted normal range or monthly normal range, whichever was smaller. Exceedances of normal ranges by individual samples was determined as a percent. An exception was dissolved oxygen, for which impacts to aquatic life occur at low, not high concentrations, and NRQs were calculated by dividing the monthly lower normal range by the concentration of individual samples.

Individual samples were screened against British Columbia guidelines for the protection of aquatic life (Table 2.1; BCMOE 2017a,b). For analytes with site-specific benchmarks (SSBMs) – nitrate, sulphate, dissolved cadmium, total selenium, and total dissolved solids – individual samples were screened against SSBMs (Teck 2014). Conservative guideline screening was undertaken, whereby chronic guidelines were used when available, and otherwise acute guidelines were used. For analyte-dependent guidelines (e.g., hardness- and pH-dependent guidelines), guidelines were calculated using analytes measured concurrently with individual samples, and these were used to screen individual samples. The frequency of guideline or SSBM exceedances was determined for each analyte and station with sufficient data, and those analytes with exceedances were reported. In order to characterize the frequency of mine-exposure related exceedances of guidelines, the frequency of individual samples in excess of both the upper limit of the normal range and guideline or SSBM were reported. In addition, monthly means used to define the normal range were screened against water quality guidelines and SSBMs in order to determine how often these values were naturally in exceedance of guidelines. For analyte-dependent guidelines, individual monthly means were screened against guidelines calculated using concurrent analyte values. The frequency of guideline exceedance was determined for each month (e.g., January for all years) for all reference stations.

Hazard quotients (HQ) were calculated for individual samples using individual sample guidelines (when applicable) by dividing the concentration by the guideline. Dissolved oxygen was an exception, since the guideline is a minimum, and the HQ was calculated by dividing the guideline by the concentration. For each station and analyte with guideline exceedances, the maximum HQ for all individual samples was reported, as well as for the subset of samples in

Table 2.1: British Columbia Water Quality Guidelines for Parameters Potentially Relevant to Teck Coal

Variable		Units	British Columbia Water Quality Guidelines [1]		Year	Status	Site Specific Benchmark [2]
			Long-term Average	Short-term Maximum			
Non-Metals	Total Alkalinity	mg/L	For dissolved calcium = < 4mg/L, WQG = <10 For dissolved calcium = 4 to 8 mg/L, WQG = 10 to 20 For dissolved calcuim = > 8 mg/L, WQG = > 20	-	2015	Working	-

[1] British Columbia Working (BCMOE 2017a) or Accepted (BCMOE 2017b) Water Quality Guidelines for the Protection of Aquatic Life. For guidelines dependent on other analytes (e.g., hardness), guidelines were screened using concurrent values.

[2] When appropriate, site specific benchmarks were applied instead of BC water quality guidelines (Teck 2014)

[3] Temperature and pH dependent; range of minimum and maximum values.

[4] Dependent on concurrent chloride, range of values reported (BCMOE 2017a)

[5] Dissolved oxygen guidelines represent a minimum value, and so exceedances were quantified below this guideline.

[6] Unrestricted change permitted within this pH range.

[7] For hardness-based guidelines, concurrent hardness values were used for calculating guidelines. If hardness values exceeding the maximum applicable hardness, then guidelines were determined using the maximum applicable hardness.

[8] Chromium(VI) is the dominant oxidation state in oxygenated environments, and so its guideline was applied.

[9] The most conservative guideline (0.00000125 mg/L) was applied.

exceedance of the normal range. In addition, for individual samples in exceedance of both the normal range and guideline, the minimum of the NRQ and HQ ratios was determined for each individual sample, and the maximum of these ratios was reported for each station.

Normal range quotients (NRQs) were calculated for the order constituents for all reference and all mine-exposed stations sampled in 2015 for each month, as the ratio of the monthly mean concentration to the upper limit of the normal range for the given month. Monthly mean hazard quotients (HQs) were calculated for all reference and all mine-exposed stations sampled in 2015 for each month, as the mean of the ratios of concentration to the site-specific benchmarks (Table 2.2) for each month.

Table 2.2: Level 1 (10%) Water Effect Benchmarks Identified in the Elk Valley Water Quality Plan

Constituent	Management Unit	Concentration	Units
Total Selenium	1	70	µg/L
	2 to 6	19	µg/L
Dissolved Cadmium	1 to 6	$10^{0.83(\log(\text{hardness}))-2.53}$ [a]	µg/L
Nitrate-N	1, 2	$10^{1.0003[\log(\text{hardness})]-1.52}$ [b]	mg/L
	3 to 6	3	mg/L
Sulphate	1 to 5	429	mg/L
	6	308	mg/L

[a] Maximum guideline at hardness = 285 mg/L
[b] Maximum guideline at hardness = 500 mg/L

A principal component analysis (PCA) was conducted on all water quality samples collected as part of Teck's routine water monitoring. The PCA is a multivariate analysis which transforms a group of n variables into a smaller new set of uncorrelated variables (the principal components; PCs). The principal components are defined to be linear combinations of the original n variables. The method was used to identify PCs that explained the most variability in water quality among areas. The PCA was conducted on $\log_{10}$-transformed data using the correlation matrix. Analytes with 50% or more values below the detection limit were excluded from the analysis.

A PCA was also conducted using the water quality data collected from lotic habitats from sampling associated with the RAEMP (i.e., concurrent with benthic invertebrate samples in September, 2015). A PCA was conducted five different ways based on input from the EMC:

- using concentrations of all water quality variables (log_{10}-transformed) and the correlation matrix;
- using hazard quotients of all water quality variables (log_{10}-transformed) and the covariance matrix;
- using hazard quotients of all water quality variables and calcite index (CI) (log_{10}-transformed) and the covariance matrix;
- using concentrations of key water quality variables and calcite index (log_{10}-transformed) and the covariance matrix; and
- using hazard quotients of key water quality variables and calcite index (log_{10}-transformed) and the covariance matrix.

A PCA was also conducted using the water quality data collected from lentic habitats from sampling associated with the RAEMP in May, August, and September, 2015.

The primary objectives of the PCAs were to identify the PC that explains the difference between mine-exposed and reference stations and identify the water quality constituents associated with that PC. Correlations among the first two PCs and each water quality variable were evaluated using Pearson correlation coefficients.

Temporal changes in key constituent concentrations (i.e., nitrate, total selenium, and sulphate) were evaluated in mine-exposed stations relative to the mean change in reference stations from 2012 to 2016. The analysis was conducted as an analysis of variance (ANOVA) on the difference in monthly mean concentrations (log_{10}-transformed) between the mine-exposed station and the monthly mean reference station with Year as a factor, with up to 12 differences calculated per year for a complete data set. The monthly means for the reference stations were based on six stations (CM_MC1, FR_UFR1, RG_CH1, GH_ER2, LC_GRCK, and LC_SLC) that were consistently sampled from 2012 - 2016. If the overall ANOVA was significant ($\alpha = 0.05$) then *post hoc* contrasts were conducted to test for linear and step changes according to the following hypotheses (for a mine-exposed station sampled in all five years):

- A linear change from 2012 to 2016;
- A step change after 2012 (i.e., a comparison of the mean in 2012 to the mean of 2013-2016);
- A step change after 2013 (i.e., a comparison of the mean of 2012-2013 to the mean of 2014-2016);

- A step change after 2014 (i.e., a comparison of the mean of 2012-2014 to the mean of 2015-2016); and
- A step change after 2015 (i.e., a comparison of the mean of 2012-2015 to the mean in 2016).

The contrasts were conducted in Microsoft Excel, following the methods described in Oehlert (2010). When more than one contrast hypothesis was identified as statistically significant ($\alpha = 0.05$), then the contrast with the best fit was used for interpretation. The contrast with the best fit was defined to be the contrast with the largest difference in the numerator of the test statistic (equivalent to selecting the contrast with the smallest p-value). The magnitude of difference for linear contrasts was calculated as:

$$\frac{10^{\bar{x}_{OBS2016exp}} - 10^{\bar{x}_{PRED2016exp}}}{10^{\bar{x}_{PRED2016exp}}} \times 100\%$$

where $\bar{x}_{OBS2016exp}$ is the observed mean for the mine-exposed station in 2016 and $\bar{x}_{PRED2016exp}$ is the predicted mean for the mine exposed station in 2016, assuming that the relative difference between reference and mine-exposed stations in 2016 is the same as the difference observed in 2012 (i.e., $\bar{x}_{PRED2016exp} = \bar{x}_{OBS2016ref} + \bar{x}_{OBS2012exp} - \bar{x}_{OBS2012ref}$). The means $\bar{x}_{OBS2016exp}$ and $\bar{x}_{PRED2016exp}$ were anti-logged prior to calculating the percent difference in order to put the concentrations in the original data units. The magnitude of difference for step change contrasts was calculated similarly as:

$$\frac{10^{\bar{x}_{OBS(Post\ Step)exp}} - 10^{\bar{x}_{PRED(Post\ Step)exp}}}{10^{\bar{x}_{PRED(Post\ Step)exp}}} \times 100\%$$

where $\bar{x}_{OBS(Post\ Step)exp}$is the observed mean for the mine-exposed station after the step change and $\bar{x}_{PRED(Post\ Step)exp}$ is the predicted mean for the mine-exposed station in 2016, assuming that the relative difference between reference and mine-exposed stations after the step change is the same as the difference observed prior to the step change (i.e., $\bar{x}_{PRED(Post\ Step)exp} = \bar{x}_{OBS(Post\ Step)ref} + \bar{x}_{OBS(Pre\ Step)exp} - \bar{x}_{OBS(Pre\ Step)ref}$).

The contrasts and magnitude of difference calculations were modified as appropriate when a mine-exposed station was not sampled in all five years to accommodate the available data.

Temporal trends for main stem stations by management unit were evaluated using the same methods described above, but the differences were calculated as the difference in the mean concentration for main stem mine-exposed stations and the mean reference stations. The temporal analyses at the station scale and the management unit scale were also conducted for mine-exposed stations without the adjustment to control for changes in the reference stations.

2.3 Toxicity Testing

2.3.1 Acute Testing

Acute toxicity tests are routinely conducted on discharge and receiving water samples collected by Teck in accordance with requirements of Sections 7.2, 10.2.2, 10.2.4, 10.3, and Appendix 2 of Permit 107517. The test organisms are *Oncorhynchus mykiss* (rainbow trout; 96-hour exposures; Environment Canada 1990b) and *Daphnia magna* (48-hour exposures; Environment Canada 1990a). Tests with no more than 50% mortality are considered acceptable (a "pass"). The results are presented in annual water quality reports (Teck 2016a, 2017a) and are summarized in this report.

2.3.2 Chronic Testing

Requirements for chronic toxicity testing are specified in Section 9.8 of Permit 107517 and a letter from the MOE to Teck, dated November 14, 2014, which approved the RAEMP study design (BCMOE 2014). Requirements include bioassays every three years, beginning in 2015, to evaluate the survival and development of wild, fertilized westslope cutthroat trout eggs incubated in a laboratory. The Permit also requires semi-annual laboratory tests using rainbow trout (survival, hatch, growth, deformity, behavior in 30-day exposures beginning with eggs that are <24 hours post-fertilization; Environment Canada 1998), quarterly tests (at all compliance points) of the water flea *Ceriodaphnia dubia* (7-day survival and reproduction; Environment Canada 2007b) and the alga *Pseudokirchneriella subcapitata* (72-hour growth; Environment Canada 2007a), and quarterly testing (at FRO and GHO Compliance Points in the Fording River and the CMO Compliance Point in Michel Creek) using the amphipod *Hyalella azteca* (28-day survival and growth; adapted from USEPA 2000) and fathead minnow (*Pimephales promelas*; survival, hatch, growth, and deformities in 30-day exposures beginning with eggs that are <24 hours post-fertilization; USEPA 1996). Annual reports of results have been prepared by Golder (2016, 2017b) and results are summarized in this report.

2.4 Calcite

2.4.1 Regional Calcite Monitoring

2.4.1.1 Approach

In 2013, Teck initiated a regional calcite monitoring program to document calcite deposition in tributary and main stem areas of the Elk River watershed (Lotic et al. 2013). Annual reports were prepared by Lotic Environmental for monitoring completed in 2013 to 2016 (Lotic 2014a, 2015-2017) and results are summarized in this report.

The regional program measures calcite deposits at one to three 100-m-long areas (depending on the reach size) in numerous reaches defined throughout the watershed. At each 100-m-long area showing any evidence of calcite, a modified Wolman (1954) pebble count procedure was applied involving random selection and measurement of 100 substrate particles throughout each 100-m-long area (and distributed in proportion to the habitat types present). Calcite deposition was characterized by recording the presence (score = 1) or absence (score = 0) of calcite on each substrate particle, and the degree of concretion was assessed by determining if the particle was removed with negligible resistance (not concreted; score = 0), noticeable resistance but removable (partially concreted; score = 1), or immovable (fully concreted; score = 2). Substrate that was too fine to be retrieved (e.g., sand, silt) and to visually discern calcite presence/absence was assigned presence and concretion scores of "0".

The results for each area were then expressed as a CI based on the following equation:

CI = CIp + CIc

Where:

CI = Calcite Index
CIp = Calcite Presence Score = (Number of particles with calcite)/(Number of particles counted)
CIc = Calcite Concretion Score = (Sum of particle concretion score)/(Number of particles counted)

This results in CI values ranging from 0 (no calcite present) to 3.0 (calcite present on all particles and fully concreted). Up to three 100 m areas were surveyed within each stream reach and the averaged calcite index value was considered representative of the linear stream distance of each reach.

2.4.2 Calcite Measurements at Biological Sampling Areas

2.4.2.1 Approach

To guide interpretation of the regional monitoring results with respect to potential effects on aquatic biota, a separate supporting study was initiated by Teck in September 2014[7] (Minnow 2015d). The study of biological effects of calcite focused initially on assessing potential relationships between calcite deposition and both benthic invertebrate community

[7] Study requirements were subsequently stipulated in the MOE's approval of the RAEMP (i.e., letter to Teck dated November 14, 2014), which stated: "Teck shall complete the assessment to determine the potential relationships between calcite and benthic invertebrate community structure, periphyton productivity, and fish spawning and incubation success. Teck shall work in collaboration with the Ministry and Ktunaxa Nation representatives ideally in a monitoring committee forum to prepare study designs for work proposed in 2015 and 2016."

structure and periphyton productivity (Minnow 2016b). Calcite deposition was evaluated at all biological sampling areas in the supporting study, using methods applied in the regional monitoring program, except for the following modifications:

- Calcite was measured only in riffle habitats in the immediate vicinity of where invertebrate samples were collected (e.g., ~10 m distance), whereas the 100-m-long areas sampled in the regional program may include glide and cascade habitats;
- No calcite score was assigned in the biological monitoring programs when fine sediments (sand, silt, clay) were encountered; instead the sampler noted the presences of fines and moved to the next rock where calcite presence or absence could be visibly ascertained; and
- Calcite measured in association with biological sampling areas was done in the first half of September, whereas regional calcite monitoring was typically completed in late September to early December, depending on the year.

The areas sampled in the supporting study in 2015 included all of the areas associated with the RAEMP, the LCO Dry Creek LAEMP (Minnow 2016a) and the LCO Line Creek LAEMP (Minnow 2016c) and additional areas specific to that study. The same approach was used for calcite measurement in 2016 for annual RAEMP sampling (this report), in the LCO LAEMPs (Minnow 2017b,c) and the first year of the FRO LAEMP (Minnow 2017a).

In 2015, the supporting study of calcite effects on biota was expanded to investigate potential effects on fish spawning and incubation success (Minnow 2016b; Ecofish 2016, 2017; Ecofish and Westslope 2017). Evaluation of potential effects on fish is on-going but the results of studies completed to date are summarized in this report.

2.4.2.2 Data Analysis

The normal range for calcite index was defined as the 2.5th and 97.5th percentiles of the distribution of calcite index values observed in reference areas sampled concurrently with the RAEMP benthic invertebrate sampling in September, 2015. Outliers were evaluated using the methods described in Section 2.2.3. NRQs for 2015 and 2016 reference and mine-exposed areas were calculated as the ratio of the CI to the upper limit of the normal range for calcite index.

The temporal analysis for calcite index was conducted using the regional calcite monitoring data collected from 2013 to 2016 (Lotic 2014a, 2015-2017). The analysis was conducted using a repeated measures (RM) ANOVA followed by *post hoc* contrasts to test for differences relative to the mean change at the reference stations. The RM ANOVA model was fit using all data as:

$$CI = Year + Steam + Station(Stream) + Stream \times Year + \varepsilon$$

where *CI* is calcite index, *Year* is a categorical factor for year, *Stream* is a fixed factor, *Station* is a fixed factor for the station and nested in *Stream* because each station is fixed within a particular stream, *Stream*×*Year* represents the interaction between stream and year, and is the ε error term. *Post hoc* contrasts were then conducted to determine which mine-exposed streams are "trending" differently from the mean reference "trend" by testing for linear and step changes (Section 2.2.3). Table 2.3 provides example contrast coefficients for a comparison of a mine-exposed stream with three stations, assuming three reference streams with two stations sampled in each reference stream.

Table 2.3: Example Contrast Coefficients for Testing for a Linear Change and A Step Change after 2013, with 4 Years of Data

Stream	Station	Contrast Coefficients (Linear)				Contrast Coefficients (Step Change After 2013)			
		2013	2014	2015	2016	2013	2014	2015	2016
Exp1	1	-1/3	-1/9	1/9	1/3	-1/3	1/9	1/9	1/9
Exp1	2	-1/3	-1/9	1/9	1/3	-1/3	1/9	1/9	1/9
Exp1	3	-1/3	-1/9	1/9	1/3	-1/3	1/9	1/9	1/9
Ref1	1	1/6	1/18	-1/18	-1/6	1/6	-1/18	-1/18	-1/18
Ref1	2	1/6	1/18	-1/18	-1/6	1/6	-1/18	-1/18	-1/18
Ref2	1	1/6	1/18	-1/18	-1/6	1/6	-1/18	-1/18	-1/18
Ref2	2	1/6	1/18	-1/18	-1/6	1/6	-1/18	-1/18	-1/18
Ref3	1	1/6	1/18	-1/18	-1/6	1/6	-1/18	-1/18	-1/18
Ref3	2	1/6	1/18	-1/18	-1/6	1/6	-1/18	-1/18	-1/18

The contrasts were conducted in Microsoft Excel, following the methods described in Oehlert (2010). When more than one contrast hypothesis was identified as statistically significant ($\alpha = 0.05$), then the contrast with the best fit was used for interpretation. The contrast with the best fit was defined to be the contrast with the largest difference in the numerator of the test statistic (equivalent to selecting the contrast with the smallest p-value). The magnitude of difference (in units of CI) for linear contrasts was calculated as:

$$\bar{x}_{OBS2016exp} - \bar{x}_{PRED2016exp}$$

where $\bar{x}_{OBS2016exp}$ is the observed mean for the mine-exposed stream in 2016 and $\bar{x}_{PRED2016exp}$ is the predicted mean for the mine exposed stream in 2016, assuming that the relative difference between reference and mine-exposed streams in 2016 is the same as the difference observed in 2012 (i.e., $\bar{x}_{PRED2016exp} = \bar{x}_{OBS2016ref} + \bar{x}_{OBS2012exp} - \bar{x}_{OBS2012ref}$). The magnitude of difference for step change contrasts was calculated similarly as:

$$\bar{x}_{OBS(Post\ Step)exp} - \bar{x}_{PRED(Post\ Step)exp}$$

where $\bar{x}_{OBS(Post\ Step)exp}$is the observed mean for the mine-exposed stream after the step change and $\bar{x}_{PRED(Post\ Step)exp}$ is the predicted mean for the mine-exposed stream in 2016, assuming that the relative difference between reference and mine-exposed streams after the step change is the same as the difference observed prior to the step change (i.e., $\bar{x}_{PRED(Post\ Step)exp} = \bar{x}_{OBS(Post\ Step)ref} + \bar{x}_{OBS(Pre\ Step)exp} - \bar{x}_{OBS(Pre\ Step)ref}$).

The contrasts and magnitude of difference calculations were modified as appropriate when a mine-exposed station was not sampled in all five years to accommodate the available data.

Temporal trends for main stem mine-exposed stations by stream and management unit were evaluated using the same methods described above, but the differences were calculated as the difference in the mean CI value for main stem mine-exposed stations and the mean CI value for reference stations.

2.5 Sediment

2.5.1 Sampling

Sampling methods in 2015 were similar to 2013 except that replicates were increased from three stations per area in 2013 to five stations per area in 2015. All samples were collected using a 10.2 cm (4 inch) inside diameter corer, stainless steel Petite Ponar grab sampler (0.023 m^2 sampling area), or stainless steel spoon, depending on the sampling conditions in each area. For example, if the corer was unable to adequately penetrate the sediments to allow for retrieval of the sample without slippage and loss of sample from the core tube (particularly in deeper areas), a Petite Ponar grab was used instead. Coring was attempted in all areas prior to using a Ponar. A spoon was only used in areas where heavy *Chara* spp. coverage and rocky substrate prevented collection of sediments using a corer or ponar. Depending on the depth of the overlying water, the sampling device was deployed from a boat or by individuals on foot. In either case, the sampling area was approached in such a way as to avoid disturbance of sediments before sampling.

Upon selection of each sediment sampling station, the location was recorded using a handheld GPS, and *in situ* water quality measurements (i.e., DO, pH, temperature and specific conductance) were taken using a field meter (i.e., YSI 650 MDS or YSI ProPlus). Water quality measurements were taken approximately 0.5 m above the sediment-water interface in areas deeper than 0.5 m, and mid-column between the water surface and sediment in areas shallower than 0.5 m.

When conditions were conducive to coring and the corer was being deployed from a boat, care was taken to control the rate of descent and to maintain the corer in a vertical position during ascent. When the corer was deployed on foot, care was taken to ensure the area being sampled was not influenced by individuals collecting the sample. After the core penetrated the sediment, it was carefully retrieved and an extruder inserted into the bottom of the core tube. The core extruder was used to push sediments upwards towards the top of the core tube in a controlled fashion to minimize suspension of fine particles. In the event of suspension, momentum was stopped to allow the solids to re-settle. Once the sediment was near the top of the tube, an extrusion collar marked in 1 cm intervals was aligned on the top of the tube and the sediment was extruded upwards to a depth of 2 cm. A core slicer was carefully inserted between the tube and the collar, the collar/slicer removed, and the sample transferred from the slicer to a clean plastic tub. Core samples were rejected if there was evidence of slippage, disturbance of the sediment-water interface, or inadequate penetration of the substrate. A photograph was taken of each core, and the total number of core attempts, penetration depths, and visible sediment characteristics (i.e., the presence of epibenthic organisms or stratification) were recorded on field sheets. This process was completed five more times (for a total of six cores), to ensure sufficient sample amount for all required analyses. The six sub-samples collected at each station were homogenized using a stainless steel spoon. The homogenized sediment was split amongst a glass jar (for analysis of polycyclic aromatic hydrocarbons [PAHs]) and a large Ziploc® bag (all other analyses – see Section 2.5.2).

In areas sampled by Petite Ponar (Appendix Table E.1), a total of six grabs were collected to form a single composite sample. Each grab sample was gently opened and lifted to release the collected sediment into a clean plastic tub. If the sample was not complete to each edge of the Ponar or lacked an intact sediment-water surface layer it was discarded and a new sample collected. The 10.2 cm core collar utilized for obtaining the surface sediments during coring was placed into the top of the sediment to a depth of 2 cm. The core slicer was inserted into the sediment immediately under the core collar and retrieved with the core collar. Excess sediment surrounding the core collar was removed and the sediment within the core collar (top 2 cm) placed into a separate tub. Collection of sediment was repeated in this manner five more times. The six sub-samples collected at each station were then homogenized using a stainless steel spoon and split amongst a glass jar and a large labelled Ziploc® bag.

The single area (STPD) that could not be effectively sampled by core or ponar was sampled using a stainless steel spoon (Appendix Table E.1). The spoon was carefully inserted approximately 2 cm into the substrate and retrieved as slow as possible through the water column to ensure minimal loss of fines. Each spoonful of sediment was then transferred to a

clean plastic tub, and after sufficient volume was obtained, the sediments were mixed using a stainless steel spoon, and split amongst a glass jar and a large labelled Ziploc® bag.

All samples were subsequently placed in a cooler with ice and transferred to a refrigerator later in the day.

2.5.2 Laboratory Analysis

Sediment samples for chemical analysis were sent to ALS Environmental in Calgary, AB for analysis. The laboratory was instructed to thoroughly homogenize each sediment sample before analysis (according to standard laboratory protocols), to ensure sub-samples were representative and comparable. Separate sub-samples were taken for analysis of moisture content, particle size, pH, TOC, and metals (<1 mm fraction[8]) from samples submitted in Ziploc® bags. Samples submitted in glass jars were used for analysis of PAHs. With respect to metals analysis, the <1 mm fraction is considered representative of whole sediments because samples were only collected from depositional areas dominated by fine-grained sediments. Laboratory screening at 1 mm ensures that the small sub-sample that is analyzed does not contain any large particles that would not be considered representative of the sample as a whole and could bias results.

Sediment samples were analyzed using the following methods: metals by Collision Reaction Cell Inductively Coupled Plasma-Mass Spectrophotometry (CRC ICP-MS; EPA 200.2/6020A), mercury by Cold Vapour Atomic Fluorescence Spectrophotometry (CVAFS; EPA 200.2/245.7), TOC by combustion method (Bartels and Sparks 2009), and PAHs by rotary extraction using hexane/acetone (EPA 3570/8270) followed by capillary column gas chromatography with mass spectrometric detection (GC/MS). Particle size distribution was determined by dry sieving (coarse particles), wet sieving (sand) and the pipette sedimentation method (fines) (SSIR-51 Method 3.2.1).

2.5.3 Data Analysis

Normal ranges and summary statistics for sediment chemistry constituents were calculated using reference area data from 2013 and 2015, following the same methods and outlier identification as for water quality (Section 2.2.3). NRQs were calculated as the ratio of the concentration of each parameter in sediment to the upper limit of the normal range. The

[8] The laboratory normally sieves out particles large than 2 mm, but a 1 mm sieve was used in 2013 and 2015 to be consistent with sampling previously completed by Teck in 2011 (Lotic 2013). In the end, data from 2011 were excluded from this report due to quality control concerns. Future sediment sampling should revert to standard 2 mm sieving prior to analysis.

maximum NRQs among replicate stations within an area for selenium and the PAH with the highest NRQ were reported in summary tables and figures.

Concentrations in sediment were compared to BC Working Sediment Quality Guidelines (SQGs) (Table 2.4). HQs were calculated as the ratio of the concentration of each parameter in sediment to the upper SQG (or the single guideline, in the case of selenium). The maximum HQs among replicate stations within an area for selenium and the PAH with the highest HQ were reported in summary tables and figures.

A PCA was conducted on the covariance matrix for HQs (HQs were $\log_{10}$-transformed) of constituents measured in samples collected at reference and mine-exposed areas in 2013 and 2015. The methods used to complete the PCA follow those described in Section 2.2.3.

Temporal changes in selenium, 2-methylnaphthalene, and PC-1 between 2013 and 2015 were evaluated using RM ANOVA followed by *post hoc* contrasts to test for differences relative to reference. The RM ANOVA model was fit using all areas as:

$$Y = Year + CI + Area(CI) + Year \times CI + Area(CI) \times Year + \varepsilon$$

where *Y* is the chemical parameter, *Year* is a categorical factor for year, *CI* is a control-impact factor (C = control or reference and I = impact or mine-exposed), *Area* is a factor for area and nested in *CI* because each area is either a reference or a mine-exposed area, *Year*×*CI* represents the interaction between *Year* and *CI, Area*(*CI*)×*Year* represents the interaction between area and year, and is the *ε* error term. When the *Area*(*CI*)×*Year* interaction is significant then there is a difference in the relative difference between the mine-exposed areas and reference areas that depends on the areas being compared. *Post hoc* contrasts are then conducted to determine which mine-exposed areas are "trending" differently from reference. The following contrast hypothesis was tested:

$$EXP_{2015} - REF_{2015} = EXP_{2013} - REF_{2013}$$

Where EXP_X and REF_X are the means for the mine-exposed and reference areas in year X, respectively. Contrasts were conducted relative to the overall reference mean, and to each of the three reference areas with data in 2013 and 2015 (LCHO, LML, and REFF). A magnitude of difference was calculated using similar methods to those described in Section 2.2.3. The 2015 mean for the mine-exposed area was compared relative to the predicted 2015 mean for the mine-exposed area, where the predicted mean was calculated as the 2015 reference mean plus the difference between mine-exposed and reference means in 2013.

Table 2.4: BC Working Sediment Quality Guidelines (SQGs)

[a] A concentration that will protect aquatic life from adverse effects of toxic substances in most situations.

[b] A concentration that if exceeded will likely cause severe effects on aquatic life.

[c] Only a single guideline has been defined.

'- No guideline.

2.6 Periphyton

2.6.1 Sampling for Productivity Assessment

Periphyton productivity was evaluated at 58 mine-exposed and 40 reference areas in September 2015, including areas sampled in the Line Creek LAEMP (Appendix Tables F.1 and F.2). Additional samples were collected at sub-set of 21 areas throughout the watershed in September 2016 as part of the RAEMP and Line Creek LAEMP (Minnow 2017b). Samples were analyzed for chlorophyll-a and ash-free dry mass (AFDM). Periphyton chlorophyll-a is an indicator of the amount of chlorophyll-producing algae within the periphyton community. Periphyton AFDM measures the total dried biomass of organisms comprising the periphyton community (e.g., algae, fungi, bacteria, protozoa).

Periphyton samples for chlorophyll-a and AFDM analysis were collected from riffle habitat with water depth of at least 5 cm, near-bottom water velocity of about 0.1-0.4 m/s, and uniform substrate characteristics, including relatively flat rocks with a diameter of at least 12 cm. When a sampling area with such characteristics was identified, five rocks were selected (excluding those that were too small, highly angular, or uncharacteristic in surface texture) and taken to shore. A thin acetate template with a 4 cm^2 opening in the middle, was placed firmly on each rock and the periphyton within the opening was scraped off using a scalpel. Scrapings from each of the five rocks were placed on a wetted Whatman GF/F glass fibre filter (e.g., 90 mm diameter, 0.7 µm pore size) to provide a single, composite sample per station for chlorophyll-a analysis. The filter paper containing the composite sample was folded in half twice and then tightly wrapped with aluminum foil. The foil-wrapped sample was placed in a labelled Whirl-Pak® bag and stored in a cooler with freezer packs (in the field) until transfer later in the day to a freezer for storage. Samples can be stored frozen for up to 30 days as long as they are not exposed to light (APHA et al. 1998).

The same five rocks sampled for chlorophyll-a analysis were used to collect separate scrapings for analysis of AFDM. The material on the scalpel from each scraping was rinsed into a small pre-labelled plastic jar with additional water added, as necessary, to cover the tissue. Each composite sample for AFDM analysis was placed in a cooler until transfer to a freezer later in the day.

With the exception of the seven locations being monitored as part of the Line Creek LAEMP, where 10 replicate stations were sampled per area in 2015 (each spaced a minimum of 5 m apart), all periphyton chlorophyll-a and AFDM monitoring consisted of collection of a single composite sample per area (each composite sample consisting of scrapings from 5 different rocks).

2.6.2 Sampling for Tissue Chemistry

Samples were collected for periphyton tissue selenium analysis in both lotic and lentic areas. Lotic tissue samples were collected in both September 2015 and September 2016 from the same 21 areas as annual periphyton productivity samples. Lentic periphyton tissue samples were collected in August 2015 from the same areas where sediment samples were collected for chemical analysis (Appendix Tables F.14 and F.15).

Periphyton samples collected in lotic areas for selenium analysis (n = 1 composite per area) were scraped from the same rocks as those sampled for evaluation of productivity, plus additional rocks (as necessary) to obtain the required sample weight. Scrapings were transferred directly into a pre-labelled cryovial (without rinsing) to minimize the amount of water in each sample. Scrapings were collected until approximately 2 g wet weight of tissue per sample was attained.

Periphyton samples collected for selenium analysis from lentic areas (n = 3 composite samples per area, corresponding to locations near the inlet, middle and outlet of each area) were suctioned from the surface of perennially submerged sediment using a wide-bore syringe. Care was taken to ensure the area being sampled was not influenced by individuals collecting the sample, and that inclusion of sediment particles in the periphyton samples was minimized (i.e., by controlling the depth of the tip of the syringe and the rate at which suction was applied). If the sediment-water interface was easily discernable from the water surface, samples were collected *in situ*. If the sediment-water interface was not visible, a 10.2 cm (4 inch) inside diameter corer was used to collect the sample. Samples were transferred directly into pre-labelled cryovials from the syringe.

All periphyton tissue samples were kept on ice in a cooler during the day and then stored in a freezer until they were shipped to the laboratory.

2.6.3 Sampling for Evaluation of Communities

Samples were collected in September 2015 for a supporting study to the RAEMP to determine if periphyton community endpoints can be used to sensitively and reliably detect mine-related effects on aquatic communities in the Elk Valley (Minnow and Larratt 2016). A total of 40 reference and 58 mine-exposed areas were sampled, corresponding to areas where benthic invertebrate communities were also sampled as part of the RAEMP (this study). Details of sampling and analysis were reported by Minnow and Larratt (2016) and results are summarized in this report.

2.6.4 Laboratory Analyses

Samples for AFDM and chlorophyll-a analysis were shipped frozen to ALS Environmental in Calgary, AB for analysis. Analysis of AFDM followed procedures modified from APHA Method 10300 C. Total AFDM was calculated as the difference between the dried sample weight and the ash weight, both of which were determined gravimetrically. Dry weight was determined by drying the sample at 105°C, and the ash weight was subsequently determined by ashing the dried sample at 500°C.

Analysis of chlorophyll-a was completed using procedures adapted from EPA Method 445.0. Chlorophyll-a was determined by routine acetone extraction followed by fluorescence detection using a non-acidification procedure (a method that is not subject to interferences from chlorophyll-b).

All periphyton samples collected for selenium analysis in 2015 and 2016, were sent to the University of Missouri's Research Reactor Center (MURR) in Columbia, Missouri, except samples collected for the Line Creek LAEMP in 2016. At MURR, the samples were freeze-dried and analyzed for selenium using Neutron Activation Analysis (NAA). Samples collected for the Line Creek LAEMP in 2016 were sent to the Saskatchewan Research Council (SRC) Laboratory in Saskatoon, SK for freeze-drying and then sent to ALS in Burnaby, BC for selenium analysis by high resolution (HR) ICP-MS. Results were reported on a dry-weight (dw) basis.

2.6.5 Data Analysis

Area-based AFDM and chlorophyll-a concentrations were calculated by dividing the total AFDM and chlorophyll-a concentrations reported by the laboratory by the surface area sampled (20 cm^2) at each station.

Normal ranges for AFDM and chlorophyll-a were calculated as the 2.5^{th} and 97.5^{th} percentiles of the distribution of values observed in reference areas sampled in September, 2015. The outlier evaluation followed the same methods as for water quality (Section 2.2.3) and also consisted of an evaluation of the percentile rank of values within each watershed to identify whether reference areas in a particular watershed were unusually high or low relative to the other reference areas. NRQs were calculated for AFDM and chlorophyll-a as the ratio of the concentration to the upper limit of the normal range. HQs were calculated for chlorophyll-a as the ratio of the concentration to the BC Ministry of Environment (BCMOE) guideline for the protection of aquatic life (100 mg/m^2) (BCMOE 2001). Water samples collected at the same time as periphyton samples during the 2015 RAEMP cycle included measurement of nutrient concentrations (e.g., nitrate, phosphorus) and those data were included in the evaluation of mine-related effects on productivity.

Periphyton tissue selenium concentrations measured in a variety of historical monitoring and baseline studies were previously summarized by Windward (2014) and Windward et al. (2014). The data pertaining to reference areas were added to data collected in the RAEMP in 2015-2016 to characterize the normal range for tissue selenium concentrations. The normal range for periphyton tissue selenium concentrations was calculated as the 2.5th and 97.5th percentiles of this distribution, with identification of outliers following the same methods as described in Section 2.2.3. NRQs were calculated for all reference and mine-exposed areas sampled in 2015 and 2016.

The evaluation of the periphyton community endpoints for the RAEMP focused on the key endpoints identified in the 2015 Periphyton Special Investigation (Minnow and Larratt 2016): Green density, *Achnanthidum* density, Fragilariacae density, and two non-metric multi-dimensional scaling axes (NMDS axis 1 and NMDS axis 3). NMDS is a method to visualize the level of similarity of samples based on the rank of the similarities (Clarke and Ainsworth 1993). The NMDS takes the n-dimensional (here N = number of taxa) coordinates of each sample (i.e., area) and defines a set of new n-dimensional coordinates that reflect the locations (rank distances) among samples. The NMDS was used to reduce the complete periphyton taxonomic data matrix to fewer dimensions. The NMDS axes retained for the evaluation of the RAEMP data were axis 1 and axis 3 (significantly correlated with PC-1 for water quality which separates reference and mine-exposed areas) from an NMDS 3-D ordination at the genus level of taxonomy using fourth-root transformed relative abundance. Further details on the NMDS analysis for the periphyton community can be found in Minnow and Larratt (2016). Normal ranges were then calculated for the community endpoints as described above for AFDM and chlorophyll-a, and also included an evaluation of the percentile rank of values within each watershed to identify whether reference areas in a particular watershed were unusually high or low relative to the other reference areas.

Mine-exposed areas sampled in 2015 were compared to the normal ranges for the key periphyton community endpoints. A correlation analysis was conducted among key periphyton community endpoints and PC-1 for water quality (Section 2.2.3) to assess whether periphyton community endpoints were responding to differences in water quality between reference and mine-exposed areas.

2.7 Benthic Invertebrates

2.7.1 Kick Sampling

Benthic invertebrate communities were sampled in September 2015 at 40 reference and 60 mine-exposed lotic areas using the Canadian Biomonitoring Network (CABIN) method

(Environment Canada 2012a) for evaluation of community structure (lowest practical level of taxonomy) (Appendix Tables G.32 to G.35). Additional community samples were collected in 2016 to support the Dry Creek, Line Creek and FRO LAEMPs (Minnow 2017a-c) and to satisfy other data needs by Teck (total of 7 reference and 32 mine-exposed areas; Appendix Tables G.36 to G.39).

The CABIN method involves 3-minutes of travelling kick sampling, with collection of disturbed organisms using a net with a triangular aperture measuring 36 cm per side and mesh having 400 µm openings (Environment Canada 2012a). During sampling, the field technician moved across the stream channel (from bank to bank, depending on stream depth and width) in an upstream direction. With the net being held immediately downstream of the technician's feet; the detritus and invertebrates disturbed from the substrate were passively collected in the kick-net by the stream current. After three minutes of sampling time, the sampler returned to the stream bank with the sample. The kick-net was rinsed with water to move all debris and invertebrates into the collection cup at the bottom of the net. The collection cup was then removed and the contents poured into a labelled plastic jar and preserved in a 10% buffered formalin solution. A single sample was collected in each area, with an additional two samples (i.e., three in total) collected at 5% of areas to assess within-area variability in community composition. Consistent with the requirements of the CABIN sampling protocol, supporting information including stream habitat characteristics was collected concurrent with benthic invertebrate samples (Environment Canada 2012a).

2.7.2 Hess Sampling

Benthic invertebrates have also been collected in the Line Creek LAEMP (annually since 2014) and in the FRO LAEMP (beginning in 2016) for analysis of tissue biomass and community composition (family level of taxonomy) (Minnow 2015c, 2016c, 2017a,b). For these samples, benthic invertebrates were collected using a Hess sampler with 500 µm mesh, for measurement of biomass and community endpoints relative to the area sampled. Stations were located a minimum of 5 m apart to ensure they were representative of the overall area (10 stations per area). A single sample was collected at each station by carefully inserting the base of the Hess sampler into the substrate to a depth of approximately 5 to 10 cm. Any gravel or cobble enclosed within the Hess sampler was carefully washed while allowing the current to carry dislodged organisms into the mesh collection net. All organisms collected into the net were rinsed into the end of the net, and then into a labelled wide-mouth plastic jar. Samples were preserved to a level of 10% buffered formalin in ambient water within approximately 6 hours of collection to ensure that biomass was not lost through predation or decomposition of tissues before the samples were sorted at the laboratory.

2.7.3 Tissue Sample Collection

Between the RAEMP and LAEMPs, benthic invertebrates were collected with kick nets for analysis of tissue selenium concentrations at 7 reference areas and 59 mine-exposed lotic areas in September 2015, as well as 5 reference and 23 mine-exposed lotic areas in September 2016 (Appendix Table G.43). Samples were a composite of representative taxa present in each area (a minimum of one sample in each lotic area, more in some areas in accordance with the respective LAEMP designs). In addition, samples of one or more common and readily identifiable taxa (i.e., Ephemeroptera, Plecoptera, or Rhyacophilidae) were also collected at areas that are monitored on an annual basis for the RAEMP and LAEMPs.

Tissue samples were also collected in 5 reference and 18 mine-exposed lentic areas in August 2015 (Appendix Table G.47). In lentic areas, three composite samples of benthic invertebrates were collected by sweeping the substrate and/or vegetation along the shoreline with a kick net. Tissue samples were taken near the inlet, middle, and outlet of each lentic area.

Invertebrates from both lotic and lentic areas were picked free of debris in the field, placed into labelled cryovials and stored in a cooler with ice packs until transferred to a freezer later in the day.

2.7.4 Laboratory Analyses

2.7.4.1 Kick Samples for Community Analysis

Benthic invertebrate community samples collected by kick net were sent to Cordillera Consulting (lead taxonomist Sue Salter), in Summerland BC, for sorting and taxonomic identification. Taxonomists at Cordillera have achieved certification for Group 1 (general Arthropods West), 2 (EPT East and West), and 3 (Chironomids West) benthic organisms in the Taxonomic Certification Program (http://nabstcp.atlanticwebfitters.ca/) of the Society for Freshwater Science (formerly the North American Benthological Society). Organisms were identified to the lowest practical level (LPL) (typically genus or species) using up-to-date taxonomic keys.

At the beginning of the sorting process, each sample was examined to estimate total invertebrate numbers. If the total number was estimated to be greater than 600, then the sub-sampling protocol was followed, otherwise the sample was sorted in its entirety. In cases where samples cannot be analyzed in their entirety, CABIN requires that a sufficient number of sub-samples be analyzed to result in the sorting of at least 300 organisms and at least 5% of the sample (Environment Canada 2014). Sorting efficiency and sub-sampling accuracy and precision were quantified using methods specified by Environment Canada (2012b).

2.7.4.2 Hess Samples for Biomass and Community Analysis

Benthic invertebrate biomass samples were sent to ZEAS Inc. (lead taxonomist Danuta Zaranko) in Nobleton, ON, for sorting and taxonomic identification. All preserved organisms in each sample were sorted from the sample debris into groups separated at the family-level of taxonomy for weighing. Each family group of organisms was placed onto a fine cloth to drain excess surface moisture (preservative) before being weighed to the nearest 0.0001 g. Total and family-level biomass were reported for each sample (preserved wet weight).

2.7.4.3 Tissue Selenium Analysis

All invertebrate samples collected for selenium analysis in 2015 and 2016, were sent to the MURR in Columbia, Missouri, except samples collected for the Line Creek LAEMP in 2016. At MURR, the samples were freeze-dried and analyzed for selenium using NAA. Samples collected for the Line Creek LAEMP in 2016 were sent to SRC in Saskatoon, SK for freeze-drying and then sent to ALS in Burnaby, BC for selenium analysis by HR ICP-MS. Results were reported on a dry-weight (dw) basis.

2.7.5 Data Analysis

2.7.5.1 Tissue Selenium Relative to Predictions, Normal Ranges and Benchmarks

Composite-taxa benthic invertebrate tissue selenium concentrations measured in 2015 and 2016 were compared to predictions that were derived from water modelling (Golder 2014a,b) and tissue bioaccumulation models developed for the EVWQP (Teck 2014).

Benthic invertebrate tissue selenium concentrations measured in a variety of historical monitoring and baseline studies were previously summarized by Windward (2014) and Windward et al. (2014). Reference area data used in those studies were obtained, along with benthic invertebrate tissue data measured in the 2015-2016 RAEMP cycle (this study), the Dry Creek LAEMP (Minnow 2016a), and the 2016 LAEMPs for Line Creek and FRO (Minnow 2017a,b), to characterize the normal range for tissue selenium concentrations. Tissue selenium concentrations observed in mine-exposed areas in 2015 and 2016 were compared to the upper limit of the reference normal range and to site-specific benchmarks developed in the EVWQP (Table 2.3). The 95% confidence interval for the 97.5th percentile [calculated following methods in Kilgour et al. (2017)] for tissue selenium in lotic habitats overlapped with the 95% confidence interval for the 97.5th percentile for tissue selenium in lentic habits, indicating no significant (α = 0.05) difference in the upper limit of the normal range for the two habitats. Thus, normal ranges were calculated as the 2.5th and 97.5th percentiles of the reference area distribution for both lotic and lentic areas combined. An outlier evaluation was conducted for the

reference area data set as described in Section 2.2.3. NRQs and HQs were calculated as the ratio of concentrations to the upper limit of the normal range and site-specific benchmarks, respectively.

2.7.5.2 Communities Relative to Normal Ranges

NMDS was used to reduce the complete family level and LPL taxonomic data matrices to fewer dimensions. The analysis used the Bray-Curtis distance as the measure of relative community similarity or dissimilarity, as recommended by McCune and Grace (2002), using PC-ORD© (McCune and Mefford 2011). Rare taxa (i.e., those occurring in less than 5% of areas) were removed from the dataset as their exclusion from multivariate statistics reduces 'noise' (Bailey et al. 2004) and improves the ecological interpretability of the resulting community ordination. The 'slow and through' option, which uses the following settings, was applied: maximum iterations = 400, instability criterion = 0.00001, number of real runs = 40, and number of randomized runs = 50 (McCune and Grace 2002). All NMDS ordinations were evaluated for solution stability, final stress <0.20, and Monte Carlo randomization determination of interpretable axes of $p<0.05$ (McCune and Grace 2002).

NMDS is a method to visualise the level of similarity of samples based on the rank (e.g. sample A is more similar to Sample B than to Sample C) of the similarities (Clarke 1993). The NMDS takes the N-dimensional (here N = number of taxa) coordinates of each sample (i.e. area) and defines a set of new n-dimensional coordinates that reflect the locations (rank distances) among samples. NMDS results of non-transformed data often leads "to shallow interpretation in which only the pattern of a few, very common species is represented" (Clarke 1993). A suite of transformations were applied (log_{10}, square root, fourth root, power 2, and power 4) and the resultant data matrix was assessed for normality based on the average skewness and kurtosis. The transformation with the lowest average skewness and kurtosis was deemed the preferred transformation as it reduced the influence of dominant taxa. Axis 1 of the NMDS was retained for the evaluation of the RAEMP data because it was significantly correlated with PC-1 for water quality which separates reference and mine-exposed areas.

Community data for samples collected in 2015 were used to investigate a total of 107 benthic invertebrate community endpoints as potential indicators of mine-related influence (Appendix Tables G.3 and G.5). Univariate endpoints having values less than the lower limit of the reference normal range at more than 10% of mine-exposed areas, or greater than the upper limit of the normal range at more than 10% of areas were included in correlations (Appendix Table G.6) with the first principal component (PC-1) of several variations of the PCA for water quality described in Section 2.2.3. Significant ($\alpha=0.05$) correlations were observed for most benthic invertebrate community endpoints and PC-1 (Appendix Table G.6) suggesting

redundancy among benthic invertebrate community endpoints as indicators of potential mine-related effects. Redundancy among endpoints was also indicated by a correlation analysis of benthic invertebrate community endpoints alone (Appendix Table G.7). Strongest correlations ($r > 0.6$ or $r < -0.6$) with PC-1 were observed for percent (%) Ephemeroptera and Ephemeroptera richness, % Ephemeroptera, Plecoptera, and Trichoptera (EPT), % Diptera, and with overall community structure as indicated by NMDS (Appendix Table G.6). These results suggested that these endpoints are the ones most sensitive to influences from coal mining. As expected, these endpoints also tended to identify the same areas as being different from reference area communities (Appendix Table G.8). Following discussion of draft results with the EMC, four univariate endpoints were selected as key community endpoints: total benthic invertebrate abundance and LPL richness (as overall indicators of the number and diversity of organisms present), as well as % Ephemeroptera and % EPT (as endpoints most sensitive to mine-related influence). NMDS Axis 1 (family-level of taxonomy; 3-D ordination on fourth rout relative abundance) was also retained as a multivariate indicator of overall community structure.

After identification of the key community endpoints, normal ranges were updated with the pooled 2012 and 2015 reference area data distribution. The normal ranges were further refined for these key community endpoints by removing outliers (Appendix Table G.10; Appendix Figure G.2). The outlier evaluation followed the same methods as described in Section 2.2.3 and also consisted of an evaluation of the percentile rank of values within each watershed to identify whether reference areas in a particular watershed were unusually high or low relative to the other reference areas. This evaluation resulted in reference areas in the upper Kootenay River watershed being excluded from the normal range for benthic invertebrate abundance based on low abundance relative to reference areas in the other watersheds (Appendix Table G.10).

Correlation analysis indicated that a variety of habitat variables were significantly correlated with benthic invertebrate community endpoints, but correlation coefficients were low in most cases (Appendix Table G.11), indicating that the habitat variables explained little of the community variability. However, based on input from the EMC, additional analyses were undertaken to determine if normal ranges for key endpoints should be further refined by taking into account community variability associated with other habitat factors (Appendix I). After discussion of results with the EMC, it was decided that the ability to detect communities deviating from normal ranges was not sufficiently enhanced to warrant the added complexity of the analysis. Therefore, reference area normal ranges were defined without covariates, as shown in Appendix Table G.10.

Key community characteristics for benthic invertebrates sampled in mine-exposed areas in 2015 and 2016 for the RAEMP and LAEMPs were compared to the respective reference normal ranges. NRQs and HQs were not calculated; comparisons were made between the observed value for each endpoint and the normal range.

2.7.5.3 Temporal Changes

Temporal changes in benthic invertebrate selenium concentrations and benthic community endpoints were evaluated using RM ANOVA followed by *post hoc* contrasts to test for differences relative to reference (similar to methods described in Section 2.5.3). The RM ANOVA model was fit using all areas as:

$$Y = Year + CI + Area(CI) + Year \times CI + \varepsilon$$

where *Y* is the endpoint, *Year* is a categorical factor for year, *CI* is a control-impact factor (C = control or reference and I = impact or mine-exposed), *Area* is a factor for area and nested in *CI* because each area is either a reference or a mine-exposed area, *Year*×*CI* represents the interaction between *Year* and *CI.* An interaction term for *Area*(*CI*)×*Year* could not be included because there was no replication in samples within an area and year. Data were transformed (log_{10}, square root, or fourth root) as required to meet assumptions of normality and homogeneity of variances in the model residuals. *Post hoc* contrasts were conducted for all mine-exposed areas to assess whether the mine-exposed areas were "trending" different from reference. The RM ANOVA requires reference area data to be collected at the same time as mine-exposed data. Due to differences in sampling schedules for the different mine-exposed areas (e.g., some areas sampled in the LAEMPs have additional data), the analysis was conducted separately for subsets of mine-exposed areas and reference areas with data collected in the same year. The contrasts consisted of tests for linear changes and tests for step changes in the relative difference between mine-exposed and mean reference across years. A magnitude of difference was calculated as described in Section 2.2.3.

Temporal trends for main stem mine-exposed areas by management unit were evaluated using the same methods described above, but the differences were calculated as the difference in the mean endpoint value for main stem mine-exposed areas and the mean endpoint value for reference areas.

2.8 Longnose Sucker

2.8.1 Sampling

All longnose sucker work was completed under fish collection permit CB15-167864, issued by the BC Ministry of Forests, Lands, and Natural Resource Operations (MFLNRO). Nine mine-

exposed and three reference study areas were targeted for LSU monitoring (Appendix Table HLSU.1). Monitoring was initially conducted at all areas in spring (i.e., mid-May), with four areas (ERUP, GO13, OTTO, and STPD) repeated in September to evaluate the effect of seasonality on catch success and population size estimates.

Fish abundance (density) was assessed using mark-recapture sampling based on an adaptation of the Schnabel method (Schnabel 1938, Krebs 1999). Lentic habitats were sampled using standard, galvanized-mesh, cylindrical minnow traps (42 cm length, 0.6 cm mesh, 2.5 cm diameter opening) deployed singly as overnight, bottom sets baited with a suitable attractant. At each study area, minnow trap locations were randomized to meet assumptions of the Schnabel method. Accordingly, each lentic water body was separated into 12 to 24 approximately equal-sized sampling zones, with a greater number of zones being defined in larger versus smaller waterbodies. Locations for each of the overnight minnow traps set at each study area were determined *a priori* using a random numbers table, with some adjustments made to ensure that only a single minnow trap was set in a sampling zone at one time and that the same set location within a sampling zone was not used sequentially. For each minnow trap set, supporting information including duration of sampling effort (i.e., “soak time”), mean sampling depth, GPS coordinates and habitat descriptions were recorded. Minnow trap sampling was conducted until a minimum of 10% of marked fish were recaptured, or for a maximum of four nights of minnow trapping effort at each study area.

All minnow traps were checked daily, with all captured fish identified to species and enumerated. Captured LSU were temporarily retained for physical measurement and marking, with any re-captures (i.e., marked LSU) and incidental captures (i.e., other species) released immediately following the recording of pertinent details. All LSU were measured for fork and total length to the nearest millimetre using a standard measuring board, and for fresh body weight to the nearest 0.001 g using an electronic balance. Each captured LSU was marked to allow identification during subsequent, within-year capture. Suitable markers included a fin clip, or a visible implant elastomer (VIE) tag. Fish captured on each successive night of fishing received a different identification mark (e.g., anal fin clip, right pectoral fin clip, left pectoral fin clip) to account for any repeated recaptures in the population estimate calculations. No marking occurred on the final day of trap checking. If high numbers of LSU (e.g., >100) were captured at any of the study areas, a sub-set of individuals (i.e., 5% of captures, up to a maximum of 10 fish) were sacrificed for otolith and/or pectoral fin ray removal to allow assessment of age. Liver and gonad weights were also recorded for these individuals, along with the ten adults being collected for selenium analysis (Section 2.9.2) Additional observations on individual fish included assessment of general condition (e.g., emaciated appearance), presence of any lesions, tumours and/or fin erosion, presence or evidence of parasites, and any other

abnormalities. Photographs were taken of fish exhibiting abnormalities or poor body condition, along with photographs of representative healthy LSU. Once LSU were measured, marked, assessed for abnormalities, and photographed, each was released near its location of capture.

2.8.2 Data Analysis

Fish community data were summarized by species presence and total number of fish captured per area. Catch-per-unit-effort (CPUE) was calculated as the number of fish captured per 24 hours per minnow trap. The LSU population of each mine-exposed and reference area was then estimated using total catch numbers and the following equation:

$$N = \sum (C_t * M_t) / (\sum R_t) + 1$$

Where N = the estimate of the number of individuals in the population;

C_t = the number of fish caught;
M_t = the number of marked fish at large; and,
R_t = the number of recaptures.

The 95% confidence intervals were calculated as follows:

$$95\% \text{ Confidence Limit} = \sum (C_t * M_t) / \sum R \text{ (Poisson)}$$

LSU density estimates (i.e., number of LSU per 100 m^2) were calculated for each water body based on the total area of the water body and the corresponding population estimate. An estimate of the LSU biomass per unit area was determined for each water body by multiplying the density estimate by the mean mass of the LSU sampled at the water body. The total area of each water body was determined using Geographical Information Systems (GIS) and/or direct field measures. The LSU population, density, and biomass estimates were compared among the mine-exposed and reference areas and can be used as a basis for tracking relative population changes over time.

Fish health for mine-exposed areas sampled in May, 2015 was evaluated relative to the reference area (FLA1) using the following endpoints and statistical methods:

- Length frequency distributions (indicator of survival/recruitment)
- Fork length (indicator of body size)
- Body weight (indicator of body size)
- Condition (indicator of energy storage)

Length frequency distributions were analyzed for each mine-exposed area relative to the reference area using the two-sample Kolmogorov-Smirnov (KS) test. A magnitude of difference

was reported as the maximum difference in the cumulative relative frequency distributions (CRFD; see Appendix Figure HLSU.4) between areas. A negative difference implied that the mine-exposed area had more fish less than the length where the maximum difference in CFRDs was observed. A positive difference implied that the mine-exposed area had fewer fish less than the length where the maximum difference in CRFDs was observed.

Fork length and body weight were analysed using ANOVA or the non-parametric Kruskal-Wallis test when the assumptions of normality and homogeneity of variance could not be met after a $\log_{10}$-transformation. Condition was analyzed using analysis of covariance (ANCOVA) with $\log_{10}$(body weight) as the response variable and $\log_{10}$(fork length) as the covariate. Regression slopes for the ANCOVA were considered parallel when the interaction term of the model was not significant ($\alpha = 0.05$) or when the slopes are considered practically significant (i.e., the coefficient of determination [R^2] of the parallel slope model was within 2% of the R^2 of the interaction model). *Post hoc* contrasts were conducted using Dunnett's method (comparison of each mine0exposed area to reference) for ANOVA and ANCOVA or Dunn's tests with a Bonferroni adjustment for Kruskal-Wallis. A significance level of 0.1 was used for testing area differences. Outliers with a Studentized residual magnitude greater than four were removed from the analysis. A magnitude of effect was calculated for each mine-exposed area relative to reference based on means (ANOVA), covariate adjusted means (ANCOVA), or medians (Kruskal-Wallis).

Length frequency distributions plotted using histograms and the cumulative relative frequency distributions of each mine-exposed area vs. the reference area were provided to support the two-sample KS tests.

Fork length, body weight, and condition factor (K= body weight [g] / total length^3 [mm] x 10^5) were plotted using boxplots.

Temporal Comparisons

Comparisons of fish condition (analyzed using ANCOVA) for longnose sucker collected from STPD, OTTO, GO13, and ERUP in May and August 2015 were initially conducted using ANCOVA (Appendix Table HLSU.12). Since no differences were observed, the May and August 2015 data were pooled for comparison to previous years. The temporal analysis consisted of comparisons of reference area FLA1 and mine-exposed areas GO13, OTTO, and STPD to 2013 data collected by Lotic (2014b) and comparisons of mine-exposed data from ERUP and EROL to 2005 data collected by LePage (2014). Temporal analyses were not conducted for fish morphometric endpoints in WCT and MW because sample sizes were small, males and females were not separated, and samples were collected at different times of the year resulting in fish being in different stages of reproductive development.

2.9 Fish Tissue Selenium Monitoring

2.9.1 Overview

All fish tissue sampling was completed under fish collection permit CB15-167864, issued by MFLNRO.

2.9.2 Longnose Sucker

Mature LSU were sampled in early-mid May in an effort to collect females with developed eggs/ovaries. A total of five mature females (for ovary analysis) and five additional adults (for whole body analysis) were targeted for tissue sampling in each area.

Mature adult LSUs retained for sampling were lethally euthanized using clove oil dissolved in ethanol. External fish condition, including the presence of any deformities, lesions, or parasites, was documented. Body mass (in grams) and fork and total length (in millimetres) were measured using a digital balance (accuracy to ± 0.1 g) and a small measuring board (± 1 mm). Otoliths were extracted and stored in small, labelled paper envelopes for age analysis. The body cavity of each LSU was opened using round-nosed scissors. Gonads and livers were removed and weighed using a digital balance. If the fish was female and not spent, both ovaries were placed into a sterile, labelled, Whirl-Pak® bag. If the female was spent, a muscle sample was collected instead of an ovary sample. The muscle was collected from the dorsal side of the fish, and all skin and bones were removed, and the filet placed in a labelled, Whirl-Pak® bag. The remaining fish carcass was then placed in a separate Whirl-Pak® bag for archive purposes. Individuals retained for whole-body analysis were placed in a Whirl-Pak® bag with all internal organs and labelled with a unique sample identification code. All fish tissues were stored on ice until transfer to a freezer (-20 ºC) later in the day.

2.9.3 Westslope Cutthroat Trout

Westslope cutthroat trout were sampled in early May (prior to spawning) and late August (during the period of more intense recreational angling) from main stem mine-exposed areas only, in accordance with the study design[9] (Minnow 2015a). For the purposes of this report, all data (May and August) were compared to site-specific benchmarks for protection of aquatic life (Table 2.5). The data were also included in a separate human health risk assessment (Ramboll Environ 2016).

[9] An adequate database of historical reference tissue data were available to characterize the reference area normal range.

Table 2.5: Selenium Benchmarks for Periphyton, Benthic Invertebrates, and Fish Tissue in the Elk Valley

Endpoint	Tissue Type	Benchmark			Source
		Value (µg/g dw)	Type	Description	
Benthic Invertebrates	Whole body	13	Site-specific benchmark	Level 1 (~10% effect) benchmark for growth, reproduction and survival of invertebrates	Table 3-1 (Golder 2014c)
	Whole body	11	Site-specific benchmark	Level 1 (~10% effect) benchmark for dietary effects to juvenile fish (growth)	Table 3-1 (Golder 2014c)
	Whole body	15	Site-specific benchmark	Level 1 (~10% effect) benchmark for dietary effects to juvenile birds	Table 3-1 (Golder 2014c)
Westslope cutthroat trout	Egg/ovary	25	Site-specific benchmark	Level 1 (~10% effect) benchmark for westslope cuttroat trout reproduction	Table 3-1 (Golder 2014c)
	Muscle/ muscle plug	15.5	Site-specific benchmark	Muscle equivalent to the 25 mg/kg dw ovary benchmark, based on the relationship observed between selenium in muscle and ovary in westslope cutthroat trout	Nautilus and Environmental and Interior Reforestation (2011)
Mountain whitefish	Egg/ovary	29.3	Site-specific benchmark	Conservative estimate of lower bound for potential effects	Nautilus (2017)
Other Fish	Egg/ovary	18	Site-specific benchmark	Level 1 (~10% effect) benchmark for reproduction effects to other species than westslope cutthroat trout	Table 3-1 (Golder 2014c)
	Muscle	18	Site-specific benchmark	Muscle equivalent to the 18 mg/kg dw ovary benchmark, based on the relationship observed between selenium in muscle and ovary in longnose sucker[a]	This report (Data in Figure 9.2)
	Egg/ovary	11	BC guideline	Combination of weight of evidence and mean of published effects data with an uncertainty factor of 2 applied	BCMOE (2014)
	Whole body	4	BC guideline	Combination of weight of evidence and mean of published effects data with an uncertainty factor of 2 applied	BCMOE (2014)
	Muscle/ muscle plug	4	BC guideline	Whole-body translation to derive muscle benchmark with no additional uncertainty factor	BCMOE (2014)

[a] The benchmark of 18 mg/kg dw ovary was estimated from the regression of log(muscle Se) on log (ovary Se): muscle BM = $10^{1.20*\log(\text{ovary BM})-0.251}$

Each captured WCT was assigned a unique identification code. Body weight was measured using an appropriately-sized spring scale (e.g., 100 g, 500 g, 1,000 g). Total and fork length were determined using a measuring board equipped with a metre stick (± 1 mm). External fish condition, including the presence of any deformities, lesions, or parasites, was documented. To the extent possible, WCT gender was determined using secondary sexual characteristics (i.e., shape of jaw, colour, and condition of vent/ovipositor). A biopsy punch (4 mm acu-punch) was inserted into the dorsal musculature, ensuring the penetration was perpendicular to the fish skin surface. Light pressure was applied while turning (twisting) the punch into the dorsal musculature (about 5 to 7 mm). The punch was then angled slightly and removed, while still turning, to separate the sample from the surrounding musculature. Skin was removed from the sample with a scalpel and the remaining muscle sample was placed into a sterile microcentrifuge tube. Following sampling, the fish was released back into the water body where it was captured. Samples were stored on ice until transfer to a freezer later in the day.

While collection of WCT was intended to be non-lethal, there was one incidental mortality of a female WCT from Henretta Lake in May 2015. The body cavity of this fish was opened using round-nosed scissors and the ovaries were extracted, weighed to the nearest 0.1 g using a top-loading digital scale, and placed into a sterile, labelled, Whirl-Pak® bag. A muscle sample (approximately 5 g) was taken from behind the dorsal fin on the dorsal side of the fish using a clean fillet knife. The muscle was filleted from the bones and the skin removed so that the sample was composed of only muscle. The muscle sample was then packaged in a sterile, labelled, Whirl-Pak® bag and frozen.

2.9.4 Mountain Whitefish

Mountain whitefish samples were collected in early October (pre-spawning). Female fish (n=5 per area) were targeted for measurement of selenium concentrations in ovaries and muscle.

Mature MWF were euthanized using clove oil dissolved in ethanol mixed in ambient water. Body weight was measured using appropriately-sized spring scales (e.g., 100 g, 500 g, 1,000 g). Total and fork length were determined using a measuring board equipped with a metre stick (± 1 mm). Otoliths and pectoral fin rays were collected, wrapped in wax paper, and stored in small paper envelopes labelled with the fish identification code. The body cavity of each fish was then opened using round-nosed scissors. If the fish was female, both ovaries were extracted, weighed to the nearest gram using a top-loading digital scale, and placed into a sterile, labelled, Whirl-Pak® bag. A muscle sample (approximately 5 g) was taken from behind the dorsal fin on the dorsal side of the fish using a clean fillet knife. The muscle was then filleted from the bones and the skin removed so that the sample was composed of only muscle.

If the fish was male (i.e., three of the five fish collected from the St. Mary's River reference area), a muscle sample (approximately 5 g) was collected as described above.

2.9.5 Laboratory Analysis

Tissue samples were sent to MURR in Columbia, Missouri for analysis. Cutthroat trout and mountain whitefish tissues were freeze dried and analyzed for total metals using ICP-MS. Tissues from longnose sucker were similarly freeze dried, and analyzed for selenium using NAA. Results were reported on a dw basis, along with moisture content (based on the difference between wet and freeze-dried sample weights) to allow conversion to wet-weight values.

2.9.6 Data Analysis

Fish tissue selenium concentrations measured in a variety of historical monitoring and baseline studies were previously summarized by Windward (2014) and Windward et al. (2014). Reference area data used in those reports were obtained, along with reference area data measured in the 2015-2016 RAEMP cycle (this study) to define reference area normal ranges. The normal ranges were calculated as the 2.5th and 97.5th percentiles of the reference area distribution after the outlier evaluation, as described in Section 2.2.3. Concentrations of selenium in fish tissues were compared to normal ranges and to applicable site-specific benchmarks developed in the EVWQP (Table 2.3). NRQs and HQs were computed by dividing observed concentrations by the upper normal range limit and site-specific benchmark, respectively. The maximum NRQ and HQ among replicate fish in a sampling area were reported in summary tables and figures.

The 97.5th percentiles of WCT muscle selenium were compared between lentic and lotic reference areas sampled between 1998 and 2012. The 95% confidence intervals were determined for the 97.5th percentile of lentic and lotic areas, and any overlap of the confidence intervals indicated that the upper normal ranges are not significantly different ($\alpha = 0.05$).

WCT muscle selenium concentrations measured in 2015 were also compared to WCT ovary selenium predictions derived from water modelling (Golder 2014a,b) and tissue selenium bioaccumulation models developed for the EVWQP (Teck 2014). The ovary selenium predictions were converted into predicted muscle selenium concentrations based on the muscle-to-ovary selenium relationship identified by Nautilus and Interior Reforestation (2011):

Muscle Se = (Egg Se/1.6862)^1.0199

A temporal analysis of fish tissue selenium concentrations was conducted for each species using ANOVA or a Kruskal-Wallis test. Due to differences in sampling months and a limited

reference data set, linear contrasts and comparisons to reference temporal changes were not conducted. The *post hoc* tests for the ANOVA and Kruskal-Wallis test comparisons were conducted among all sampling periods using Tukey's HSD method (ANOVA) or Dunn's tests (Kruskal-Wallis) using $\alpha = 0.05$.

2.10 Integrated Data Evaluation

2.10.1 Addressing Key Questions within the RAEMP

Monitoring results for the various types of samples described in Sections 2.2 to 2.9 were compiled into summary tables to support integrated evaluation of results within each MU relative to the key questions specified in the RAEMP study design (Minnow 2015a):

1. What are the mine-related chemical and physical changes to aquatic ecosystems and where do they occur?
2. Are mine-related chemical and physical changes to the aquatic environment resulting in unacceptable biological effects and where do they occur?
3. What are the specific mine-related sources of any unacceptable changes to chemical, physical, or biological conditions?
4. How are chemical, physical, and biological conditions changing over time?
5. What are the consequences of observed biological effects to the aquatic ecosystem?
6. Are the mine-related chemical and physical changes and/or biological effects impacting water and aquatic ecosystem uses?

To facilitate evaluation of the data matrix, results were tabulated and colour-coded to represent categories of "good", "marginal", and "poor" environmental quality as defined in Tables 2.6 to 2.8. These categories are reflected in data tables presented throughout this report.

Key Question #1 (mine-related chemical and physical changes) was addressed by computing normal range quotients (NRQs) for:

- water quality, calcite, and tissue selenium concentrations in lotic areas, and
- water quality, sediment quality, and tissue selenium concentrations in lentic areas.

Data for local and regional reference areas were used to approximate pre-mining conditions. NRQs greater than 1.0 indicated monitoring areas having physical or chemical conditions outside of the normal range for reference areas, providing evidence of mine-related changes.

Table 2.6: Categories for Classifying Physical and Chemical Data Relative to Normal Ranges (NR)

Habitat Type	Sample Type	Measurement Endpoints	Data Source	Statistic Used to Compare to NR	Normal Range Values		Good (Well Within NR)	Marginal (Upper End of NR in direction of adverse effect)	Poor (Outside NR in direction of adverse effect)
Lotic	**Water**	Nitrate, Sulphate, Selenium	Samples collected concurrently with biological samples in 2015	Single concentration	See Appendix Tables C.14 - C.17		<0.7	0.7 to 1.0	>1.0
			Teck routine monitoring data for 2015	Monthly mean concentration			<0.7	0.7 to 1.0	>1.0
	Calcite	Calcite Index	Calcite measured at invertebrate community sampling areas of the RAEMP in 2015	Single value	1.0		<0.5 (80th percentile of reference areas)	0.5 to 1.0	>1.0
	Benthic Invertebrates	Abundance	Benthic Invertebrate sampling areas of the RAEMP in 2015	Single value	$P_{2.5}$ = 471	P_{20} = 832	>20th percentile of reference distribution	2.5th to 20th percentile of reference distribution	<2.5th percentile of reference distribution
		Total Richness (LPL)		Single value	$P_{2.5}$ = 21	P_{20} = 24			
		% EPT		Single value	$P_{2.5}$ = 38	P_{20} = 68			
		% Ephemeroptera		Single value	$P_{2.5}$ = 21	P_{20} = 37			
	Tissue	Selenium concentration in specific tissue type	Invertebrate and fish tissue selenium concentrations measured in the RAEMP in 2015	Maximum concentration	Benthic Invertebrates: 7.82 mg/kg dw		<0.7	0.7 to 1.0	>1.0
					Westslope cutthroat trout muscle: 5.98 mg/kg dw				
					Mountain whitefish muscle: 4.97 mg/kg dw				
					Mountain whitefish ovary: 34.7 mg/kg dw				
Lentic	**Water**	Nitrate, Sulphate, Selenium	Samples collected concurrently with biological samples in 2015	Single concentration	See Appendix Tables C.27		<0.7	0.7 to 1.0	>1.0
	Sediment	Selenium, PAH (PAH with highest quotient)	Sediment samples collected in the RAEMP in 2015 (or 2013 if not sampled in 2015)	Maximum concentration	See Appendix Tables E.8 and E.10, E.12		<0.7	0.7 to 1.0	>1.0
	Tissue	Concentration in specific tissue type	Invertebrate and fish tissue selenium concentrations measured in the RAEMP in 2015	Maximum concentration	Benthic Invertebrates: 7.82 mg/kg dw		<0.7	0.7 to 1.0	>1.0
					Longnose sucker muscle: 6.09 mg/kg dw		<0.7	0.7 to 1.0	>1.0
					Longnose sucker ovary: 6.41 mg/kg dw		<0.7	0.7 to 1.0	>1.0

Table 2.7: Categories for Classifying Data used as Direct or Indirect Indicators of Effects

Habitat Type	Sample Type	Measurement Endpoints	Data Source	Statistic Used to Compare to Benchmark	Benchmark	Good	Marginal	Poor
Lotic	**Water**	Nitrate, Sulphate, Selenium	Samples collected concurrently with biological samples in 2015	Single concentration	See Appendix Tables C.23 - C.26	<0.7	0.7 to 1.0	>1.0
			Teck routine monitoring data for 2015	Monthly mean concentration		<0.7	0.7 to 1.0	>1.0
	Acute Toxicity	Rainbow trout and *Daphnia magna* % Mortality	Teck routine monitoring data for 2015	Maximum percent mortality observed for all tests conducted in 2015	Percent Mortality > 20%	0% to 10%	10% to 20%	>20%
	Chronic Toxicity	Rainbow trout embryo viability, *C. dubia* reproduction, *P. subcapitata* Cell Yield, *Hyalella azteca* dry weight	Teck data from chronic toxicity testing program	Lowest quarterly mean that is (in order of priority): significantly different from both reference area samples, different from one reference area sample, or did not differ from the reference area(s).	Fording River Reference and Elk River Reference	Not significantly different from both reference areas	Significantly different from one reference area	Significantly different from both reference areas
	Calcite	Calcite Index	Calcite measured at invertebrate community sampling areas of the RAEMP in 2015	HQ Single value	1.0	<0.5 (80th percentile of reference areas)	0.5 to 1.0	>1.0
	Benthic Invertebrates	Abundance	Benthic Invertebrate sampling areas of the RAEMP in 2015	Single value	$P_{2.5}$ = 1,005 / P_{20} = 3,510	>20th percentile of reference distribution	2.5th to 20th percentile of reference distribution	<2.5th percentile of reference distribution
		Total Richness (LPL)		Single value	$P_{2.5}$ = 20 / P_{20} = 25			
		%EPT		Single value	$P_{2.5}$ = 63.0 / P_{20} = 76.6			
		%Ephemeroptera		Single value	$P_{2.5}$ = 21.3 / P_{20} = 36.9			
	Tissue	Selenium concentration in specific tissue type	Invertebrate and fish tissue selenium concentrations measured in the RAEMP in 2015	HQ Maximum concentration	Benthic Invertebrates: 13 mg/kg dw	<0.7	0.7 to 1.0	>1.0
					Westslope cutthroat trout muscle: 15.5 mg/kg dw[a]			
					Mountain whitefish ovary: 29.3 mg/kg dw			
Lentic	**Water**	Nitrate, Sulphate, Selenium	Samples collected concurrently with biological samples in 2015	HQ Single concentration	See Appendix Tables C.27	<0.7	0.7 to 1.0	>1.0
	Sediment	Selenium, PAH (PAH with highest quotient)	Sediment samples collected in the RAEMP in 2015 (or 2013 if not sampled in 2015)	HQ Maximum concentration	See Appendix Tables E.9 and E.11, E.12	<0.7	0.7 to 1.0	>1.0
	Sediment Toxicity	Survival, weight, and biomass for *Hexagenia* spp. 21-day test and *Hyalella azteca* 14-day test	2015 sediment toxicity data	Mean relative to reference	FLA1, LCHO, and LML reference sediments	No toxicity observed = none of the six endpoints show a significant difference from any two reference sediments	-	Toxicity observed = at least two of the six endpoints show a significant difference from at least two reference sediments
	Tissue	Selenium Concentration in specific tissue type	Invertebrate and fish tissue selenium concentrations measured in the RAEMP in 2015	HQ Maximum concentration	Benthic Invertebrates: 13 mg/kg dw	<0.7	0.7 to 1.0	>1.0
					Longnose sucker ovary: 18 mg/kg dw			
	Longnose Sucker	Condition	Fish health survey conducted in May 2015 for the RAEMP	Adjusted mean[c] compared to adjusted means for two reference areas[b] Magnitude expressed as a percentage relative to reference	5.57 and 6.11 g	p-value > 0.1 or p-value < 0.1 and magnitude < 7%	p-value < 0.1 and magnitude of 7-10%	p-value < 0.1 and magnitude >10%

Note: 'NA' - not applicable; BI = benthic invertebrate; WCT = westslope cutthroat trout; MW = mountain whitefish; LSU = longnose sucker

[a] muscle equivalent benchmark based on ovary EC10

[b] the percentage with the smallest magnitude was carried forward to the summary table

[c] adjusted to a fork length of 8.19 cm

Table 2.8: Categories for Classifying Temporal Changes for RAEMP Data

Habitat Type	Data Type	Endpoints	Data Source	Approach	Good (no change or change in favorable direction)	Marginal	Poor (statistically significant change in unfavorable direction)
Lotic	**Water**	Nitrate, Sulphate, Selenium	Teck's routine monitoring data 2012 to 2016	Seasonal Kendall test on monthly means	negative slope	NA	p-value < 0.1 and positive slope
	Benthic Invertebrates	Abundance	Benthic invertebrate sampling areas 2012 -2015	Paired t-test between 2012 and 2015 within a MU	2015 mean > 2012 mean	NA	p-value < 0.1 and 2015 mean < 2012 mean
		Total Richness (LPL)					
		%EPT		Linear regression on year by sampling area	positive slope	NA	p-value < 0.1 and negative slope
		%Ephemeroptera					
	Tissue	Selenium concentration in specific species and tissue type	Benthic invertebrate and fish tissue selenium from regional monitoring 2006 - 2015	Linear regression of selenium concentration on year	negative slope	NA	p-value < 0.1 and positive slope
Lentic	**Sediment**	Selenium, PAH (PAH with highest quotient)	Sediment samples collected in the RAEMP in 2013 and 2015	Paired t-test by station	2015 mean > 2012 mean	NA	p-value < 0.1 and 2015 mean < 2013 mean
	Tissue	Selenium concentration in specific tissue type	Invertebrate and fish tissue selenium from regional monitoring 2006 - 2015	Linear regression of selenium concentration on year	negative slope	NA	p-value < 0.1 and positive slope
	Longnose Sucker	Condition	2015 RAEMP data compared to 2005 or 2013 data	Analysis of covariance on adjusted body weight relative to fork length	increasing or no significant change	NA	significant (p-value <0.1) decrease

Note: 'NA' - not applicable

These areas were highlighted in pink ("poor") in summary tables presented in Section 12. The "marginal" (yellow) category was generally defined as values near the outer limit of the normal range (e.g., NRQs of 0.7 to 1.0), except in the case of calcite for which the "marginal" category was defined as a calcite index of 0.5 (the calcite target specified in the EVWQP and Permit 107517) to 1.0 (Table 2.4). Areas with chemical or physical values well within the reference area normal range were highlighted in green ("good") (e.g., NRQs < 0.7), except in the case of calcite for which the "good" category was defined as calcite index of < 0.5. Concentrations were also discussed relative to predictions made in the EVWQP to identify any locations where conditions were outside of the expected range (i.e., for water quality and for selenium concentrations in benthic invertebrates and cutthroat trout).

Biological effects referred to in Key Question #2 were identified primarily through evaluation of benthic invertebrate community endpoints for lotic main stem and tributary areas were evaluated relative to normal reference area ranges for each endpoint. This was supported by other lines of evidence, such as HQs water quality, calcite index, and tissue selenium concentrations in a weight of evidence approach to assess if benthic invertebrate responses were potentially mine-related (e.g., Are areas with evidence of effects to benthic invertebrate communities associated with aqueous nitrate, aqueous or tissue selenium, or aqueous sulphate concentrations above site-specific effect benchmarks?). Periphyton productivity and community data were not included in the integrated evaluation because the evaluation presented in Section 7 concluded that results for these endpoints are strongly confounded by influences other than mining, and that mining has not affected productivity through increases of the limiting nutrient, phosphorus. Results of the upper Fording River WCT study (Cope et al. 2016) were also considered in the interpretation of mine-related effects. Longnose sucker condition was included as an indicator of potential mine-related effects in lentic areas within applicable MUs, along with evaluation of water and sediment quality and tissue selenium data in the same areas.

Key Question #3 (identification of mine sources) was addressed, to the extent possible based on existing information, as part of the evaluation associated with Key Questions #1 and #2 (locations of chemical and physical changes and observed or potential biological effects, respectively). This occurred by identifying and interpreting spatial patterns for data within each MU as part of the weight of evidence for determining if observed effects may be mine-related. For example, a large increase in NRQs and HQs for mine-related substances between two water monitoring stations on a main stem receiver would corroborate a conclusion that observed biological effects at the downstream area may be mine-related and would also suggest that mining activities or discharges located between the two main stem stations are likely sources. Historical evaluations of mine-related constituent loads were referenced to, where applicable, as further evidence of the locations of key sources of mine-related stressors.

The concept of whether or not mine-related effects or changes are “unacceptable”, which is a component of Key Questions #2 and #3, relates to societal judgements about aquatic ecosystem health, which are discussed in Section 2.10.2.

Temporal analyses were completed for abiotic endpoints to identify how conditions have been changing over time (Key Question #4). Results were expressed as percent magnitude of change per unit of time.

Key Question #5 (aquatic ecosystem consequences) considers the spatial scale of mine-related effects to contribute to the weight of evidence in evaluating if observed biological effects are of potential concern for aquatic ecosystem health at a management unit scale. However, like the portion of Key Question #2 that refers to “unacceptable” biological effects, Key Question #5 cannot be addressed solely by science and will involve societal value judgements about the type, spatial scale, and rate of mine-related changes that are considered important enough to warrant management action. This is the point at which the RAEMP and other monitoring programs link to the AMP, which is discussed further in Section 2.10.2.

The RAEMP also gathers information that contributes to addressing Key Question #6 (Effects on Water or Ecosystem Uses). Guidelines have been developed in BC pertaining to a variety of potential water uses including source drinking water, aquatic life, agriculture, recreation and aesthetics, and industrial water supply (BCMOE 2017a,b). The RAEMP focuses mainly on evaluation of potential mine-related effects on aquatic life. Other monitoring programs by Teck evaluate potential effects of mining on human uses of water. For example, Teck monitors, evaluates, and reports on groundwater quality related to potable water use and screens groundwater against the various receptor/use guidelines (Permit 107517, Sections 7.8 and 9.2). Teck has also conducted a human health risk assessment (Permit 107517, Section 9.9), which incorporated fish tissue data collected in the RAEMP to evaluate potential risks to human consumers.

Based on the above, the integrated interpretation for each MU (in Section 12) was first organized into three sections:

- identifying where mine-related chemical and physical changes have occurred, as well as mine-related sources (Key Question #1 and #3);
- identifying where biological effects have occurred and assessing if they are mine-related (Key Questions #2, #3, and #5); and
- identifying changes over time (Key Question #4).

Once each MU was organized into the three section above, further integrated evaluation of the RAEMP results for each MU was completed as summarized in Section 2.10.2 below.

2.10.2 Data Evaluation Steps

The overarching purpose of data from the RAEMP is to evaluate the state of the aquatic ecosystem from a biological, water quality and physical habitat perspective, to help determine if the goal of the EVWQP to protect aquatic ecosystem health is being met, and to identify areas of concern and uncertainty. Through evaluation of the status, changes, and uncertainties in chemical, physical, and biological conditions, the RAEMP also plays an important role in supporting adaptive management.

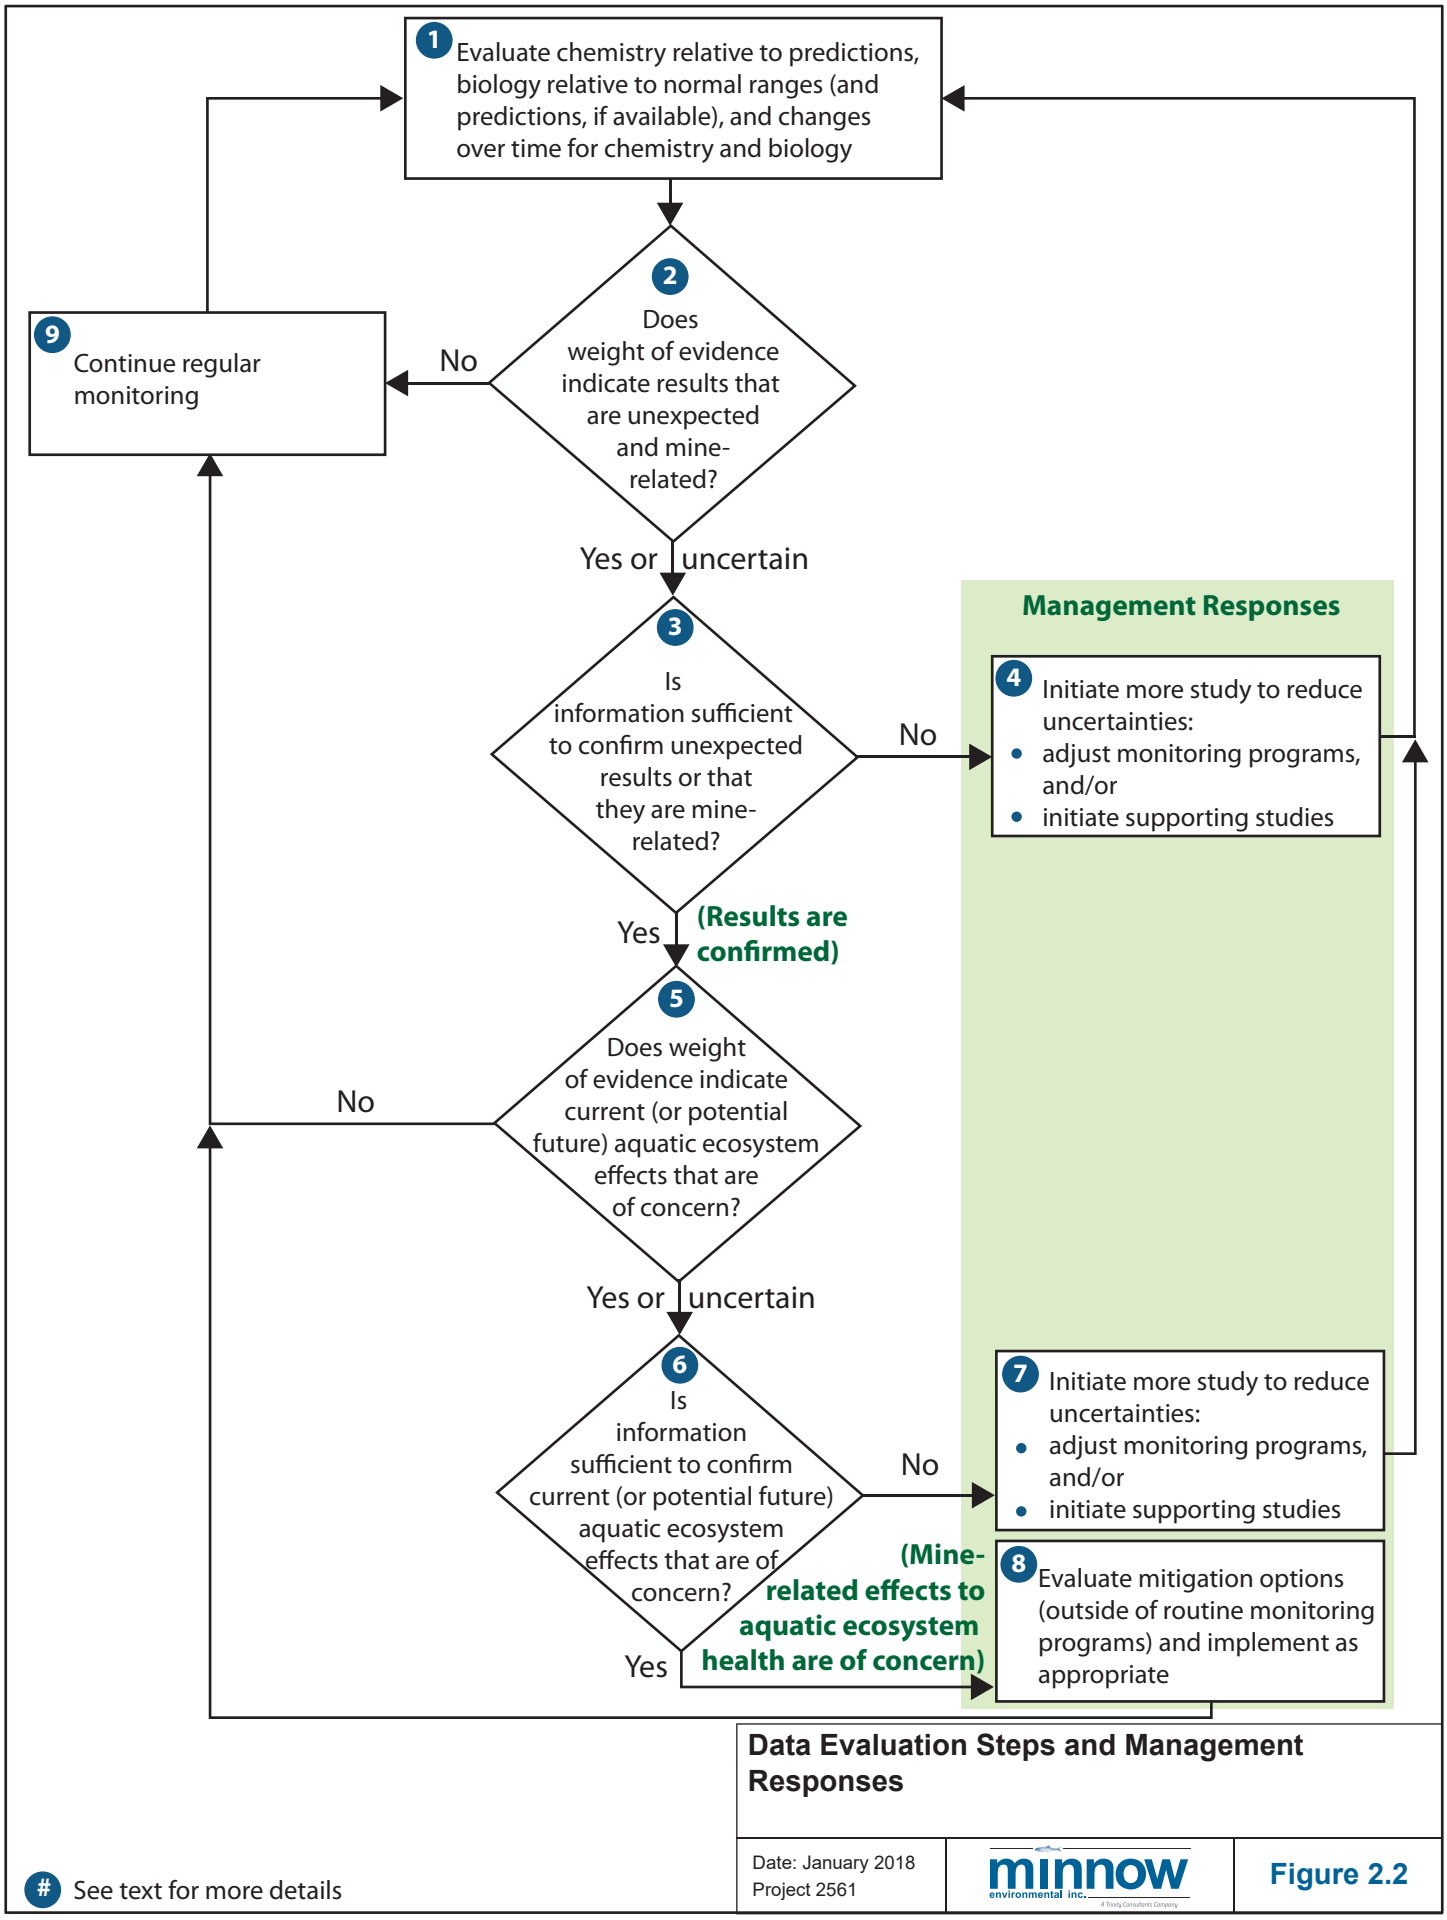
As noted in Section 1.4, ecosystem health is not an objective scientific concept and instead is defined by societal values and goals. The implication of this is that the RAEMP, and other monitoring programs managed by Teck, measure and report on the condition of various ecosystem attributes to the extent supportable by current scientific methods and understanding, but final determination of acceptability of existing conditions or the need for mitigation is based on judgements made by Teck with input from the EMC as part of the adaptive management process, with the final decision resting with the ENV. Thus, the monitoring program reports will identify the magnitude and spatial extent of mine-related effects, and identify the source(s) of mine-related stressor(s) to the degree possible based on available information. Based on the results, Teck will work through the Adaptive Management Plan response framework (Teck 2016b) to investigate and confirm results, and based on that investigation, determine if adjustments to mitigation, monitoring, or evaluation required. Teck is currently working with the EMC to develop triggers for management responses based on biological monitoring data.

Within the context described above, the general steps for evaluation of data within the RAEMP, including links to management responses, are outlined in Figure 2.2. Data evaluation steps corresponding with the numbers in blue circles in Figure 2.2, are described in more detail below.

Step 1 in Figure 2.2 refers to the evaluation steps described in Section 2.10.1 (addressing key RAEMP questions), which are a routine part of RAEMP (and LAEMP) reporting. In particular, this will include:

- Comparing water and tissue chemistry results to predictions made in the EVWQP[10] and/or Environmental Assessments (EAs) for mine expansion;

[10] Evaluation of observed to predicted water quality is done by Teck as a reporting requirement to the Ministry of Energy and Mines separate from Permit 107517 (e.g., Golder 2017a). RAEMP reports will include a summary of results, as applicable. The RAEMP will also compare observed tissue selenium concentrations to predictions made in the EVWQP.



Data Evaluation Steps and Management Responses

See text for more details

Figure 2.2

- identifying zones within the watershed where mining influence is evident by comparing water and sediment chemical concentrations, and calcite index values to reference area normal ranges and past observations for the same area;
- comparing biological endpoints to reference area normal ranges (and predictions, if available) and comparing chemistry data to relevant effect benchmark, to identify potential mine-related effects; and
- comparing recent monitoring results to historical data to evaluate changes over time.

Step 2 in the data evaluation process is to identify unexpected results or data patterns. The word "unexpected" is used to highlight that different expectations exist in different parts of the watershed depending on the stage of mine development, trends that were predicted in the EVWQP or approved EAs, and/or the stage of local or upstream mitigation or habitat enhancement actions. For example, streams that have been permanently altered by historical mining are not expected to reflect conditions associated with undisturbed reference areas. In other areas, particularly in main stems, biological communities are expected to have characteristics typical of reference areas. Expectations for temporal patterns also differ. For example, changes in a positive (good) direction may be expected in areas near or downstream from locations where remediation is implemented[11] Generally, changes in a negative (bad) direction are not expected unless articulated in the EVWQP (e.g., temporary increase in concentrations of nitrate or selenium in water until treatment can be implemented) or an approved EA (concentrations of mine-related constituents in water may be expected to increase in certain tributaries as mining progresses). Other unexpected patterns would include water or tissue selenium concentrations that are outside of predicted ranges, or degrading trends in benthic invertebrate community endpoints even if values are still within normal reference area ranges.

Step #3 in Figure 2.2 involves investigation of unexpected results to determine if they are mine-related. This considers factors such as whether there has been a change to mine operations over a relevant time frame that could explain the response. The evaluation also explores potential relationships (e.g., temporal and/or spatial correlations) between specific mine-related stressors and biological responses to investigate if mine-related stressors are at levels that could explain the unexpected biological response (e.g., above guidelines or benchmarks for effects to aquatic life). This evaluation step is also a standard part of RAEMP or LAEMP

[11] For example, commissioning of active water treatment to meet commitments in the EVWQP, fish habitat creation, or enhancement as part of the Regional Fish and Fish Habitat Program, and/or rehabilitation under the Tributary Management Program.

reporting, to the extent supportable, based on existing information. Typically the draft results are presented to and discussed with the EMC before the report is completed, so the EMC has input the data assessment, as well as the scope and timing of follow up actions.

It may be decided that more study is needed to confirm unexpected results or verify if they are mine-related. This may occur because multiple potential factors may explain or contribute to the observed response, because certain information is lacking, or because available data are ambiguous (e.g., weak signal of effect, conflicting lines of evidence). This will require a management response aimed at addressing the uncertainties by adjusting the scope, sampling frequency, sampling intensity, or timing of sampling within regular monitoring programs, or by initiating a targeted one-time supporting study (Step #4 in Figure 2.2). As with regular monitoring, the study design and draft results, along with any management responses that have already been planned or undertaken by Teck, would be discussed with the EMC.

Step #5 in Figure 2.2 occurs when mine-related effects have been (at least largely) confirmed and the evaluation begins to incorporate judgements by Teck and the EMC about the implications to aquatic ecosystem health. Step #6 reflects that some questions or uncertainties may still remain, which would necessitate further study (Step #7). The design and results of new studies will continue to be promptly discussed with the EMC and input will be incorporated into reports. In reality, Steps #3-6 are not distinct steps but instead represent a continuum of increasing evidence that unexpected effects are occurring that are mine-related and warrant investigation or mitigation. As uncertainties are resolved, and if evidence continues to push towards Step #6, efforts related to evaluation of mitigation options will escalate (Step #8).

Regular monitoring or supporting studies may provide evidence to conclude that effects are not occurring, are not mine-related, or are not of sufficient concern to warrant further management responses (i.e., “No” answer at question Steps #2 or #5). In such cases, and also while other management responses are triggered (Steps #4, #7, or #8), Teck will continue with regular monitoring.

Thus the intention of each RAEMP (and LAEMP) reporting cycle is to identify if conditions are consistent with expectations and, if not, to determine if unexpected changes are mine-related (to the extent supportable by existing information). It may take several cycles of RAEMP (or LAEMP) monitoring to move through the steps summarized in Figure 2.2 and resolve uncertainties about specific observations that have warranted more study, whereas other observations will not trigger additional investigation and will continue to be monitored according to the scope and schedule of the approved study design. Through Teck’s internal adaptive management plan process, and through discussion with the EMC, management responses will be initiated as appropriate.

The type, degree, and spatial extent of observed effects in LAEMPs and the RAEMP will be presented and discussed as described above within the existing regulatory process. In some cases, further discussion may be required with the EMC, outside of the RAEMP and within the context of Teck's AMP, about the acceptability of the observed effects and potential need for mitigation. In other words, this RAEMP report aims to present and assess all of the relevant available monitoring data to determine if expected and unexpected mine-related effects are occurring in the watershed. This information will allow Teck, in consultation with the EMC to decide if observed type(s), degree(s), and spatial extent(s) of effects are "acceptable" or warrant mitigation. Teck will continue to work with the EMC to develop a more formalized approach for evaluating monitoring data using a weight of evidence approach and to develop triggers for management responses based on biological monitoring data.

3 WATER QUALITY

3.1 Overview

Water quality is routinely monitored by Teck at stations distributed throughout the watershed, as required by Permit 107517 and to support management decisions. The data are reported annually (e.g., Teck 2016a, 2017a). Water quality samples were also collected in September 2015 as part of the RAEMP at all lotic areas where periphyton and benthic invertebrate community samples were collected, which included some areas that are not routinely monitored by Teck. In addition, water samples were collected in lentic areas in August 2015, which are not routinely monitored by Teck, where sediment or biological samples were collected.

Figures 3.1 and 3.2 show Teck's water monitoring locations. Maps of areas where water samples were collected for the RAEMP are presented in subsequent sections of this report.

In addition to regular monitoring and reporting of water quality data, Teck has been working with the EMC to evaluate the water quality data for the purpose of identifying values to serve as early warning of potential future, undesirable trends or conditions (i.e., "early warning triggers"). The analysis of water quality data for this purpose has taken place in parallel with the water quality data evaluation presented in this report. Potential differences in methods and/or conclusions that emerge from these parallel processes will be evaluated and discussed with the EMC.

3.2 Flows

Water flows in the Elk River watershed vary annually, particularly during spring freshet, which typically begins in April and peaks in late June (Figure 3.3). After the freshet peak, flows gradually decline toward winter minima. Peak spring water flows in 2012 to 2014 exceeded 10-year averages, especially in 2013 when record flows were observed in mid-June. In 2015, peak freshet flows were near the average, but declined more quickly in June and July. In 2016, freshet flows began earlier and peaked at below-average levels.

3.3 General Water Quality Characteristics

3.3.1 Seasonal Patterns

Monthly mean concentrations of general water quality variables were plotted for representative stations in the Elk River, Fording River, and Michel Creek[12] to illustrate patterns in water quality.

[12] Two Order or Compliance stations were selected on each main stem stream that represented different elevations, stream sizes, and mining influences.

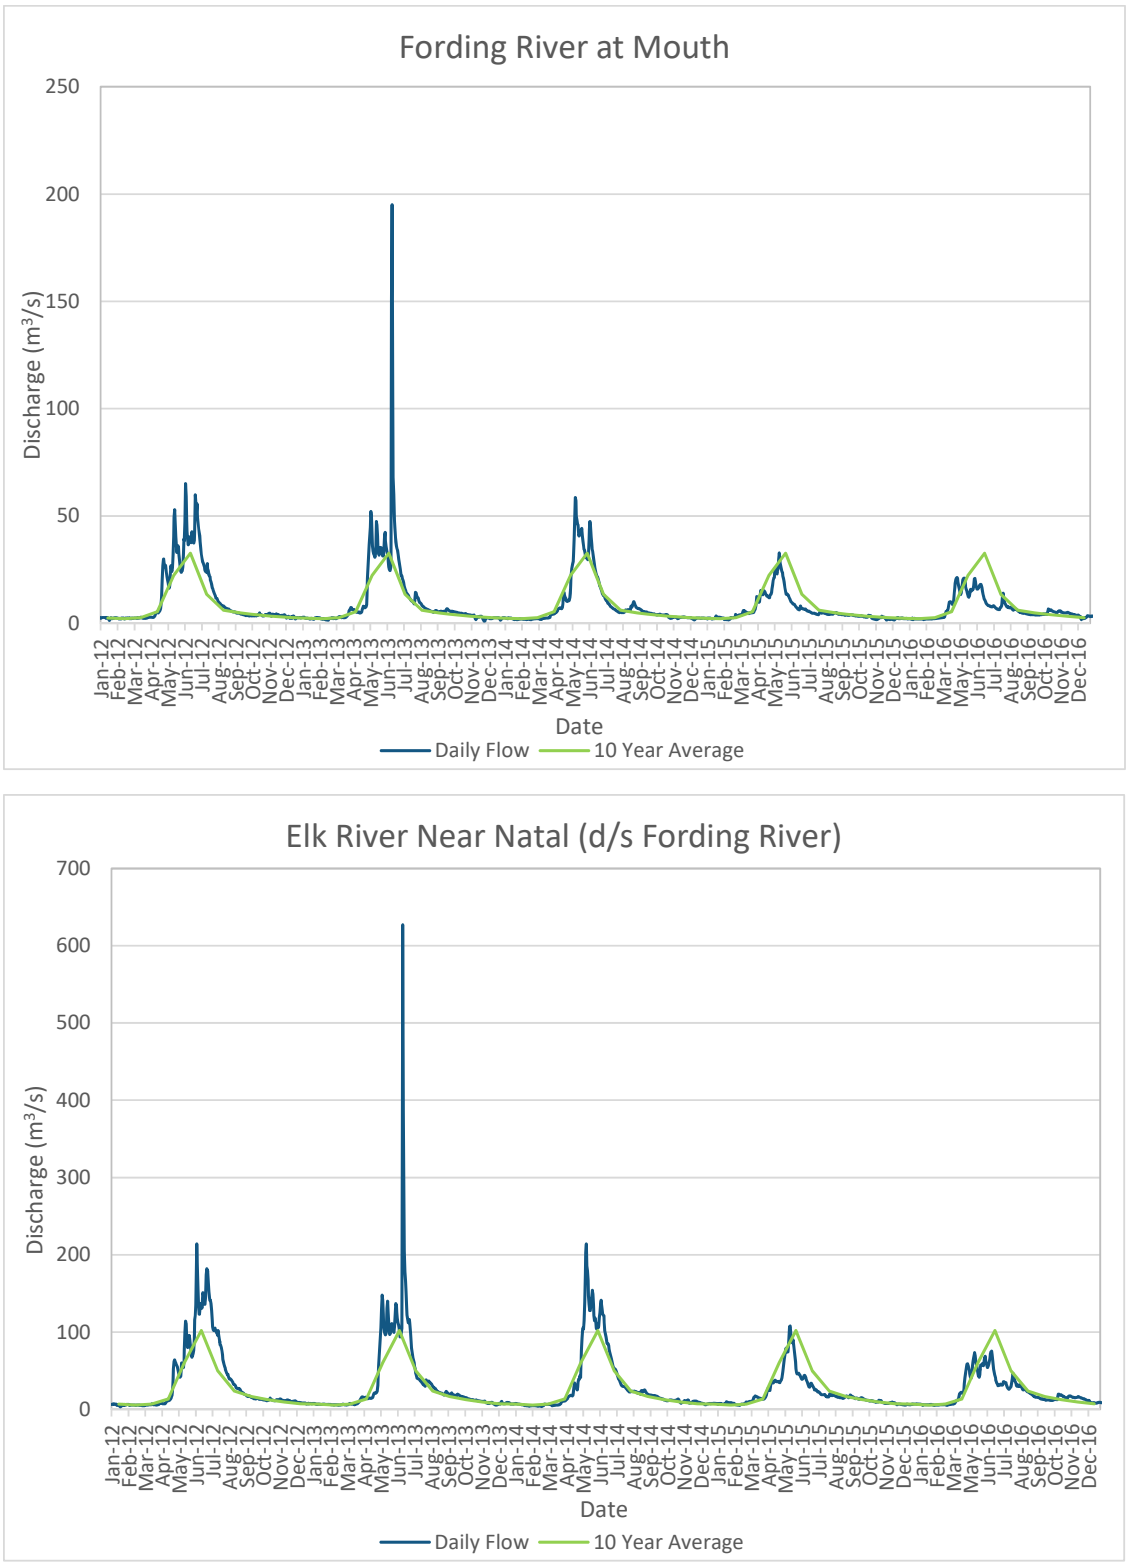

Figure 3.3: Flow Measurements at the Fording River (08NK018) and Elk River Near Natal (08NK016) Water Survey of Canada Stations from 2012 to 2016

Note: 10 year average calculated from 2006-2015 average monthly flows.

Aqueous pH is typically around eight and the water is well oxygenated (Figure 3.4). Water temperatures vary from winter lows near zero to summer highs of about 10 to 15 ºC. Total suspended solids (TSS) and turbidity concentrations are typically highest during spring freshet, but precipitation/melt events also cause periodic spikes in concentration.

Monthly mean concentrations of key mine-related constituents nitrate, selenium, and sulphate tend to be lowest in the upper Elk River and highest in the Fording River (Figure 3.5). Most stations show a similar seasonal pattern of lowest concentrations in winter and highest concentrations during spring freshet, although there is variability that may relate to periodic precipitation events.

3.3.2 Relationships Among Water Quality Variables

PCA was used to summarize water quality characteristics for reference and mine-exposed stations monitored in 2015 (n=1,395 samples). The first two Prinicipal Components explained 61.3% of the variability in the data set (Figure 3.6; Appendix Table C.3). Water quality characteristics were relatively similar among reference stations, as indicated by the tight cluster of green symbols in the upper left of the first panel in Figure 3.6. The spread of water quality data for samples from mine-exposed stations along PC-1 was associated with increasing concentrations of Order constituents (cadmium[13], nitrate, total selenium[14], and sulphate), as well as many other correlating analytes (bottom panel in Figure 3.6). The other variables correlating strongly with PC-1 (r>|0.6|) were substances that are also relatively soluble: total calcium, magnesium, nitrite, sodium, and potassium, as well as total and dissolved antimony, boron, calcium, chloride, lithium, magnesium, molybdenum, nickel, nitrite, potassium, strontium, and uranium (Appendix Table C.3). Alkalinity, conductivity, hardness, and total dissolved solids (TDS) concentrations were also strongly correlated with PC-1, and reflect concentrations of soluble constituents in water.

Separation of water sample results along PC-2 in the negative direction was associated with higher concentrations of TSS and turbidity (Figure 3.6), likely reflecting samples collected during high flow events such as spring freshet. Other variables associated with negative scores on PC-2 (aluminum, arsenic, iron, lead; Appendix Table C.3) tend to be related to particulates in the water column. Total organic carbon (TOC) and phosphorus were also associated with negative scores on PC-2 and likely reflect the mobilization of organic matter (e.g., microorganisms dislodged from periphyton, terrestrial plant detritus) during high flows.

[13] Correlation with PC-1 was stronger for total cadmium (r=0.62) than for dissolved cadmium (r=0.46).

[14] Also dissolved selenium.

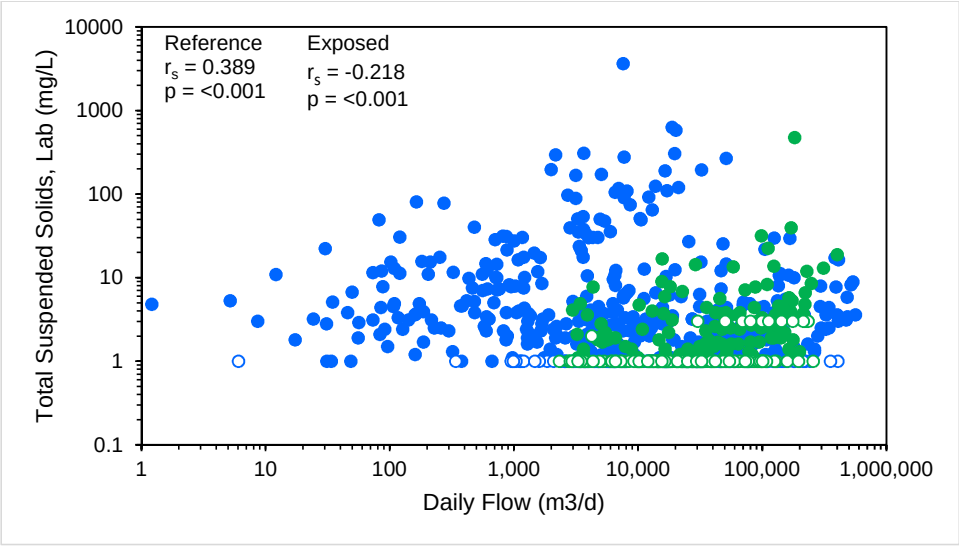
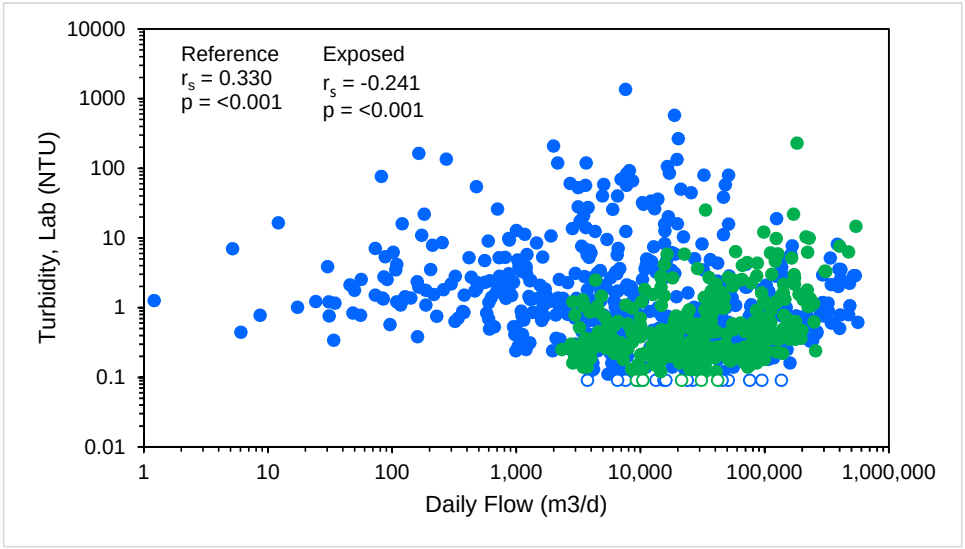
Notes: "L-" = lab measured; "F-" = field measured, "T-" = total; "D-" = dissolved

Further general evaluation of water quality data involved correlation analysis performed separately on data sets for reference versus mine-exposed stations monitored by Teck in 2015. Among mine-exposed stations, aqueous concentrations of key mine-related variables nitrate, selenium, and sulphate correlated strongly with each other, and with the other variables associated with PC-1 described above (conductivity, hardness, TDS, total calcium, magnesium, and potassium, dissolved antimony, and total and dissolved lithium, molybdenum, nickel, and uranium; Appendix Table C.4). Dissolved cadmium concentrations did not correlate strongly ($r<|0.5|$) with any water quality constituents other than total cadmium ($r=0.898$). Interestingly, a similar sub-set of analytes correlated amongst each other when only the reference stations were considered (e.g., conductivity, total and dissolved selenium, sulphate, total and dissolved uranium; Appendix Table C.5). This latter list of correlates may have been shorter than that for mine-exposed monitoring stations because at least 50% of reference station values for many of the other analytes associated with PC-1 were below detection and not included in the correlation. Turbidity, which correlated with PC-2 in Figure 3.6, was also correlated with total aluminum, iron, and manganese concentrations among reference stations. Therefore, the correlation analysis for separate reference and mine-exposed water quality data sets suggested that many of the water quality relationships observed among analytes in mine-exposed stations also occur naturally among reference stations, although concentrations are lower, on average, among reference stations.

PCAs for water samples collected in lotic and lentic areas concurrent with other RAEMP samples, each showed a similar water quality pattern to that described above for lotic stations monitored by Teck, with PC-1 predominantly reflecting soluble mine-related variables and PC-2 reflecting TSS, organic material, and metals that tend to adsorb to particulates (Appendix Figures C.1 and C.2 and Appendix Tables C.6 and C.7).

Data presented above indicated there is natural variation in concentrations associated with variations in water flows and particulate concentrations in water. These relationships were explored further using correlation analysis and data plots. Aqueous TSS and turbidity correlated only weakly with water flow ($p<0.001$, $r<|0.4|$), but correlated strongly with each other ($p<0.001$; $r>0.6$) when data were combined for reference versus mine-exposed monitoring stations in 2015 (Figure 3.7; Appendix Tables C.8 and C.9). Strong negative correlations with water flow ($p<0.001$; $r>|0.6|$) were observed for concentrations of alkalinity, as well as total and dissolved lithium, molybdenum, and strontium among reference station samples (Appendix Table C.8), but specific conductivity and dissolved organic carbon were the only constituents that correlated strongly with water flow ($p<0.001$; $r>|0.6|$) among samples collected at mine-exposed stations (Appendix Table C.9).





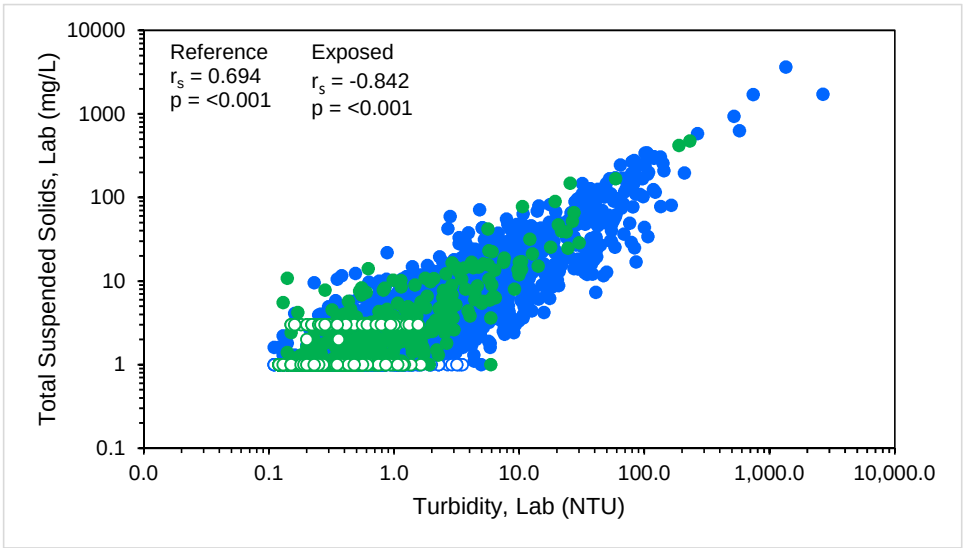


Figure 3.7: Relationships between Total Suspended Solids, Turbidity, and Flow Rates Among Samples Collected at Reference and Mine-exposed Stations in 2015

Stronger relationships between water quality and flow were observed when data were evaluated for individual reference stations (Figure 3.8). However, the relationships differed among reference stations, even those in close proximity (e.g., FR_HC3 [Upstream Henretta] versus FR_UFR1 [Upstream Fording]) or in the same sub-watershed (e.g., first five sets of panels in Figure 3.8 are all tributaries to the Fording River; note differences in x- and y-axis scales among stations). These natural differences among tributaries account for the relatively weaker correlations between flow and TSS or turbidity when data for multiple reference areas were combined (Appendix Table C.8). Natural differences in the relationships between water quality and flow among reference tributaries, even those in close proximity, suggest that prior to mining, water quality along each main stem stream (Elk River, Fording River, or Michel Creek) may have varied naturally from the respective upstream headwaters due to tributary inputs. This makes it challenging to define the water quality that may have existed at any given place in the watershed prior to mining.

3.4 Defining Upper Limit of the Normal Range

Results of the water quality evaluation in Section 3.3 indicated that concentrations of some water quality variables are related to water flow (Appendix Tables C.8 and C.9). The EMC had suggested potential use of flow as a covariate to adjust normal ranges for water quality. Although flow is measured in all mine-exposed tributaries, it is monitored at only a few reference tributaries and some mine-exposed main stem stations, which hampers development and application of flow-adjusted normal ranges for water quality evaluation. Also, there were weak or no relationships between water flow and the concentrations of most constituents among mine-exposed stations (Appendix Table C.9). Therefore, normal ranges for water quality constituents were not directly adjusted for flows. However, normal ranges for each constituent were defined for each month, as described below, which indirectly adjusted for natural seasonal variations in flow.

Results in Section 3.3 suggested that pre-mining water quality along main stem streams may have differed from water quality in the headwaters of the same stream because of variation in natural inputs from tributaries situated in between. This means that water quality at a single upstream reference station is not necessarily a better indicator of “expected” (i.e., normal, non-mine-influenced) concentrations farther downstream than is the water quality at other reference streams in the watershed. Also, multiple reference tributaries are monitored in some portions of the watershed (e.g., upstream Fording, Henretta, Chauncey, Line, South Line, and Grace Creek associated with the Fording River in MUs 1 and 2), whereas only a single main stem reference area is measured in MU3 (upstream Elk River). This also makes it challenging to define “normal” water quality for any given mine-exposed monitoring station in the watershed. Based

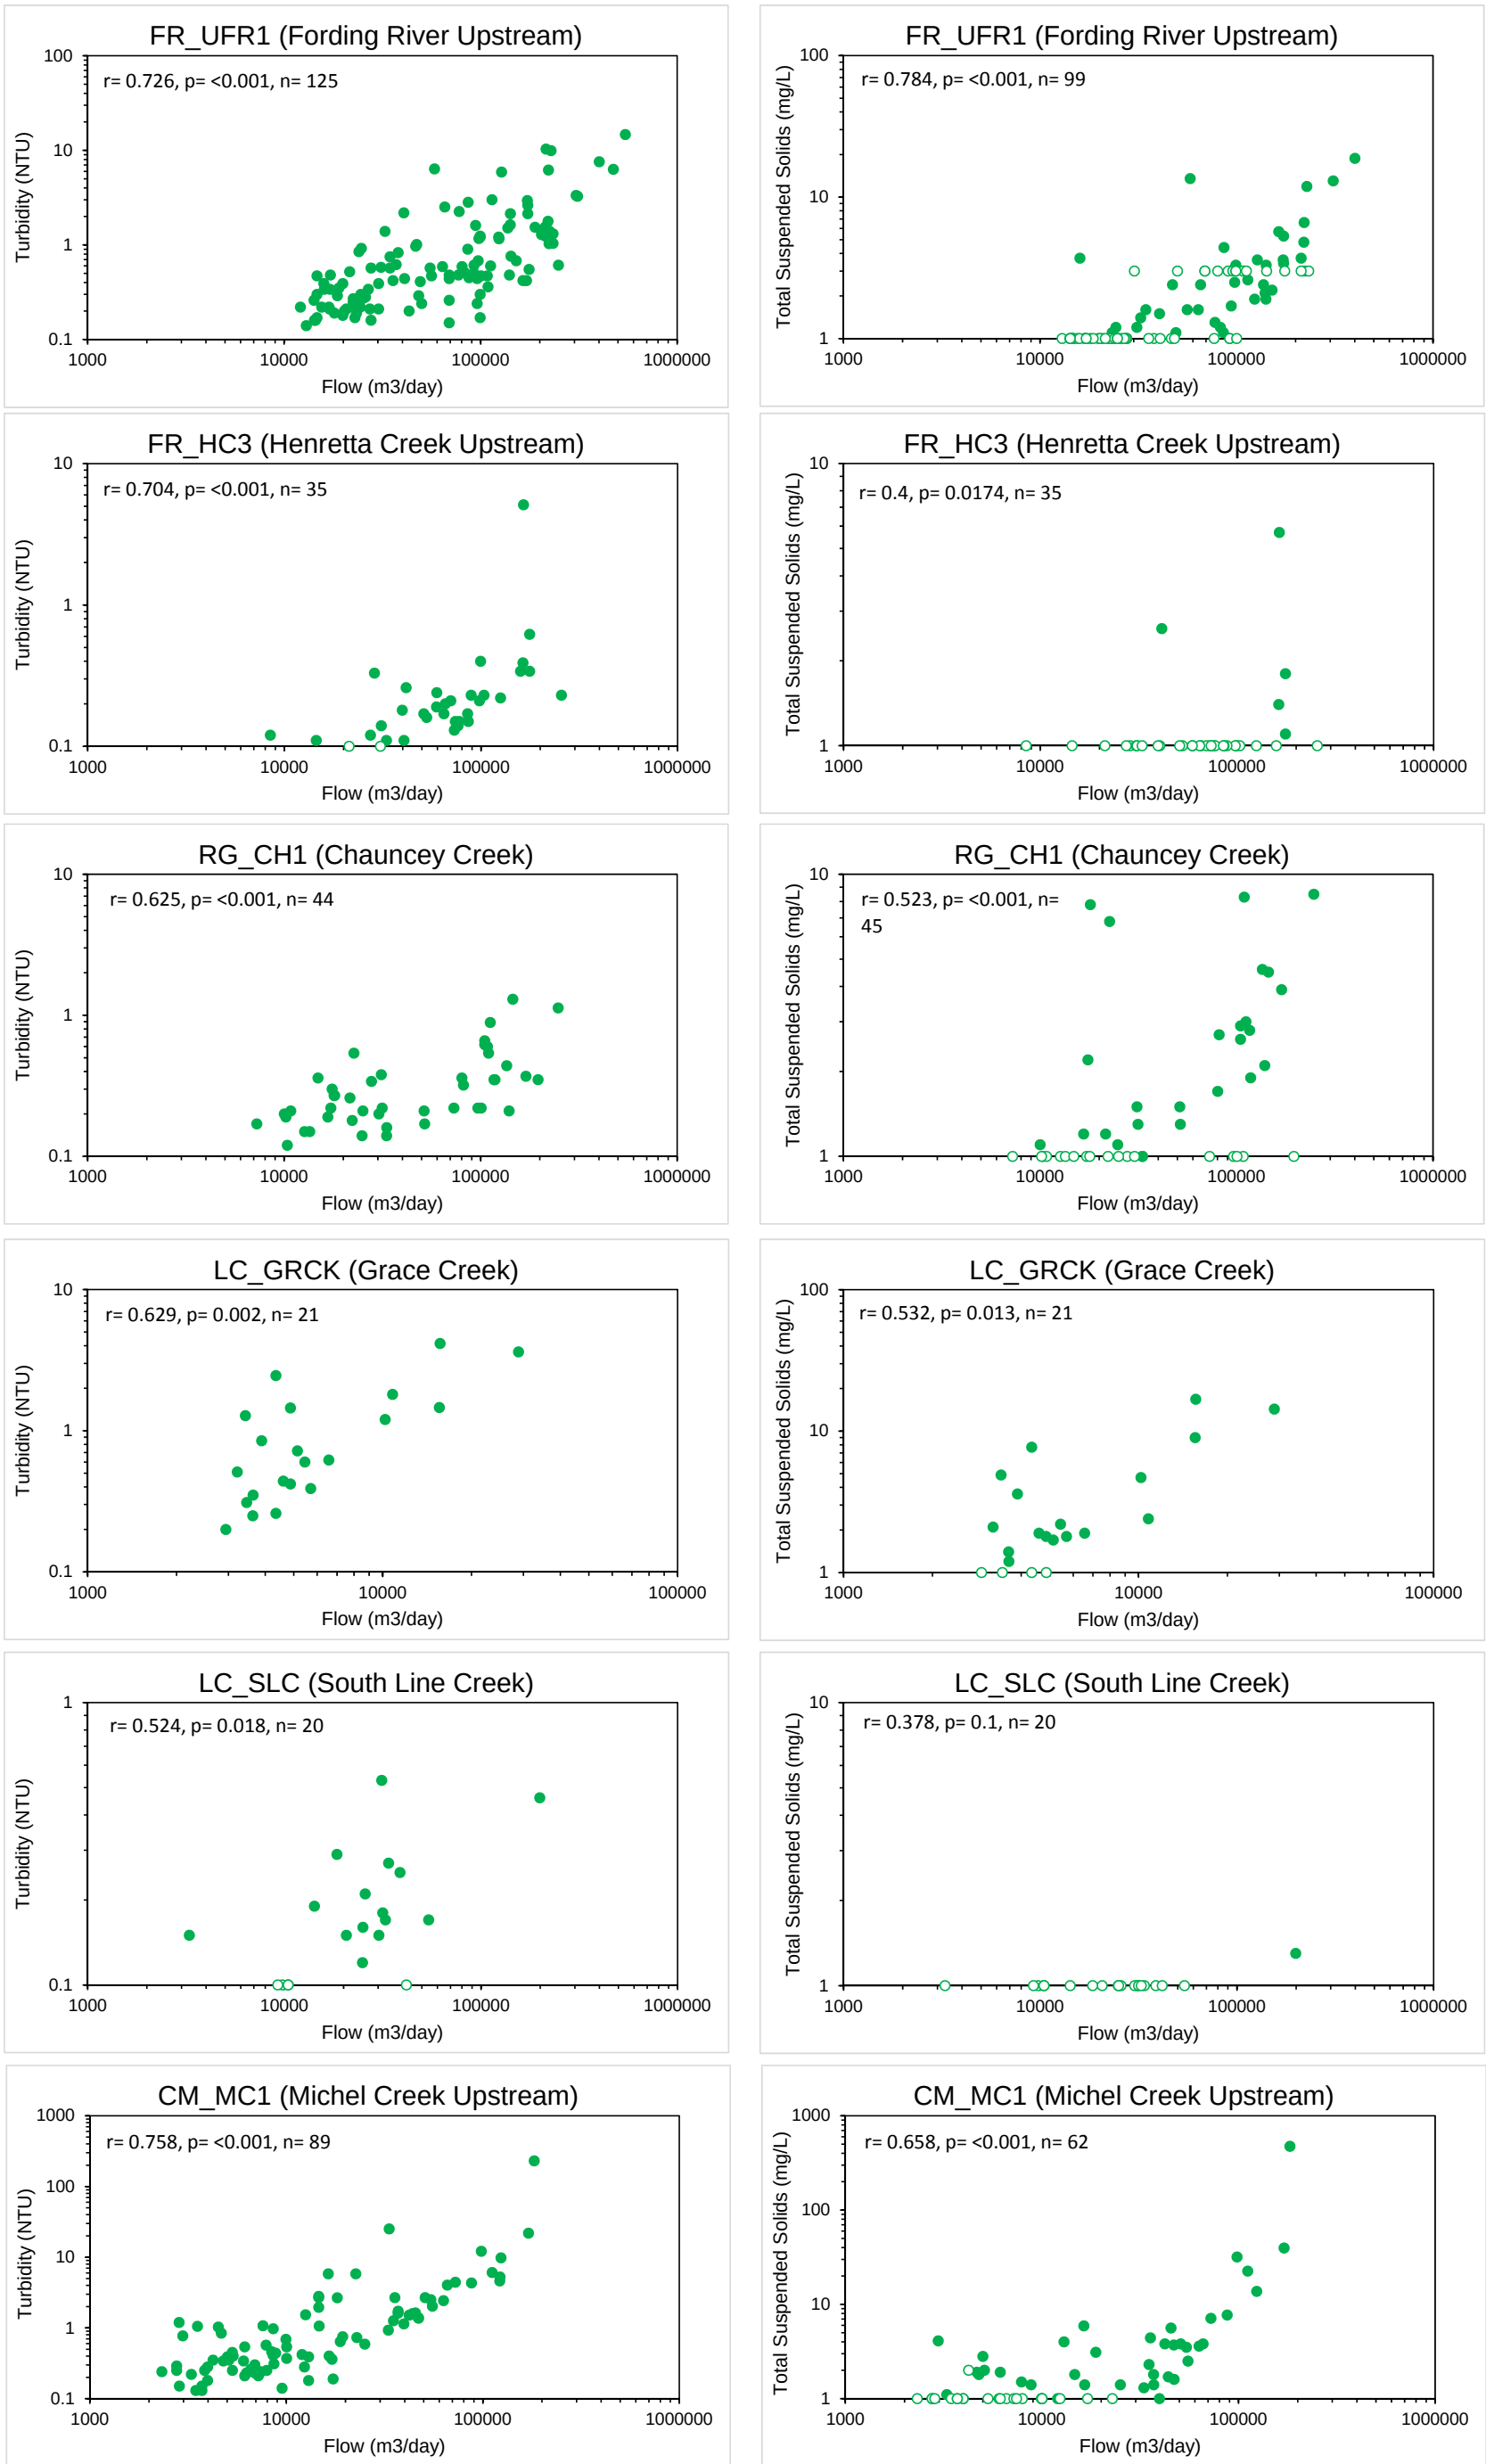

Figure 3.8: Flow versus Total Suspended Solids or Turbidity at Reference Stations where Significant Spearman Correlations ($p < 0.05$) were Observed

Notes: Axis scales vary among panels. Open symbols indicate data below the laboratory reporting limit (LRL).

on discussions with the EMC about this evaluation, it was decided that a single normal range would be defined for all water quality variables based on combining data for all reference water quality stations monitored by Teck. This was deemed adequate for identifying areas of the watershed that are being affected by mining because concentrations at mine-exposed areas that are above the normal range for all reference stations combined provides strong evidence of mine-related influence. Subtle differences in water quality associated with areas being newly affected by mine development (i.e., where comparison to a regional reference normal range might "miss" a small change in water quality in early stages of mining) will be detected through station-specific trend analysis that incorporates pre-mining water quality data.

Upper normal range limits were defined for each water quality constituent by pooling data for 2012 to 2016 across reference stations within each month and computing the reference 97.5th percentile for each constituent in each month (Appendix Figure C.3; Appendix Table C.10). Reference station normal ranges for the Order constituents were well below site-specific benchmarks in all months (Figure 3.9). Concentrations of all other constituents at reference stations were also below BC guidelines for protection of aquatic life, except for total beryllium, total chromium, total iron, and total mercury concentrations (Appendix Figure C.3).

Total aqueous concentrations of metals such as aluminum, arsenic, iron, lead, and manganese, as well as total phosphorus and TOC, correlated strongly and positively ($p<0.001$, $r>0.6$) with TSS and/or turbidity, especially among mine-exposed stations, whereas correlations were weaker for dissolved fractions of those constituents (Appendix Tables C.8 and C.9). For aluminum, iron, manganese, and total phosphorus, which correlated strongly with TSS and/or turbidity among reference stations (Appendix Table C.8), normal ranges were also defined using a covariate approach[15]. TSS or turbidity, whichever exhibited the strongest linear regression relationship, was used as the covariate (Appendix Figure C.4; Appendix Table C.12). The normal range applicable to a given sample was defined as the 97.5th percentile of the residuals up to a maximum value corresponding to the maximum monthly covariate value for the same month.

Although concentrations of other variables (e.g., total arsenic, total lead, and TOC) at mine-exposed areas were also strongly associated with elevated TSS and/or turbidity levels ($r>0.6$ Appendix Table C.9), correlations were not as strong ($r<0.6$) for samples collected at reference areas (Appendix Table C.8). Therefore, covariate-adjusted normal ranges were not developed

[15] i.e., The covariate-adjusted approach was a second way of defining the upper limit of reference station normal ranges that was applied to aluminum, iron, manganese, and phosphorus, in addition to the monthly 97.5th percentiles computed for all constituents.

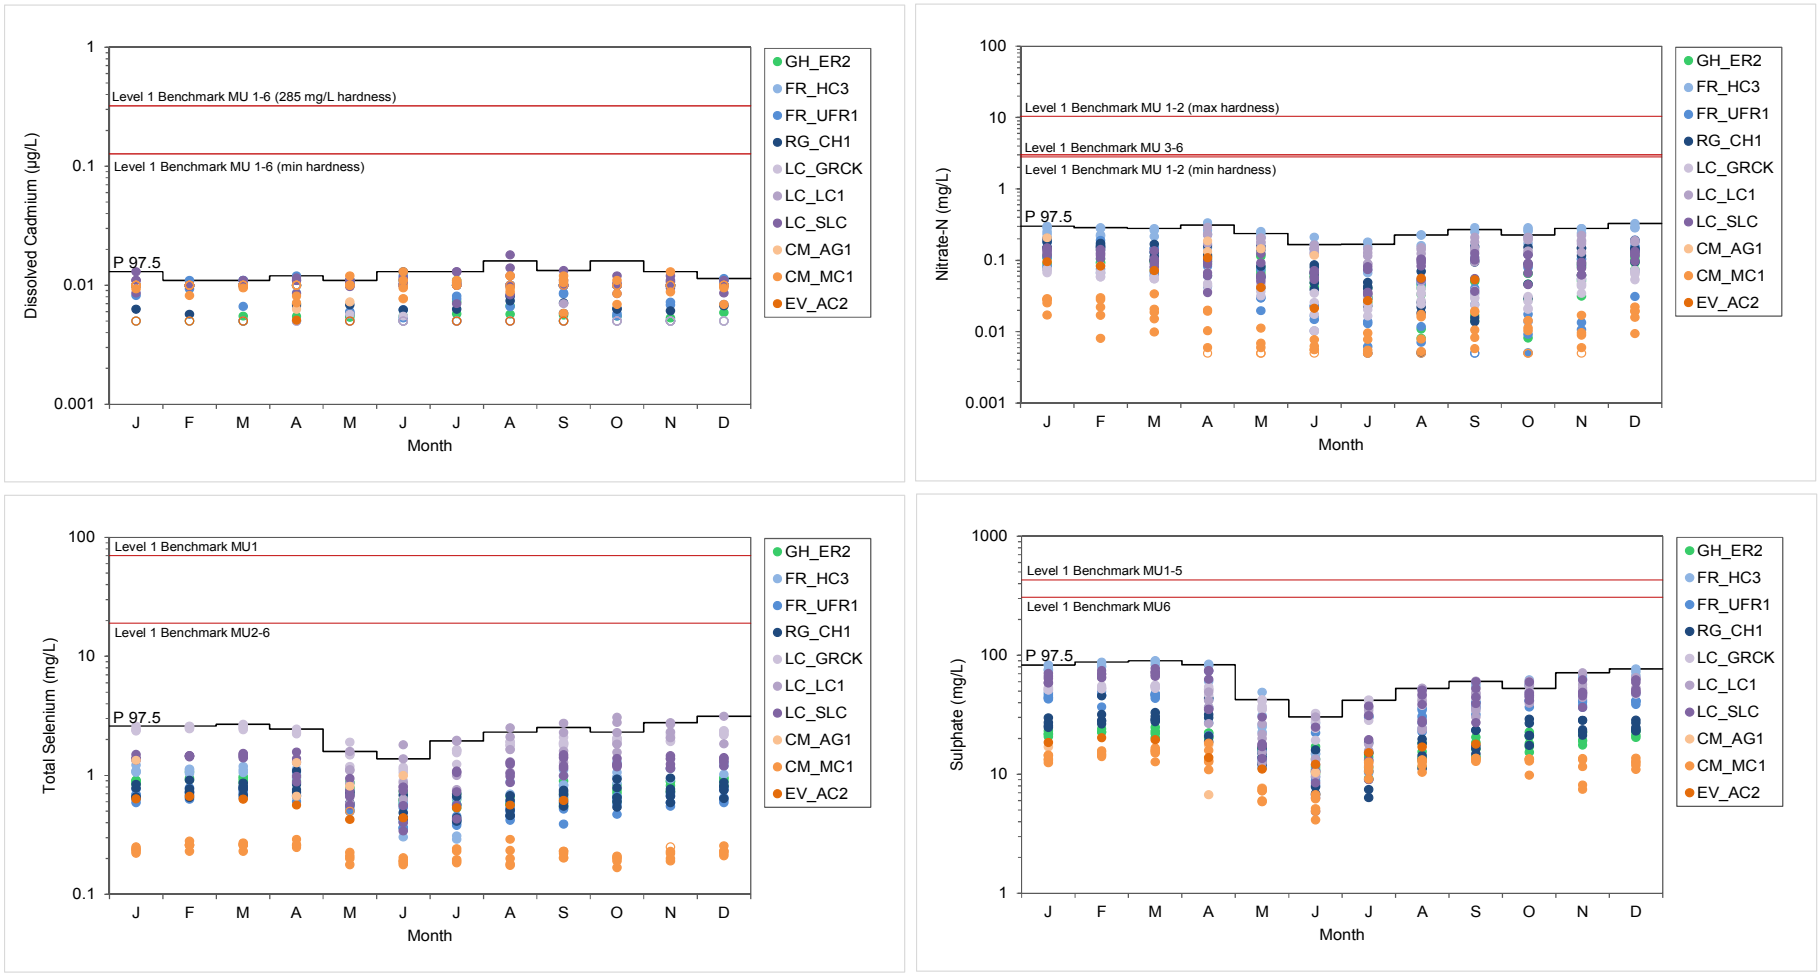

Figure 3.9: Normal Ranges Computed by Month for Dissolved Cadmium, Nitrate-N, Total Selenium, and Sulphate

for these constituents. Nevertheless, strong positive correlations of these variables with TSS and/or turbidity among mine-exposed stations indicate strong association with elevated particulate levels for these constituents (Appendix Figure C.5).

3.5 Concentrations at Mine-Exposed Stations Relative to Normal Ranges

3.5.1 Lotic Monitoring Stations

A low percentage (e.g., ~2.5%) of all samples could be expected to naturally exceed normal ranges that are based on the 97.5th percentile of reference station values. Differences in flow regimes from year to year may increase the frequency of samples naturally exceeding normal ranges. For example, normal ranges for total cadmium and total chromium (that were based on reference station data from 2012 to 2016 combined) were exceeded in a high percentage of reference station samples collected in 2015 (Appendix Table C.13). Elevated concentrations of both of these metals tend to be associated with high TSS/turbidity events (Appendix Figure C.5). Similarly, variation in sampling frequency among months may contribute to a higher frequency of individual samples exceeding normal ranges (i.e., >2.5% of samples). For example, higher sampling frequency during freshet months is likely to increase the percentage of samples exceeding normal ranges for any constituents for which concentrations are positively correlated with flow, TSS, or turbidity. To identify substances having a high probability of being elevated as a result of mining, subsequent evaluation of water quality data relative to normal ranges for mine-exposed stations focused mainly on constituents that were elevated above normal ranges in at least 10% of samples collected in 2015.

Normal ranges for most total and dissolved metals were exceeded in more than 10% of samples collected at more than half of the monitoring stations downstream from mining (Appendix Tables C.13 and C.14). Exceptions included total and dissolved beryllium, bismuth, mercury, silver, and tin, as well as dissolved chromium, iron, lead, and vanadium, which exceeded normal ranges in more than 10% of samples at only a small number of tributary monitoring stations (i.e., ≤7 of 62 mine-exposed stations). Of non-metal constituents, bromide and fluoride also rarely exceeded normal ranges among mine-exposed stations, and dissolved oxygen was usually above the lower limit of the normal range, indicating little or no influence of mining on these constituents. All samples collected in 2015 at the four monitoring stations in MU5, downstream from all mining, had selenium and nitrate concentrations greater than normal ranges. In addition to elevated total selenium and nitrate concentrations, total and dissolved barium, chloride, and nitrite concentrations were above normal ranges in more than 50% of samples collected at the same four stations, suggesting these eight constituents are the ones most strongly indicative of mine influence (i.e., conservative tracers).

Comparison of aluminum, iron, and manganese concentrations at individual mine-exposed stations to covariate (TSS- or turbidity-) adjusted normal ranges typically identified a similar or lesser frequency of normal range exceedances than comparison to monthly (97.5th percentile) normal ranges (Appendix Table C.13). However, the covariate-adjusted normal range for phosphorus identified more normal range exceedances than the monthly normal range approach at most stations (Appendix Table C.15). These results will be discussed with the EMC to determine the best approach for future evaluation of concentrations of constituents having strong relationship to flow, TSS, and/or turbidity levels.

The frequency of normal range exceedances among all samples collected at each station did not necessarily reflect the proportion of the year over which concentrations were elevated, because weekly samples are collected in some months and a single sample in other months based on Permit 107517 requirements[16] (i.e., weekly sampling during months when concentrations are elevated inflates the proportion of samples exceeding normal ranges compared to when the sampling frequency is the same for all months). As requested by the EMC, the monthly mean aqueous concentration of each Order constituent observed at each mine-exposed station in 2015 was divided by the upper normal range limit for the same month to derive normal range quotients (NRQs) (Appendix Tables C.17 to C.20). There were no consistent patterns with respect to the month in which maximum NRQs were observed among stations for the Order constituents although, generally, more maximum NRQs were observed between March and August than in other months of the year. Maximum monthly mean NRQs for the key[17] mine-related constituents nitrate, selenium, and sulphate were greater than one at most mine-exposed lotic stations in 2015. Consistent with the evaluation of frequency of normal range exceedances (above), the NRQs indicated a general pattern of mine influence on water quality throughout the watershed downstream from mining activities (Appendix Table C.21). Highest NRQs in Appendix Table C.21 indicate stations where concentrations were highest.

NRQs computed for water samples collected concurrent with other RAEMP samples in September 2015 agreed well with September results from Teck's water monitoring program, except with respect to some cadmium values (Appendix Figure C.6). Detection limits for Teck samples hovered around the upper limit of the normal range, which increases uncertainty for cadmium NRQs near one. Lower detection limits were achieved with RAEMP water samples

[16] Analysis by Minnow and PLA (2012) concluded monthly sampling was sufficient to monitor mine-related contaminant concentrations and loads over time.

[17] Cadmium concentrations tend to be relatively less elevated above EVWQP Level 1 benchmarks (see Section 3.6) than nitrate, sulphate, or selenium concentrations. Also, total and dissolved cadmium concentrations did not correlate strongly with any other water quality variables. Therefore, of the four Order constituents, the latter three are considered key mine-related variables.

and resulted in lower NRQs for some areas than those based on Teck data for the same areas in September. Good agreement between programs for September water data, especially for the key mine-related variables (Appendix Figure C.6) justified the use of either data set in analyses in later sections of this report.

3.5.2 Lentic Sampling Areas

NRQs greater than one were observed at 12 of 17 lentic areas (Appendix Table C.22). NRQs < 1 were observed at some of the lentic areas associated with the Elk River (EROU, ERUP, UNWNMO), Fording River (FOXL, FWDEC), and Michel Creek (MIWW) indicating that mine-related influence is minimal in these areas (i.e., limited connectively to mine-influenced surface or groundwater) or occurs only seasonally (i.e.., during high flow periods).

The Fording Meadow Upstream of Chauncey Creek (FMUCK) is where the Fording River deepens, flow is slower, and the substrate is finer than other areas of the river. This main stem area was sampled because of its semi-lentic qualities and because it provides over-winter habitat for westslope cutthroat trout (Cope et al. 2016). A water sample was collected here concurrent with collection of sediment and benthic invertebrate tissues for the RAEMP (see Sections 6 and 8), which explains why data for this area are included in Appendix Table C.22.

Area FO10 was formerly a lentic habitat and referred to as the Fording River Oxbow. It was altered to a flowing side-channel in the record storm event of June 2013 (Figure 3.3) and therefore is now a lotic rather than lentic habitat. A water sample was collected here concurrent with collection of sediment and benthic invertebrate tissues to evaluate the change of flow regime on tissue selenium accumulation (see Section 8).

3.6 Concentrations at Mine-Exposed Stations Relative to Benchmarks and Guidelines

3.6.1 Lotic Habitats

Although BC water guidelines for long-term exposure are based on 30-day mean concentrations, concentrations in individual samples were compared to site-specific benchmarks (SSBMs) or BC guidelines (Table 2.1) to conservatively identify constituents being elevated above guidelines as a result of mining. Normal reference station ranges occasionally exceeded water quality guidelines for total beryllium, total iron, total chromium, and total mercury (Appendix Figure C.3). Aqueous concentrations measured at mine-exposed stations in 2015 exceeded SSBMs or sample-specific guidelines, as well as reference area normal ranges[18], for nitrate, sulphate, dissolved cadmium, selenium, total dissolved solids, total and

[18] Occasionally, normal ranges also exceeded SSBMs/guidelines. Discussion focuses on samples from monitoring stations that exceeded both normal ranges and SSBMs/guidelines to reflect the mine-related influence on guideline

dissolved iron, dissolved aluminum, total barium, total beryllium, chloride, total chromium, total cobalt, total mercury, total nickel, nitrite, ammonia, total silver, total thallium, total uranium, and total zinc in one or more samples at one or more monitoring stations (Table 3.1). However, the highest frequencies of exceedances (i.e., >20% of samples at more than three monitoring stations) were observed for nitrate, sulphate, dissolved cadmium, total selenium, total dissolved solids, and total uranium.

Concentrations of constituents observed in individual samples were divided by corresponding SSBMs or generic water quality guidelines for BC to compute HQs reflecting the magnitudes of exceedances. Highest HQs (HQ > 2) were observed at multiple (> 3) stations for nitrate, sulphate, total selenium, total dissolved solids, total iron, dissolved aluminum, total beryllium, total chromium, total mercury, nitrite, and total uranium (Appendix Table C.24). Of those constituents, guideline exceedances for iron, aluminum, beryllium, chromium, and mercury were relatively few (<~20% of samples at most [≥ 94% of] stations; Table 3.1) and, when they occurred, were associated with elevated TSS/turbidity events (Appendix Figure C.5). Guidelines for iron and aluminum are based on dissolved fractions, but dissolved concentrations also tended to be elevated when TSS/turbidity were elevated (Appendix Figure C.5). As suggested by the EMC, dissolved metal concentrations were compared to total metal guidelines to reduce the confounding effect of elevated TSS/turbidity events on guideline exceedances for metals with strong affinity for particulates. This resulted in no exceedances for most metals, and relatively few exceedances (<20% of samples at all stations) for chromium, cobalt, and mercury. Concentrations of dissolved selenium and uranium were frequently elevated above SSBMs/guidelines for the total fraction (Appendix Table C.27a), consistent with these constituents being highly water soluble (Section 3.3.2).

Overall, the evaluation of water quality data for 2015 relative to SSBMs/guidelines and reference area normal ranges indicated that the constituents tending to be most elevated above normal ranges and guidelines in the Elk River watershed as a result of mining were nitrate, total and dissolved selenium, sulphate, total dissolved solids, total (but not dissolved) iron, dissolved aluminum, and total and dissolved uranium.

Frequencies of exceedances described above may overestimate the proportion of the year when concentrations were elevated, if exceedances occurred in months when sampling frequency was weekly instead of monthly. Also, the evaluation of concentrations relative to a 30-day rolling average is challenging to implement and interpret in routine monitoring because

exceedances. Frequency of exceedances of SSBMs/guidelines and associated maximum HQs, irrespective of normal ranges, are presented in Appendix Tables C.25 and C.26.

Shading indicates frequency exceeded 0%.

[1] Only stations with data for at least 8 months were included. One exception, LC_LC1, had data for 7 months. Values less than the laboratory reporting limit (LRL) were excluded from evaluation if the LRL was greater than the SSBM/Guideling. Only constituents that had at least one guideline exceedance are reported.

[2] For total iron, normal ranges were adjusted for total suspended solids for each month. Refer to methods for details.

[3] For total mercury, the most conservative guideline was applied (0.00000125 mg/L).

Shading indicates frequency exceeded 0%.

[1] Only stations with data for at least 8 months were included. One exception, LC_LC1, had data for 7 months. Values less than the laboratory reporting limit (LRL) were excluded from evaluation if the LRL was greater than the SSBM/Guideling. Only constituents that had at least one guideline exceedance are reported.

[2] For total iron, normal ranges were adjusted for total suspended solids for each month. Refer to methods for details.

[3] For total mercury, the most conservative guideline was applied (0.00000125 mg/L).

[2] For total iron, normal ranges were adjusted for total suspended solids for each month. Refer to methods for details.

[3] For total mercury, the most conservative guideline was applied (0.00000125 mg/L).

multiple exceedances can occur if a single sample had a sufficiently elevated concentration to elevate means for each 30-day period that included that particular sample value (i.e., during weekly monitoring, multiple 30-day means may exceed the guideline based on elevated concentrations in only a single sample).

As requested by the EMC, mean monthly[19] concentrations of Order constituents observed in routine monitoring by Teck in 2015 were divided by corresponding EVWQP Level 1 benchmarks (Table 2.2) to compute an HQ for each month (Appendix Tables C.28 to C.31).

Maximum monthly HQs were less than one for cadmium, selenium, and sulphate in all main stem areas except in the Fording River (selenium and sulphate at FR_FRCP1; selenium at GH_PC2, FR_FRABCH, LC_LC6, and LC_LC5), and in lower Michel Creek (selenium at EV_MC2) (Appendix Table C.21). Maximum monthly HQs were near or greater than one for nitrate at most stations in the Fording River downstream from mining, in the Elk River downstream from the Fording River (EV_ER4 and EV_ER2), and at two stations in Michel Creek (CM_MC2, EV_MC2).

Maximum monthly HQs greater than one were observed for nitrate, selenium, and/or sulphate in numerous tributaries of MU1 to MU4 (there are no mine-exposed tributaries in MU5). In MU1, highest HQs for nitrate and selenium were observed at Clode Settling Pond decant (FR_CC1), Kilmarnock Creek (FR_KC1), Swift Creek Sediment Pond decant and bypass (GH_SC1 and GH_SC2, respectively), and Cataract Creek Sediment Pond decant (GH_CC1) (Figure 3.10; Appendix Tables C.21 and C.28 to C.31). Kilmarnock Creek is the single largest source of mine-related constituents in MU1 (Zajdlik and Minnow 2013). Water from Kilmarnock, Swift, and Cataract will be directed to an active water treatment facility (AWTF) that is expected to reduce aqueous concentrations of nitrate and selenium in the Fording River.

In MU2, highest HQs for aqueous mine-related constituents were observed among the mine-exposed stations in Line Creek, which are located downstream from the LCO rock drain (Figure 3.8). Line Creek was formerly identify as a major source of mine-related constituents to the Fording River (Zajdlik and Minnow 2013), and an AWTF was commissioned in late 2015 (commencing full scale operation in early 2016) to reduce concentrations of selenium and nitrate discharging from West Line Creek into Line Creek. The results summarized for 2015 (Appendix Table C.21 and Figure 3.8) precede changes in water quality associated with operation of the AWTF. There is further discussion about changes observed in 2016 associated with the West Line Creek AWTF in subsequent sections of this report.

Figure 3.10

Maximum monthly HQs for main stem Elk River monitoring stations were less than one, indicating low potential for mine-related effects. HQs in MU3 were highest in GHO west-side tributaries Leask (GH_LC1, GH_LC2), Wolfram (GH_WC1, GH_WC2), and Thompson (GH_TC2; Appendix Table C.21), which have had longer historical exposure to mining than the tributaries farther north. The GHO LAEMP was initiated in fall 2017 to characterize conditions in the valley bottom and Elk River side channel into which these tributaries discharge (Minnow and Lotic 2017). Data from the GHO LAEMP will be used to inform future RAEMP reports.

As with other MUs, highest HQs for mine-related variables in MU4 were observed in tributaries draining to upper Michel Creek near CMO (Corbin Creek [CM_CC1]) and into lower Michel Creek near EVO (Erickson [EV_EC1], South Pit [EV_SP1], Gate [EV-GT1], and Bodie [EV_BC1]). No EVWQP Level 1 benchmarks were exceeded for stations in the lower Elk River (MU5).

3.6.2 Lentic Habitats

HQs > 1 were observed for nitrate and/or selenium at FMUCK (MU1), R5-3 (MU2), GO13 (MU4), and Stanford Pond (MU5) (Figure 3.11; Appendix Table C.22).

3.7 Comparison to Predictions

Golder (2017a) evaluated water quality in the Elk River watershed in 2016 relative to concentrations predicted by Teck's Regional Water Quality Model (RWQM) that was developed in support of the EVWQP. Water quality performance was evaluated for nitrate, selenium, and sulphate at the 12 Order and Compliance Stations within the Elk River watershed, and at the Compliance Station in Koocanusa Reservoir (Table 3.2). In most cases, concentrations were consistent with or less than modelled. Selenium and sulphate concentrations in water were greater than the modelled concentrations at the FRO Compliance Point (FR_FRCP1; MU1) in 2016 (Golder 2017a). Compliance Points are intended to monitor fully mixed conditions in the receiving environment (i.e., main stem river) of all or most of the direct or indirect discharges from one mine operation. Water quality and quantity monitoring data have indicated that surface water flow at FR_FRCP1 is predominantly discharge water from the mine-impacted Cataract Creek during winter low flows.

In MU2, aqueous nitrate concentrations at the LCO Compliance Point (LC_LCDSSLCC) in 2016 were greater than the modelled concentrations due to greater than anticipated loads from Line Creek upstream from West Line Creek (Golder 2017a). Observed concentrations were also greater than modelled concentrations for one or more constituents at each of the three Compliance Stations in MU4 (Table 3.2). In the case of EV_HC1, nitrate concentrations remained below water quality guidelines. Higher than expected concentrations at Michel Creek

Figure 3.11

Table 3.2: Comparison of Monitoring Observations to Model Predictions for Order and Compliance Stations in the Elk Valley

Management Unit	Stream Name	Teck Water Station Code	Station Description	MOE EMS Number	Observed Concentrations Relative to Predictions			Potential Explanation(s) for Observed Concentrations Being Greater than Predictions
					Nitrate	Selenium	Sulphate	
1	Fording River	FR_FRCP1 (Compliance)	d/s Cataract, u/s Porter	E300071	✓	↑	↑	Water collected at this location during the winter low flow period is predominantly discharge from Cataract Creek so concentrations are not representative of combined and fully mixed contributions from FRO discharages within the Fording River.
	Fording River	GH_FR1 (Order - FR4 and Compliance)	d/s GHO and Greenhills Cr.	200251	↓	↓	✓	-
2	Fording River	LC_LC5 (Order - FR5)	d/s Line Creek	200028	↓	↓	✓	-
	Line Creek	LC_LCDSSLCC (Compliance)	immediately d/s of South Line Cr. confluence	E297110	↑	✓	✓	Source loadings of nitrate were greater than anticipated.
3	Elk River	GH_ERC (Compliance)	220 m d/s of Thompson Cr. and d/s all GHO	E300090	↓	↓	✓	-
	Elk River	GH_ER1 (Order - ER1)	d/s GHO, u/s Fording R. and u/s Boivin Cr.	206661	↓	↓	✓	-
4	Elk River	EV_ER4 (Order - ER2)	d/s Fording R., u/s Grave Cr.	200027	✓	✓	✓	-
	Harmer Creek	EV_HC1 (Compliance)	dam/spillway at d/s end of Harmer Pond	E102682	↑	✓	✓	Although the model has been underestimating nitrate concentrations, concentrations are less than water quality guidelines and not a significant contributor to regional loads.
	Michel Creek	CM_MC2 (Compliance)	d/s Corbin Creek and CMO, 50 m u/s Andy Good Cr.	E258937	↑	↑	✓	The model also underestimated observed concentrations during the model calibration period and may be because the model overestimated flows at this location.
	Michel Creek	EV_MC2 (Compliance)	lower Michel Compliance; between Bodie Cr. and Aqueduct Cr., d/s HWY #3 bridge (Shell Plant)	E300091	↑	✓	↑	Higher than predicted nitrate and sulphate values may relate to overestimation of flows or lack of integration of pumping data at this location.
5	Elk River	EV_ER1 (Order - ER3)	d/s Sparwood & Michel Creek, d/s EV_ER1	200393	✓	✓	✓	-
	Elk River	RG_ELKORES (Order - ER4)	at Elk Reservior	E294312	✓	✓	✓	-
6	Koocanusa Reservoir	RG_DSELK (Order)	Lake Koocanusa - South of Elk River	E300230	✓	↓	↓	-

✓ Observed concentrations were consistent with predictions.
↑ Observed concentrations were higher than predictions.
↓ Observed concentrations were lower than predictions.
Shade indicates stations where model underestimated concentrations

Compliance Stations (CM_MC2 and EV_MC2) may have been due to overestimation of water flows in the RWQM (Golder 2017a). The RWQM was updated in 2017, so future comparisons of observed to modelled concentrations will be based on the updated model.

3.8 Temporal Changes

Temporal trends were evaluated for monthly mean nitrate, selenium, and sulphate concentrations using RM ANOVA, followed by *post hoc* contrasts to test for linear and step changes relative to mean reference area temporal changes. Step change decreases, particularly for nitrate, were observed at many areas (Appendix Tables C.32 to C.35). This was contrary to expectations, and was found to be at least partially attributable to temporal increases in concentrations of nitrate among reference areas, and not necessarily decreases among mine-exposed areas (Appendix Figure C.8).

The hypothesis that reference area temporal changes were dominating temporal changes reported for mine-exposed areas was evaluated further. Instead of assessing changes in concentrations at each of the mine-exposed areas relative to the reference mean (as reflected in Appendix Tables C.32 to C.34), the analyses were repeated to evaluate absolute changes over time for each water station (Appendix Tables C.36 to C.38). Very few decreases remained, with more stations showing no change or increases in concentrations when reference area trends were not taken into account (Appendix Table C.36 to C.38). Although not all changes in concentrations over time were statistically significant, there was a pattern of increasing concentrations at most reference areas (6 of 8 reference stations for selenium; 7 of 8 reference stations for nitrate and sulphate) year-over-year (Appendix Tables C.36 to C.38). Therefore, the data indicate that decreases that were reported among mine-exposed areas in Appendix Tables C.32 to C.34 were largely attributable to increases among reference areas. The reason for observed increases among reference areas is currently unknown.

Step decreases in aqueous concentrations observed among mine-exposed areas after 2013 may also be related to effects of the record flood in June 2013 (Figure 3.3).

Statistically significant increases in nitrate concentrations were observed at six mine-exposed water monitoring stations after 2014 (GH_COUGAR 377%; GH_MC1 1,539%) or 2015 (FR_CC1 99%, LC_DC3 83%, GH_ER1 28%, EV_MC3 65%) (Figure 3.12; Appendix Table C.32). Significant increases in selenium were observed at four stations: Kilmarnock Creek (FR_KC1 22% after 2012), upper Dry Creek stations LC_DC3 (38% after 2015) and LC_DCDS (27% after 2015), and Mickelson Creek (GH_MC1 186% after 2014) (Figure 3.12; Appendix Table C.33). Increasing sulphate concentrations were observed in Line Creek upstream from the AWTF (LC_LCUSWLC 15% after 2012), at the GHO Elk River Order station

Nitrate-N

Notes: Grey shading represents the reference area normal range (2.5th and 97.5th percentiles for the 2012-2016 reference area data).

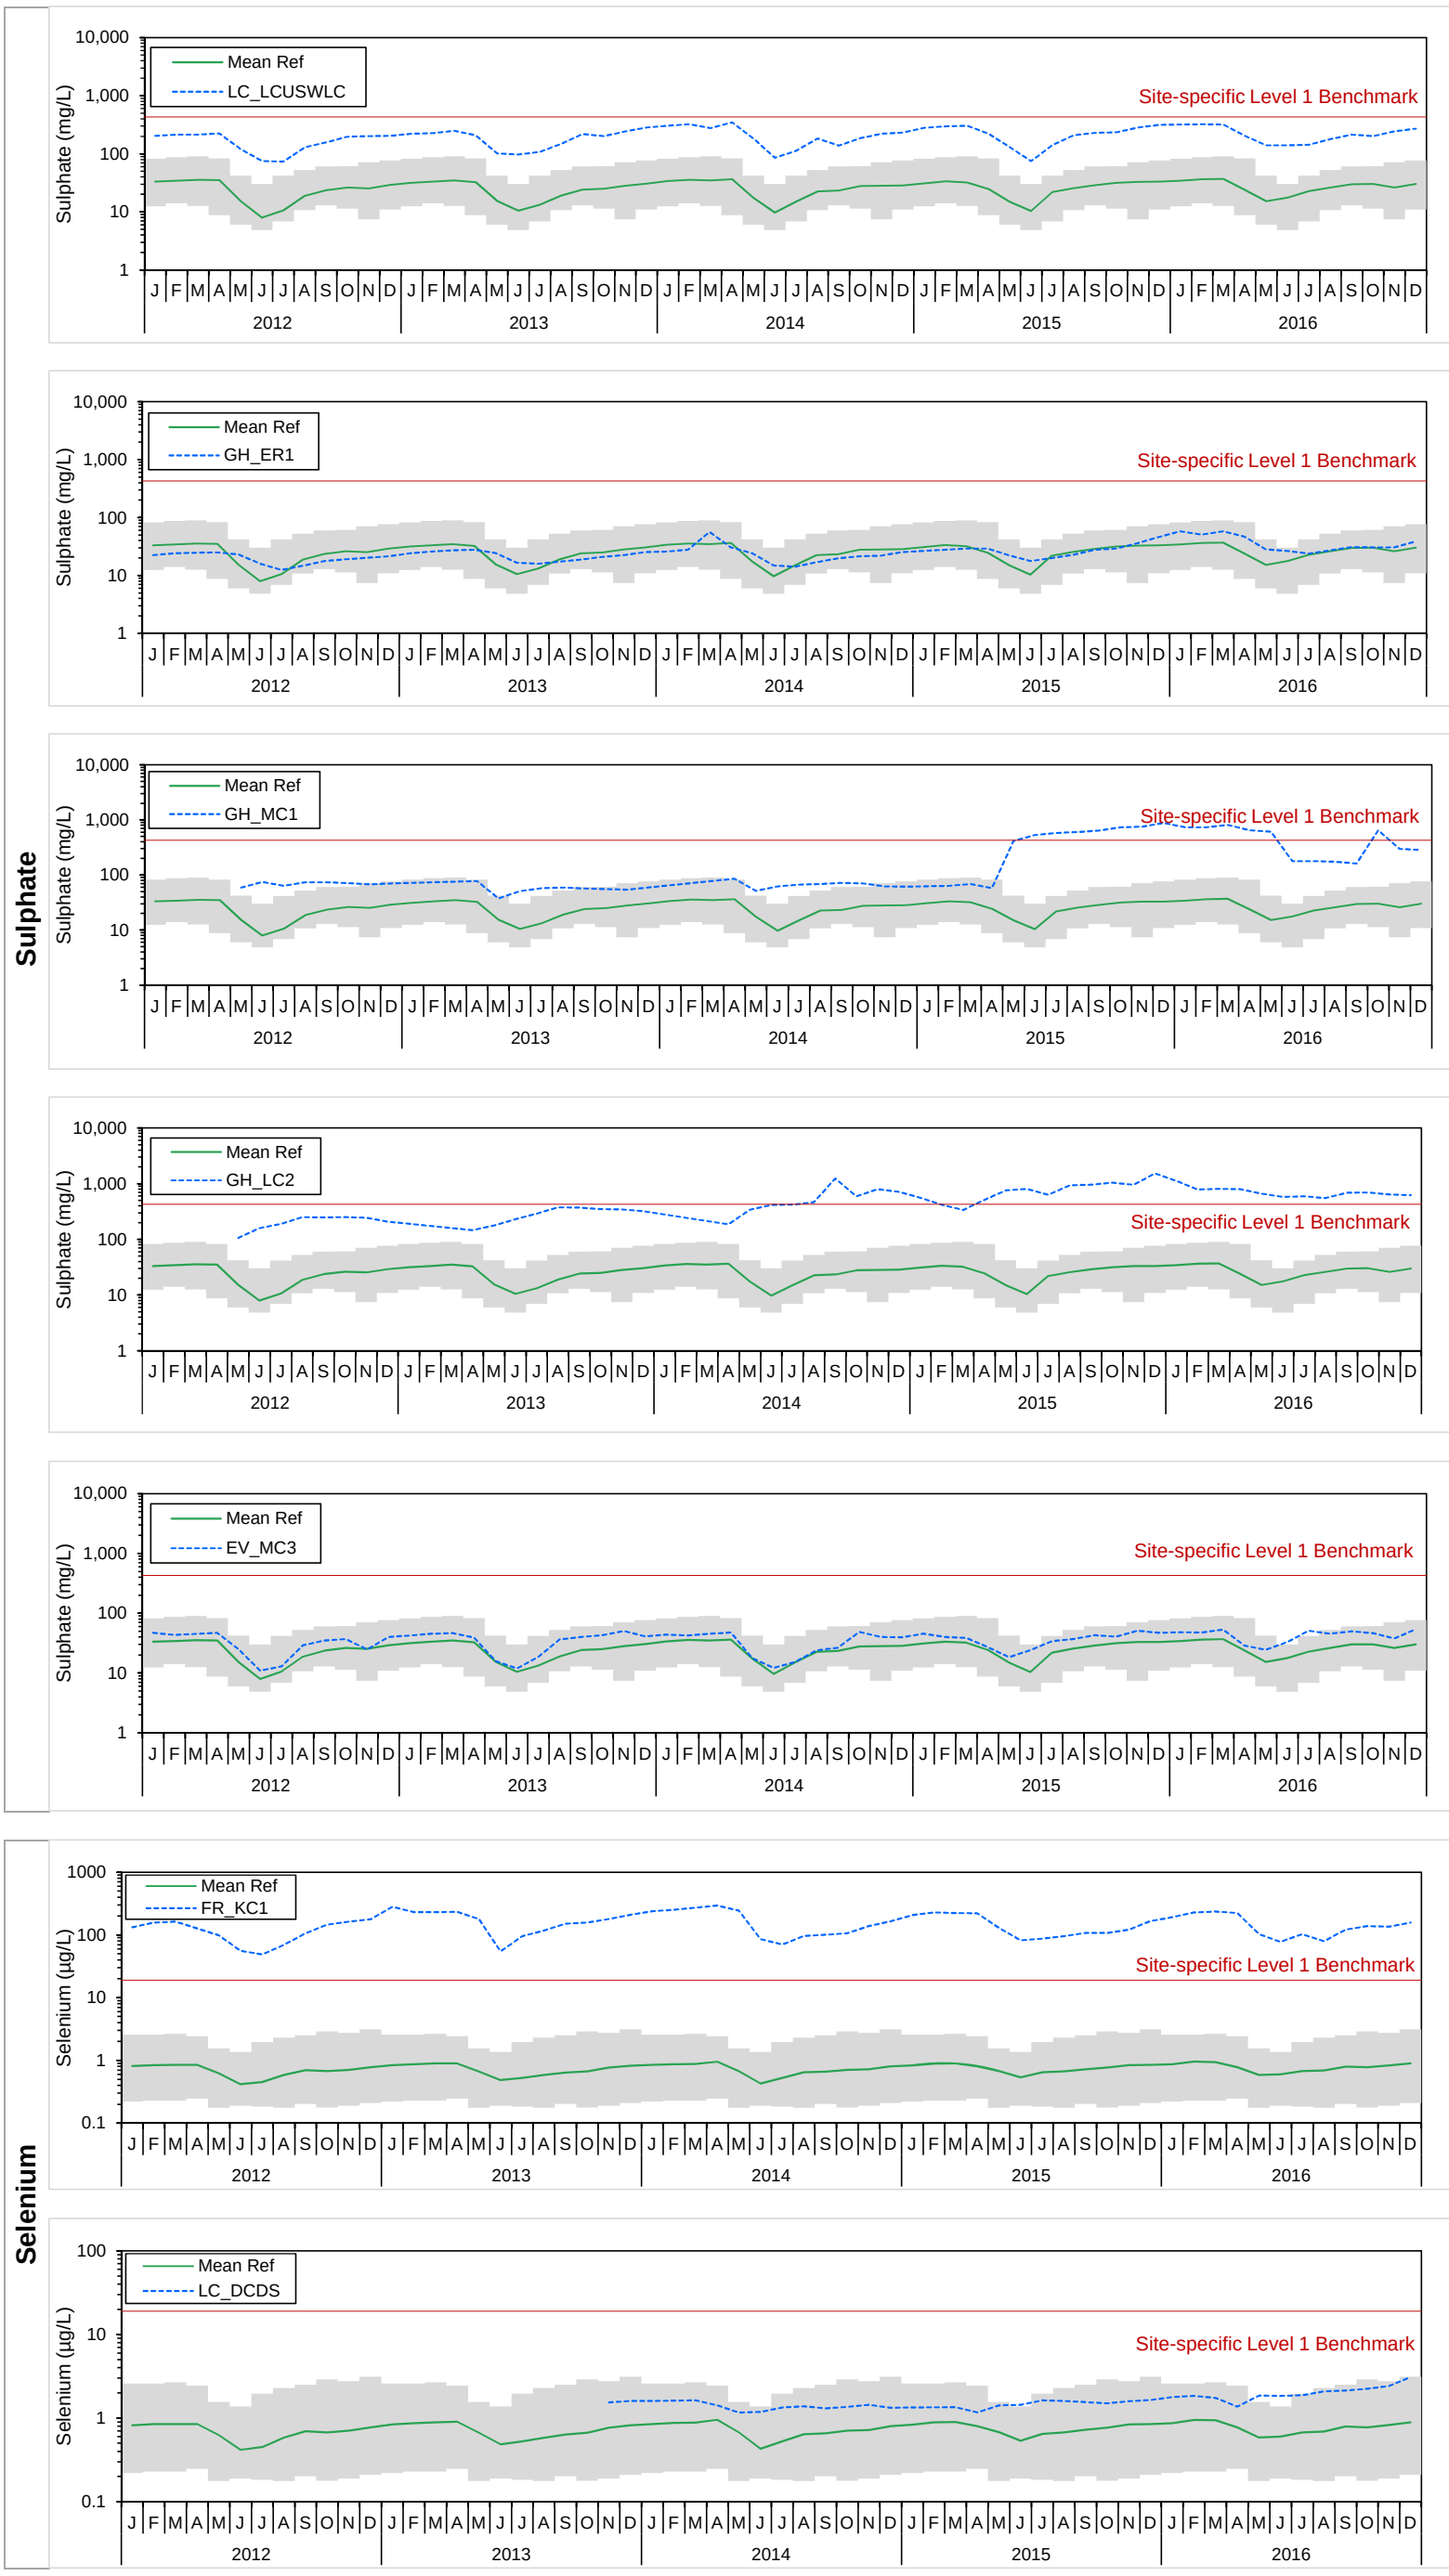

Figure 3.12: Significant Increasing Temporal Changes for Nitrate-N, Total Selenium, and Sulphate Relative to Mean Reference Concentrations, 2012 - 2016

Notes: Grey shading represents the reference area normal range (2.5th and 97.5th percentiles for the 2012-2016 reference area data).

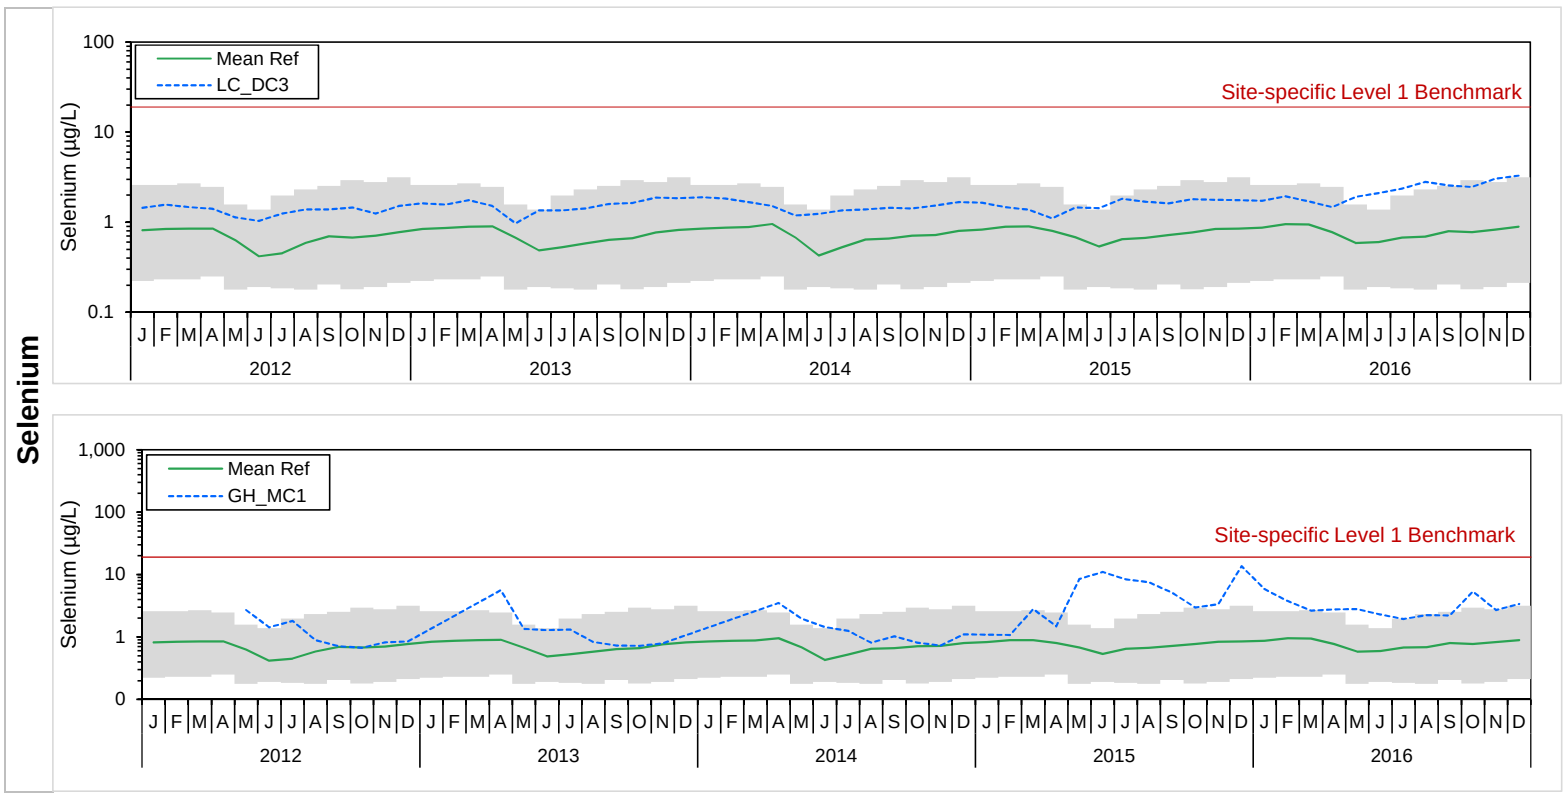

Figure 3.12: Significant Increasing Temporal Changes for Nitrate-N, Total Selenium, and Sulphate Relative to Mean Reference Concentrations, 2012 - 2016

Notes: Grey shading represents the reference area normal range (2.5th and 97.5th percentiles for the 2012-2016 reference area data).

(GH_ER1 53% between 2012 and 2016), at Mickelson Creek (GH_MC1 407% after 2014), at Leask Creek (GH_LC2, 142% after 2013), and in Michel Creek upstream from Erickson Creek (EV_MC3; 18% after 2015) (Figure 3.12; Appendix Table C.34).

Although decreases in nitrate concentrations were detected in Line Creek downstream from the AWTF (LC_LC3; Figure 3.13; Appendix Table C.32), decreases of similar magnitude were observed in previous years (i.e., after 2013 and 2014) and were also observed widely among mine-exposed areas (i.e., related to reference area increases not decreases at mine-exposed areas).

Potential temporal changes were also evaluated for the overall main stem receiver within each MU relative to reference areas. Significant increases in nitrate and sulphate concentrations were identified for the Elk River in MU3 (Appendix Table C.35), but concentrations remained below EVWQP Level 1 benchmarks (Table 3.1). Average concentrations of nitrate, selenium, and sulphate decreased or remained unchanged in the other main stem receivers (Appendix Table C.35).

3.9 Summary

Water flows in the Elk River watershed vary annually, particularly during spring freshet, after which flows gradually decline toward winter minima. Peak spring water flows in 2012 to 2014 exceeded 10-year averages, especially in 2013 when record flows were observed in mid-June. In 2015, peak freshet flows were near the average, but declined more quickly in June and July. In 2016, freshet flows began earlier and peaked at below-average levels.

Water quality variability among stations downstream of mining relates mainly to variation in concentrations of Order constituents (nitrate, total selenium, and sulphate, and to a lesser degree cadmium), as well as alkalinity, conductivity, hardness, TDS, calcium, magnesium, nitrite, sodium, and potassium; and total and dissolved antimony, boron, calcium, chloride, lithium, magnesium, molybdenum, nickel, nitrite, potassium, strontium, and uranium. Water quality variability among mine-exposed stations was also associated with variation in concentrations of TSS and turbidity, and substances often associated with particles in the water column (e.g., aluminum, iron, manganese) as well as TOC and phosphorus (which likely reflect the mobilization of organic matter during high flows).

Monthly mean concentrations of the key mine-related constituents (nitrate, selenium, and sulphate) tend to be lowest in the upper Elk River and highest in the Fording River. Most stations show a similar seasonal pattern of lowest concentrations in winter and highest concentrations during spring freshet, although there is variability that may relate to periodic precipitation events.

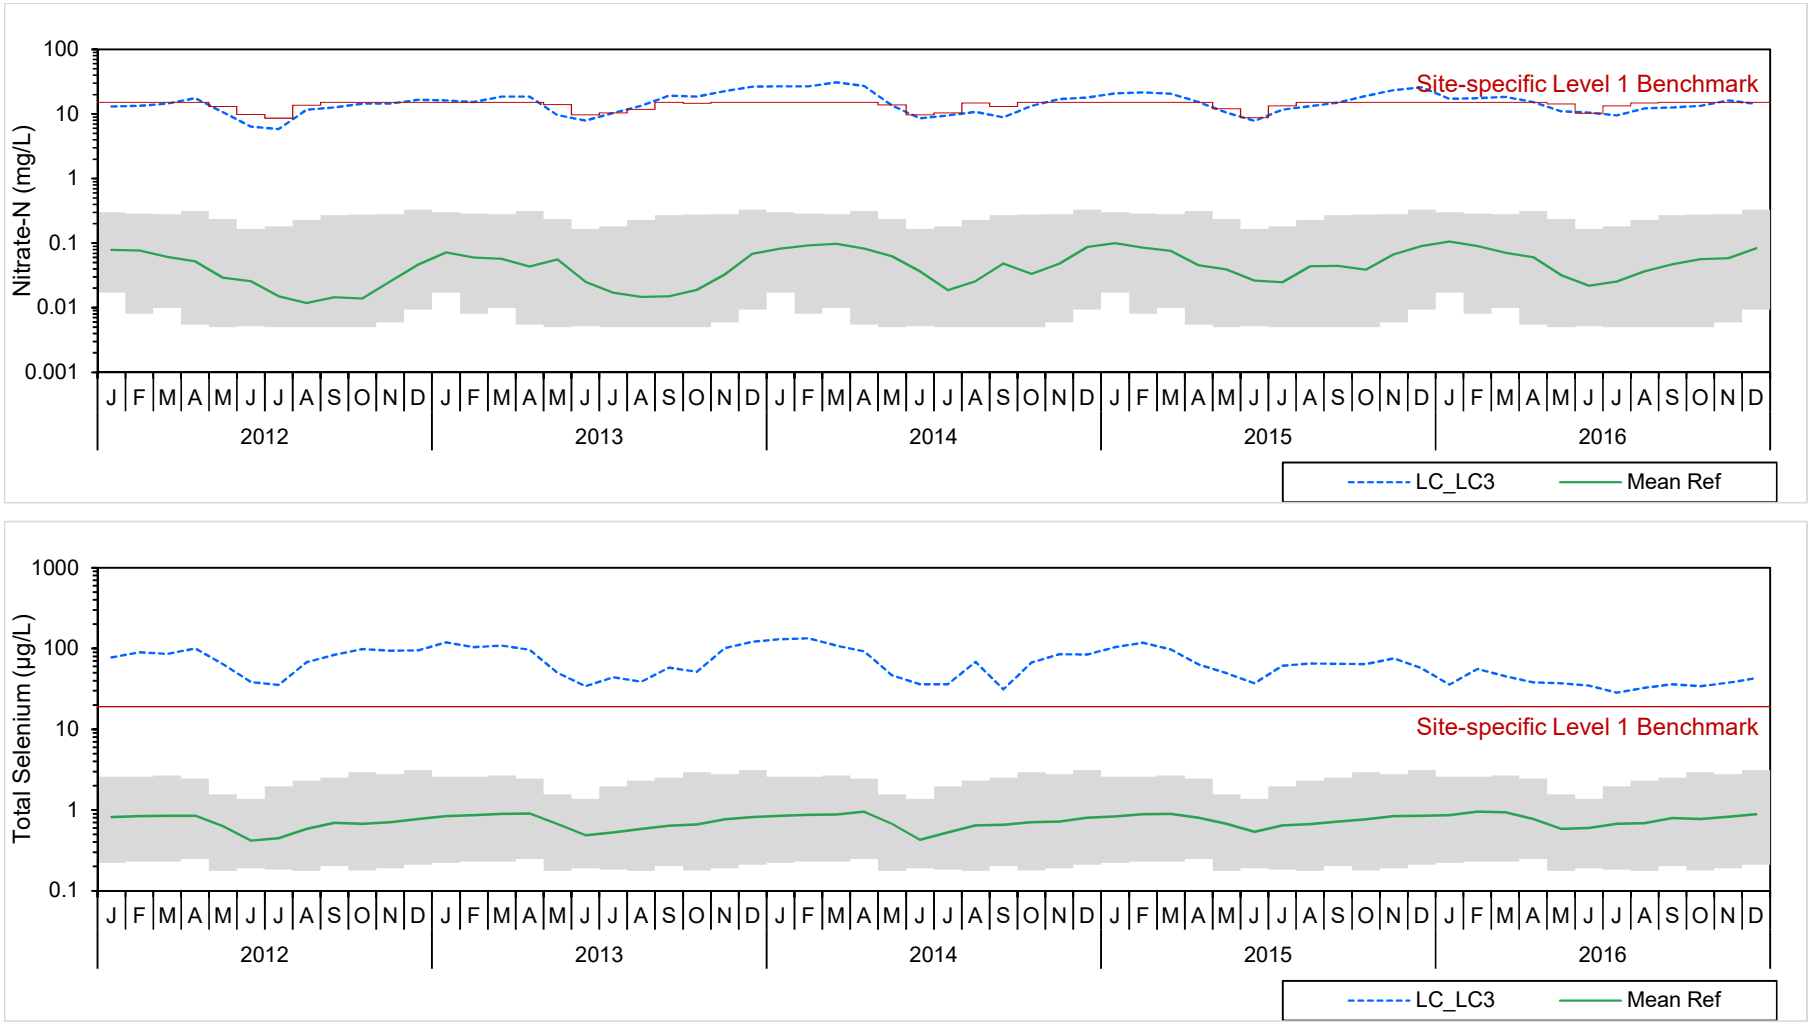

Figure 3.13: Time Series Plots for Monthly Mean Nitrate and Total Selenium Concentrations at LC_LC3 and for the Mean of the Reference Areas, 2012 - 2016

Notes: Grey shading represents the reference area normal range (2.5 th and 97.5th percentiles for the 2012-2016 reference area data).

Strong negative correlations with water flow (r>|0.6|) were observed for concentrations of alkalinity, as well as total and dissolved lithium, molybdenum, and strontium among reference station samples, but specific conductivity (r = 0.9) and dissolved organic carbon (r = -0.6) were the only constituents that correlated strongly with water flow among samples collected at mine-exposed stations. Aqueous TSS and/or turbidity correlated strongly (r>0.6) with water flow at most individual reference stations, but only weakly when data for reference stations were combined (r<0.4), indicating that relationships between flow and TSS/turbidity vary naturally among stations, even among reference stations within close proximity in the watershed. The results suggest that prior to mining, water quality along main stem streams may have varied naturally from headwaters due to differences in water quality among tributary inputs.

A single normal (reference) range was defined for each water quality variable based on combining data for all reference water quality stations monitored by Teck (2012 to 2016) within each month. The upper limit of the normal range was defined as the 97.5th percentile of the combined reference station concentrations for each month (i.e., the upper limit of "normal" was defined for each month, thereby partially accounting for natural seasonal varations in flow and water quality). This was deemed adequate for identifying areas of the watershed that are being affected by mining because concentrations at mine-exposed areas that are above the normal range for all reference stations combined provides strong evidence of mine-related influence. For aluminum, iron, manganese, and total phosphorus, which correlated strongly with TSS and/or turbidity among reference stations, normal ranges were also defined using a covariate approach. TSS or turbidity, whichever exhibited the strongest linear regression relationship, was used as the covariate.

Normal ranges for most total and dissolved metals were exceeded in more than 10% of samples collected at more than half of the monitoring stations downstream from mining. All samples collected in 2015 at the four monitoring stations in MU5, downstream from all mining, had selenium and nitrate concentrations greater than normal ranges indicating mine-related influence on water quality extends at least to the mouth of the Elk River. In addition to elevated selenium and nitrate concentrations, total and dissolved barium, chloride, and nitrite concentrations were above normal ranges in more than 50% of samples collected at the most downstream station on the Elk River (RG_ELKMOUTH), suggesting these eight constituents are the ones most strongly indicative of mine influence (i.e., conservative tracers). Comparison of aluminum, iron, and manganese concentrations at individual mine-exposed stations to covariate-adjusted normal ranges typically identified a similar or lesser frequency of normal range exceedances than comparison to monthly normal ranges. However, the covariate-adjusted normal range for phosphorus identified more normal range exceedances than the monthly normal range approach at most stations. Results will be discussed with the EMC to

determine the preferred approach for future evaluations of mine-related influence on water quality relative to reference station concentrations.

Although BC water guidelines for long-term exposure are based on 30-day mean concentrations, concentrations in individual samples were compared to the guidelines to conservatively identify constituents being elevated above guidelines as a result of mining. Normal reference station ranges occasionally exceeded water quality guidelines for total iron, total chromium, and total mercury. Aqueous concentrations measured at mine-exposed stations in 2015 exceeded SSBMs or BC guidelines, as well as reference area normal ranges in one or more sample(s) collected at one or more mine-exposed station(s) for nitrate, sulphate, dissolved cadmium, selenium, total dissolved solids, total and dissolved iron, dissolved aluminum, total barium, total beryllium, chloride, total chromium, total cobalt, total mercury, total nickel, nitrite, ammonia, total silver, total thallium, total uranium, and total zinc. The constituents tending to be most elevated above normal ranges and guidelines in the Elk River watershed as a result of mining were nitrate, total and dissolved selenium, sulphate, total dissolved solids, total (but not dissolved) iron, dissolved aluminum, and total and dissolved uranium. Highest concentrations of all constituents were observed in tributaries closest to mine sources compared to main stem areas. An analysis of water quality data for development of early warning triggers has taken place in parallel with the water quality data evaluation presented in this report. Potential differences in methods and/or conclusions that emerge from these parallel processes will be evaluated and discussed with the EMC.

Concentrations of Order constituents were also evaluated based on maximum (calendar) monthly mean concentrations. Monthly means did not exceed EVWQP Level 1 effect benchmarks for cadmium, selenium, and sulphate among main stem stations, except in the Fording River (selenium and sulphate at FR_FRCP1; selenium at GH_PC2, FR_FRABCH, LC_LC6, and LC_LC5), and in lower Michel Creek (nitrate and selenium at EV_MC2).

Statistically significant increases in nitrate concentrations were observed at six mine-exposed water monitoring stations after 2014 (GH_COUGAR 377%; GH_MC1 1,539%) or 2015 (FR_CC1 99%, LC_DC3 83%, GH_ER1 28%, EV_MC3 65%). Significant increases in selenium were observed at four stations: Kilmarnock Creek (FR_KC1 22% after 2012), upper Dry Creek stations LC_DC3 (38% after 2015) and LC_DCDS (27% after 2015), and Mickelson Creek (GH_MC1 186% after 2014). Increasing sulphate concentrations were observed in Line Creek upstream from the AWTF (LC_LCUSWLC 15% after 2012), at the GHO Elk River Order station (GH_ER1 53% between 2012 and 2016), at Mickelson Creek (GH_MC1 407% after 2014), at Leask Creek (GH_LC2, 142% after 2013), and in Michel Creek upstream from Erickson Creek (EV_MC3; 18% after 2015).

Water quality performance was evaluated for nitrate, selenium, and sulphate at the 12 Order and Compliance Stations within the Elk River watershed, and at the Compliance Station in Koocanusa Reservoir (Golder 2017a). In most cases, observed concentrations were consistent with or less than modelled concentrations. Selenium and sulphate concentrations in water samples collected at the FRO Compliance Point (FR_FRCP1; MU1) in 2016 were greater than the modelled concentrations. The data indicated that surface water flow at FR_FRCP1 is predominantly discharge water from the mine-impacted Cataract Creek during winter low flow months, which explained the high concentrations of selenium and sulphate observed in winter samples.

In MU2, aqueous nitrate concentrations at the LCO Compliance Point (LC_LCDSSLCC) in 2016 were greater than the modelled concentrations due to greater than anticipated loads from Line Creek upstream from West Line Creek (Golder 2017a). Observed concentrations were also greater than modelled concentrations for one or more constituents at each of the three Compliance Stations in MU4. In the case of EV_HC1, nitrate concentrations remained below water quality guidelines. Higher than expected concentrations at Michel Creek Compliance Stations (CM_MC2 and EV_MC2) may have been due to overestimation of water flows in the RWQM (Golder 2017a). The RWQM was updated in 2017, so future comparisons of observed to modelled concentrations will be based on the updated model.

4 TOXICITY TESTING

4.1 Overview

Laboratory toxicity tests can contribute to the understanding of conditions observed in the field by testing samples collected in the field using standard test species in a controlled laboratory environment. Teck routinely collects discharge water samples for acute toxicity testing in accordance with requirements of Permit 107517. The results are presented in annual water quality reports (Teck 2016a, 2017a). Chronic toxicity testing of surface water samples is also undertaken and reported in accordance with Permit 107517 (Golder 2016, 2017c). A summary of acute and chronic toxicity test results related to surface water monitoring stations[20] sampled in 2015 to 2016 is presented below and details can be found in the reports cited above.

4.2 Acute Toxicity

Acute toxicity tests with rainbow trout and *D. magna* are considered a "pass" if at least 50% of the test organisms exposed to each sample survive. All tests except one completed in 2015 and 2016 using rainbow trout (n = 225) were considered passes, as were most tests completed using *D. magna* (218 of 229 = 95%) (Table 4.1; Appendix Table C.33). Samples with more than 50% mortality were collected at Smith Pond (MU1; one sample in 2016), Swift Creek (MU1; one sample in 2015), Cataract Creek (MU1; seven samples in 2015 and 2016), Wade Creek (MU3, one sample in 2015), Pengelly Channel (MU4; one sample in 2015), and EVO Dry Creek (MU4, one sample in 2016) (Appendix Table C.33).

Further investigation of the failed *D. magna* tests suggested that the standard laboratory procedure of warming water samples to 20 ± 2°C (i.e., above field water temperatures) may have enhanced formation of a mineral precipitate that affected *D. magna* survival (Teck 2017a). Although it was not confirmed if the mineral precipitate was calcite or another form of carbonate mineral, calcite formation is known to be greater at higher than lower water temperatures (Langmuir 1997). When samples were split for duplicate testing at the standard test temperature of 20ºC and at a lower temperature of 10ºC, consistently fewer mortalities were observed in the same sample adjusted to the lower temperature (Teck 2017a).

Bogart et al. (2016) tested the effects to *D. magna* of rapid and extreme shifts in water hardness (38–600 mg/L as $CaCO_3$) and alkalinity (30–420 mg/L as $CaCO_3$) both independently and in combination. Within these ranges, if no calcite precipitate formed, shifts in water hardness

[20] Teck (2016, 2017) included acute toxicity test results for samples collected at discharge stations LC_LC7, LC_WTF_OUT, and WL_BRWB_OUT. As this report focuses on aquatic health in tributaries and receiving environments of the Elk River watershed, toxicity data for those stations were not included in this report.

Table 4.1: Summary[a] of Acute Toxicity Results, 2015 - 2016

[a] See detailed results in Appendix Table C.31.

[b] Up to 10% mortality is considered acceptable test performance for control organisms (Environment Canada 1990a,b)

and/or alkalinity were not toxic to *D. magna*. By comparison, water with high hardness (600 mg/L as $CaCO_3$) and alkalinity (420 mg/L $CaCO_3$) formed a calcite precipitate that was ingested by and coated the *D. magna*, resulting in 98-100% mortality within 96 h of exposure. Thus, the literature (e.g., Langmuir 1997 and Bogart et al. 2016) provides support for the hypothesis that *D. magna* mortalities observed in some water samples collected in the Elk River watershed may have been associated with the effects of calcite precipitate formation within the laboratory test vessels. The degree to which the observed mortalities reflects a degree of calcite precipitation that would occur under field conditions is unknown, although the rate observed in the laboratory is expected to exceed that of field conditions given the temperature-dependence of the mortalities (Teck 2017a).

More than 97% of samples that were "passes" (<50% mortality) had mortalities of less than 10% (Appendix Table C.34), which is within the accepted performance range for test control organisms based on the test methods (Environment Canada 1990a,b). Mortalities between 10% and 50% were observed among *D. magna* exposed to only four samples collected at Cataract (GH_CC1; MU1), Porter (GH_PC1; MU1), Thompson (GH_TC1; MU3), and South Pit (EV_SP1; MU4) creeks and among rainbow trout exposed to one sample from Corbin Creek (CM_CC1; MU4).

4.3 Chronic Toxicity

Interpretive reports were prepared by Golder (2016, 2017c) to present the results of quarterly and semi-annual chronic toxicity tests undertaken in 2015 and 2016 for Teck's coal mining operations in the Elk Valley. In 2015 and 2016, a total of 70 *Ceriodaphnia dubia* (water flea), 70 *Pseudokirchneriella subcapitata* (green alga), 32 *Hyalella azteca* (amphipod), 16 *Pimephales promelas* (fathead minnow), and 36 *Oncorhynchus mykiss* (rainbow trout) chronic toxicity tests were conducted on surface water samples collected in the Elk Valley (Table 4.2). The following conclusions were summarized from Golder (2017c):

- In 2015, there was no evidence of statistically significant adverse effects in the majority of quarterly and semi-annual toxicity tests relative to one or more reference waters. In 2016, there was no evidence of statistically significant adverse effects in the majority of tests conducted with *P. subcapitata* and *P. promelas*, but significant effects were observed in half of the tests conducted with *C. dubia* and the majority of tests conducted with *H. azteca* and *O. mykiss* relative to one or more reference waters.
- Of tests for which a statistically significant response (relative to one or more reference waters) was identified, approximately one third showed a significant effect relative to one but not both reference waters and/or had mean responses within the typical range of test

[c] Copper-treated tests were not conducted in 2015.

organism performance in reference waters (characterized as a 'reference envelope'). Statistical analysis of water chemistry did not identify any consistent relationships that could explain the statistically significant responses, so there is uncertainty regarding whether the results represent an adverse response to toxicants in the test water or variance in test organism performance related to background water quality.

- To evaluate whether temporal variation in test organism performance (batch sensitivity) was a potential confounding factor, mean responses in reference waters in 2016 were compared to the paired batch-specific laboratory control for each test species and endpoint. Most chronic toxicity endpoints (i.e., all response data for that endpoint including reference waters and test waters) were control-normalized before performing subsequent data analyses. This procedure did not result in major differences in the data interpretation (i.e., most responses indicative of toxicity would be classified similarly either with or without control normalization).
- In 2015, two tests exhibited a response that was statistically significantly different from reference, outside the normal range of variability of test organism performance and that were potentially attributable to water quality constituents in test waters. Statistically significant adverse responses in Q1 tests with C. dubia and P. subcapitata were observed at the Fording River Compliance Point (FR_FRCP1) that were associated with nitrate and sulphate concentrations above chronic BC WQG and/or effects concentrations determined in previous toxicity testing with Elk Valley waters.
- In 2016, there were eight tests that exhibited responses that were statistically significantly different from reference, below the reference envelope, and that were potentially attributable to water quality constituents in test waters. Statistically significant adverse responses were observed in the Q1 FR_FRCP1 tests with C. dubia, P. subcapitata, and H. azteca. Nitrate may have contributed to observed responses in these tests, although the magnitude of responses observed is greater than indicated by other site-specific testing. In 2016, nitrate concentrations in five other C. dubia tests (FR_FRCP1 [Q2, Q3, Q4], GH_FR1 [Q2], LC_LCDSSLCC [Q2]) may have contributed to the observed response, although the evidence for nitrate toxicity as the primary explanatory factor in these experiments was weak based on comparison to C. dubia responses in other quarterly tests.

Overall, no water quality parameter was identified as a potential cause of most statistically significant test results observed in 2015 and 2016. The Q1 FR_FRCP1 tests resulted in adverse effects attributed to water quality in both 2015 (*C. dubia* and *P. subcapitata*) and 2016 (*C. dubia*, *P. subcapitata,* and *H. azteca*). Other statistically significant adverse test responses

did not align with the concentration-response patterns for mine-related constituents determined in previous toxicity testing with Elk Valley waters, indicating that some other source of variance was affecting the results.

4.4 Summary

All acute tests completed in 2015 and 2016 using rainbow trout (n = 176) were passes (≤50% mortality), as were most tests (169 of 179 = 94%) completed using *D. magna*. Further investigation of the failed *D. magna* tests suggested that the laboratory procedure of warming water samples from the ambient field temperature to the laboratory test temperature of 20 ± 2°C may have affected survival due to formation of a mineral precipitate (potentially calcite). More than 97% of samples resulting in "passed" *D. magna* or rainbow trout tests had mortalities of 10% or less, which is within the accepted performance range for test control organisms based on the test methods.

In 2015 and 2016 a total of 70 *C. dubia* (water flea), 70 *P. subcapitata* (green alga), 32 *H. azteca* (amphipod), 16 *P. promelas* (fathead minnow), and 36 *O. mykiss* (rainbow trout) chronic toxicity tests were conducted on surface water samples collected in the Elk Valley. Of tests for which a statistically significant response (relative to one or more reference waters) was identified, approximately one third showed a significant effect relative to one but not both reference waters and/or had mean responses within the typical range of test organism performance in reference waters. A review and statistical analysis of water chemistry did not identify any consistent relationships that could explain most of the statistically significant responses, so there is uncertainty regarding whether the results represent an adverse response to toxicants in the test water or variance in test organism performance related to background water quality. In 2016, eight tests exhibited a response that was statistically significantly different from responses in reference water samples, below the reference envelope, and potentially attributable to water quality constituents in test waters. Effects to organisms observed in tests with first-quarter samples collected at the Fording River Compliance Point (FR_FRCP1) were attributed to water flowing from Cataract Creek, because the reach of the Fording River upstream of FR_FRCP1 goes dry during the winter low flow period.

4.5 Additional On-going Work

Additional investigations are underway to evaluate potential causes of the toxicity observed in a subset of the quarterly and semi-annual tests. From the annual reporting conducted separately for 2015 and 2016, it is apparent that concentrations of nitrate and sulphate do not, on their own, explain the patterns of toxicity observed in the quarterly and semi-annual chronic toxicity tests. However, the frequency of statistically significant responses warrants further investigation

to confirm patterns over time and/or spatial location, and to identify causes where possible. The following work is being conducted under the Chronic Toxicity testing program to assist evaluation of toxicity data:

- Additional representation of toxicity endpoint patterns - as multiple rounds of toxicity test response data are accumulated, the results will be integrated and summarized in future interpretive report. Based on discussions with EMC, these reports will organize toxicity responses by sampling location, and will explicitly evaluate whether statistically significant responses are confirmed in successive sampling events. These evaluations will also incorporate EMC input regarding the treatment of data (e.g., control-normalization, use of reference comparisons) for evaluating magnitude.
- Additional statistical analysis of contaminant mixtures - from the concentration-response evaluations of 2015 and 2016 test data, most water quality parameters evaluated in the concentration-response analysis exhibit concentrations below water quality guidelines or orders of magnitude below effect concentrations. Based on the different mechanisms of action and low exposure concentrations relative to toxicological benchmarks, there is a low potential for additive effects of multiple constituents. It is unlikely that combined effects among the parameters would occur; nevertheless the EMC has identified some additional approaches to statistical evaluation of the water chemistry data (e.g., summation of “toxic units” relative to site-specific benchmarks or water quality guidelines) to assess potential for mixture responses. There procedures will be applied in the next cycle of annual interpretative reporting.
- Validation of sulphate and nitrate benchmarks - as part of Permit 107517 testing and the associated RAEMP approvals, Teck has conducted additional testing of site waters amended with supplemental sulphate and nitrate concentrations across a wide range of concentrations and multiple site waters (Golder 2017c). Overall, results of these supplemental tests in fall 2016 confirmed that benchmark levels derived in support of the EVWQP, and the associated Site Performance Objective values, remain protective of aquatic life.
- Toxicity identification evaluations - when the magnitude of toxicity in an individual test is large, a toxicity identification evaluation (TIE) can provide information regarding causation. A TIE consists of multiple supplemental treatments based on adjusting the original sample characteristics to discern which adjustments increase of decrease the magnitude of response. Future potential TIE tests will contribute to evidence regarding causes of toxicity.

- Additional test refinements - in some cases, investigations of root causes have identified information sufficient to determine that adjustments to toxicity test methods are required. For example, the testing with fathead minnows in 2015 identified that amendment of water samples with copper was necessary to control for microbial responses. Other refinements, such as supplementing test waters for *H. azteca* with halides, have also been necessary to meet test performance criteria and isolate potential chemical responses from confounding factors unrelated to mine-influence. Teck has conducted multiple stages of supplemental testing to help reduce uncertainty in the results of Permit-mandated tests, and have obtained EMC approvals where protocol modifications are required..

5 CALCITE

5.1 Overview

Calcite is created by the reaction of dissolved calcium (Ca^{2+}) and carbonate (CO_3^{2-}) ions under conditions of supersaturated carbonate and/or increasing water pH or calcium concentrations (Rupp and Adams 1981). Although calcite deposits can occur naturally in streams, calcite build-up can increase if water passes through mine waste rock, which elevates aqueous concentrations of both calcium and carbonate. Over time, as calcite particles collect on the substrate, they can cement together (Photos 5.1 to 5.4).

Stream calcite formation is not strictly governed by the laws of chemical thermodynamics and instead is the product of complex interplay among factors such as angle of slope, water temperature and discharge rate, and plant and microbial community abundance and composition (Pedley 1990; Pedley and Rogerson 2010). Periphyton photosynthesis may be almost as important as chemical solubility in mediating calcite precipitation, depending on water temperature and velocity (Rupp and Adams 1981).

In 2013, Teck initiated a regional calcite monitoring program to document calcite deposition in tributary and main stem areas of the Elk River watershed (Robinson et al. 2013). To guide interpretation of the regional monitoring results with respect to potential effects on aquatic biota, a separate supporting study was initiated by Teck in September 2014 (Minnow 2015d). The study of calcite effects on biota focused initially on assessing potential relationships between calcite deposition and both benthic invertebrate community structure and periphyton productivity (Minnow 2016b). In 2015, the study was expanded to investigate potential effects on fish spawning and incubation success (Minnow 2016b; Ecofish 2016, 2017; Ecofish and Westslope 2017). The results of the supporting biological effects studies completed to date are summarized below. Calcite deposition associated with biological monitoring in the RAEMP and LAEMPs is also discussed in later sections of this report, where applicable.

5.2 Regional Calcite Monitoring Program

5.2.1 Results in 2015 and 2016

Monitoring results in 2015 and 2016 were similar to those reported in 2013 and 2014 (Lotic 2016, 2017). All (100% of) reference streams assessed had CI of 0.5 or less. Most of the mine-exposed stream kilometres that were assessed (in MUs 1-4 and a portion of MU5) also had a CI of 0.5 or less (≥75% of tributaries and ≥81% of main stem Fording and Elk Rivers).

5.2.2 Temporal Changes

Of the 124 stream reaches sampled in the 2015 regional calcite monitoring program, 119 were sampled in all three years (2013 to 2015; Lotic 2017). Regression analysis was used by Lotic (2017) to identify any stream reaches showing an increasing or decreasing trend in mean CI over the three-year period. An increase was reported for one reach in Erickson Creek (ERIC3; MU4; 2.36 to 3.00 = 0.32 CI/year), and decreasing trends were reported for one reach each at Eagle Pond Outlet (EPOU1; MU1; 1.90 to 0.58 = -0.66 CI/year), Grace Creek (GRAC1; MU2; 0.31 to 0.05 = -0.13 CI/year), and Otto Creek (OTTO1; MU4; 0.30 to 0.10 = -0.10 CI/year). No trends were reported for the other 115 reaches that were sampled in all three years (Lotic 2016).

The study design was modified in 2016 to sample at 85 “indicator” reaches throughout the valley. The purpose of the indicator reach sampling on an annual basis is to detect large scale changes. In addition to the annual surveillance monitoring, long-term trend monitoring will take place at a three-year interval (Lotic and Teck 2016). Of the 85 indicator reaches sampled in 2016, 10 showed a significant change in CI from 2013 to 2016 (Lotic 2017; Table 5.1). After inclusion of data for 2016, EPOU1 and GRAC1 continued to show decreasing trends, while trends previously suggested for ERIC3 and OTTO1 were not apparent. Decreasing trends were indicated in a total of six reaches, while increasing trends were indicated in four reaches (Table 5.1).

Now that a sufficient number of years of data are available, temporal trends in the regional calcite monitoring program were re-evaluated for the purposes of this report using statistical methods recommended by the EMC for data evaluation within the RAEMP (RM ANOVA, followed by post-hoc contrasts to test for linear and step changes relative to reference areas). The RM ANOVA contrasts differ from the regression approach previously used in the 2016 Calcite Monitoring Annual Report (Lotic 2017) because multiple hypotheses for a temporal change (i.e., a linear trend as well as a potential step change after each year), are tested and temporal changes are assessed relative to the mean reference temporal change.

The RM ANOVA contrasts, which accounted for the mean trends among reference areas, and detected step changes in addition to linear trends, identified substantially more temporal changes in CI among mine-exposed reaches than were detected by trend analysis using linear regression. Significant increasing trends in CI were identified in 27 reaches (27% of a total of 101 mine-exposed areas having at least three years of data) over the 2013 to 2016 regional

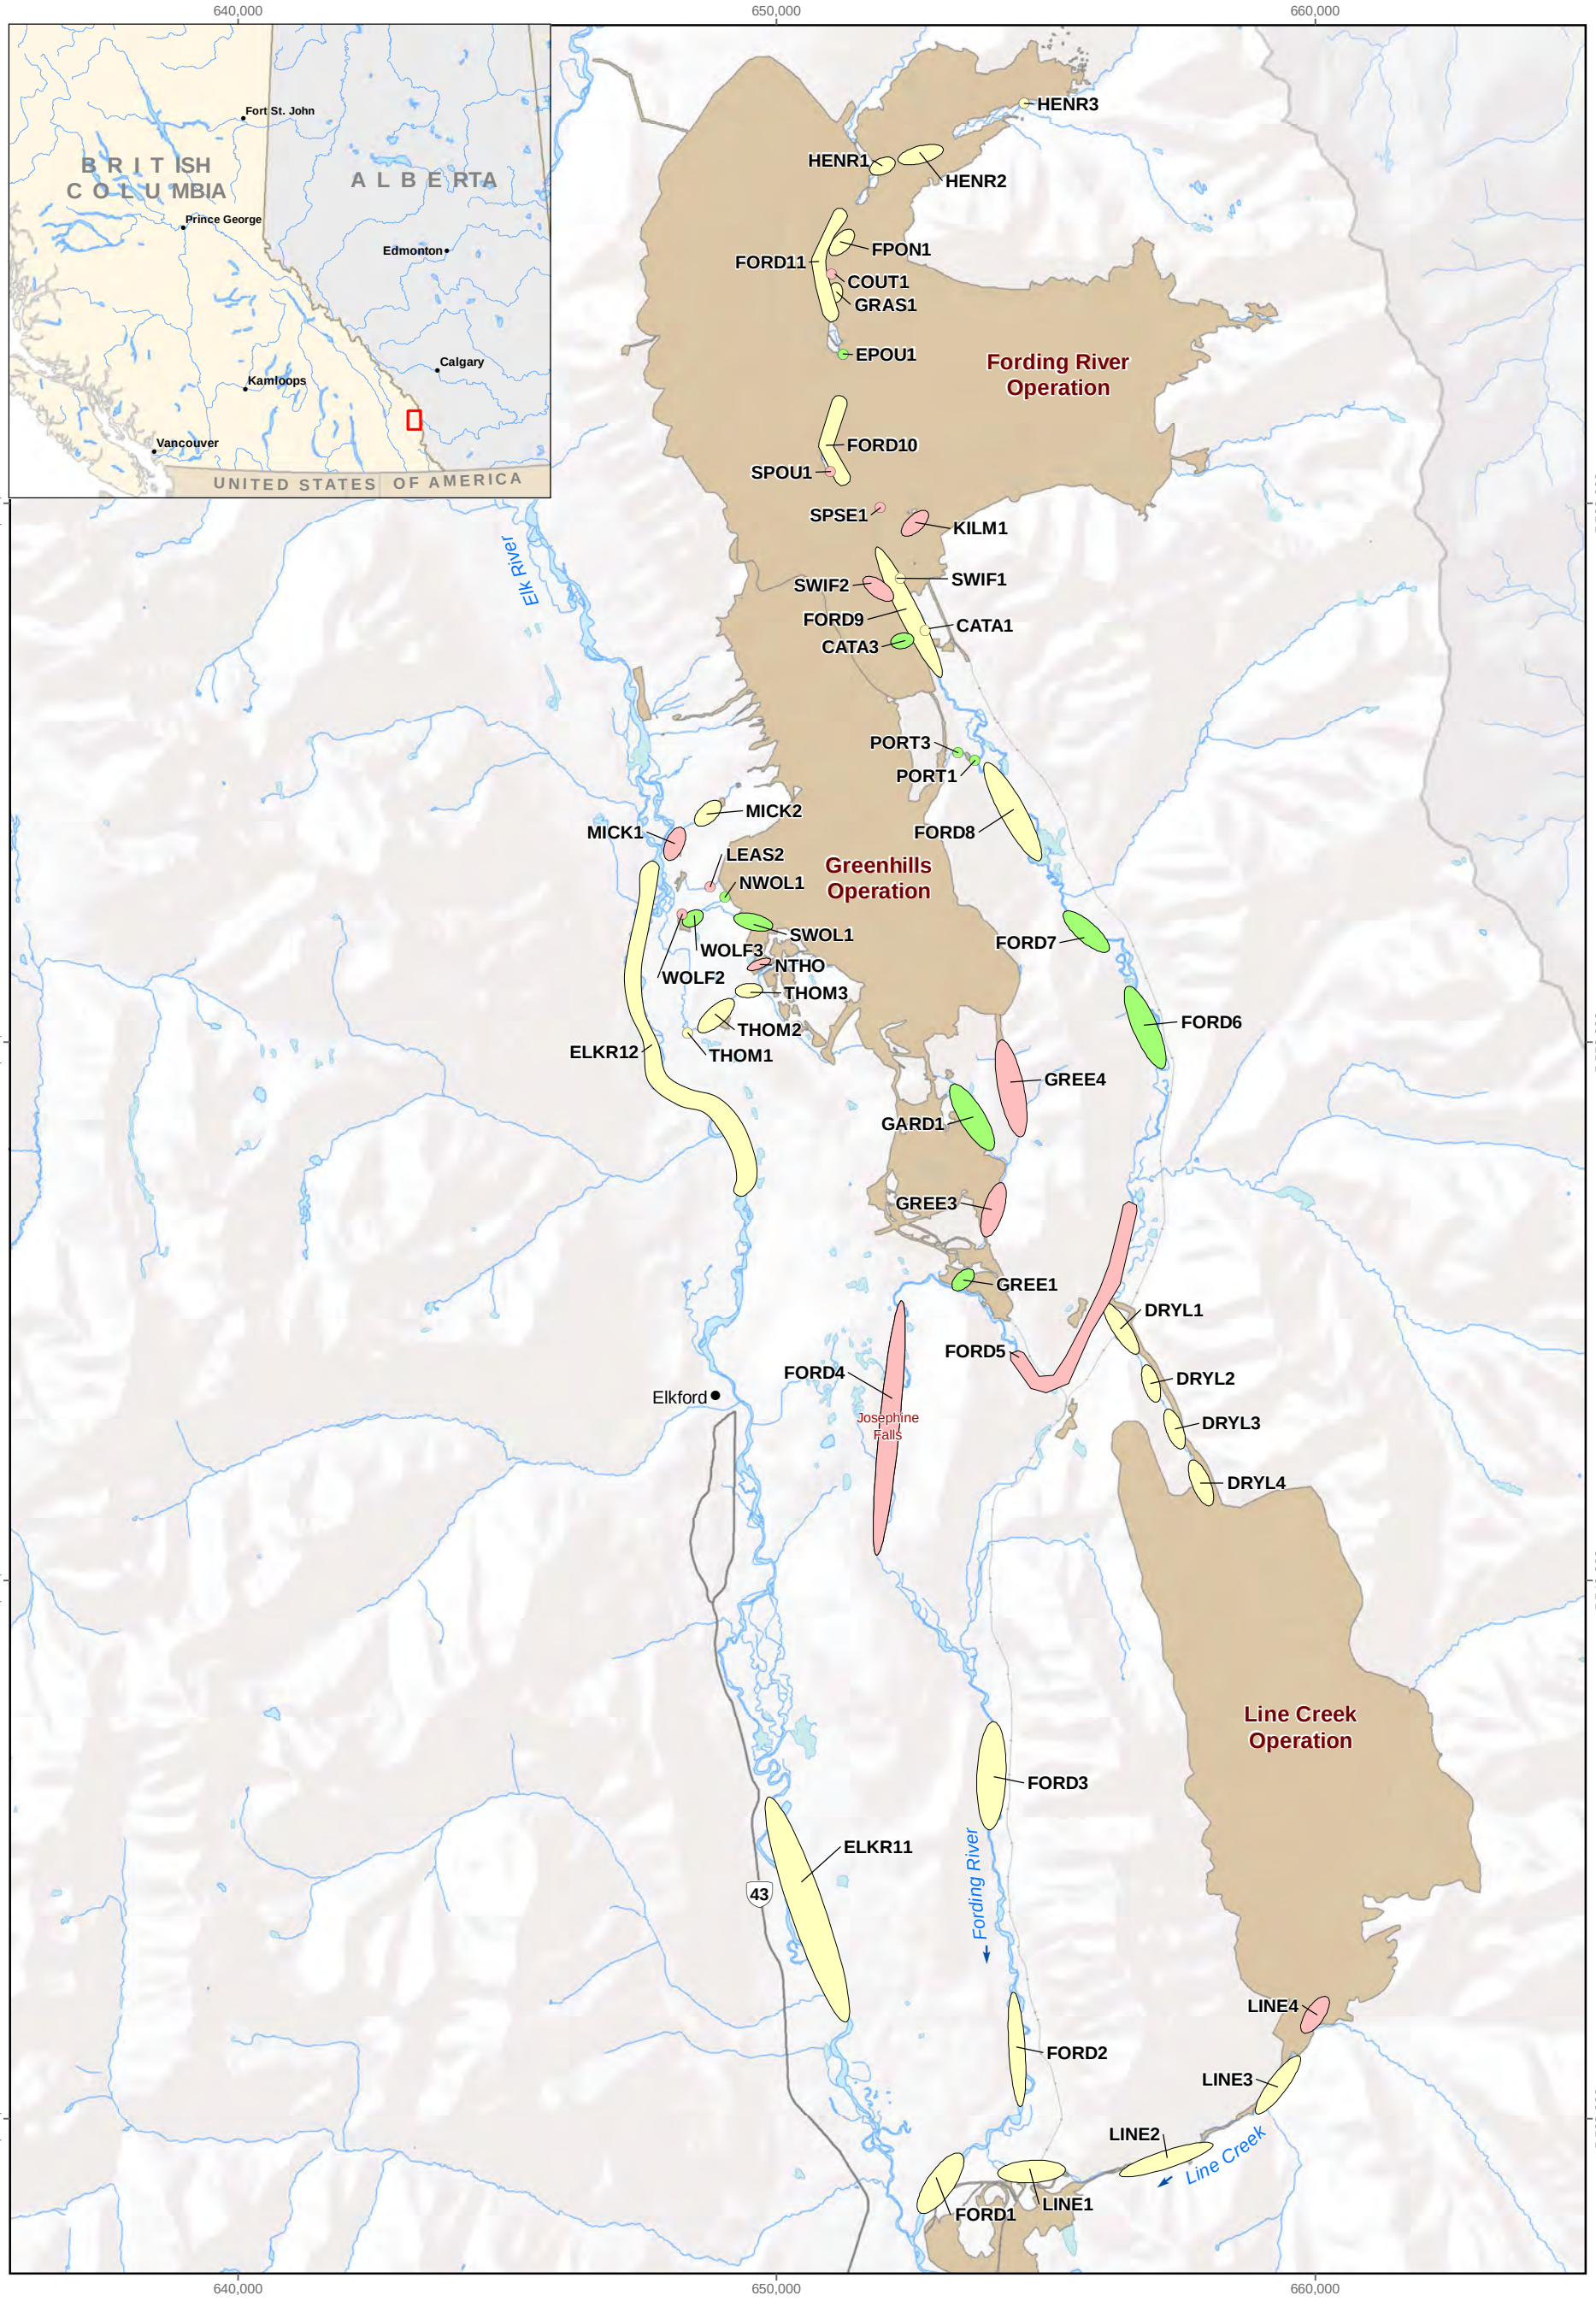
Table 5.1: Temporal Changes in Calcite Index Reported in Regional Calcite Monitoring Program, 2013 - 2016 (Adapted from Lotic 2017)

Management Unit	Main Watershed	Stream Name	Reach	Regression P-value	Slope (ΔCI/year)	Change
1	Fording River	Eagle Pond Outlet	EPOU1	0.01	-0.58	Decrease
		Porter Creek	PORT3	0.06	-0.40	Decrease
			PORT1	0.08	-0.05	Decrease
2	Fording River	Grace Creek	GRAC1	0.09	-0.08	Decrease
3	Elk River	North Wolfram Creek	NWOL1	0.02	-0.55	Decrease
		Wolfram Creek	WOLF2	0.06	0.15	Increase
4	Michel Creek	Pengally Creek	PENG1	0.09	-0.03	Decrease
		South Pit Creek	SPIT1	0.06	0.55	Increase
		Gate Creek	GATE2	0.09	0.47	Increase
	Elk River	CCR Seep	CSEE1	0.05	0.50	Increase

calcite monitoring period (Appendix Table D.1). Significant decreasing trends were observed in 19 reaches (19%). Results plotted in Figures 5.1 and 5.2 reflect the direction of trends/step changes that best fit the contrast model (shown in bold text in Appendix Table D.1). Approximately half (49%) of the reaches showed no significant linear trend or annual step change over the 2013 to 2016 monitoring period (Appendix Table D.1).

Most reaches showing significant temporal changes were in tributaries. However, significant increases were observed after 2014 for Fording River reaches FORD4 (upstream from Line Creek) and FORD5 (vicinity of LCO Dry Creek; Figure 5.1; Appendix Table D.1; Appendix Figure D.1).

When temporal trends in CI were analyzed for main stem mine-exposed stations by MU, increasing average trends were only observed in MU1 (step from 2013 to 2014) and MU2 (step from 2015 to 2016) (Appendix Table D.2; Appendix Figure D.2). A decreasing trend was observed in MU5 after 2013, and no changes were identified in MU3 or MU4.



Calcite Trend

5.3 Calcite Measurements within the RAEMP

5.3.1 Calcite Reference Normal Range

Calcite has been measured concurrently with collection of benthic invertebrate community samples in the RAEMP and in LAEMPs. Calcite measurements made among 40 reference areas sampled in 2015 were used to characterize the normal range, and the upper limit (97.5th percentile) was defined as CI = 1.0 (Appendix Table D.3 and Appendix Figure D.3). Eighty percent of reference areas had CI<0.50[21], which is a long-term (Year 2029) Site Performance Objective specified in Permit 107517 for streams that provide or flow directly into fish habitat.

5.3.2 Evaluation of Calcite in Mine-Exposed Areas

Most (91%) of the mine-exposed areas sampled in the 2015 RAEMP cycle had CI>0.5 but 62% of areas sampled had CI within the upper limit of the normal range (i.e., ≤ 1.0; values highlighted in yellow on Figure 5.3; Appendix Table D.4). Areas sampled in some tributaries (Kilmarnock, Swift, Cataract, Greenhills, Wolfram, Thompson, and Corbin) and two areas in the upper Fording River (FOBSC and FOBCP) had CI greater than the upper normal range limit of 1.0. Greenhills Creek has been identified as a priority stream for calcite treatment, which began in October 2017 in accordance with requirements of Permit 107517.

Teck is aware that calcite measurements at biological sampling areas have, in some cases, varied from those reported by the regional calcite monitoring program for the same stream. This may be due to the differences between programs in the approach, as well as timing for calcite measurement (described in Section 2.5). Teck audited field sampling programs in the fall of 2017 to achieve better standardization among programs for characterizing calcite deposition and will continue to have discussions with the EMC regarding this topic.

Relationships between biological monitoring endpoints and calcite are also discussed in Sections 7 to 10, where potentially relevant in explaining biological responses observed downstream from mining.

5.4 Calcite Relationships with Biota

5.4.1 Relationships with Periphyton Productivity and Benthic Invertebrates

The effects of calcite on biota are being studied in phases, with initial focus on assessment of potential relationships between calcite deposition and both benthic invertebrate community

[21] Results differ slightly from the regional monitoring data, which are expressed relative to stream km monitored in the regional program, while the RAEMP data are expressed relative to the total number of RAEMP monitoring areas.

Figure 5.3

structure and periphyton productivity (Minnow 2016b). In the first year of study (2014), field activities included collection of water samples, benthic invertebrate community samples (using the CABIN 3-minute travelling kick approach), and periphyton productivity samples (i.e., chlorophyll-a and AFDM), along with *in situ* water quality measurements and field documentation of substrate characteristics, aquatic habitat, and calcite at 31 areas within the Elk River watershed. In 2015, 114 areas (74 mine-exposed and 40 reference) situated throughout the Elk River watershed and in adjacent watersheds within the region, including all RAEMP monitoring areas, were sampled using methods similar to those in 2014.

Periphyton chlorophyll-a and AFDM values were weakly positively correlated (i.e., $r < 0.5$) with CI values among areas (Minnow 2016b). The results suggested that calcite deposits may provide a surface favourable for periphyton growth, that periphyton growth alters water quality near the periphyton surface in a manner that favours calcite formation, and/or bioavailable nutrient concentrations may be elevated in areas with more calcite (Minnow 2016b). Hypothesized relationships between periphyton and calcite are supported by the scientific literature, which indicates calcite formation is the product of complex interactions of abiotic habitat and periphyton community characteristics (e.g., Pedley 1990, Pedley and Rogerson 2010, Rupp and Adams 1981), as mentioned in Section 5.1. The study did not indicate a specific CI value above which periphyton productivity would be expected to deviate from the reference normal range (defined as the range bounded by the 2.5th and 97.5th percentiles of reference area calcite observations) (Minnow 2016b).

A total of 82 benthic invertebrate community endpoints were evaluated as potential indicators of calcite effects on biota using data collected in 2015 (Minnow 2016b). Seven of the 82 endpoints were selected as the strongest univariate indicator endpoints because they identified at least 10% of mine-exposed areas as having community characteristics outside of the normal range and they also correlated with CI values ($r > 0.6$). In addition to the univariate endpoints, 11 multivariate indicators were examined, including six that represented overall community structure based on NMDS. The multivariate endpoints showed strong agreement among each other and relative to the univariate endpoints in identifying areas with community characteristics that differed from the normal range observed among reference areas. The results also indicated that the selected univariate community endpoints were effective in identifying areas that were unusual based on overall community structure.

Overall, the data indicated that benthic invertebrate community structure, and especially the proportion of Ephemeroptera, tended to deviate from the normal range when CI was greater than 1.0 (Minnow 2016b). However, the analysis also showed that there was strong correlation between CI and the concentrations of mine-related constituents in water among areas. Areas

having CI greater than 1.0 also tended to have concentrations of selenium, nitrate, and/or sulphate that were greater than the Level 1 invertebrate benchmarks identified in the EVWQP, indicating potential for water quality effects. Therefore, the effects of calcite could not be distinguished from those associated with water quality (i.e., in areas where effects were observed, the effects may be due to calcite or water quality, or both, depending on relative constituent concentrations in each area).

5.4.2 Relationships with Fish Spawning and Incubation Success

In 2015, the study was expanded to include initial evaluation of potential effects on fish spawning and incubation success. Minnow (2016b) reported that, of 10 spawning areas in the upper Fording River watershed where calcite was assessed in both in the spring and fall of 2015, CI was greater in the fall than in the spring at 8 areas. CI was less than one at all but one redd location in the spring and two locations in the fall, potentially indicating preferential utilization of areas with relatively low CI. It was hypothesized that this is because spawning trout preferentially select areas with moveable gravels, and avoid areas where calcite concretion makes substrates immovable.

Evaluation of potential effects of calcite on fish spawning and incubation success continued in 2016 (Ecofish 2016). Calcite is hypothesized to affect spawning success through several mechanisms including access to useable spawning gravels, egg incubation conditions, rearing conditions for juveniles, and food availability (e.g., production of invertebrate prey) (Ecofish and Westslope 2017). Potential linkages between calcite and incubation conditions were investigated in 2016, and focused specifically on testing if observed calcite conditions on stream substrates affect hyporheic flow and dissolved oxygen concentrations. Representative spawning areas used by westslope cutthroat trout within the upper Fording River watershed (upper Fording River main stem, Clode Creek outlet, lower Greenhills Creek) were selected as study areas. Spawning was visually confirmed (redds, spawning fish) in late June and areas were revisited in late August and early September 2016 to measure CI, hyporheic conditions of DO and flow with depth, and other naturally varying factors (e.g., fish habitat variables, hyporheic water quality, substrate composition, and surface hydrology). Flow and DO were measured with a piezometer standpipe. Both a hydraulic head method and a temperature method were used to measure hyporheic flow. Results were used to model relationships between hyporheic conditions and CI, taking into consideration site characteristics and covariates (e.g., % fines) (Ecofish and Westslope 2017). Response variables were DO concentrations and hyporheic flow measured by either of the two methods. Predictor variables included in the model were CI, habitat, and sampling variables suspected to affect hyporheic

conditions (e.g., depth in substrate, water temperature, water quality, water depth, flow, substrate composition, season, sampling area).

The CI measured near the piezometers showed good agreement with CI measured at the mesohabitat scale, suggesting that the CI values for mesohabitat scale are representative of conditions at the scale of WCT redds (Ecofish and Westslope 2017). There was little variation in CI score by season (June versus August/September). CI score was an important predictor of DO in the substrate but not of hyporheic flow as measured by either the hydraulic head or temperature methods. The model for DO predicted that average instantaneous DO would decrease to less than 8 mg/L at a depth of 30 cm and CI of about 2.3. At a depth of 50 cm, average instantaneous DO was predicted to decrease below 6 mg/L at CI near 3. The average redd depth for WCT is 10-30 cm, so model predictions suggested average DO concentrations would be above the BC guideline for protection of aquatic life instantaneous minimum threshold for buried embryos/alevins of 6 mg/L. However, variability around the modelled relationships resulted in a conclusion that areas with high calcite levels would likely experience some reduction in incubation conditions. The authors cautioned that the data set was small and the effect of calcite on DO was most apparent at depths deeper than those typical of WCT redds, to guide prioritization of on-going work.

Continued study in 2017 investigated the extent to which calcite influences incubation conditions in the shallow hyporheic zone, and the data will be evaluated to characterize the relationship between calcite and spawning habitat suitability and use among mine-exposed tributaries in the Elk River watershed (Ecofish 2017).

5.5 Summary

Monitoring results in 2015 and 2016 were similar to those reported in 2013 and 2014 (Lotic 2016, 2017). All (100% of) reference streams assessed had CI of 0.5 or less. Most of the mine-exposed stream kilometres that were assessed (in MUs 1-4 and a portion of MU5) also had a CI of 0.5 or less (≥75% of tributaries and ≥81% of main stem Fording and Elk Rivers).

Calcite has been measured concurrently with collection of benthic invertebrate community samples in the RAEMP and in LAEMPs. Calcite measurements made among 40 reference areas sampled in 2015 defined the upper limit (97.5th percentile) of the normal range for reference areas as CI = 1.0. Eighty percent of reference areas sampled had CI<0.50, which is a long-term (Year 2029) Site Performance Objective specified in Permit 107517 for streams that provide or flow directly into fish habitat. Most (91%) of the mine-exposed areas sampled in the 2015 RAEMP cycle had CI>0.5 but 62% of areas had CI within the upper limit of the normal range (i.e., ≤ 1.0). Areas that were sampled in some tributaries (Kilmarnock, Swift, Cataract,

Greenhills, Wolfram, Thompson, and Corbin) and a portion of two areas in the upper Fording River (FOBSC and FOBCP) had CI greater than the upper normal range limit of 1.0.

Analysis of temporal changes in calcite (using data collected from 2013 to 2016, as part of the regional calcite monitoring program) resulted in approximately half of all mine-exposed study areas (52 of 101) showing a significant increase or decrease over time, after accounting for mean trends among reference areas. More specifically, significant increasing trends in CI were identified in 27 reaches and significant decreasing trends were observed in 19 reaches, with most reaches showing significant temporal changes being in tributaries. Significant increases were only observed at two locations in the main stem Fording River: FORD4 (upstream from Line Creek) and FORD5 (vicinity of LCO Dry Creek). In both cases, the increase was due to a step change from 2014 to 2015. When temporal trends in CI were analyzed for main stem mine-exposed stations by MU, increasing average trends were only observed in MU1 (step from 2013 to 2014) and MU2 (step from 2015 to 2016). A decreasing trend was observed in MU5 after 2013, and no changes were identified in MU3 or MU4.

A supporting study observed that periphyton chlorophyll-a and AFDM concentrations were weakly (i.e., $r < 0.5$) positively correlated with CI values among areas (Minnow 2016b). The results suggested that calcite deposits may provide a surface favourable for periphyton growth, that periphyton growth alters water quality near the periphyton surface in a manner that favours calcite formation, and/or bioavailable nutrient concentrations may be elevated in areas with more calcite. Hypothesized relationships between periphyton and calcite are supported by the scientific literature, which indicates calcite formation is the product of complex interaction of abiotic habitat and periphyton community characteristics (e.g., Pedley 1990; Pedley and Rogerson 2010, Rupp and Adams 1981). The study did not indicate a specific CI value above which periphyton productivity would be expected to deviate from the normal range for reference areas (Minnow 2016b).

The same supporting study showed that benthic invertebrate community structure, and especially the proportion of Ephemeroptera, deviated from the reference area normal range when CI was greater than 1.0 (Minnow 2016b). However, the analysis also showed that there was strong correlation between CI and the concentrations of mine-related constituents in water among areas such that the effects of calcite could not be conclusively distinguished from potential effects associated with water quality.

Calcite is also hypothesized to potentially affect spawning success through several mechanisms, including access to useable spawning gravels, egg incubation conditions, rearing conditions for juveniles, and food (e.g., production of invertebrate prey) (Ecofish and Westslope 2017). A study conducted in 2016 evaluated potential calcite effects on hyporheic

flow and dissolved oxygen concentrations within substrates of cutthroat trout spawning redds in areas of the upper Fording River watershed. CI score was inversely related to DO in the substrate at some depths, but was not related to hyporheic flow. The resulting model predicted that average DO concentrations at substrate depths relevant for cutthroat trout redds would be above the BC guideline for protection of aquatic life instantaneous minimum threshold for buried embryos/alevins of 6 mg/L. However, the data set was limited and it was concluded that variability around the modelled relationships may mean that areas with high calcite levels would experience some reduction in incubation conditions. Further study continued in 2017 to investigate the extent to which calcite influences incubation conditions in the shallow hyporheic zone, and to characterize the relationship between calcite and spawning habitat suitability and use among mine-exposed tributaries in the Elk River watershed (Ecofish 2017).

6 SEDIMENT

6.1 Overview

Suspended and bed sediments can play an important role in the transport and fate of chemicals in aquatic systems, particularly with respect to hydrophobic chemicals that adsorb to particle surfaces (Jain and Ram 1997). Settling of particles from the water column to substrates is inversely related to particle size and water velocities (Chin 2006), such that streams that are continuously or seasonally fast flowing tend to be dominated by coarse particles. Chemicals that have a tendency to adsorb to particles are typically found at highest concentrations in areas with fine compared to coarse bed sediments because fine particles offer greater surface area for adsorption (Chin 2006, Horowitz and Elrick 1987, Blanton et al. 1995). TOC content also tends to be higher in sediments with fine rather than coarse particles (Blanton et al. 1995, Dinakaran and Krishnayya 2011).

Lentic areas of the Elk River watershed were sampled for the RAEMP because these areas were expected to have highest sediment accumulations of mine-related substances compared to lotic habitats that are more directly affected by scouring associated with spring freshet and seasonal storm events. Lentic areas sheltered from seasonal scour also allow for sediment to accumulate year over year, which makes them more physically stable and amenable to tracking changes over time compared to lotic habitats in which fine substrates are routinely re-suspended and transported downstream.

Sediment chemistry was evaluated at a total of 31 areas in 2013 (Minnow 2014b) and/or 2015 (this study), including 10 reference areas (Figure 6.1; Appendix Table E.1). Some of the areas sampled in 2013 were not re-sampled in 2015 to re-distribute the sampling effort in 2015 among additional reference and mine-exposed areas, including areas targeted for evaluation of longnose sucker populations and health (Section 9). Observed concentrations were compared to BC sediment quality guidelines for protection of aquatic life. Potential temporal changes were assessed for all areas that were sampled in both years. Results of a supporting study of sediment toxicity (Minnow 2016d), which was completed in response to ENV's conditions related to approval of the RAEMP study design (BCMOE 2014)[22], are also summarized below. Photos of each lentic area sampled in the RAEMP are presented in Appendix A.

[22] The condition was: "Teck shall develop, in consultation with the Ministry and Ktunaxa Nation representatives ideally in a monitoring committee forum, the sediment toxicity study as discussed in Section 4.3.2 of the RAEMP study design..."

6.2 Chemistry

6.2.1 General Characteristics

Most of the areas chosen for sediment sampling in the Elk Valley have little or no surface water connection to the main channel flow for at least part of the year. Consequently sediment samples collected among the 31 study areas were dominated by fine particles (silt and clay; Figure 6.2). Sand content was highest at FO10 (the former Fording River Oxbow, which became a flowing side channel of the Fording River after the record flood in 2013) and FMUCK (main stem Fording River upstream from Chauncey Creek), which are areas experiencing continuous water flow throughout the year.

Sediment TOC content was 10% or less in more than 70% of samples, but ranged from 2% (one sample at Grave Lake) to 36% (one sample at Otto Ponds) (Figure 6.2; Appendix Tables E.2 to E.5). Concentrations of constituents in sediment such as PAHs and many metals are usually positively related to TOC content and the proportion of fine particles in sediment (Blanton et al. 1995, Wang et al. 2001, Chin 2006).

HQs[23] for sediment variables are discussed in more detail in Section 6.2.3, but are mentioned here because they were used in a preliminary principal components analysis (PCA) to illustrate variability in sediment quality among areas. The first two principal components explained 83.3% of the variability in HQs among areas. Mine-exposed areas separated in the direction from the bottom left quadrant to the top right quadrant of Figure 6.3, corresponding to differences in HQs for selenium and PAHs, indicating that these are the mine-related variables of potential concern. Concentrations of selenium and PAHs are discussed in subsequent sections relative to reference area normal ranges and sediment quality guidelines.

[23] Ratio of concentration to sediment quality guideline.

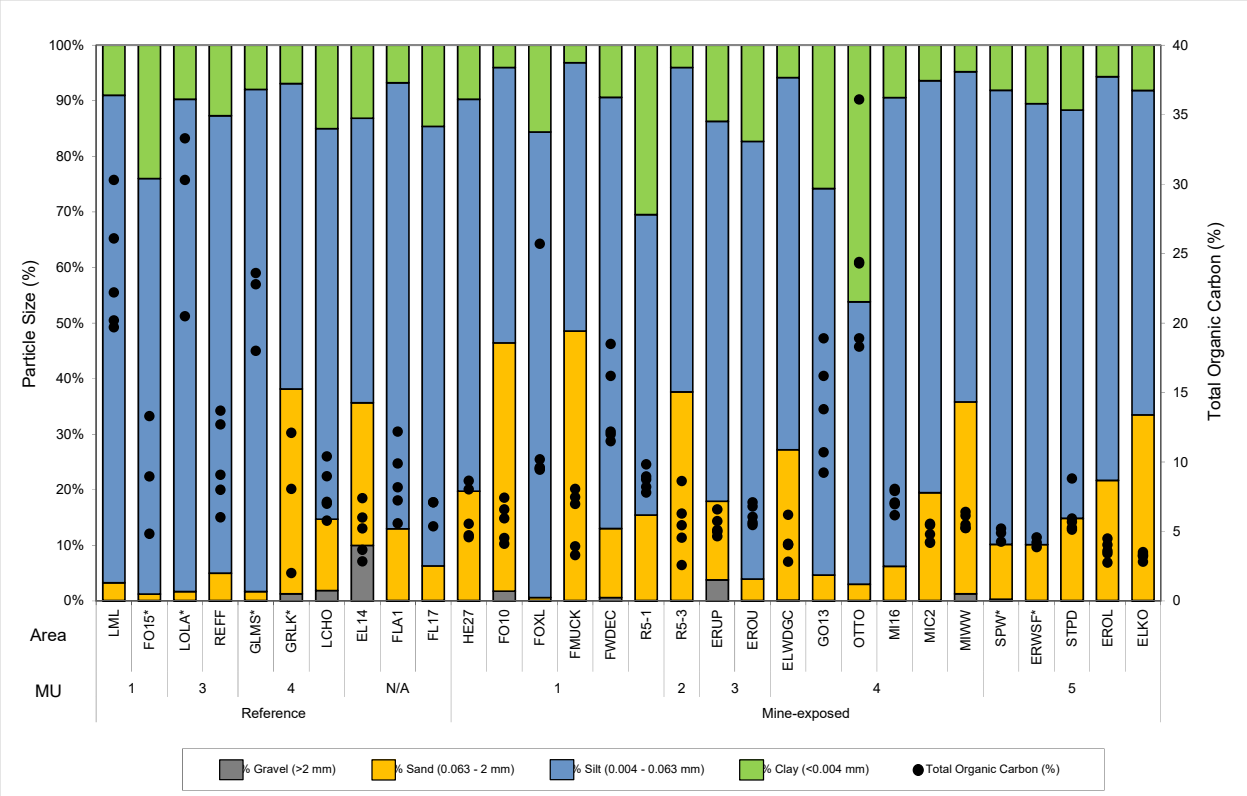

Figure 6.2: Mean Particle Size (%) and Total Organic Carbon Content (%) in Sediments, August 2015 Except for Areas Sampled Only in 2013 (asterisk)

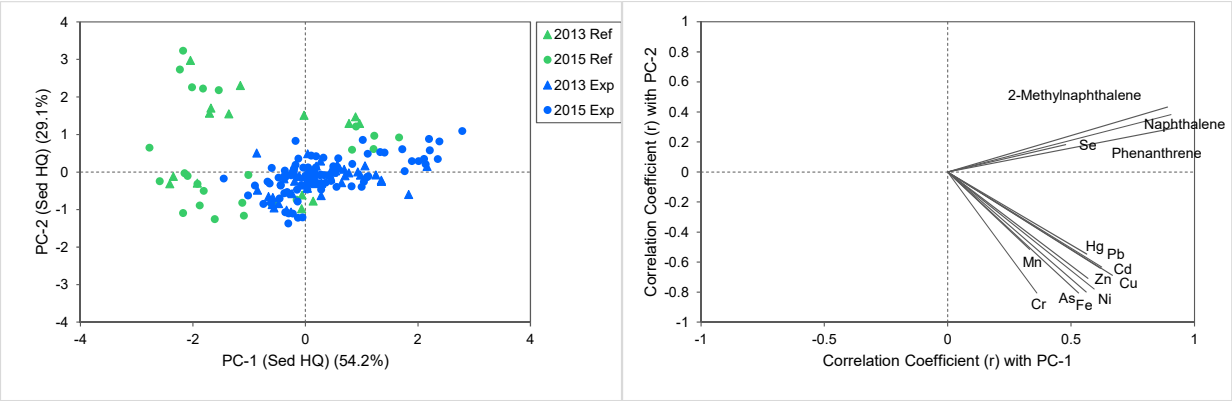

Figure 6.3: PCA of Hazard Quotients for Sediment Quality Variables

Notes: PCA was conducted on the covariance matrix for hazard quotients (hazard quotients were log_{10}-transformed). Scatterplot of Pearson correlation coefficients for PC-1 and PC-2 for each variable (Right Panel) show the correlation of each variable to the PCs. Data are for samples collected in reference (n = 15) and mine-exposed (n = 51) stations in 2013 and reference (n = 25) and mine-exposed (n = 90) stations in 2015 (n = 3 or 5 stations per sampling area). Correlation coefficients and p-values are shown in Appendix Table E.13.

6.2.2 Comparisons to Normal Reference Ranges

A total of 49 samples were collected among 10 reference areas in 2013 and 2015 (Appendix Table E.6), and the data were used to derive reference normal ranges for sediment metals and PAHs (i.e., 2.5th and 97.5th percentiles; Appendix Table E.7; Appendix Figures E.1 and E.2). More than 92% of almost 7,000 concentrations reported for 52 constituents measured among 22 lentic areas in 2013 or 2015 were within the normal range for reference areas.

Concentrations observed among mine-exposed areas were divided by the upper limit of the normal range for each parameter to derive NRQs (Figure 6.4). The largest NRQs were observed for numerous PAHs measured in one of the samples collected from Stanford Pond (STPD), near Fernie (Appendix Tables E.8 and E.9). In samples collected closer to mine sources, anthracene was the PAH that was most often observed at concentrations above background levels. Anthracene and other PAHs were also elevated in sediment samples from reference area Lake Mountain Lake (LML, in MU1), indicating that sediment PAH concentrations are naturally elevated in some areas of the watershed. Concentrations of many PAHs were elevated above the reference normal range in the sediment samples from Otto Ponds and Goddard Marsh (Appendix Table E.8). Of all the metals/metalloids, selenium was most often elevated above the reference normal range in sediment collected among mine-exposed areas.

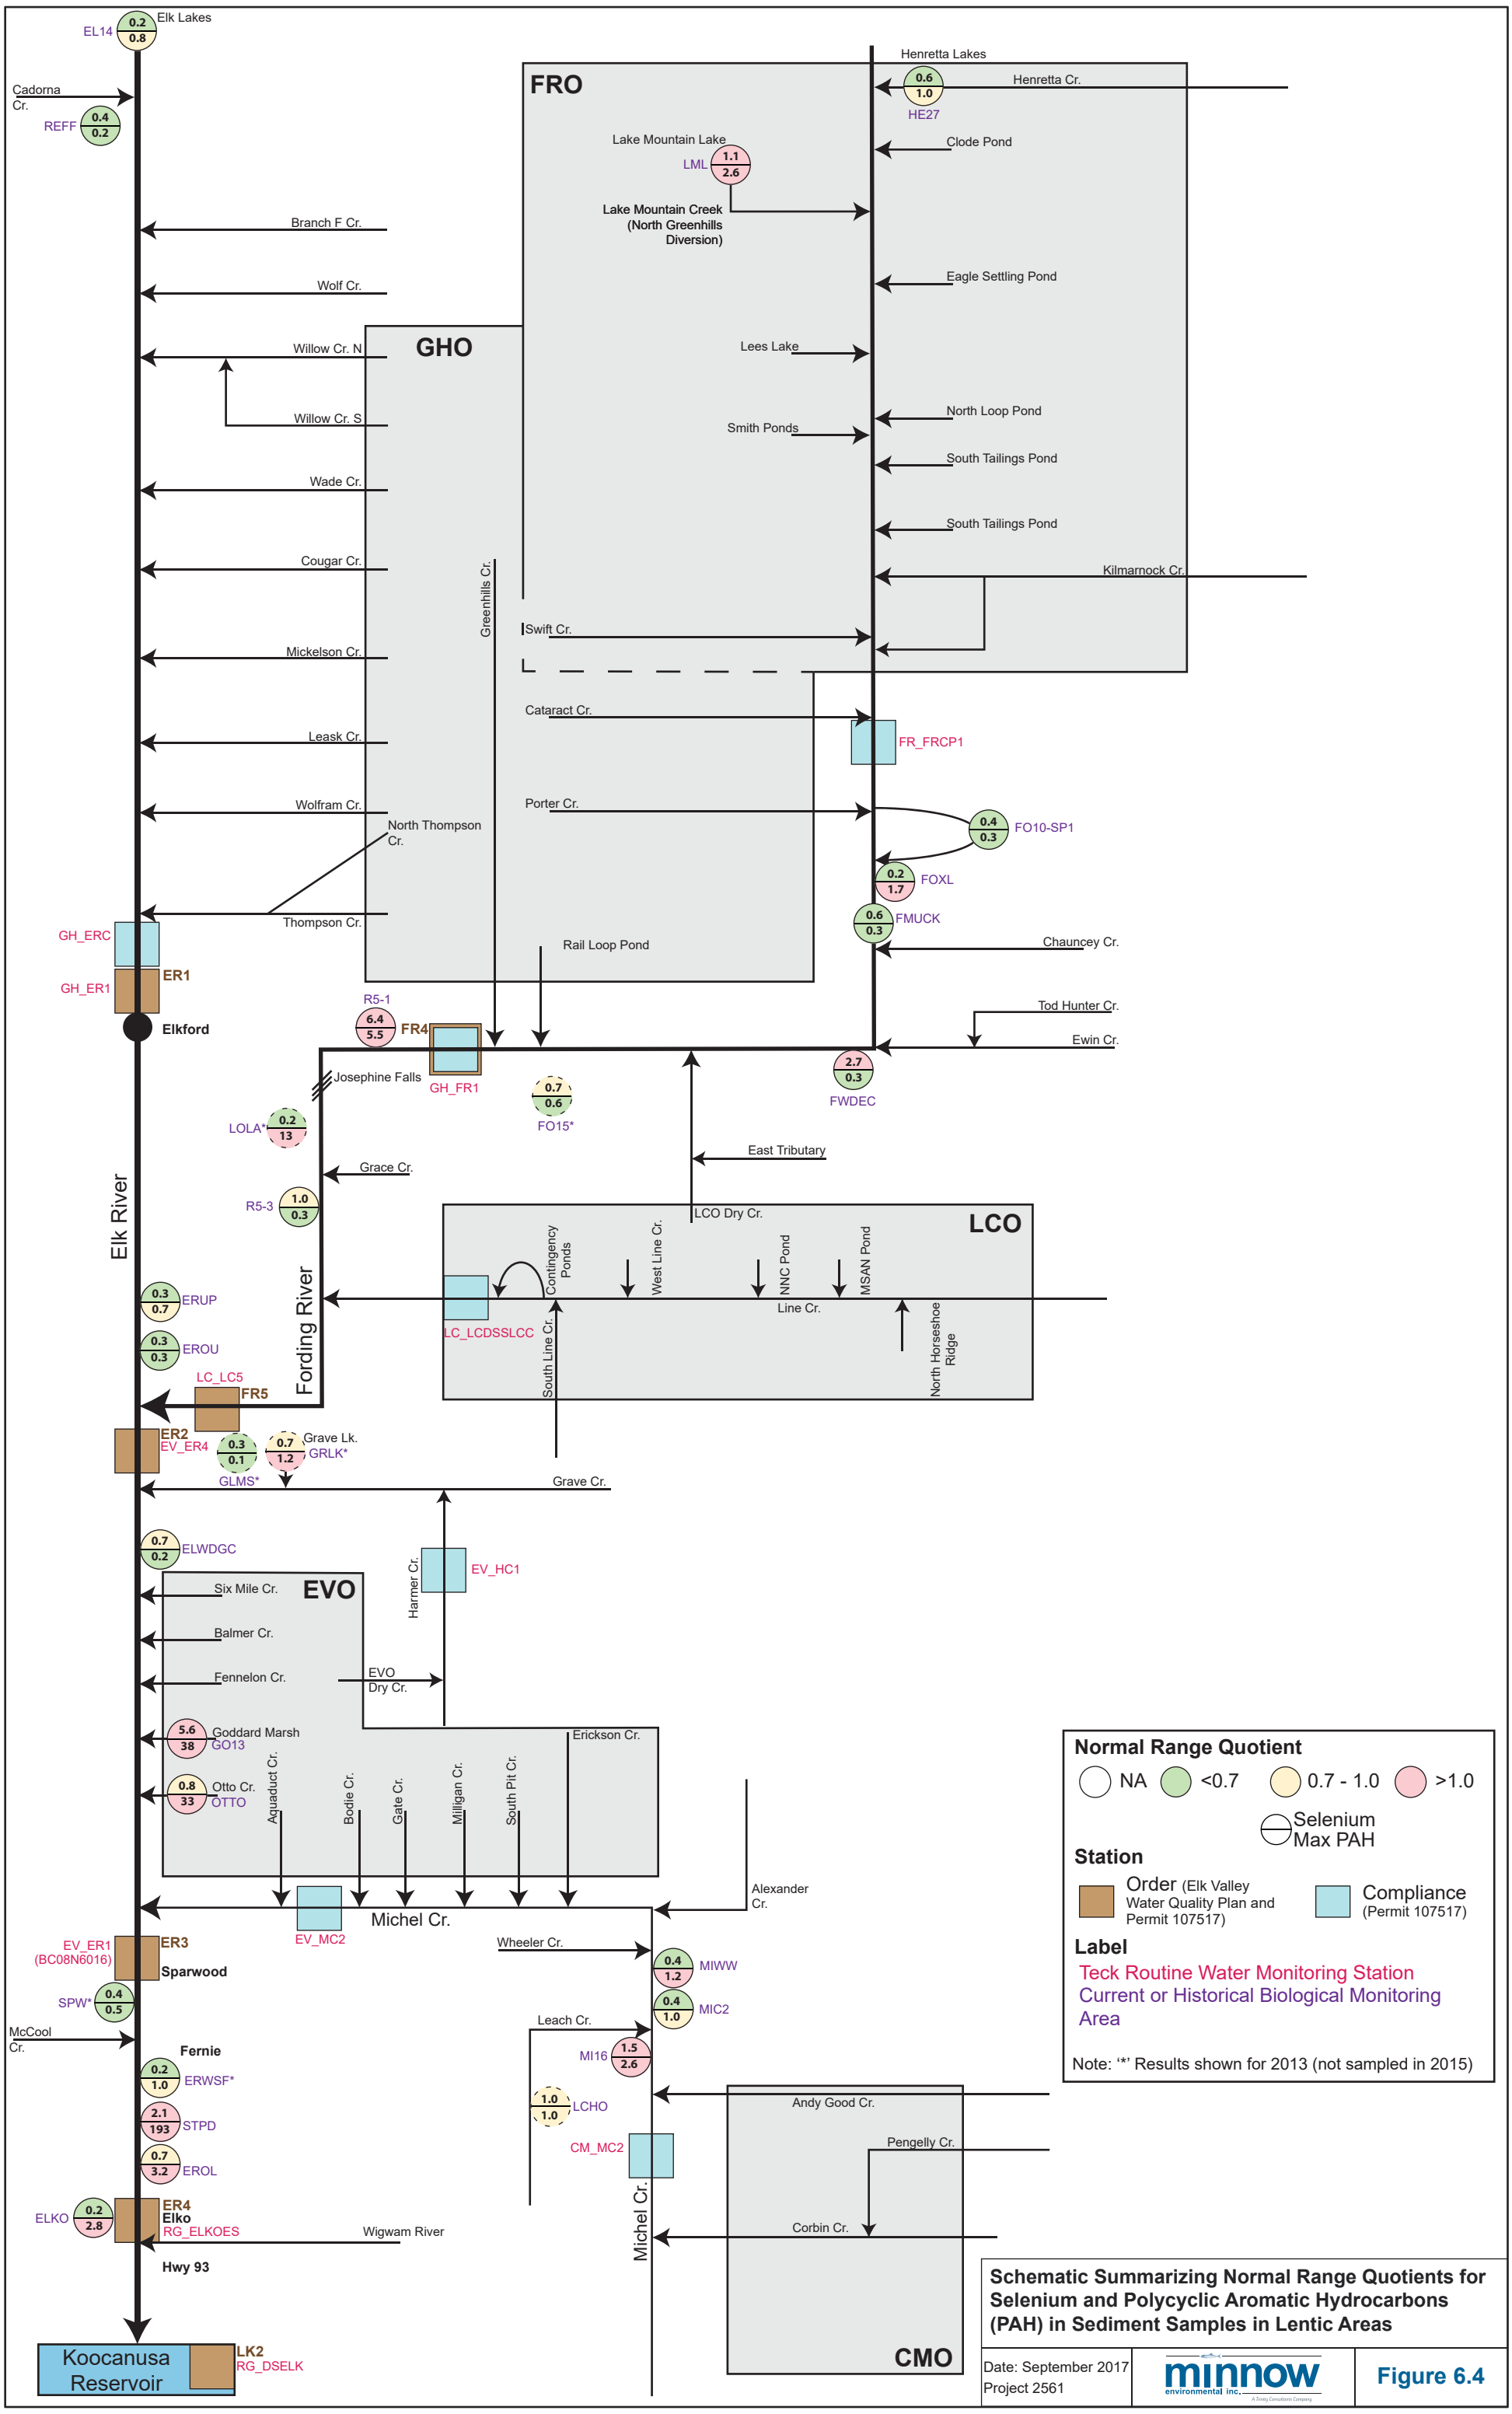
Areas of the Elk River watershed that were monitored in 2013 and/or 2015 and had sediment PAH and/or selenium concentrations above the reference area normal range, are indicated by pink symbols in Figure 6.4. NRQ values for selenium and the PAH with highest NRQ in each area are also shown in the figure. The specific PAH corresponding to the NRQ values in Figure 6.4 are listed in Appendix Table E.12.

6.2.3 Comparisons to Guidelines

Selenium was the metal[24] most often observed at concentrations above the working sediment quality guideline (SQG) (Figure 6.5; Appendix Tables E.2 to E.5). Highest concentrations of selenium in sediment were observed at R5-1 (wetland adjacent to the Fording River, near GHO) and GO13 (Goddard Marsh) (Figure 6.5).

Of the metals having both a high and low SQG, cadmium was reported at a concentration greater than the upper guideline in one sample from one reference area (LCHO – Leach Creek Oxbow) and one mine-exposed area (MI16 – Michel Creek wetland), and manganese was

[24] Selenium is a metalloid, but is included in metal scan results reported by analytical laboratories. It is referred to as a metal in subsequent sections of this report for brevity and ease of reading.



Schematic Summarizing Normal Range Quotients for Selenium and Polycyclic Aromatic Hydrocarbons (PAH) in Sediment Samples in Lentic Areas

Date: September 2017
Project 2561

minnow environmental inc.

Figure 6.4

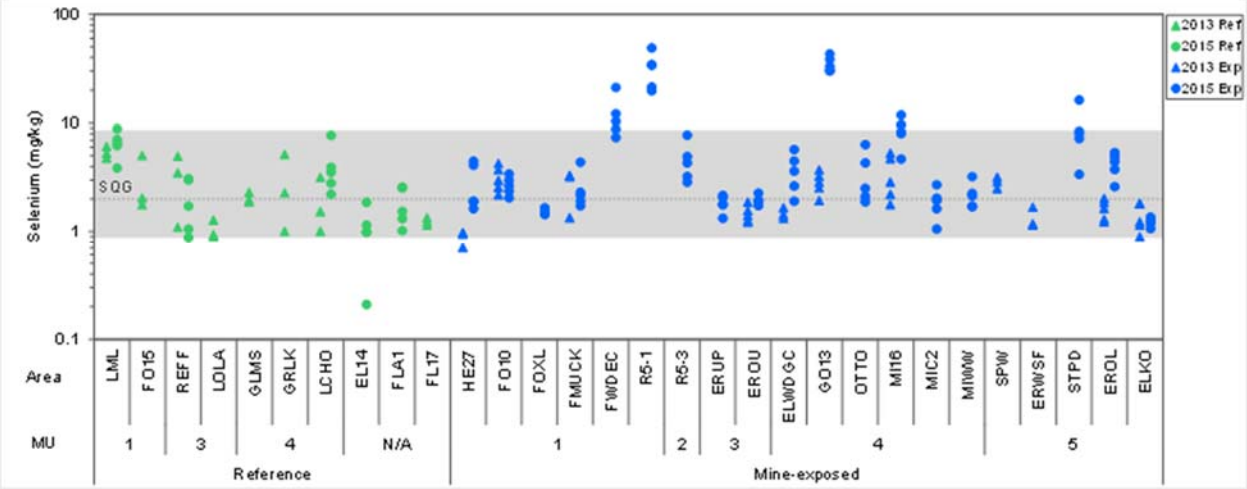


Figure 6.5: Selenium Concentrations Measured in Sediment Samples Relative to the Guideline

Notes: Sampling areas are shown in Figure 6.1. Concentrations below the LRL are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).

found at concentrations above the upper guideline at three areas (HE27 [Henretta Lake], R5-3 [lentic area adjacent to the Fording River downstream from Josephine Falls], and EROU [upper Elk River oxbow]; Figure 6.6; Appendix Figure E.3; Appendix Tables E.2 to E.5).

BC has SQGs for 16 of the 18 routine PAHs and none of the alkylated PAHs. Of the 16 routine PAHs, 12 were observed at concentrations greater than the upper SQG in one or more of the study areas (Appendix Figure E.4). 2-Methylnapthalene was the PAH most frequently exceeding the upper guideline in sediment samples (Figure 6.7). HQs were computed by dividing the concentrations observed in sediment samples by the upper SQG for each parameter. The upper normal range for 2-methylnaphthalene exceeded the upper SQG (Appendix Figure E.1), so HQs were typically higher, but NRQs were lower for this PAH than for other PAHs (Appendix Tables E.8 to E.12). Concentrations of PAHs were highest in sediments collected at Stanford Pond (STPD) and Otto Ponds (OTTO), with concentrations of many routine PAHs being highest at STPD and concentrations of most alkylated PAHs being highest at OTTO (Figure 6.8; Appendix Figure E.4). These data suggest STPD may be influenced by factors in addition to mining (e.g., municipal stormwater).

The upper limit of the normal range for reference area concentrations (97.5th percentile) exceeded the lower SQG for numerous metals and PAHs (arsenic, cadmium, nickel, selenium, zinc, benz(a)anthracene, benzo(a)pyrene, benzo(g,h,i)perylene, chrysene, dibenz(a,h)anthracene, fluorine, 2-methylnaphthalene, naphthalene, phenanthrene, and pyrene)

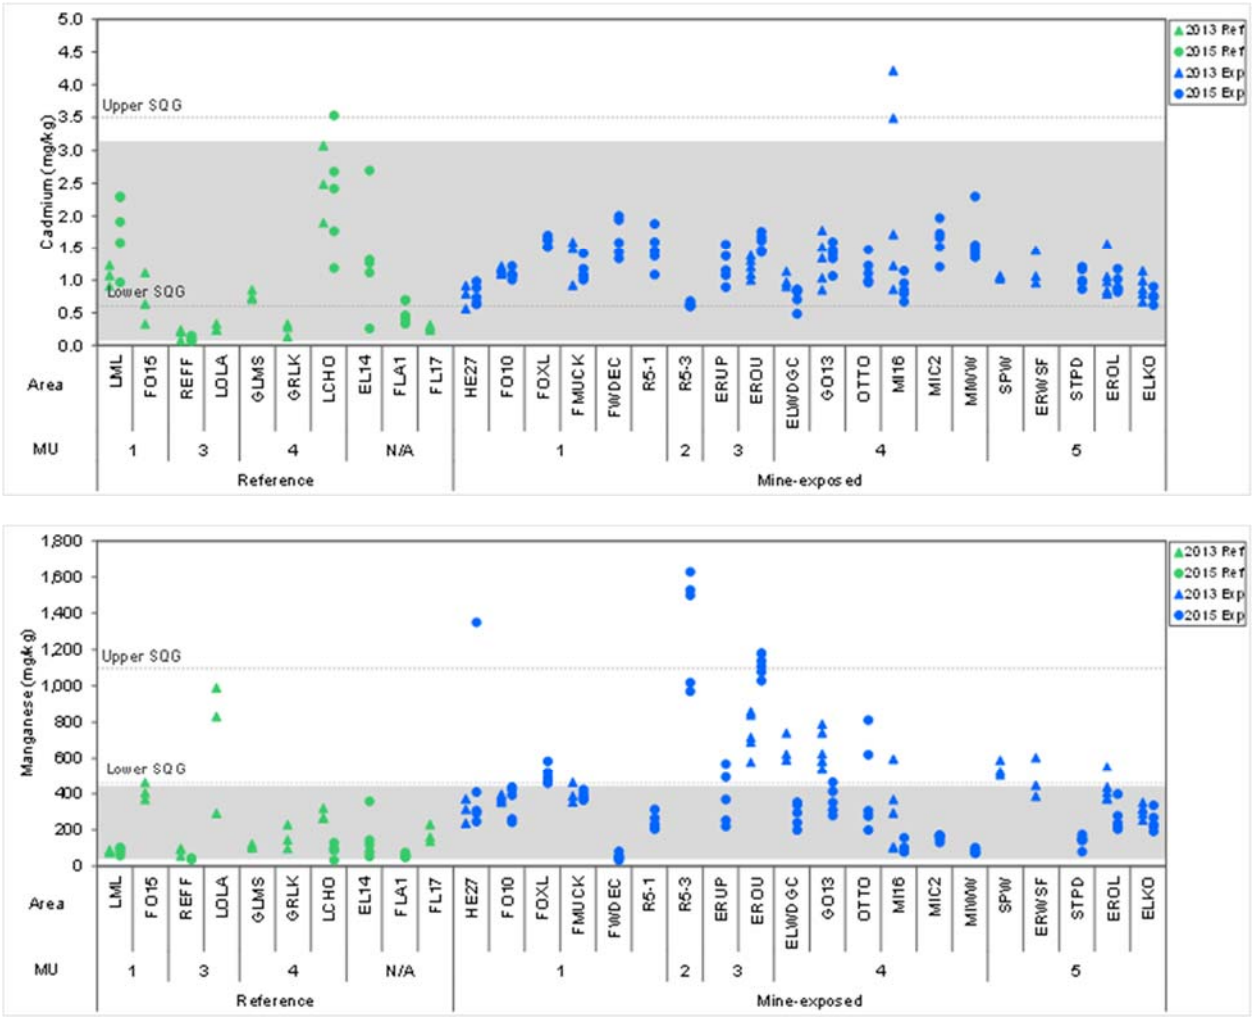

Figure 6.6: Cadmium and Manganese Concentrations in Sediment Samples Relative to Guidelines

Notes: Sampling areas are shown in Figure 6.1. Concentrations below the LRL are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).

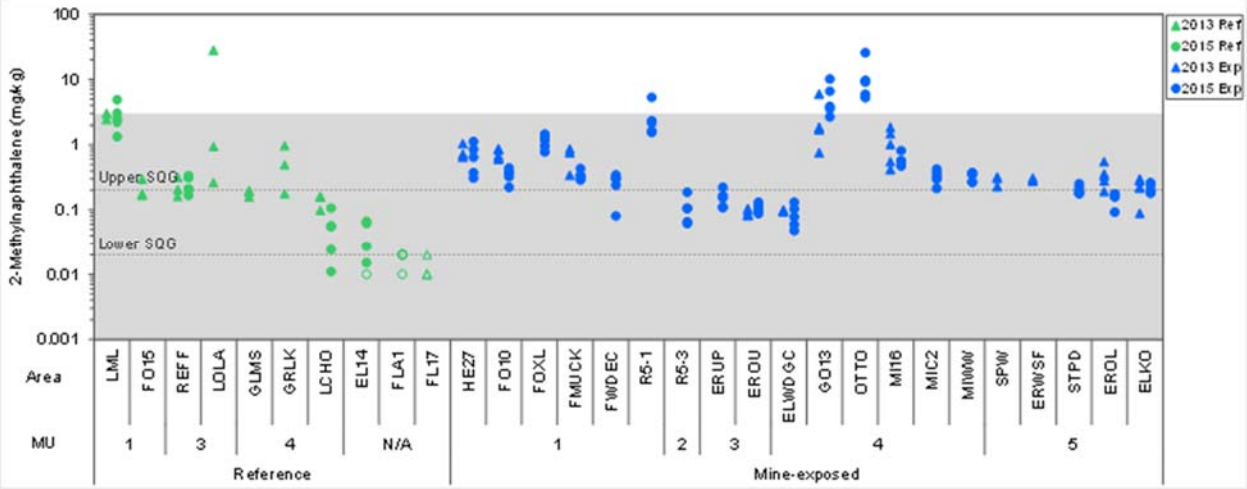

Figure 6.7: Concentrations of 2-Methylnapthalene in Sediment Samples Relative to Guidelines

Notes: Sampling areas are shown in Figure 6.1. Concentrations below the LRL are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).

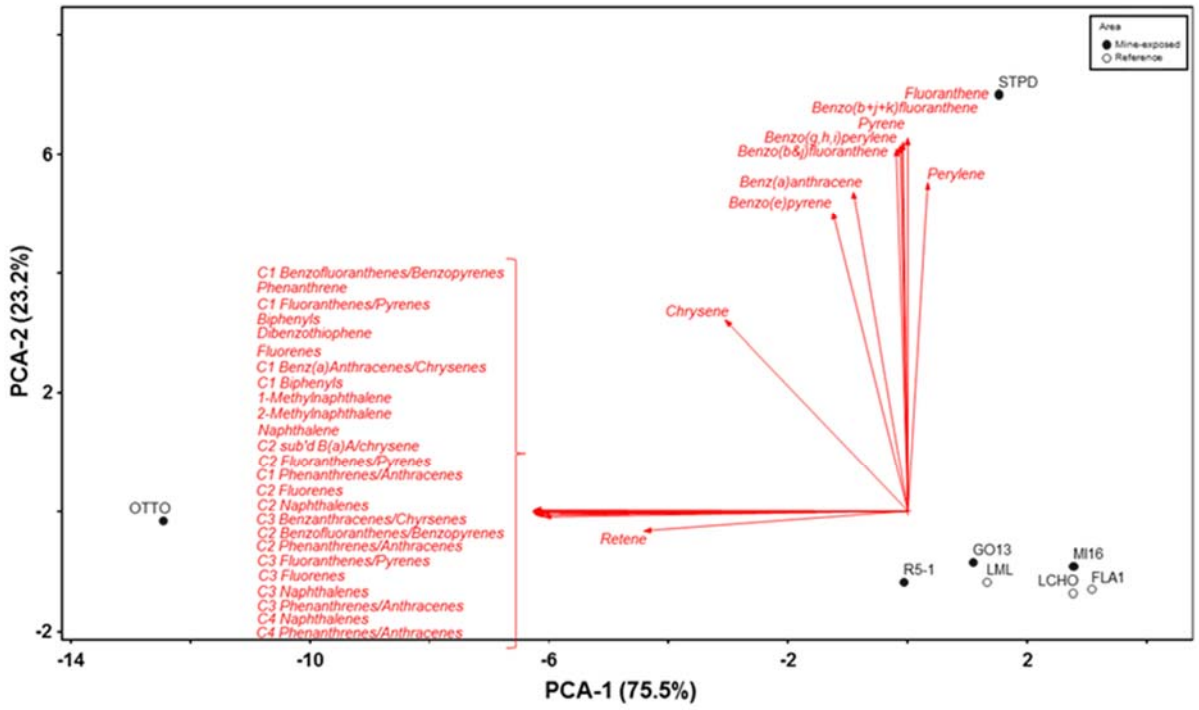

Figure 6.8: PCA of PAHs measured in sediment samples collected in 2015

(Appendix Figure E.1). The upper limit of the normal range also exceeded the upper SQG for selenium[25], fluorene, 2-methylnaphthalene, naphthalene, and phenanthrene.

Of PAHs, the highest HQs were associated with 2-methylnaphthalene in sediment samples collected at OTTO (HQs of 26 to 128 in samples collected in 2015) (Appendix Tables E.10 and E.11). HQs greater than 20 were also observed for 2-methylnaphthalene in one or more sediment samples collected at R5-1 (Fording River wetland downstream from GHO), GO13 (Goddard Marsh) and reference area LML (Lake Mountain Lake) (Figure 6.9; Appendix Table E.10). HQs greater than 20 were also observed for fluorene (OTTO), phenanthrene (OTTO), and selenium (R5-1 and GO13) (Appendix Table E.10). All of these (2-methylnaphthalene, fluorene, phenanthrene, and selenium) are substances for which reference area normal ranges also exceeded the upper SQG. For these substances, NRQs were less than one-third the corresponding HQ (Appendix Tables E.8 and E.9).

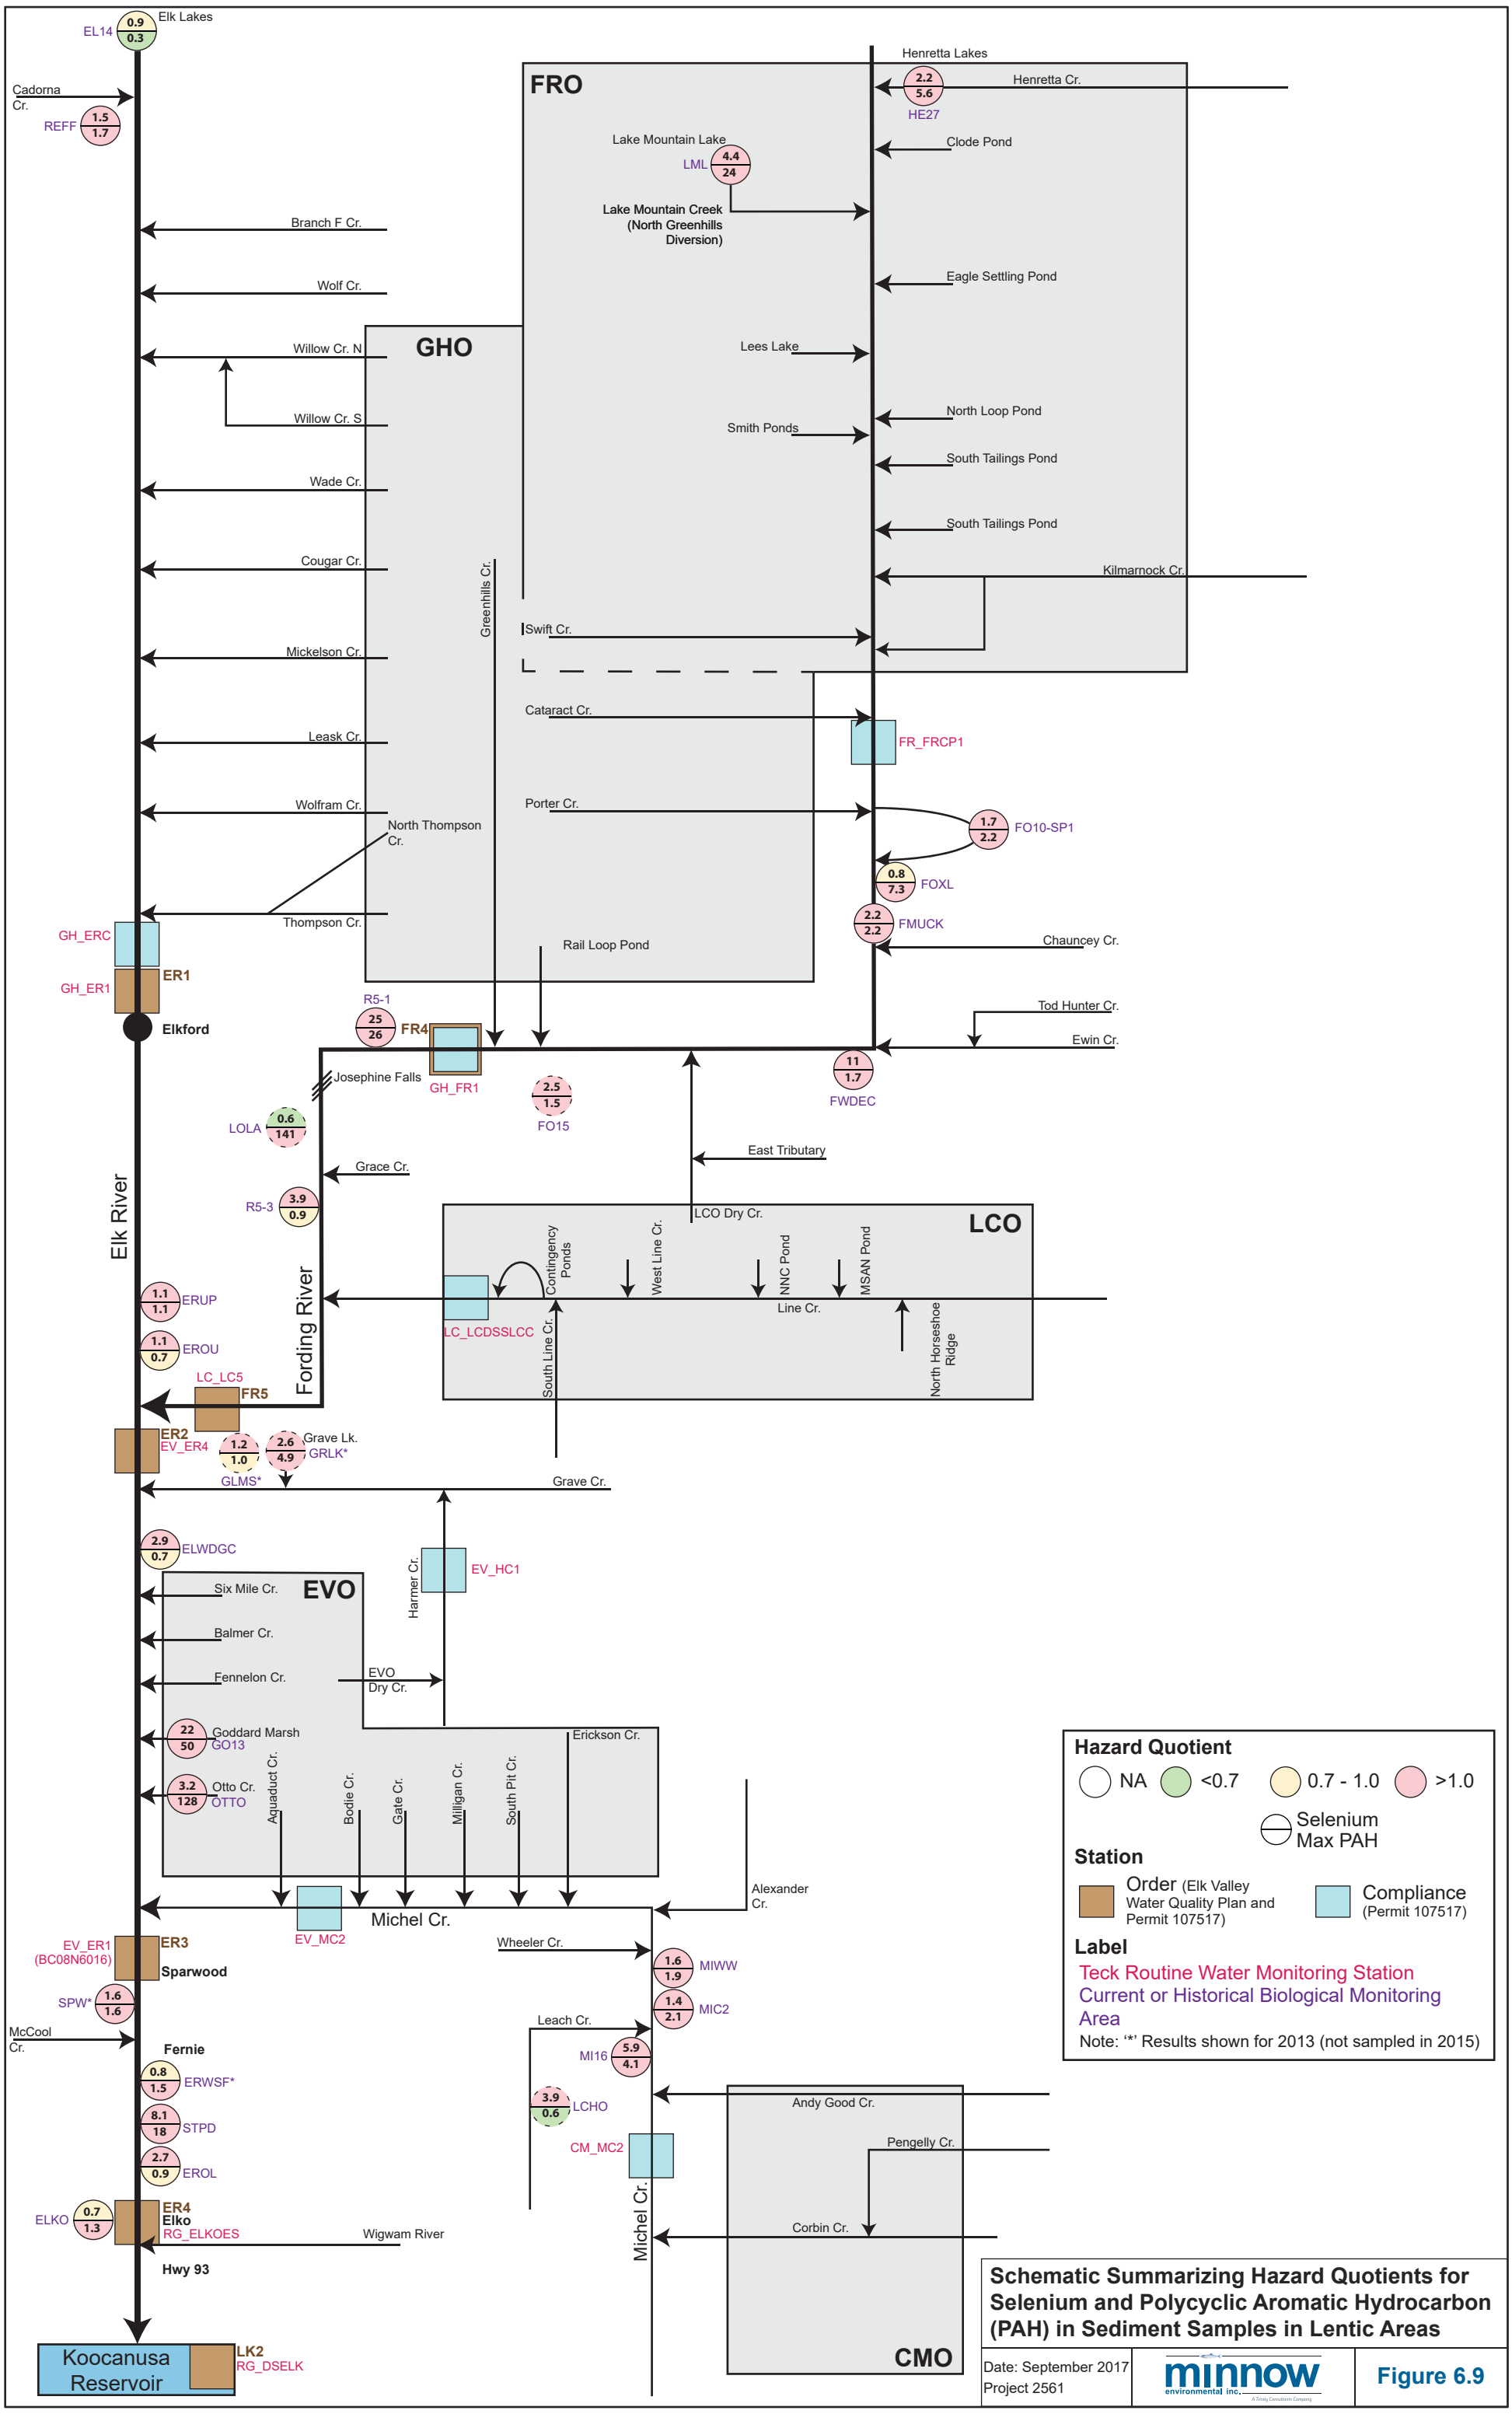
6.2.4 Temporal Changes

Potential temporal changes in sediment quality were tested for all areas that were sampled in both 2013 and 2015 using a RM ANOVA (three reference areas and nine mine-exposed areas; Appendix Tables E.14 to E.16). Contrasts after the ANOVA tested the relative difference in sediment quality between each mine-exposed area and both the mean of reference areas and each individual reference area between 2013 and 2015. Goddard Marsh (GO13) was the only area in which the change in sediment quality in 2015 compared to 2013 was significantly different from the change in reference area mean and the change for each of the three individual reference areas. Concentrations of both selenium and PAHs (based on 2-methylnaphthalene) at GO13 were above SQGs in both years and increased significantly in 2015 (Figure 6.10). The magnitude of temporal change for 2-methylnaphthalene was partially attributable to a decrease in mean reference area concentrations in 2015 (Figure 6.10).

6.3 Toxicity

A sediment toxicity supporting study was previously undertaken to evaluate a variety of test species, test durations, and biological endpoints to decide which test(s) is (are) the most appropriate for evaluating sediment toxicity in the Elk Valley (Minnow 2016d). To support selection of sampling areas for the toxicity study, sediment chemistry data (Section 6.2) were evaluated for the 19 mine-exposed and 5 reference areas sampled in August 2015. Based on input from the EMC, Teck selected a subset of mine-exposed areas for evaluation of sediment toxicity based on having the highest concentrations of mine-related constituents of interest (e.g.,

[25] Selenium has only a single guideline, which is why it is listed here as well as in the previous sentence.

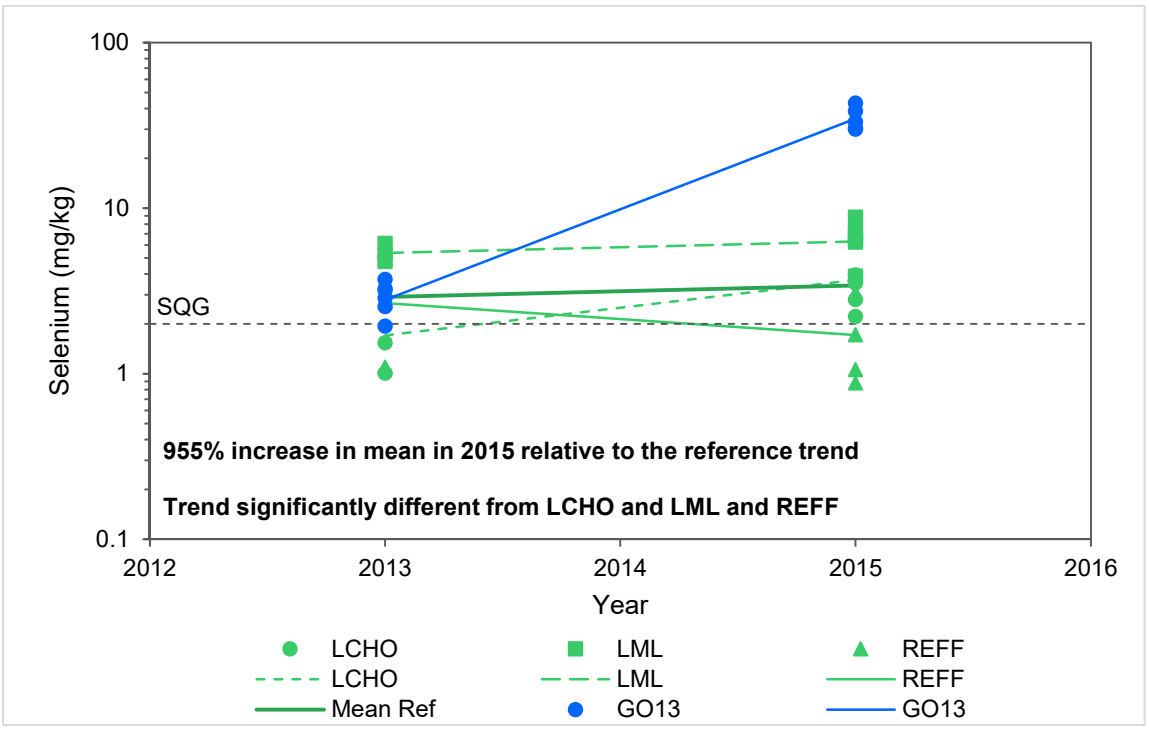


Schematic Summarizing Hazard Quotients for Selenium and Polycyclic Aromatic Hydrocarbon (PAH) in Sediment Samples in Lentic Areas

Date: September 2017
Project 2561

minnow environmental inc.

Figure 6.9



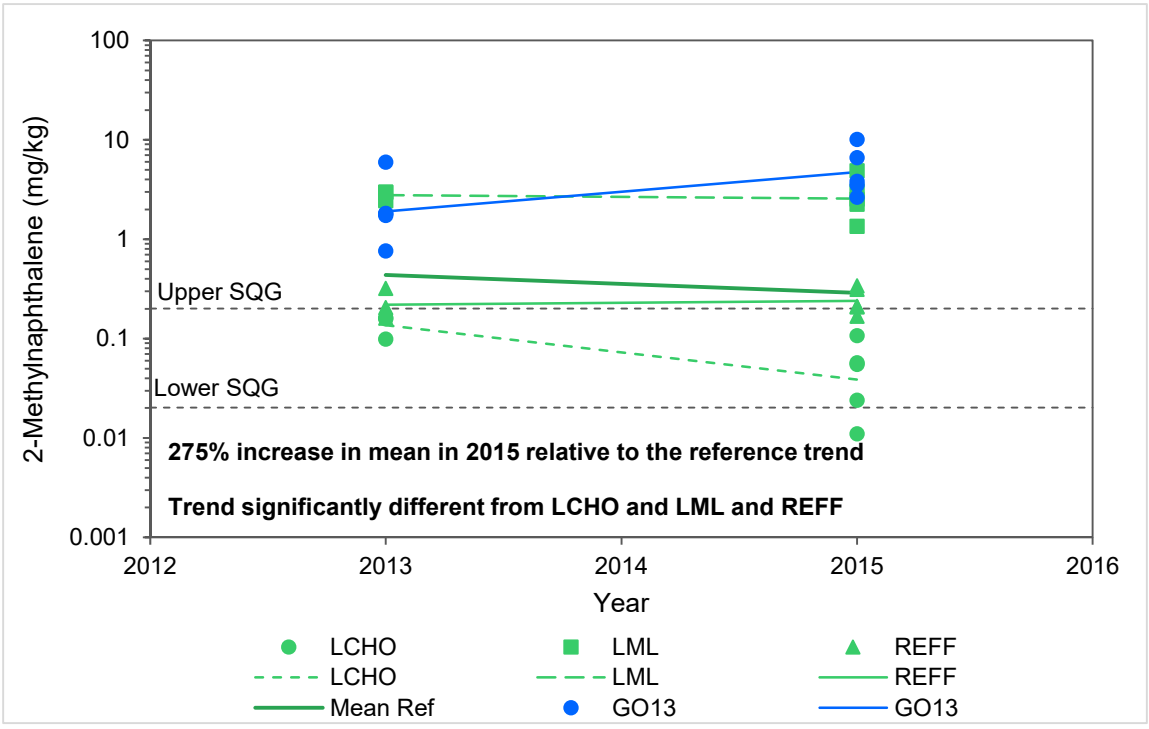


Figure 6.10: Temporal Changes in Concentrations of Selenium and 2-methylnaphthalene in Sediment (2015 compared to 2013) at Goddard Marsh (GO13) Relative to Reference Areas

selenium, cadmium, and PAHs). This was done to maximize the probability of detecting sediment toxicity (if present). Reference areas were also selected based on having a similar range of physical substrate characteristics (particle size distribution, sediment texture, and TOC content) to the sediments from mine-exposed areas, as well as a natural range of metal and PAH concentrations. This approach facilitated the comparison of test endpoint sensitivity by increasing the range of responses that might be expected among the tests, and helped to distinguish biological responses from underlying test variance. In total, five mine-exposed (R5-1, OTTO, GO13, STPD, MI16) and three reference areas (LML, LCHO, FLA1) were sampled for evaluation of three test species and a variety of test durations and endpoints:

- *Hexagenia* 21-day survival, growth, and biomass;
- *Hyalella* 14-day and 28-day survival, growth, and biomass;
- *Hyalella* life-cycle survival, growth, biomass, and reproduction;
- *Chironomus* 10-day and 20-day survival, growth, and biomass; and
- *Chironomus* life-cycle emergence and reproduction.

The results were evaluated based on a variety of factors, including test:

- representativeness - the degree of ecological and taxonomic representation to organisms that reside in Elk Valley aquatic habitats.
- sensitivity - the ability of a candidate test endpoint to detect biological impairment when the impairment exists.
- specificity - the ability of a candidate test endpoint to correctly conclude lack of impairment when no impairment exists.
- reliability - the ability of a test to consistently meet test performance criteria using a standard test method, such that results can be interpreted with confidence.
- variability - the tendency for a test to yield high variance when testing is repeated across laboratory or field replicates. Such variance affects the statistical power to detect biological changes relative to control or reference conditions.
- practicality - the ability to implement tests at reasonable cost and effort within the constraints of laboratory space, sample volume, sample holding times, and other practical considerations.
- The results are summarized in Table 6.1 and key findings were reported as follows (Minnow 2016e):

Table 6.1: Sediment Toxicity Test Results

[a] Sample was significantly different from laboratory control sediment.

[b] Sample was significantly different from reference area LML-TOX-1.

[c] Sample was significantly different from reference area FLA1-TOX-1.

[d] Sample was significantly different from reference area LCHO-TOX-1.

[e] 41 to 58 days, depending on the sample.

Significant relative to one reference area.

Significant relative to two reference areas.

Significant relative to three reference areas.

- Survival, growth, and, where applicable, reproduction of tests organisms in field reference samples were usually similar to or greater than those of laboratory control samples. Physical characteristics of the reference samples were also more comparable to the mine-exposed samples than the (sandy) laboratory control sample.
- Toxicity to *Hexagenia* was observed for four of five mine-exposed sediments based on significant differences from at least two reference sediment samples. By comparison, only two samples caused toxicity to *Hyalella*. Results for *Chironomus* were variable, depending on the test duration and endpoint considered, and which reference areas results were compared.
- There were significant correlations among results for species exposed for multiple test durations, and effects were not observed in longer term tests with *Hyalella* or *Chironomus* that were not observed for the standard short-term tests using the same species (e.g., 14-days and 10-days, respectively) or using *Hexagenia*.
- There were significant correlations among endpoints for different test organisms, suggesting similarity in biological responses and redundancy among tests.
- Growth of all three species was most reduced at the two areas having highest concentrations of PAHs relative to SQGs. Similarly, survival of the three test species tended to be reduced at the areas with highest selenium concentrations. These results provided evidence of cause-effect relationships for mine-related constituents, and thus provided evidence that these test species are relevant for evaluating mine-related effects on sediment quality.
- Tests for all organisms were reliable based on achieving method-specific Quality Assurance/Quality Control (QA/QC) criteria.
- *Hexagenia* tests showed the largest absolute magnitude of effect and highest ratio of the magnitude of difference to the minimum statistically detectable difference. The *Hexagenia* test also showed the highest test sensitivity and specificity

Based on the conclusions presented above, the following recommendations were provided (Minnow 2016e):

- Although laboratory control samples are an important component of within-laboratory quality control for test systems, they often have different physical characteristics from mine-exposed sediments. Therefore, sediment toxicity testing programs should include collection of at least one, and preferably more, reference-area sediment samples having similar physical characteristics to sediments from mine-exposed areas being tested.

The field reference samples should be used in statistical evaluations to identify and interpret effects associated with mine-exposed sediments.

- The 21-day *Hexagenia* test is recommended based on highest ratio of magnitude of effect to minimum detectable biological response, as well as greatest overall test sensitivity and specificity compared to the other test species, durations, and endpoints. However, reliable methods for laboratory culturing are lacking and the test method has not been developed or used to the same degree as for other sediment species. Therefore, it is recommended to be used in conjunction with another test species.
- Based on the availability of standard methods for laboratory culturing and testing, it is recommended that the *Hyalella* 14-day test also be applied for sediment toxicity testing to corroborate results obtained for *Hexagenia* tests. Longer-term tests with *Hyalella* are not recommended because they did not indicate toxicity for samples that was not evident in the 21-day *Hexagenia* and 14-day *Hyalella* tests.
- None of the *Chironomus* test durations or endpoints identified effects that were not observed in the *Hexagenia* 21-day or *Hyalella* 14-day tests, so testing with this species is not recommended.

Concentrations of Se and five PAHs (2-methylnaphthalene, pyrene, phenanthrene, naphthalene and fluorene) in sediment samples collected from reference and mine-exposed areas from August, 2015 were depicted in a histogram showing the frequency of concentrations for each constituent (Appendix Figure E.8). The concentrations of each constituent in the areas that showed no toxicity are marked on the plots, with the highest non-toxic concentration highlighted with a circle. The majority of the concentrations for each constituent fall under the highest non-toxic concentration.

6.4 Summary

Sediment chemistry was evaluated at a total of 31 areas in 2013 and/or 2015, including 10 reference areas. Most of the areas chosen for sediment sampling have little or no surface water connection to the main channel flow for at least part of the year. Consequently sediment samples collected among the 31 study areas were dominated by fine particles (silt and clay). These areas were expected to have the highest sediment accumulations of mine-related substances compared to lotic habitats that are regularly affected by seasonal high flows and associated scouring.

Mining influence on sediment chemistry was most evident as elevated concentrations of selenium and PAHs. Highest concentrations of selenium in sediment were observed at R5-1 (wetland adjacent to the Fording River, near GHO) and GO13 (Goddard Marsh). Highest PAH

concentrations were observed in a sample collected at STPD (Stanford Pond near Fernie), but the pattern of PAHs suggested a source other than, or in addition to, coal mining. At areas closer to mining, 2-methylnaphthalene was the PAH found at highest concentrations relative to guidelines, particularly at OTTO (Otto Creek ponds), GO13, and reference area LOLA (Lost Lake). The upper limit of the reference area normal range exceeded the upper sediment quality guideline for selenium, fluorene, 2-methylnaphthalene, naphthalene, and phenanthrene.

Goddard Marsh (GO13) was the only mine-exposed area in which the change in sediment quality in 2015 compared to 2013 was significantly different from the change in reference area mean and the change for each of the three reference areas sampled in both 2013 and 2015. Concentrations of both selenium and PAHs (based on 2-methylnaphthalene) at GO13 were greater than the upper SQGs in both years and increased significantly in 2015 relative to the reference areas.

A sediment toxicity supporting study evaluated a variety of test species, test durations, and biological endpoints to decide which test(s) is (are) the most appropriate for evaluating sediment toxicity in the Elk Valley. A subset of five mine-exposed areas was chosen for the study based on having the highest concentrations of mine-related constituents of interest (e.g., selenium, cadmium, and PAHs). Three reference areas were also selected based on having a similar range of physical substrate characteristics (particle size distribution, sediment texture, and TOC content) to the sediments from mine-exposed areas as well as a natural range of metal and PAH concentrations. The study found that toxicity was observed in samples having highest concentrations of selenium and/or PAHs. The 21-day *Hexagenia* survival and growth test and the 14-day *Hyalella* survival and growth test were recommended for future testing of potential mine-related sediment toxicity.

7 PERIPHYTON

7.1 Overview

Periphyton represents an important component of aquatic food webs in the streams within the Elk River watershed and consists of a complex matrix of organisms that can include algae, fungi, bacteria, and protozoa. These organisms take up inorganic nutrients such as nitrogen (e.g., nitrate, nitrite) and phosphorus (e.g., ortho-phosphate), as well as other substances dissolved in water (e.g., selenate), to serve physiological functions and which thereby become available via dietary pathways to consumer organisms at higher trophic levels.

Periphyton productivity was evaluated as part of the RAEMP (2015-2016), in the supporting study to evaluate the effects of calcite on biota (Minnow 2016b), and in the Line Creek and FRO LAEMPs (Minnow 2015c, 2016c, 2017a,c). Periphyton chlorophyll-a and ash-free dry mass (AFDM) were the endpoints used to evaluate primary productivity in comparison to reference normal ranges. Periphyton chlorophyll-a concentrations were also compared to the provincial guideline of 100 mg/m^2.

Periphyton tissue selenium concentrations measured in mine-exposed areas in the 2015-2016 RAEMP cycles, the Line Creek LAEMP (Minnow 2016c), and the 2016 LAEMPs for Line Creek and FRO (Minnow 2017a,c) were compared to the upper limit of the reference normal range.

Evaluations of potential mine-related effects on community characteristics were completed in supporting studies to the RAEMP (Minnow 2014c, Minnow and Larratt 2016) and the results are summarized in this report.

Figures 7.1 to 7.3 show the sampling locations discussed in this section.

7.2 Productivity

7.2.1 Nutrient Levels

Most reference and mine-exposed areas sampled in September 2015 had ratios of aqueous total nitrogen to total phosphorus concentrations (N:P) greater than 15 (Figure 7.4), indicating that phosphorus is the limiting nutrient based on categories defined by McDowell et al. (2009) for mass concentrations:

N:P < 7	Nitrogen-limited
7 < N:P < 15	Co-limited (nitrogen and phosphorus)
N:P > 15	Phosphorus-limited

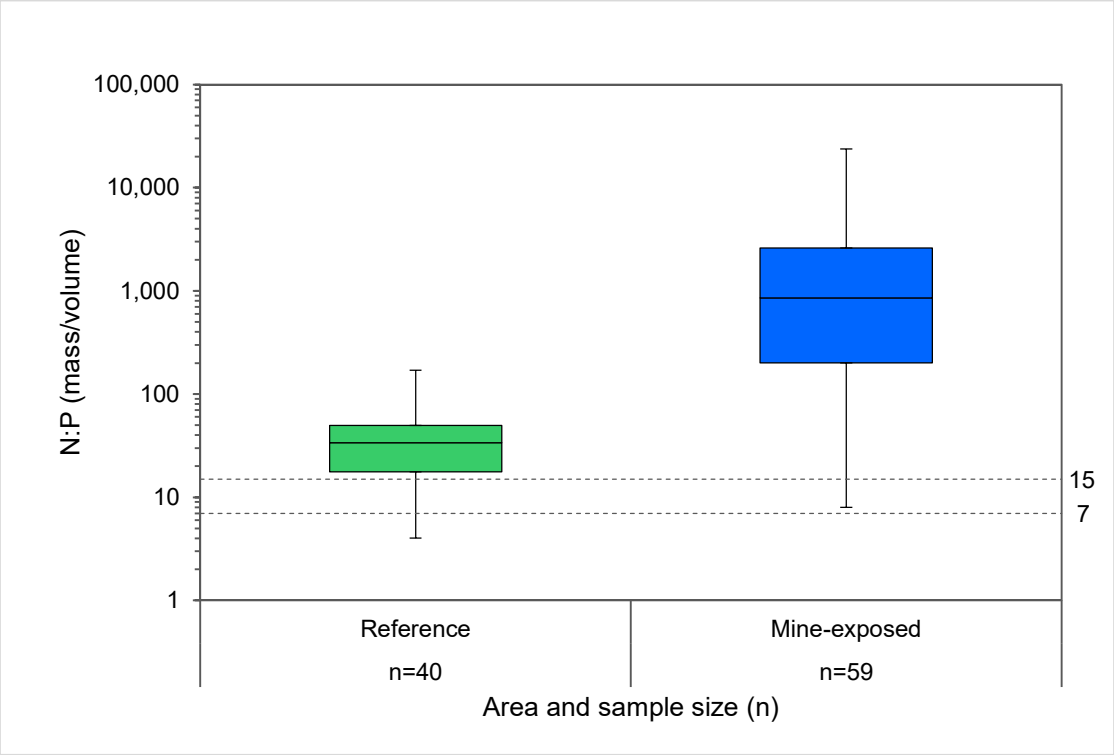

Figure 7.4: Boxplot of Ratio of Total Nitrogen to Total Phosphorus (Concentrations Expressed as Mass/Volume) Based on Samples Collected for the RAEMP, September 2015

Notes: The box represents the 25th percentile, median, and 75th percentile and the whiskers represent the minimum and maximum values. Ratio <7 indicates nitrogen limitation, Ratio >15 indicates phosphorus limitation (McDowell et al. 2009)

Of the 59 mine-exposed areas sampled in 2015, 56 would be considered phosphorus-limited, while three would be considered co-limited (Figure 7.5). This means that aquatic productivity is

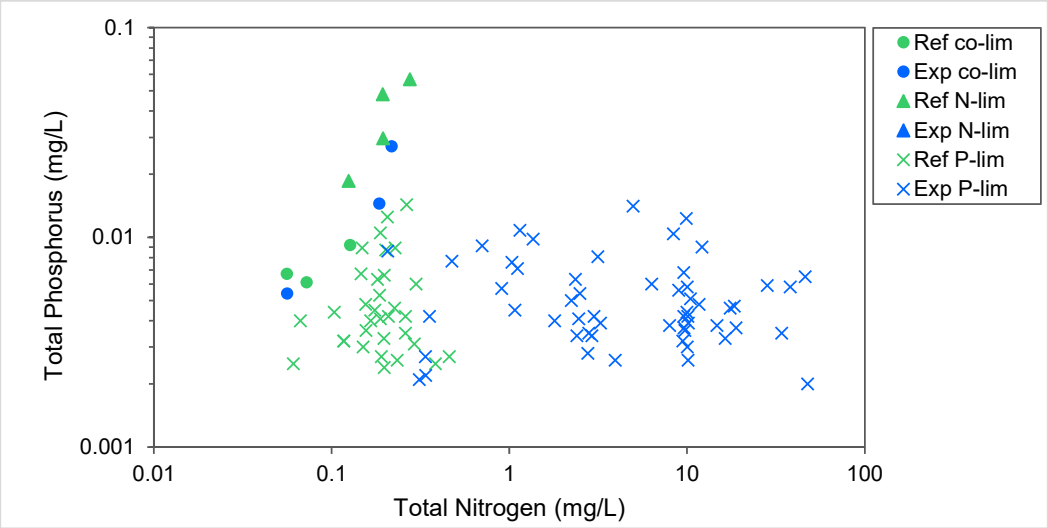

Figure 7.5: Scatterplot of Concentrations of Total Phosphorus versus Total Nitrogen for Reference (n = 40) and Mine-exposed Areas (n = 59) Grouped by N:P Ratios for Stations Sampled for the RAEMP, September 2015

not likely sensitive to changes in nitrogen concentrations, but productivity would likely increase at any locations where phosphorus concentrations increased.

7.2.2 Comparisons to Normal Reference Ranges

Periphyton AFDM and chlorophyll-a were measured at 40 reference and 58 mine-exposed areas in 2015 as part of the RAEMP, and were measured at a sub-set of areas in 2013, 2014, and 2016 for various other purposes (Figures 7.6 and 7.7; Appendix Tables F.1 and F.2). Normal ranges were defined for periphyton chlorophyll-a and AFDM based on the samples collected at 40 reference areas in 2015 (Appendix Table F.3; Appendix Figure F.1). Chlorophyll-a and AFDM levels in 2015 were within respective reference normal ranges at 76% (44 of 58 areas) and 78% (45 of 58 areas) of mine-exposed areas, respectively (Appendix Table F.4). The sub-set of areas sampled in 2016 had similar or higher periphyton AFDM and chlorophyll-a values compared to 2015, including reference area FO26 on the Fording River upstream from FRO, where levels of both endpoints were within normal ranges in 2015 and greater than the normal range in 2016 (Appendix Table F.5).

Periphyton AFDM and chlorophyll-a were elevated above the reference area normal range at 14 and 10 areas, respectively, of 58 mine-exposed areas sampled in 2015 (Figures 7.6 and 7.7; Appendix Table F.4). There was no direct relationship between periphyton chlorophyll-a concentrations and aqueous total phosphorus or orthophosphate concentrations, even though phosphorus is the limiting nutrient (Figure 7.8). Dodds et al. (2002) concluded that, although

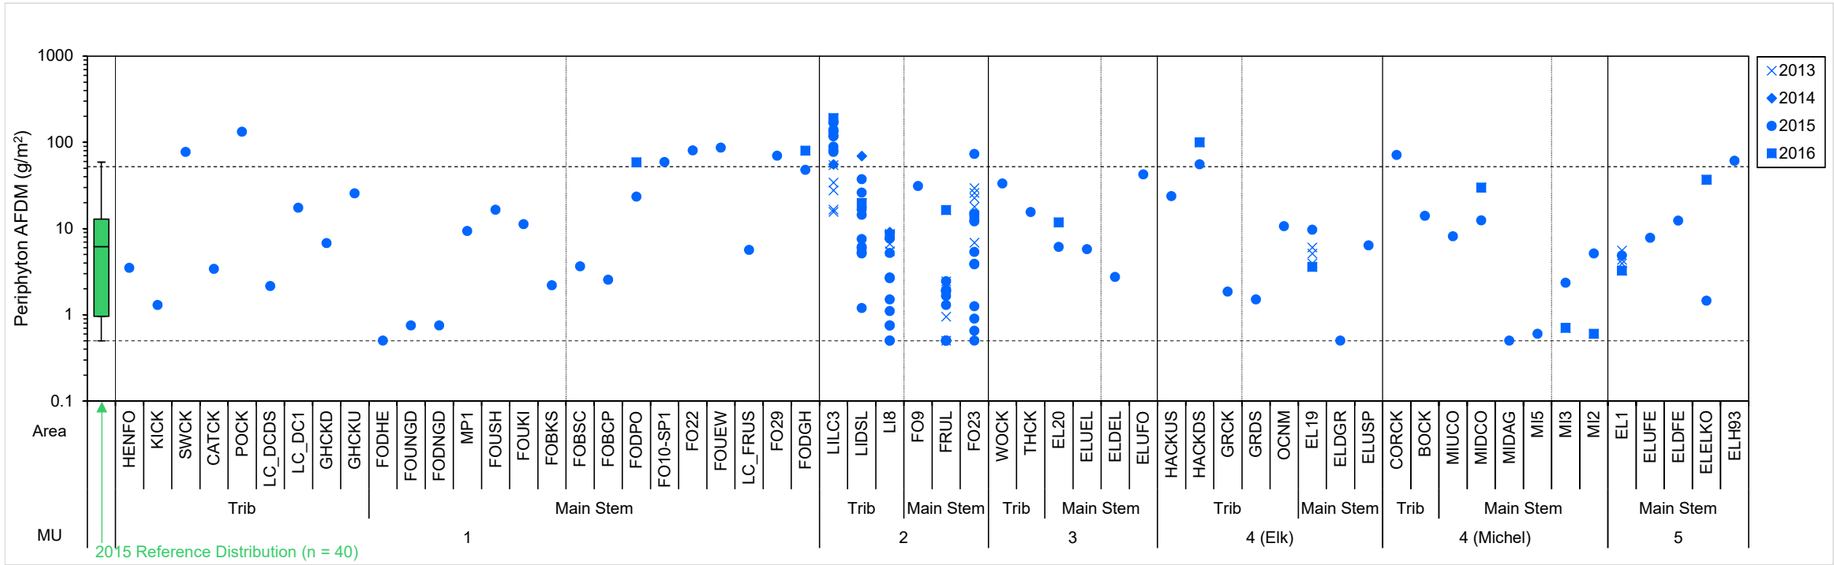

Figure 7.6: Periphyton Ash-free Dry Mass (AFDM) Concentrations in Samples Collected in Lotic Habitats, 2013 - 2015

Note: Dashed horiztonal lines represent the limits of the reference area normal range

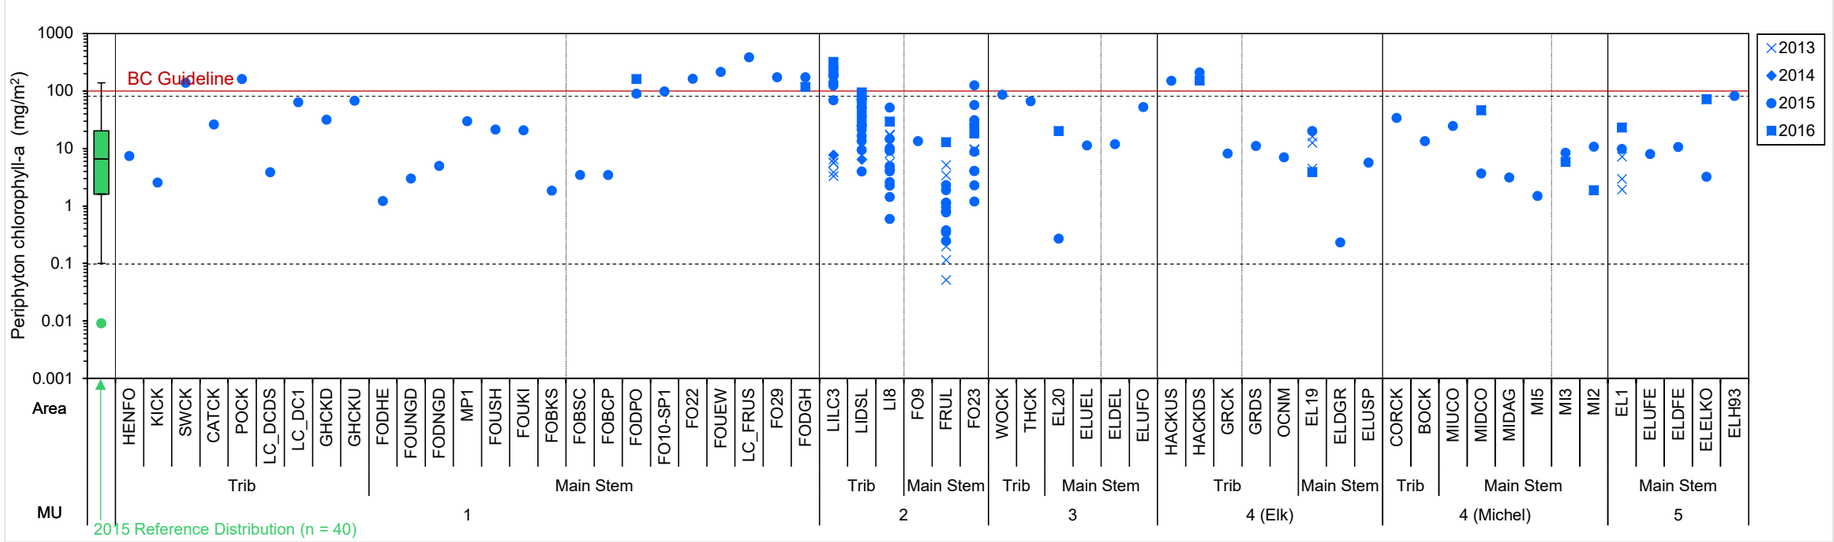

Figure 7.7: Periphyton Chlorophyll-a Concentrations in Samples Collected in Lotic Habitats, 2013 - 2015

Note: Dashed horiztonal lines represent the limits of the reference area normal range

nutrient availability can explain as much as 40% of the variability in periphyton biomass among areas, multiple factors affect primary productivity. Much of the scientific literature shows inconsistent to no statistical linkages between nutrient and chlorophyll-a concentrations, especially in aquatic habitats with low nutrient concentrations (see meta-analysis: Francoeur 2001). There appears to be a threshold (P > 0.030 mg/L, N > 0.040 mg/L) above which periphyton growth is more closely associated with nutrient concentrations, and below which primary productivity is mostly related to other habitat factors (Lewis and McCutchan 2010). The phosphorus threshold of 0.03 mg/L is most relevant to the Elk River watershed, because it is the limiting nutrient.

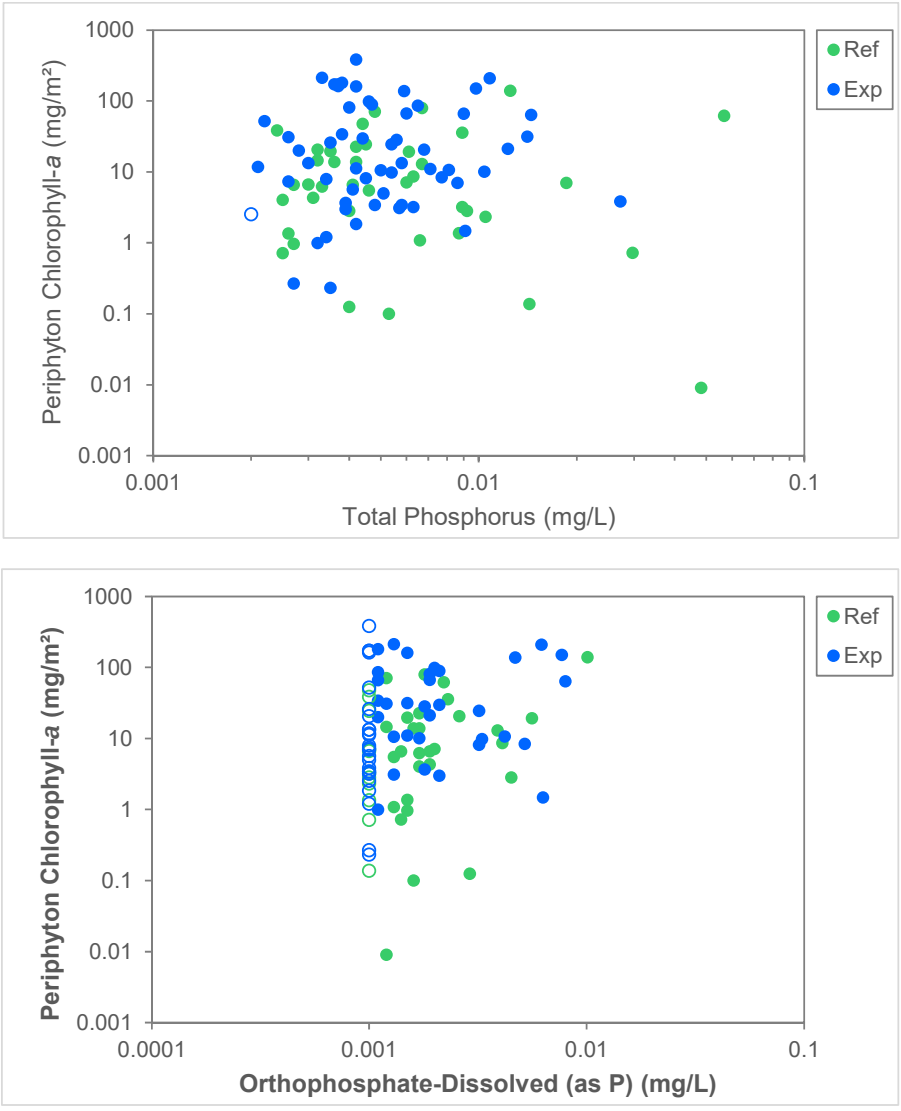

Figure 7.8: Periphyton Chlorophyll-a Compared to Orthophosphate Concentrations in Reference (n=40) and Mine-exposed (n=57) Areas

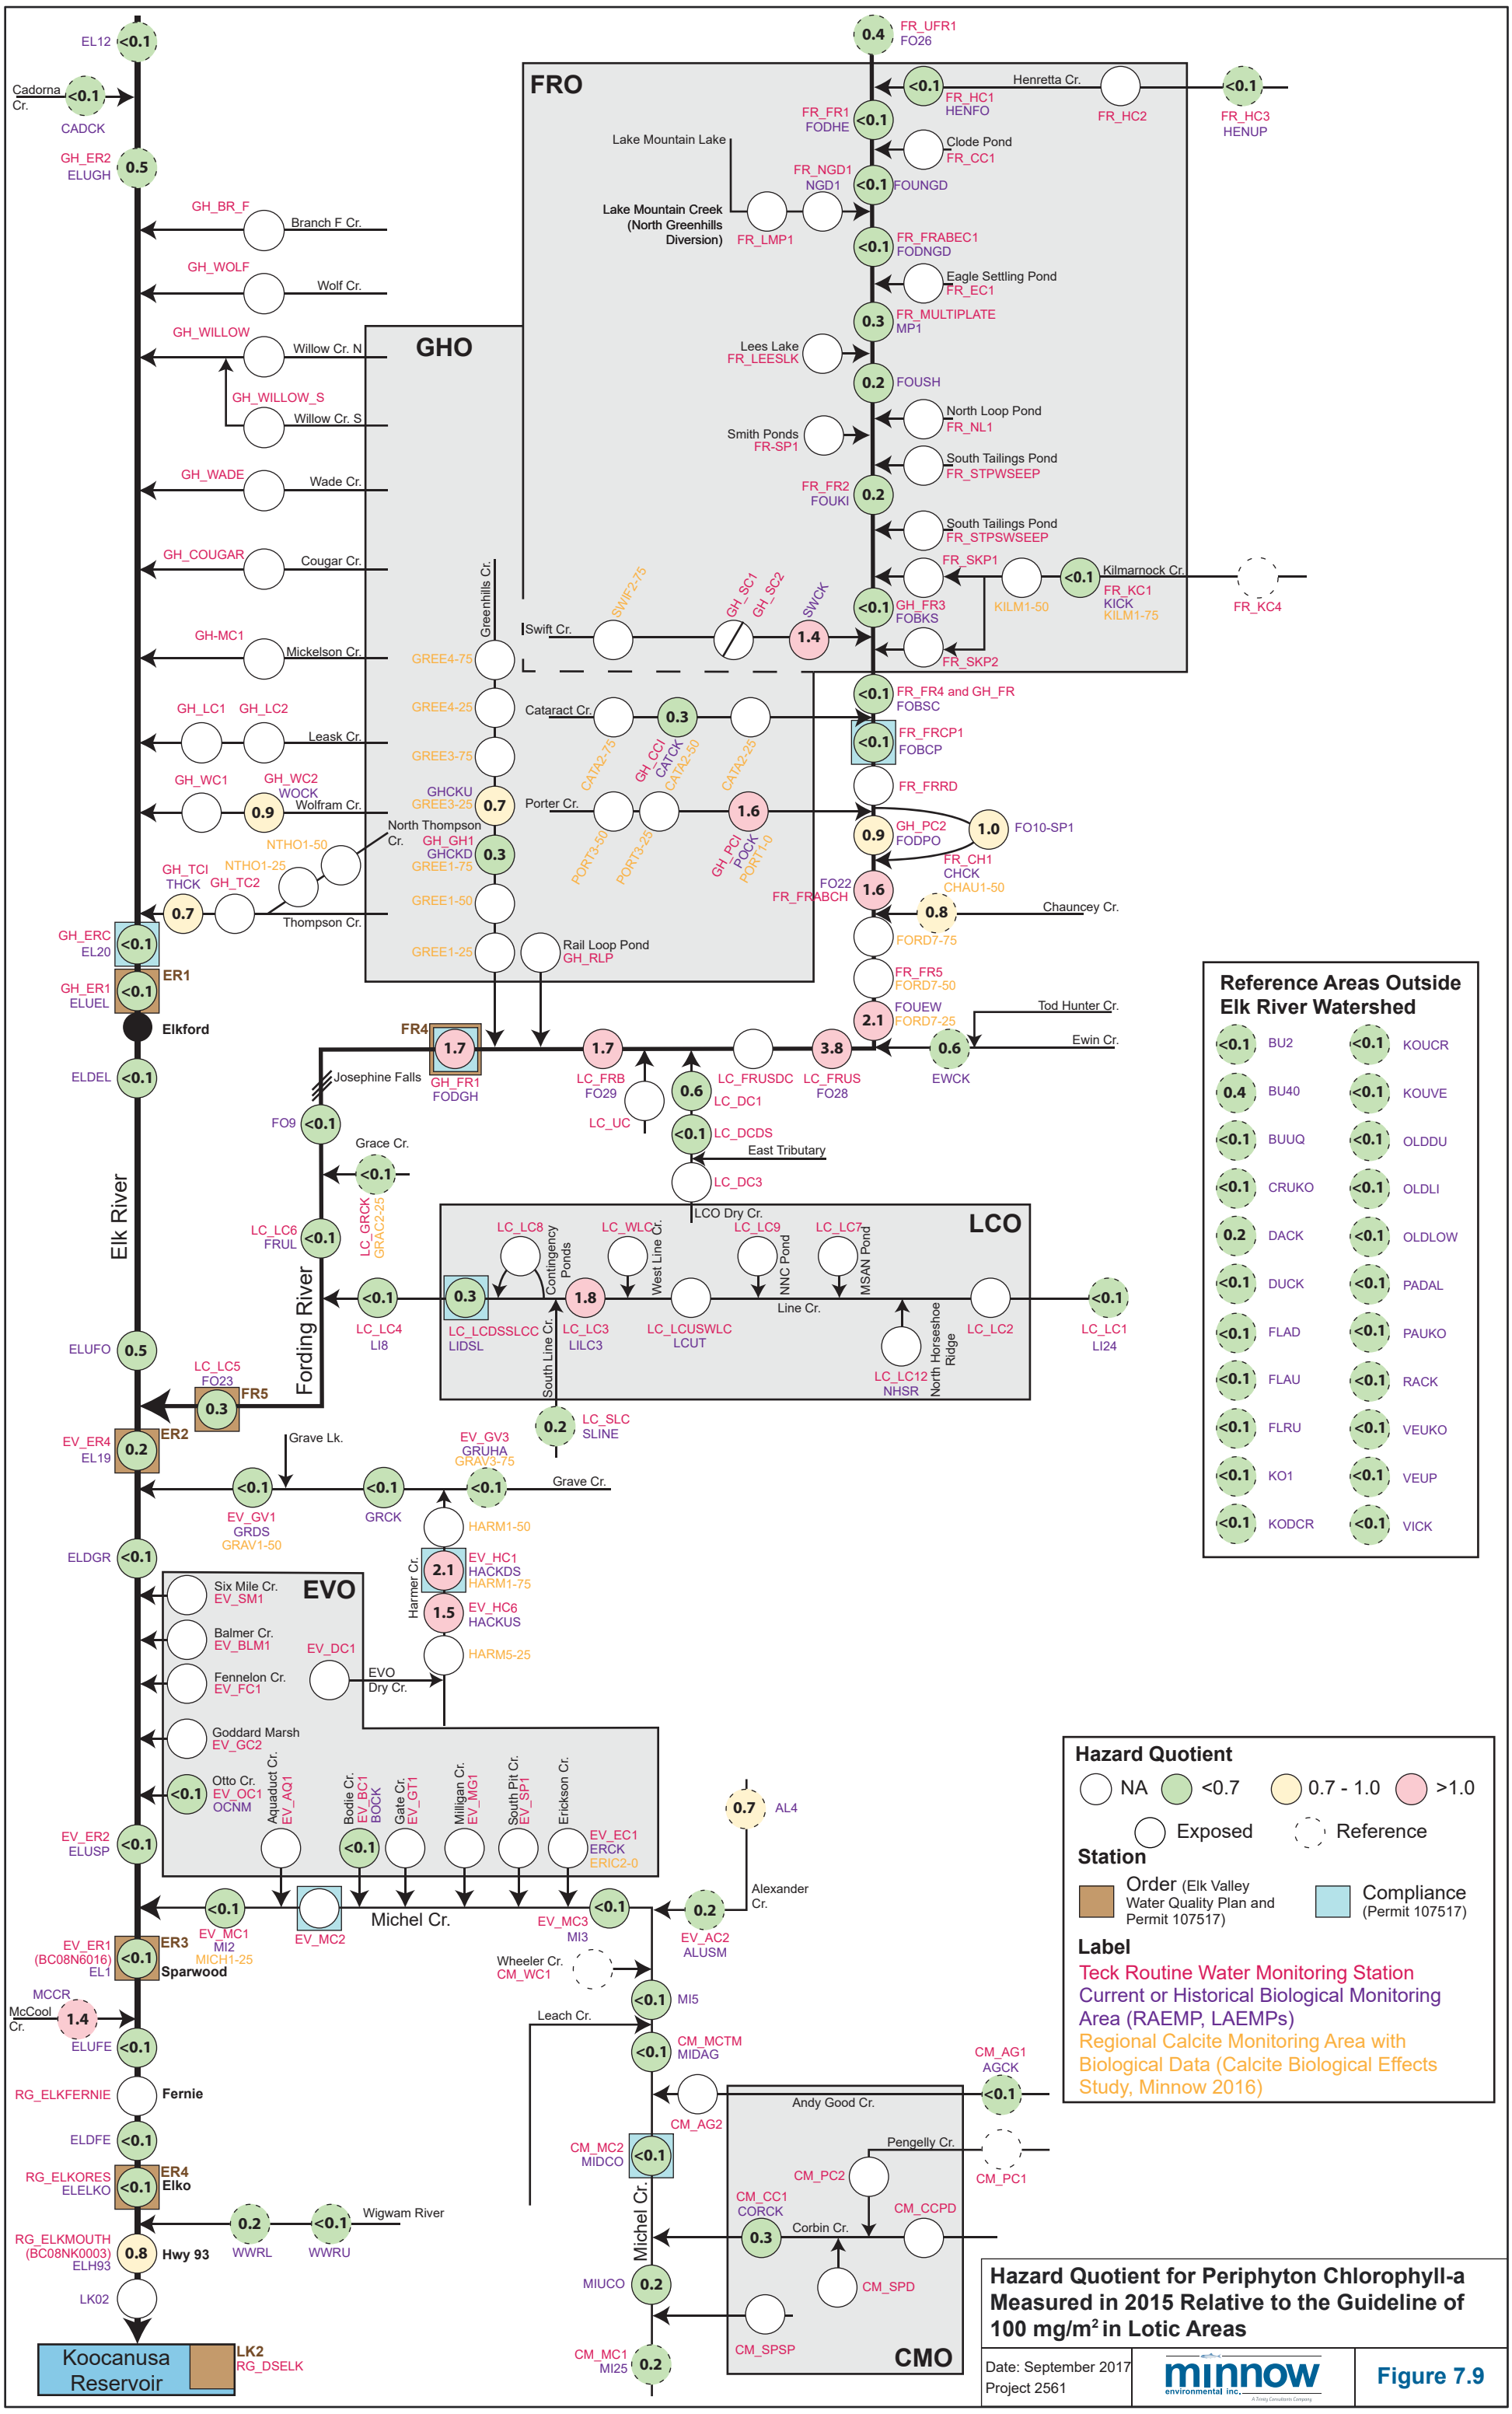
Note: Open circles indicate values less than laboratory reporting limit.

Of other habitat factors, Lewis and McCutchan (2010) identified water temperature and the length of growing season as primary factors contributing to periphyton biomass in streams of the Colorado Mountains and foothills. Periphyton productivity, as indicated by chlorophyll-a concentrations, may also be influenced by stream gradient and light intensity (Dudgeon and Chan 1992, Dodds et al. 2002, Death and Zimmerman 2005, Lewis and McCutchan 2010). In addition, substrate disturbance associated with variation in discharge regimes appears to positively correlate with producer richness and net production of biomass (Cardinale et al. 2005). The abundance of grazing benthic macroinvertebrates does not seem to consistently explain low periphyton biomass, as several studies have shown a strong positive correlation between primary productivity and invertebrate abundance and richness (Death and Zimmerman 2005, Dudgeon and Chan 1992, Kiffney and Richardson 2001, Lewis and McCutchan 2010, Quinn et al. 1997). Studies reporting a negative relationship between invertebrate grazers and periphyton biomass were typically laboratory experiments in which grazer abundance was controlled; such relationships were much less evident in short-term experiments conducted in the field (reviewed in Feminella and Hawkins 1995).

In the Elk Valley, the strongest relationship between periphyton productivity endpoints and habitat variables was with calcite index when considering reference areas alone or reference and mine-exposed areas together ($p<0.001$, $r=0.55$; Appendix Tables F.6 and F.7; Appendix Figure F.3). Periphyton potentially provides nucleation sites for calcite formation and/or calcite deposits serve as a suitable substrate for growth of some periphyton species (Section 5.4.1). Absolute correlation coefficients (r) for all other variables were less than 0.5, indicating they explained little of the variation in productivity endpoints among areas. Also, some significant relationships were in a direction opposite to those expected (e.g., chlorophyll-a concentrations were inversely related to variables related to stream size and agricultural activity; Appendix Tables F.6 and F.7).

7.2.3 Comparisons to Guidelines

Periphyton chlorophyll-a concentrations were greater than the BC guideline of 100 mg/m^2 at some reference and mine-exposed areas sampled since 2013 (Figures 7.7 and 7.9; Appendix Tables F.1 and F.2) Chlorophyll-a concentrations were less than the guideline at 48 of 58 (83%) mine-exposed areas sampled in September 2015 as indicated by HQs less than 1.0 (Figure 7.9; Appendix Table F.5). HQs greater than 1.0 were mainly associated with some tributary or main stem areas of the Fording River, but were also observed in Harmer Creek.



Hazard Quotient for Periphyton Chlorophyll-a Measured in 2015 Relative to the Guideline of 100 mg/m² in Lotic Areas

Date: September 2017
Project 2561

minnow environmental inc.

Figure 7.9

7.2.4 Temporal Changes

Temporal trends were not evaluated for periphyton productivity endpoints because a recent evaluation that used data from both the Line Creek LAEMP and the RAEMP, showed that benthic invertebrate abundance (kick samples), density, and biomass (Hess samples) correlated with periphyton productivity endpoints, and this finding was consistent with results from a variety of studies in the scientific literature (Minnow 2017d). Within-area variability was less for invertebrate than for periphyton productivity endpoints, indicating that changes in biological productivity over time are more likely to be statistically detected with invertebrate than periphyton endpoints for a given sample size, α and β (Minnow 2017d).

7.3 Community Characteristics

7.3.1 2013 Supporting Study

In 2013, Teck completed a study to investigate the utility and the relative sensitivity of periphyton community endpoints for evaluating mine-related effects compared to benthic invertebrate community monitoring (Minnow 2014c). Periphyton and benthic invertebrates were collected at 13 reference areas and 13 mine-exposed areas of the Elk Valley. The reference condition was defined as the range capturing 95% of reference area values for each endpoint (similar to the approach used in this report). Significant reductions in proportions of the invertebrate group EPT (Ephemeroptera, Plecoptera, Trichoptera) with concurrent increases in chironomid proportions at some mine-exposed areas (Line Creek-LILC3, Michel Creek-MI2, Fording River-MP1, Thompson Creek-THCK) suggested adverse effects that were not observed or only weakly evident in periphyton community analyses for the same areas. None of the mine-exposed areas were significantly different from the reference condition for the dominant periphyton taxa *Hydrurus* sp. or *Achnanthes* sp. (now identified as *Achnanthidium*), nor for NMDS axis scores of overall community composition, likely owing to the large variation among reference areas for these endpoints. For example, the coefficients of variation (CV, i.e., standard deviation/mean * 100) for proportions of the periphyton genera *Hydrurus* and *Achnanthes* among reference areas were 68% and 168%, whereas CVs for proportions of the benthic invertebrate groups EPT and Ephemeroptera were 12% and 36%, respectively. This suggested that only major shifts in periphyton community composition among mine-exposed areas were likely to be statistically detectable, compared to relatively smaller changes in benthic invertebrate community composition. It was concluded that periphyton community assessment is less sensitive for statistical detection of potential mine-related effects on aquatic ecosystems than benthic invertebrate community assessment, based on high natural variability of periphyton community composition among areas (Minnow 2014c).

7.3.2 2015 Supporting Study

7.3.2.1 Comparisons to Normal Ranges

As a condition of ENV's approval of the RAEMP study design, Teck was required to undertake an additional supporting study "to evaluate the effects of mine-related discharges on periphyton community structure" (BCMOE 2014). The study design was submitted on December 19, 2014, and sampling was undertaken in 2015. The detailed results were reported by Minnow and Larratt (2016) and are summarized below.

A total of 40 reference and 58 mine-exposed areas were sampled for analysis of periphyton community structure. The majority of periphyton communities in reference and mine-exposed areas were dominated by diatoms, however, both reference and mine-exposed areas showed large variation in community composition even at a major group level (Figures 7.10 and 7.11).

A total of 50 periphyton community endpoints were investigated as potential indicators of mine-related influence (Appendix Table F.8). Ten univariate endpoints identified the most areas outside of the reference normal range and significantly correlated with a mine-related gradient in

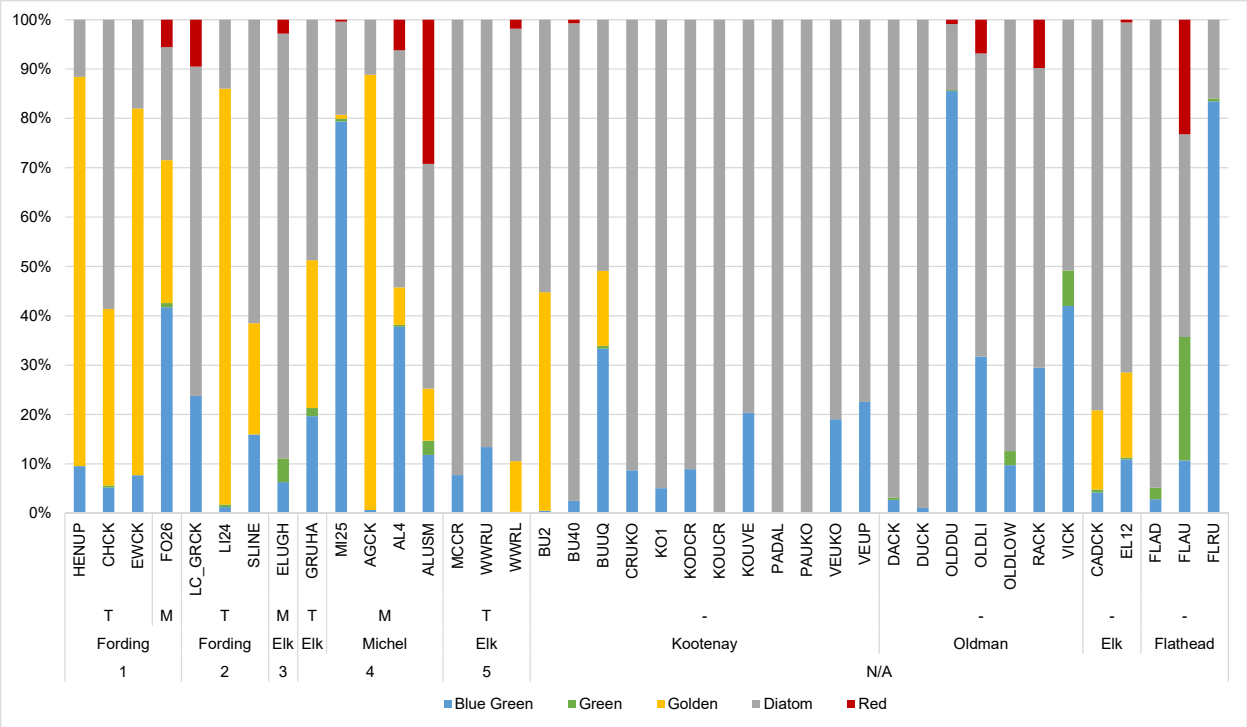


Figure 7.10: Proportions of Major Periphyton Groups among Reference Areas (n = 40), September 2015

Note: Stream Type: 'M' = Main Stem, 'T' = Tributary

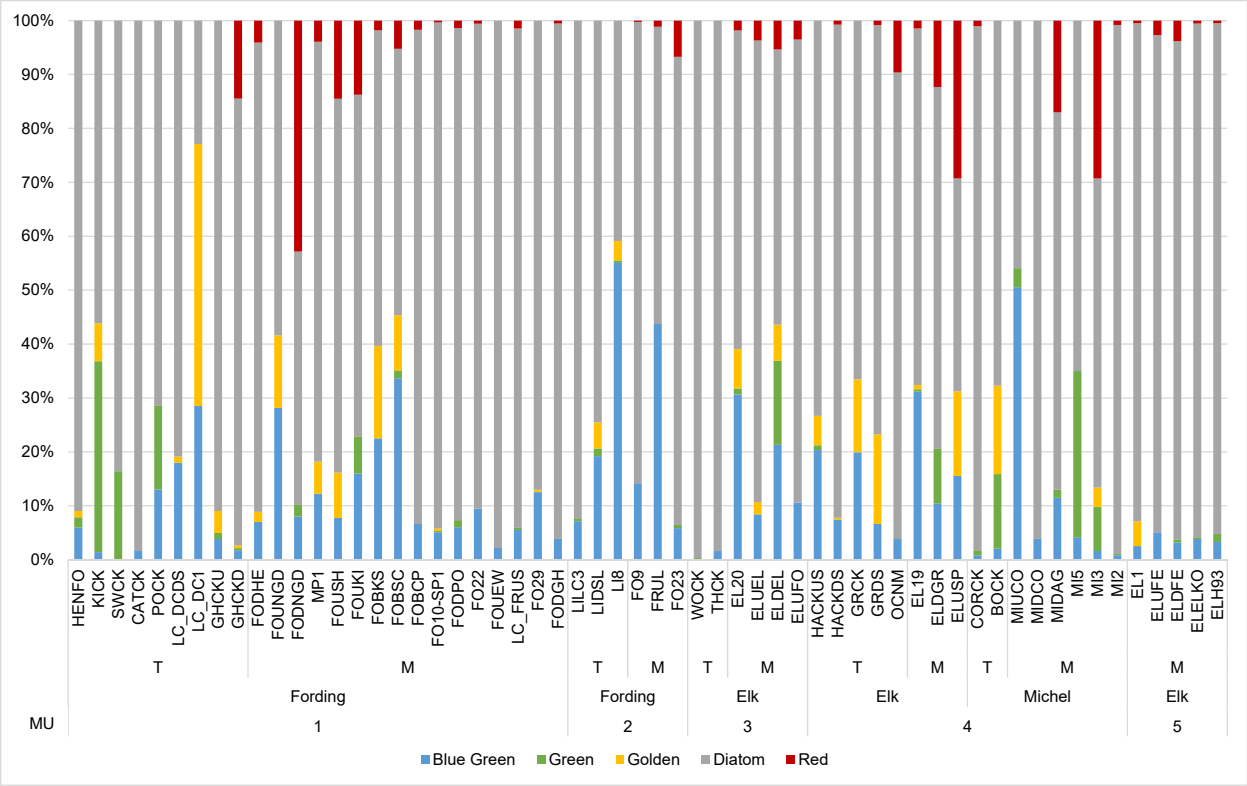

Figure 7.11: Proportions of Major Periphyton Groups among Mine-exposed Areas (n = 58), September 2015

Note: Stream Type: 'M' = Main Stem, 'T' = Tributary

water quality indicated by the first axis in a PCA of water quality data (Appendix Table F.9). There was strong correlation among the ten endpoints and three were selected (green algal density, *Achnanthidium* density, Fragilariaceae density) for evaluation of communities in mine-exposed areas to those in reference areas (see Minnow and Larratt 2016 for further details). For the purposes of this report, overall periphyton community structure, as summarized by NMDS Axes 1 and 3[26] has also been evaluated.

Normal ranges were derived for each of the five periphyton community endpoints (Appendix Table F.10). Of the 58 mine-exposed areas, 38 had at least one of the final five community endpoints outside of the reference area normal range (2.5th and 97.5th percentiles) (Table 7.1; Appendix Figures F.5 to F.7). Only four areas were identified as having overall community structure that was different from reference areas based on NMDS Axis 1 (which explained 35%

[26] Community structure summarized by NMDS Axes 1 and 3, but not Axis 2, correlated with variations of PC-1 for water quality (with and without calcite), and expressed as either concentrations or hazard quotients (Appendix Table F.9). These NMDS results were derived from the raw data presented by Minnow and Larratt (2016) but the results were not presented in that report.

value > upper limit ($P_{97.5}$) of the normal range

value < lower limit ($P_{2.5}$) of the normal range

of overall community variance). More differences in community structure between mine-exposed and reference areas were identified by NMDS Axis 3 (18% of overall community variance). There was no consistent pattern among endpoints with respect to identifying areas that had communities differing from reference areas.

Weak correlations ($r < |0.45|$) between periphyton community endpoints and PC-1 for water quality indicated that a gradient of mine-related influence on water quality and calcite explained little of the community variability among areas (Appendix Table F.9). There was also high natural variability in periphyton community composition even among reference areas (Appendix Table F.10). Also, for data sets of reference areas only, and reference plus mine-exposed areas, only a small amount of the variability in community composition among areas was explained by more than 50 GIS- and field-derived natural and anthropogenically-influenced habitat variables measured in the study (Appendix Table F.11). Potential detection of mine-related effects was not improved by further analyses completed for this report involving adjustment of normal ranges for periphyton community endpoints to account for habitat covariates (Appendix I). It is concluded that periphyton communities in the Elk Valley are sensitive to a variety of habitat factors that likely cannot be measured or effectively controlled in sampling designs or through data analysis, and confound detection of mine-related effects[27].

The periphyton community results are compared to the benthic invertebrate community results in Section 8.

7.3.2.2 Data Reliability and QA/QC

The study by Minnow and Larratt (2016) also reported the following conclusions:

- Only a small proportion of each periphyton sample (e.g., <0.01%) can be practicably sub-sampled in the laboratory for organism enumeration, which makes it difficult to accurately enumerate taxa, especially non-dominant ones.
- Counts for the most dominant taxon in within-laboratory sub-samples were within 20% of each other for all but one of 14 samples and no sub-samples differed by more than 50%, which is considered indicative of good sub-sampling precision.
- The proportion of all genera that were identified by two laboratories for a given (split) sample averaged 52% (ranging from 38 to 80% among 11 samples).

[27] The study also concluded that artificial substrate samplers may be useful in some applications, however, they may not be sufficiently reflective of natural conditions to be used to evaluate and manage mine-related effects on the aquatic environment within the Elk Valley.

- Counts for the three key community endpoints identified as strongest indicators of mine-related influence (green algae density, *Achnanthidium* density, and Fragilariaceae density) differed by more than 50% between laboratories for six, eight and nine samples, respectively, of the eleven split samples.
- Clumped distributions, if encountered during enumeration, confound density estimates, and may contribute to both within and between laboratory differences.

The above results reflect the inherent challenges associated with periphyton community analyses, rather than poor laboratory performance. Nevertheless, they affect the confidence with which periphyton community data can be used as a reliable indicator of mine-related aquatic effects.

7.3.2.3 Temporal Changes

Periphyton communities sampled in 2015 were compared to those sampled in 2013 (Minnow and Larratt 2016). The three endpoints used as indicators of mine-exposure on periphyton communities showed large variation between years, including at reference areas. Such shifts in community structure are commonly observed and are thought to reflect habitat factors, such weather and flow (Schleppe et al. 2013, Azim et al. 2005). These results corroborate conclusions from the evaluation of periphyton productivity, that periphyton communities are naturally sensitive to changes in a variety of environmental factors that confound detection of mine-related effects.

7.4 Tissue Selenium

7.4.1 Comparisons to Concentrations in Water

Selenium accumulation in aquatic biota begins with uptake from water at the base of the food web where algae, bacteria and other microorganisms typically concentrate selenium in tissues by at least two orders of magnitude relative to concentrations in water (Stewart et al. 2010). The ratio of the selenium concentration in tissues of algae and microorganisms to the concentration in water is described as an enrichment factor or enrichment function (EF) or as a distribution coefficient (K_d) (Young et al. 2010). Almost all of the selenium accumulated by organisms at higher levels of the food web is acquired through dietary exposure rather than direct uptake from water (Stewart et al. 2010). Selenate is the oxidized form of selenium that makes up most (~98%) of the total aqueous selenium in the Elk River watershed. Accumulation and toxicity of selenate are reduced by sulphate (Williams et al. 1994, Ogle and Knight 1996, Brix et al. 2001, Fournier et al. 2010, Eastham 2015), which is also elevated in streams downstream from coal mining in the watershed. Studies have also shown that accumulation in the food web tends to be greater in lentic than lotic systems with similar concentrations of

selenium in water (Hillwalker et al. 2006, Orr et al. 2012, USEPA 2016, Deforest et al. 2017). Such pattern was not obvious for periphyton samples collected in the Elk Valley in 2012 and 2015, with overlap in periphyton tissue selenium concentrations in lotic and lentic areas over a wide range of aqueous selenium concentrations (Figure 7.12). The tissue data collected since 2013 are being incorporated into an update of the Elk Valley selenium bioaccumulation model.

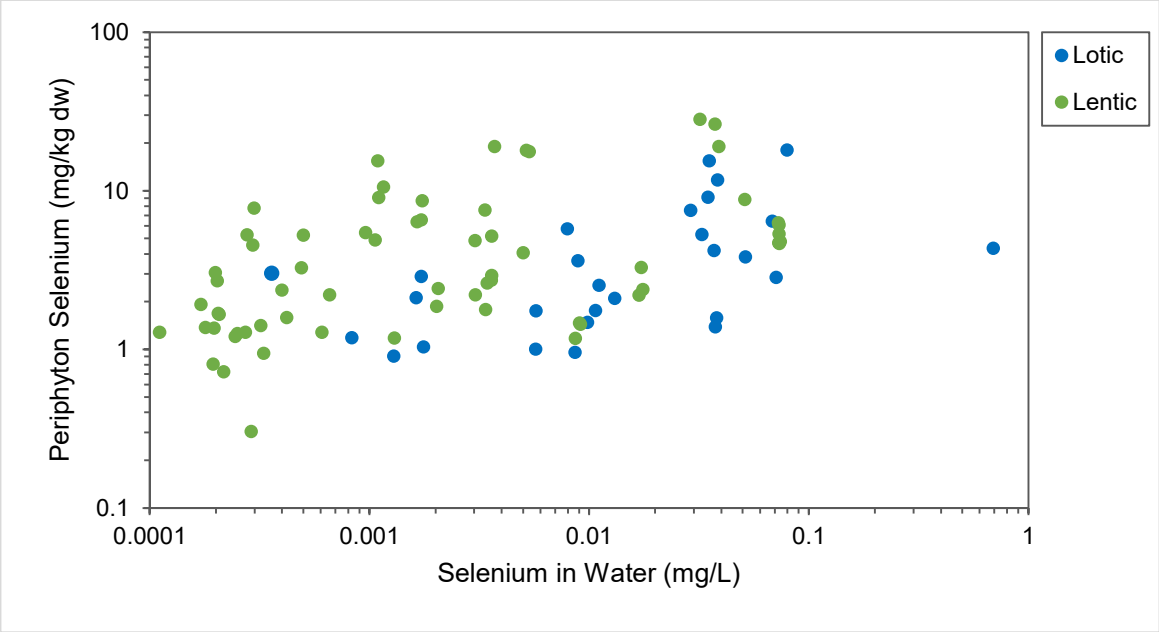

Figure 7.12: Scatterplot of Selenium Concentrations in Periphyton versus Selenium Concentrations in Water in the Elk Valley for Lotic and Lentic Habitats, 2012 and 2015

7.4.2 Comparisons to Normal Reference Range

The distributions of reference area periphyton selenium concentrations were similar between lotic and lentic areas and resulted in 97.5th percentiles that were not significantly different (Appendix Table F.12). Therefore periphyton tissue selenium concentrations measured at both lotic and lentic reference areas sampled since 1996 were combined (n=102 samples) to characterize the reference normal range (Appendix Table F.13; Appendix Figure F.8). The upper limit of the normal range was defined as 5.35 mg/kg dw of selenium in tissue.

Of samples collected among 15 mine-exposed lotic areas in 2015 and 2016[28], three and five, respectively, had concentrations greater than the upper limit of the normal range, resulting in

[28] Periphyton tissue samples were collected at only a sub-set of RAEMP monitoring areas, consistent with the RAEMP study design (Minnow 2015a). This was because food web accumulation is considered better reflected by benthic invertebrate tissue selenium concentrations (e.g., periphyton samples can be confounded by selenium

NRQs >1.0 (Figures 7.13 and 7.14; Appendix Tables F.14 and F.16; Appendix Figure F.9). Among lentic areas (sampled in 2015 only), mean periphyton selenium concentrations were greater than the upper normal range limit at one (of five) reference area(s) and at six (of 16) mine-exposed areas (Appendix Tables F.15 and F.17).

7.4.3 Temporal Changes

Temporal changes in tissue selenium concentrations were not completed for periphyton because there is a larger data set (more areas and more years of data) for benthic invertebrate tissue selenium concentrations, which will better identify trends in food web selenium concentrations among areas.

7.5 Summary

Periphyton AFDM and chlorophyll-a concentrations were within the reference area normal range at ≥ 75% of 58 mine-exposed areas sampled in 2015. Chlorophyll-a concentrations were less than the guideline at 48 of 58 (83%) mine-exposed areas. There was no direct relationship between periphyton chlorophyll-a concentrations and aqueous total phosphorus or orthophosphate concentrations, even though phosphorus is the limiting nutrient within the watershed. Data from the literature suggest there is a threshold ($p > 0.030$ mg/L) above which periphyton growth may be related to nutrient concentrations, but concentrations in the Elk River watershed are typically less than this value. Instead, primary productivity in the Elk River watershed appears to be mostly related to other habitat factors. The strongest relationship between periphyton productivity endpoints and more than 50 habitat variables evaluated in this study was with calcite index ($p<0.001$, $r=0.55$). Periphyton potentially provides nucleation sites for calcite formation and/or calcite deposits serve as a suitable substrate for growth of some periphyton species.

Two supporting studies that evaluated periphyton communities in mine-exposed areas compared to reference areas concluded that periphyton communities in the Elk Valley are sensitive to a variety of habitat factors that likely cannot be measured or effectively controlled in sampling designs or data analysis, and confound detection of mine-related effects.

Of periphyton tissue selenium samples collected among 15 mine-exposed lotic areas in 2015 and 2016, three and five, respectively, had concentrations greater than the upper limit of the normal range, resulting in NRQs >1.0. Among lentic areas (sampled in 2015 only), mean periphyton selenium concentrations were greater than the upper normal range limit at one (of

contributions from abiotic particles – see Minnow 2017b). Samples were collected at a sub-set of areas to potentially support the re-evaluation of site-specific bioaccumulation models.

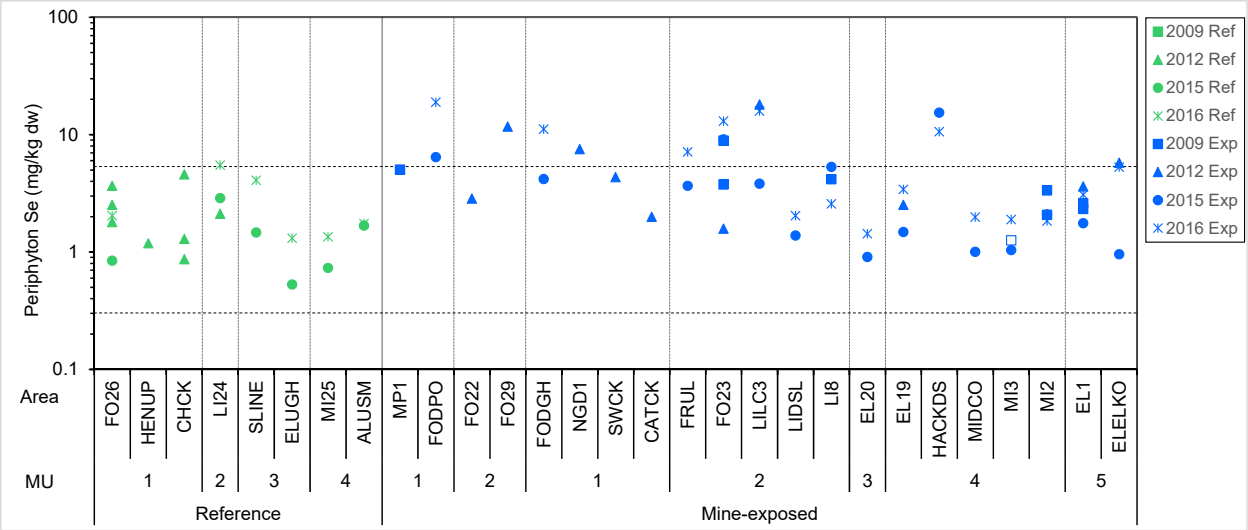

Figure 7.13: Periphyton Selenium Concentrations Measured in Lotic Areas Relative to the Normal Range

Note: Concentrations less than the LRL are plotted as open symbols at the LRL. Dashed horizontal lines represent the limits of the reference area normal range.

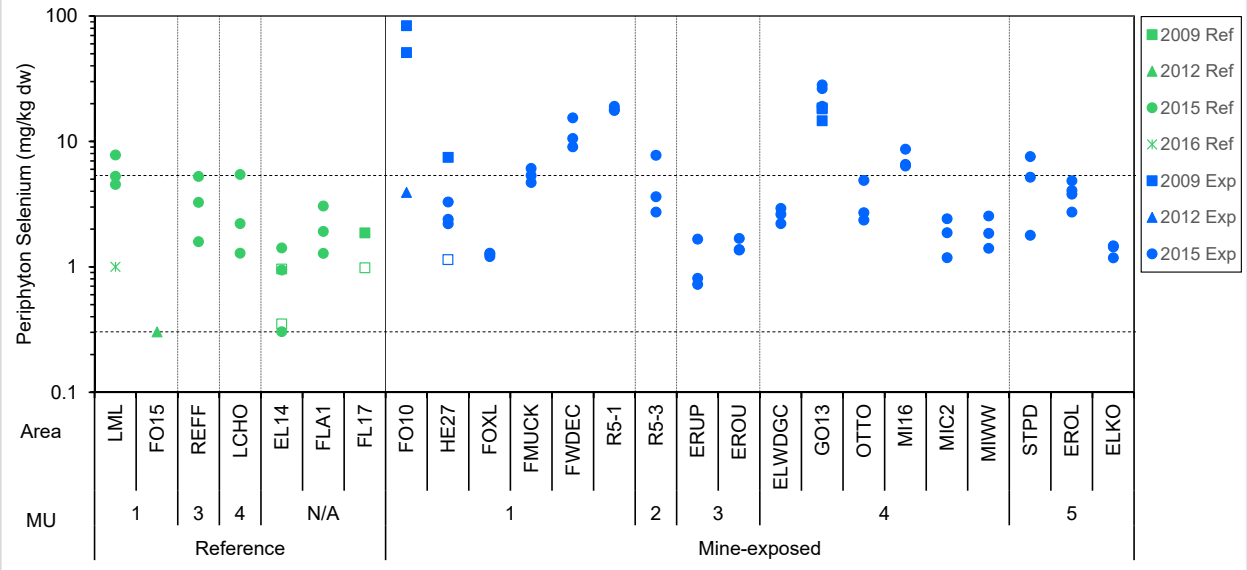

Figure 7.14: Periphyton Selenium Concentrations Measured in Lentic Areas Relative to the Normal Reference Area Range

Note: Concentrations less than the LRL are plotted as open symbols at the LRL. Dashed horizontal lines represent the limits of the reference area normal range. FO10 was lentic only for 2009 and 2012

five) reference area(s) and at six (of 16) mine-exposed areas. Temporal analyses were not completed for periphyton tissue selenium concentrations because there is a larger data set (more areas and more years of data) for benthic invertebrate tissue selenium concentrations, for evaluating spatial patterns and temporal trends in food web selenium concentrations.

8 BENTHIC INVERTEBRATES

8.1 Overview

Benthic invertebrates are excellent biomonitors for assessing potential effects of physical and chemical habitat changes in aquatic systems (Barbour et al. 1999, Feltmate and Fraser 1999, Beatty et al. 2006). This is because

- they are relatively sessile and are therefore good indicators of localized conditions;
- they reflect the community level of organization, including a range of trophic levels and chemical tolerances, providing numerous useful assessment endpoints;
- they are relatively easy to sample, identify and quantify; with minimal detrimental effect on the resident community;
- there is technical guidance for standardization of sample collection, laboratory sample processing, and laboratory QA/QC (Environment Canada 2012a,b, 2014) and
- they serve as an important direct or indirect food source for fish and aquatic dependent wildlife (e.g., amphibians, birds).

Potential mine-related effects on benthic invertebrate communities were identified by comparing community characteristics in mine-exposed areas to normal ranges defined based on data collected at 40 reference areas in 2012 and 2015. Reference areas were selected to match the range of habitat characteristics observed among mine-exposed areas (see Minnow 2015a and Appendix A). Water samples collected at the same time as benthic invertebrate samples during the 2015 RAEMP cycle, as well as calcite measurements made in the vicinity of invertebrate samples, were used in the evaluation of mine-related effects on benthic invertebrate communities.

Benthic invertebrate tissue selenium concentrations measured in 2015 and 2016 as part of the RAEMP and LAEMPs were compared to the upper limit of the reference normal range, and to predictions and site-specific tissue selenium benchmarks in the EVWQP (Teck 2014). Benthic invertebrate tissue selenium and community characteristics observed in 2015 and 2016 were compared to historical data to evaluate changes over time.

Figures 8.1 to 8.3 show the sampling locations discussed in this section (Appendix Tables G.1 and G.2). Photo 8.1 presents representative photographs of benthic invertebrate sampling.

Photo 8.1: Benthic Invertebrate Sampling (field crew, Hess sampler, representative organisms)

8.2 Community Characteristics (Kick Samples)

8.2.1 Dominant Taxa

A total of 40 reference and 59 mine-exposed areas were sampled for analysis of benthic invertebrate community composition in 2015, and a sub-set of 7 reference and 32 mine-exposed areas were sampled in 2016. Benthic invertebrate communities sampled in reference areas were composed mainly of Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies), collectively referred to as EPT (Figure 8.4). Many mine-exposed areas also had communities dominated by EPT (Figure 8.5), but others reflected a shift in community structure to organisms such as chironomids (part of the Diptera Order) that are more tolerant of degraded conditions (Barbour et al. 1999, Taylor and Bailey 1997), and this was evaluated as potential indication of a mine-related effect (Section 8.2.3).

8.2.2 Evaluation of Kick Sampling Method

The CABIN kick sampling method (Environment Canada 2012a) is standardized based on the length of time sampled (3 minutes) instead of the area sampled. At a subset of 15 areas sampled in 2015, benthic invertebrates were collected using the standard 3-minute approach and by kick-sampling three separate 1 m^2 areas[29] (Minnow 2016b). The total abundance of benthic invertebrates present in 3-minute kick samples was a strong predictor ($p < 0.001$; $r^2 = 0.867$) of the number of invertebrates measured in the density-based kick samples (Figure 8.6). The total abundances for dominant taxa based on 3-minute kick samples were also strong

[29] The three samples from the 1 m^2 areas were pooled into a single composite sample for taxonomic identification and enumeration.

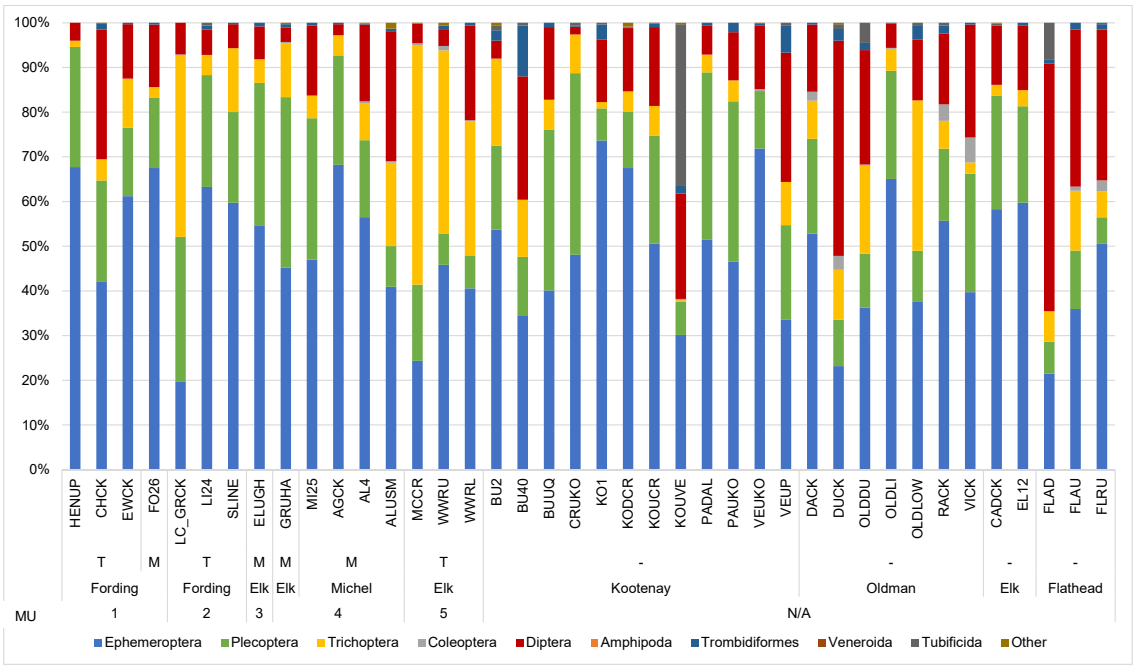

Figure 8.4: Proportions of Major Benthic Invertebrate Groups among Reference Areas (n = 40), September 2015

Notes: Other includes Orders Hemiptera, Lepidoptera, Megaloptera, Odonata, Basommatophora, Oribatei, Lumbriculida and an unknown Order in Class Gastropoda. Stream Type: 'M' = Main Stem, 'T' = Tributary.

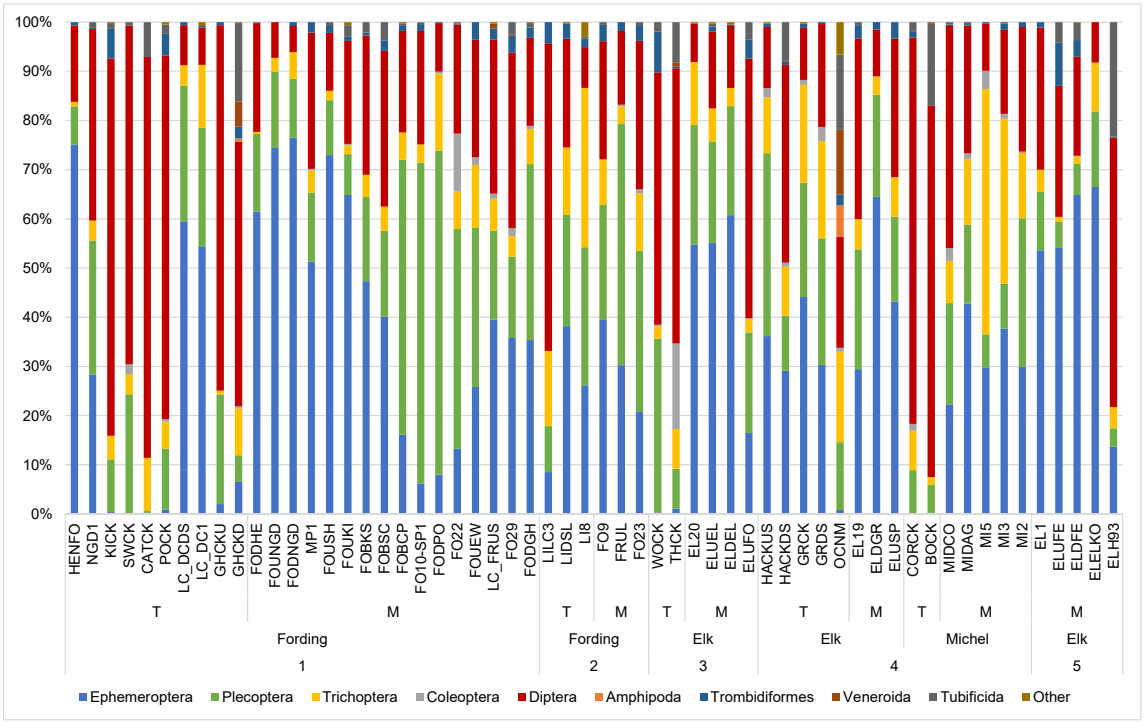

Figure 8.5: Proportions of Major Benthic Invertebrate Groups among Mine-exposed Areas (n = 59), September 2015

Notes: Other includes Orders Hemiptera, Lepidoptera, Megaloptera, Odonata, Basommatophora, Oribatei, Lumbriculida and an unknown Order in Class Gastropoda. Stream Type: 'M' = Main Stem, 'T' = Tributary.

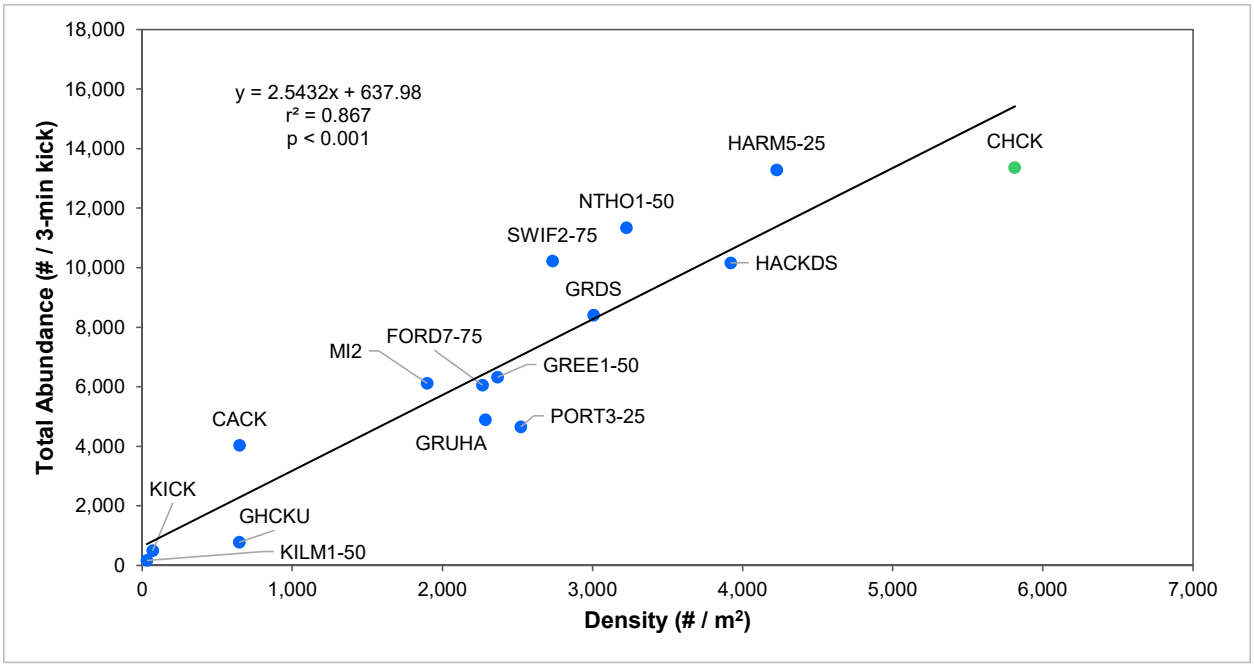

Figure 8.6: Benthic Invertebrate Density (# / m^2) Based on Kick Sampling Over Three 1 m^2 Areas Versus Total Sample Abundance for 3-minute Travelling Kick Samples

predictors of densities of those taxa (Minnow 2016b). These results indicate that the abundance of organisms in 3-minute travelling kick samples can be interpreted as reasonable approximations of benthic invertebrate density.

Replicate 3-minute kick samples were used to evaluate within-area variability of the CABIN method for characterizing benthic invertebrate communities. Coefficients of variation (CV) for abundance ranged up to 53%, but were 21% on average (Table 8.1). CVs for the other key community characteristics were low (consistently ≤25% and averaging ≤12%). These results indicate that individual kick samples reasonably approximate community characteristics in a given area. Further analysis comparing community results for kick versus Hess sampling methods is presented in Minnow (2017f).

8.2.3 Comparisons to Normal Reference Ranges

Of the 59 mine-exposed areas sampled in 2015, almost half (27 of 59=46%) had % EPT and/or % Ephemeroptera less than the reference area normal range (Table 8.2). Most of the areas with reduced % EPT and/or % Ephemeroptera were associated with NMDS scores above the normal range for reference areas, indicating differences in community structure were mainly

[a] Normal range estimates are the 2.5th and 97.5th percentiles of the 2012 and 2015 reference area data (from an ordination of 2012 and 2015 reference area data and all areas in 2016)

value > upper limit ($P_{97.5}$) of the normal range

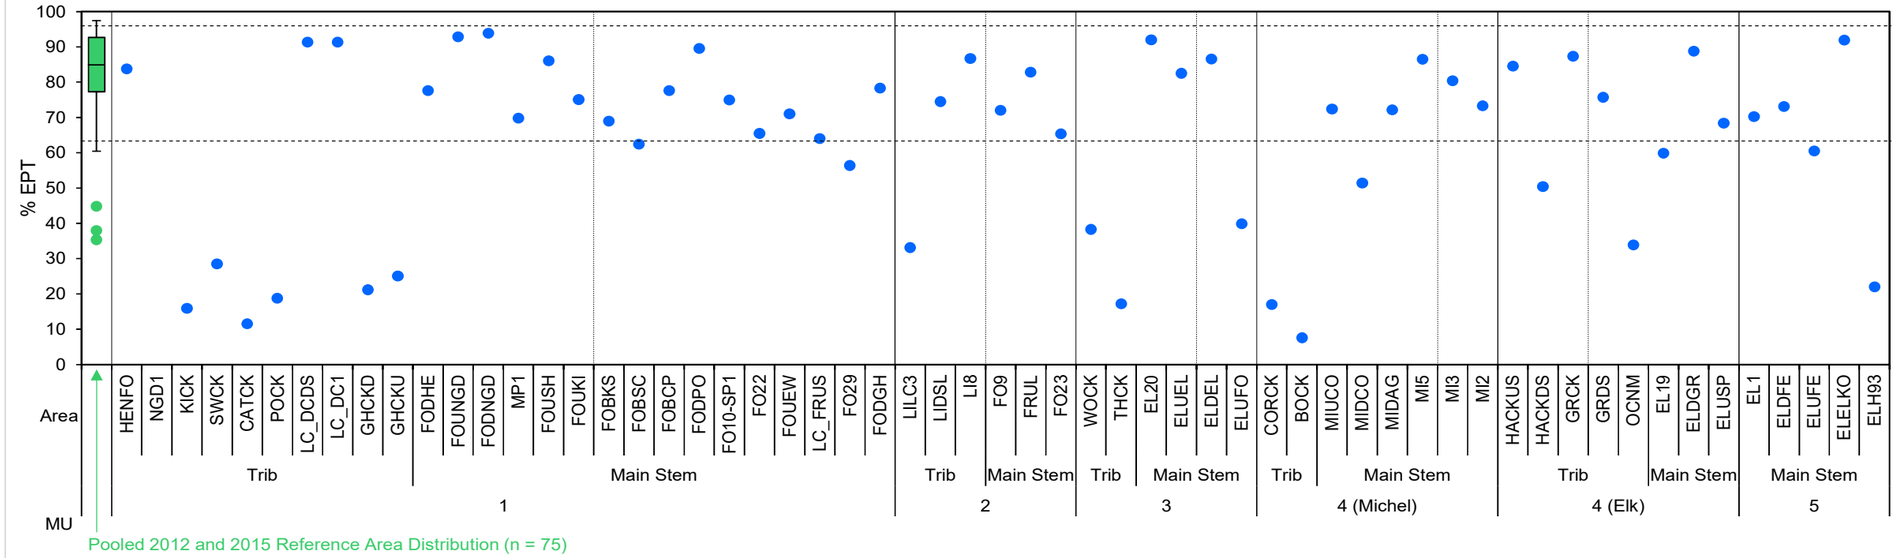
value < lower limit ($P_{2.5}$) of the normal range

associated with proportional reductions in these taxa[30]. All three endpoints correlated significantly ($p<0.001$) with PC-1 for water quality, yielding r-values > 0.6 (Appendix Table G.6). This is evidence that community changes associated with mining are related to decreases in % EPT and % Ephemeroptera. Where they occurred, reductions in relative abundance of EPT and Ephemeroptera were due to decreases in absolute abundance of these taxa (particularly Ephemeroptera), rather than increases in abundance of other taxa (e.g., Diptera).

Benthic invertebrate community abundance was greater than the normal range at 10 mine-exposed areas throughout the watershed. Higher abundances suggests potentially increased productivity in those areas, although the evaluation in Section 7.2 indicated that differences in productivity among areas was not associated with mine-related effects on aqueous nitrogen or phosphorus concentrations. Although productivity evaluations in aquatic ecology tend to focus on major nutrients in water like nitrogen and phosphorus, aquatic biota also require other elements for normal physiological function (e.g., selenium). Greater invertebrate abundance among reference areas in the Elk River watershed than among reference areas in the upper Kootenay River watershed and some of the areas in the Oldman River watershed (Appendix Table G.10) suggests that that the Elk River watershed may be naturally more productive than some other watersheds in the region.

Reductions in % EPT were mainly associated with tributaries (Figure 8.7). However, data from 2015 identified a pattern of lower % Ephemeroptera in the Fording River, particular downstream from Cataract Creek (FOBCP) to upstream from Ewin Creek (FOUEW) (Figure 8.7). This pattern was also evident in data collected in 2016 for the FRO LAEMP (Minnow 2017a). Temporal evaluation of the data in the FRO LAEMP report also suggested a potential pattern of decreasing total organism abundance, % EPT, and % Ephemeroptera among the same areas of the Fording River over time (also see Section 8.2.5 below). Minnow (2017a) concluded that elevated nitrate concentrations (but not likely selenium or sulphate concentrations) may have contributed to the spatial pattern of decreasing % Ephemeroptera with distance downstream, but did not explain the apparent change in benthic invertebrate community structure over time. Conversely, increased temperature trends (and/or associated variation in annual flow regimes) may partially explain the temporal changes in community structure, but did not fully explain the spatial pattern of benthic invertebrate community change observed in the Fording River in 2016. As well, temperature variations in the Elk River are based on 'spot' measures, which vary diurnally, and may reflect only the time of day the temperature was recorded). Seasonal

[30] Detailed NMDS results are presented in Appendix G based on LPL abundance (Appendix Tables G.20 to G.22), LPL proportional abundance (Appendix Tables G.23 to G.25), family-level abundance (Appendix Tables G.26 to G.28) and family-level proportional abundance (Appendix Tables G.29 to G.31) data matrices.



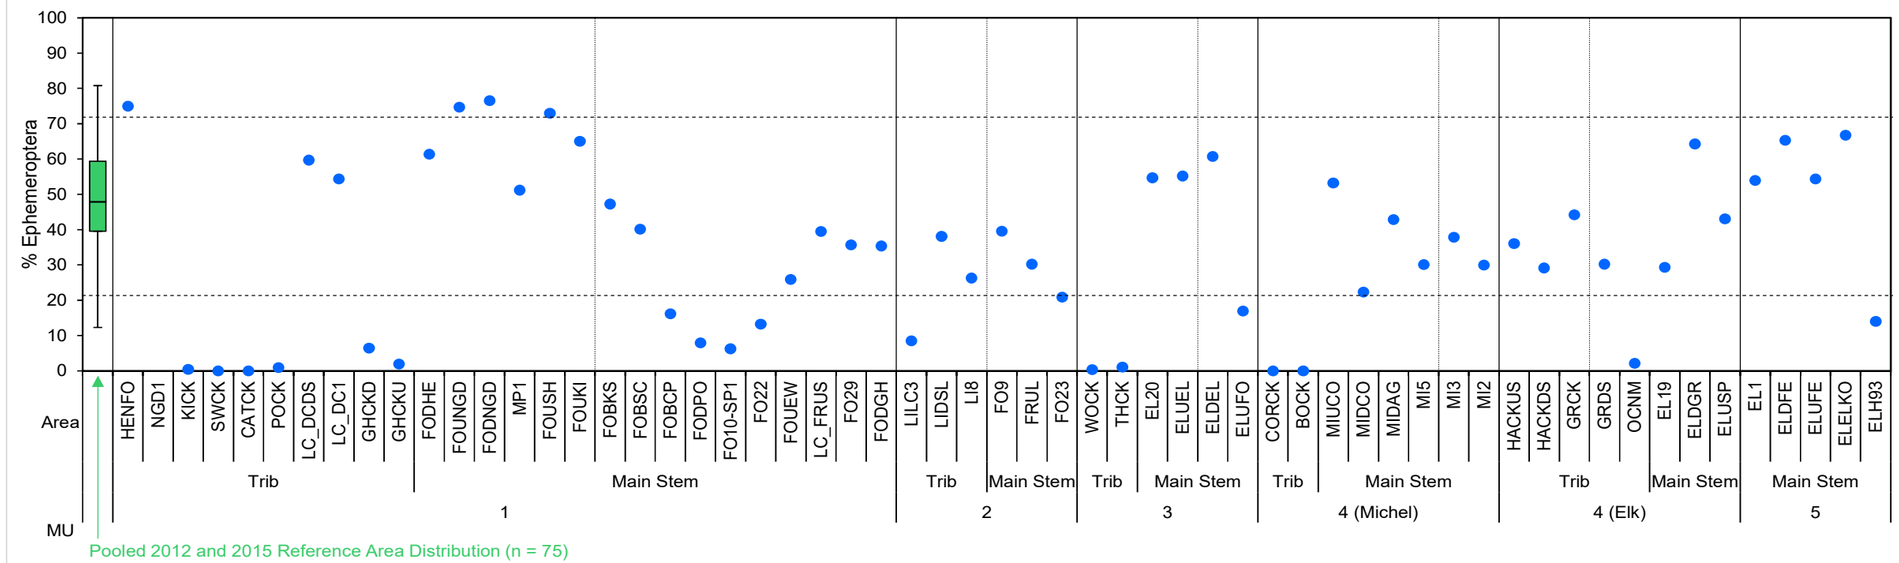


Figure 8.7: % EPT and % Ephemeroptera from 3-minute Kick Samples Collected in Lotic Habitats, 2015

Note: Dashed horizontal lines represent the limits of the reference area normal range. The reference area distribution that is plotted in the boxplot includes all reference areas prior to the removal of outliers.

dewatering and/or calcite deposition in portions of the Fording River are additional factors potentially influencing benthic invertebrate communities.

Further examination of the temporal data for Ephemeroptera (Appendix Figure G.7) showed that the major changes from 2012 to 2016 in the upper Fording were due to decreases in total abundance of Ephemerellidae and Heptageniidae, but not Baetidae (Table 8.3; Ameletidae was the only other Ephemeroptera family found in the upper Fording, which typically represented between 0 and 2% of organisms in this taxonomic Order). Over the same time period, total abundance of the same families appeared to increase in reference areas (particularly at FO26; Table 8.3).

Baetis are found in erosional and depositional areas of streams where they cling to stones, aquatic vegetation, and detritus, and where they function trophically as collector-gatherers of organic matter and scrapers of the periphyton community (Merritt et al. 2008). *Drunella* mayflies, which were the most common genus in the family Ephemerellidae, have similar habitat requirements to that of *Baetis*, but function both as scrapers and as facultative engulfing predators, as well as collector-gatherers. *Epeorus* and *Rhithrogena*, the most commonly identified genera in the family Heptageniidae, are restricted to cold, swift-moving waters in erosional areas of streams, where they cling onto rocks and function as scrapers of periphyton and collector-gatherers of organic materials (Merritt et al. 2008). These two genera have requirements of meso-to-stenothermal cold waters of neutral to alkaline pH, and are considered intolerant of organic enrichment (Hubbard and Peters 1978).

It is possible that factors such as competition among taxa could impact densities of certain organisms. For example, the grazing *Glossosoma* caddisflies could impact densities of

scraping-grazer mayflies such as *Baetis* (e.g., Baetidae abundance dropped from 1,060 to 0 at FODPO from 2012 to 2015, when *Glossosoma* increased from 0 to 1,200; Appendix Tables G.40 and G.41; Minnow 2014a). Habitat-related factors may also contribute to differences over time. For instance, accumulation of loose calcite may provide additional habitat for species that can burrow in this type of matrix, such as *Rhyacophila* and elmid beetles, whereas concretion of calcite over time may lead to reduced habitat availability. There is insufficient information in the literature to determine if the mayfly families that appear to be most affected (Ephemerellidae, Heptageniidae) are relatively more sensitive to mine-related consitutents in water such as nitrate, selenium, or sulphate, or to calcite formation.

Consistent with adaptive management, the FRO LAEMP design was adjusted to support further investigation of the cause(s) of benthic invertebrate community changes in September 2017 (Minnow 2017e).

Some tributaries also had communities that differed from reference area communities (i.e., endpoints outside of normal ranges), but those observations were expected based on the legacy of upstream mining activities and observed concentrations of mine-related substances. Community effects that were unexpected are being investigated further to determine the cause, as discussed in Section 12.

8.2.4 Comparison to Periphyton Community Results

Benthic invertebrate community results for 2015 were compared to periphyton community results from the same year (Section 7.3.2). There was high natural variability in periphyton community composition even among reference areas, resulting in large reference area normal ranges (Appendix Table G.13), even after adjustment to account for habitat covariates (Appendix I). Consequently, fewer community differences were detected between mine-exposed and reference areas based on periphyton endpoints (54 of 295 endpoints among areas = 18%) than benthic invertebrate endpoints (78 of 295 endpoints = 26%). More importantly, there was less consistency among periphyton endpoints in terms of identifying areas outside of reference area normal ranges than among benthic invertebrate endpoints. For example, overall benthic invertebrate community structure, as summarized by NMDS Axis 1 scores, was frequently outside of the normal range at the same areas where % EPT and/or % Ephemeroptera values were outside of normal ranges. These three benthic community endpoints correlated more strongly ($r>|0.6|$) with a mine-related gradient of water quality (as summarized by PC-1, Appendix Table G.6), than did any of the periphyton community endpoints ($(r < |0.45|$; Appendix Table F.9). These results indicate that periphyton communities in the Elk Valley are sensitive to a variety of habitat factors that confound detection of mine-related

effects, whereas mine-related effects to the aquatic ecosystem can be detected using benthic invertebrate community endpoints, particularly % EPT and % Ephemeroptera.

8.2.5 Temporal Changes

Temporal trends in benthic invertebrate community characteristics were evaluated using RM ANOVA, followed by *post hoc* contrasts to test for linear and step changes relative to reference areas. Linear trends were evaluated for all areas having data in at least 2012 and 2015, and potential step changes were evaluated for areas with data in one or more additional years. Areas where a significant change was detected are summarized in Figure 8.8.

Changes in invertebrate abundance were detected for four areas, but only two years of data were available for two of the areas (CATCK, GHCKU), so results for those areas should be interpreted with caution. Both areas had lower abundance in 2015, but abundance at CATCK was near the reference mean in 2015, whereas GHCKU had abundance less than the normal range in 2015 (Figure 8.8; Appendix Table G.18). Invertebrate abundance in lower Corbin Creek (CORCK) increased from a value near the lower limit of the normal range in 2012 to greater than the normal range in 2015 and 2016. Abundance at Harmer Creek upstream from the settling pond (HACKUS) decreased in 2015-2016 compared to 2012, but was greater than the normal range in all three years of sampling. Values less than, rather than above, the normal range (e.g., GHCKU) are of greatest concern with respect to mine-related effects (see Section 8.2.3 regarding productivity in the Elk Valley).

Similarly, of four areas showing significant change in LPL richness, two had data for only 2012 and 2015 (Porter Creek [POCK] and lower Greenhills Creek [GHCKD]). Both areas had greater LPL richness in 2015 than 2012 (Figure 8.8). Richness at EL1 (Elk River downstream from Michel Creek) was lower in 2016 compared to previous years and the reference mean, but still within the normal range, whereas richness increased farther downstream at ELUFE (Elk River upstream from Fernie) in 2016 compared to reference areas and previous years.

Changes in % EPT were observed at five areas, of which four had at least three years of data (Figure 8.8). Values of % EPT less than the reference area normal range were evident in 2015 (and 2016, if sampled) at four of the areas (Swift Creek [SWCK], Elk River upstream of Fording River [ELUFO], Thompson Creek [THCK], and Elk River near the mouth [ELH93]), whereas all four areas had values within the normal range in 2012. At lower Michel Creek (MI2), % EPT values were in the normal range in 2015 and 2016, representing an increase over values below the normal range in 2012 and 2013.

More significant temporal changes were observed for % Ephemeroptera than the other benthic invertebrate community endpoints. Lower values were observed in 2015 and 2016 relative to

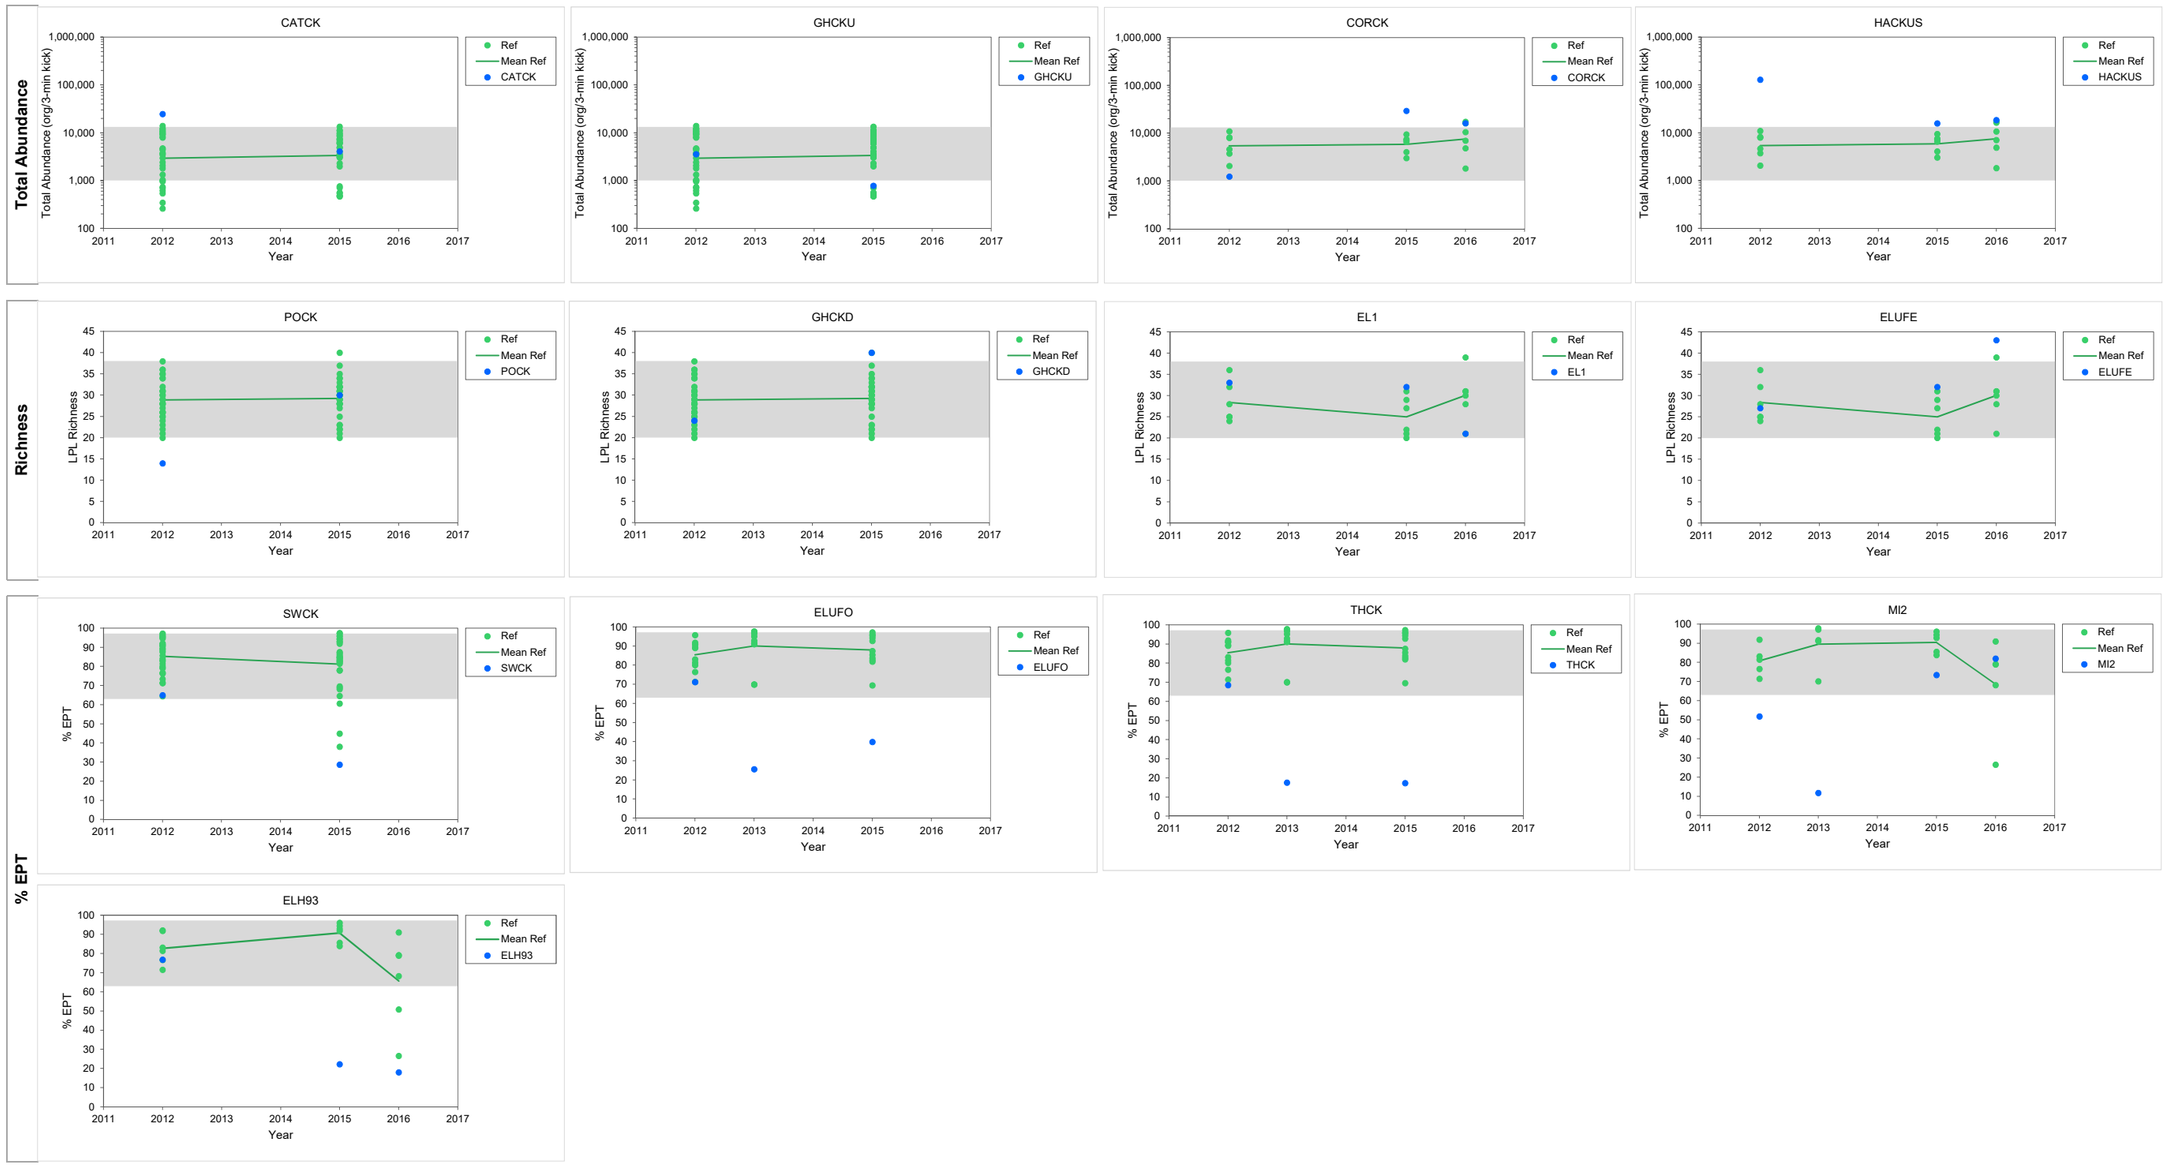

Figure 8.8: Scatterplot of Abundance, Richness, % EPT, and % Ephemeroptera versus Year for Mine-exposed Areas with a Significant Temporal Change Relative to the Mean Reference Area Temporal Change

Notes: Shaded region represents the normal range (2.5th and 97.5th percentiles for the pooled 2012 and 2015 reference area distribution). Reference area data in each plot represent the reference data used in that specific contrast

Notes: Shaded region represents the normal range (2.5th and 97.5th percentiles for the pooled 2012 and 2015 reference area distribution). Reference area data in each plot represent the reference data used in that specific contrast

2012 at main stem areas of the upper Fording River upstream from Ewin Creek (FOUKI, FOBKS, FOBCP, FODPO, and FOUEW) and at the Elk River mouth (ELH93; Figure 8.8). The other areas (Fording River downstream from Greenhills Creek [FODGH] and upstream [FRUL] and downstream [FO23] from Line Creek, as well as mid [MI3] and lower [MI2] Michel Creek showed a pattern of lower % Ephemeroptera in 2013 compared to 2012, followed by increases in 2015[31] and 2016, with 2016 values being near the reference mean.

When temporal changes were analyzed by MU, decreasing trends in % Ephemeroptera were apparent in the upper Fording River (MU1) and the lower Elk River (MU4, MU5), with a step change after 2012 in all locations (Appendix Table G.19, Appendix Figure G.12). A decreasing trend in % EPT was detected after 2012 in MU5, while % EPT appears to be increasing in the Michel Creek portion of MU4 (Appendix Table G.19, Appendix Figure G.12).

The observed changes are discussed further in Section 12 as part of the integrated evaluation of data for each monitoring area within each MU. Management responses that have been planned or initiated in response to findings are also discussed.

8.3 Biomass and Density (Hess Samples)

Invertebrate biomass and density have been monitored in the Line Creek LAEMP since 2014 to evaluate potential changes in productivity associated with operation of the AWTF (e.g., Minnow 2017b). Invertebrate biomass was greater downstream from the AWTF (LILC3 and the LIDSL) than at reference area SLINE, but this difference was apparent prior to AWTF operation and did not increase after the AWTF became fully operational in 2016 (based on before-after control-impact [BACI] analysis) (Figure 8.9). Biomass is also being monitored in the FRO LAEMP beginning in 2017 (Minnow 2017a) to evaluate baseline conditions prior to commissioning of the future upper Fording River AWTF, which is planned to treat water from Swift, Cataract, and Kilmarnock creeks. In addition, biomass monitoring began in the GHO LAEMP in 2017 (Minnow and Lotic 2017) and these data will be used to inform future RAEMP reports.

8.4 Tissue Selenium

8.4.1 Comparisons to Concentrations in Water

As noted in Section 7.4.1, selenium is taken up from water by organisms at the base of aquatic food webs (Stewart et al. 2010). Once incorporated into the base of the food web, selenium is transferred to higher levels of the food web through dietary pathways. In the Elk Valley, benthic

[31] The exception was FODGH, where % Ephemeroptera in 2015 was similar to that observed in 2013.

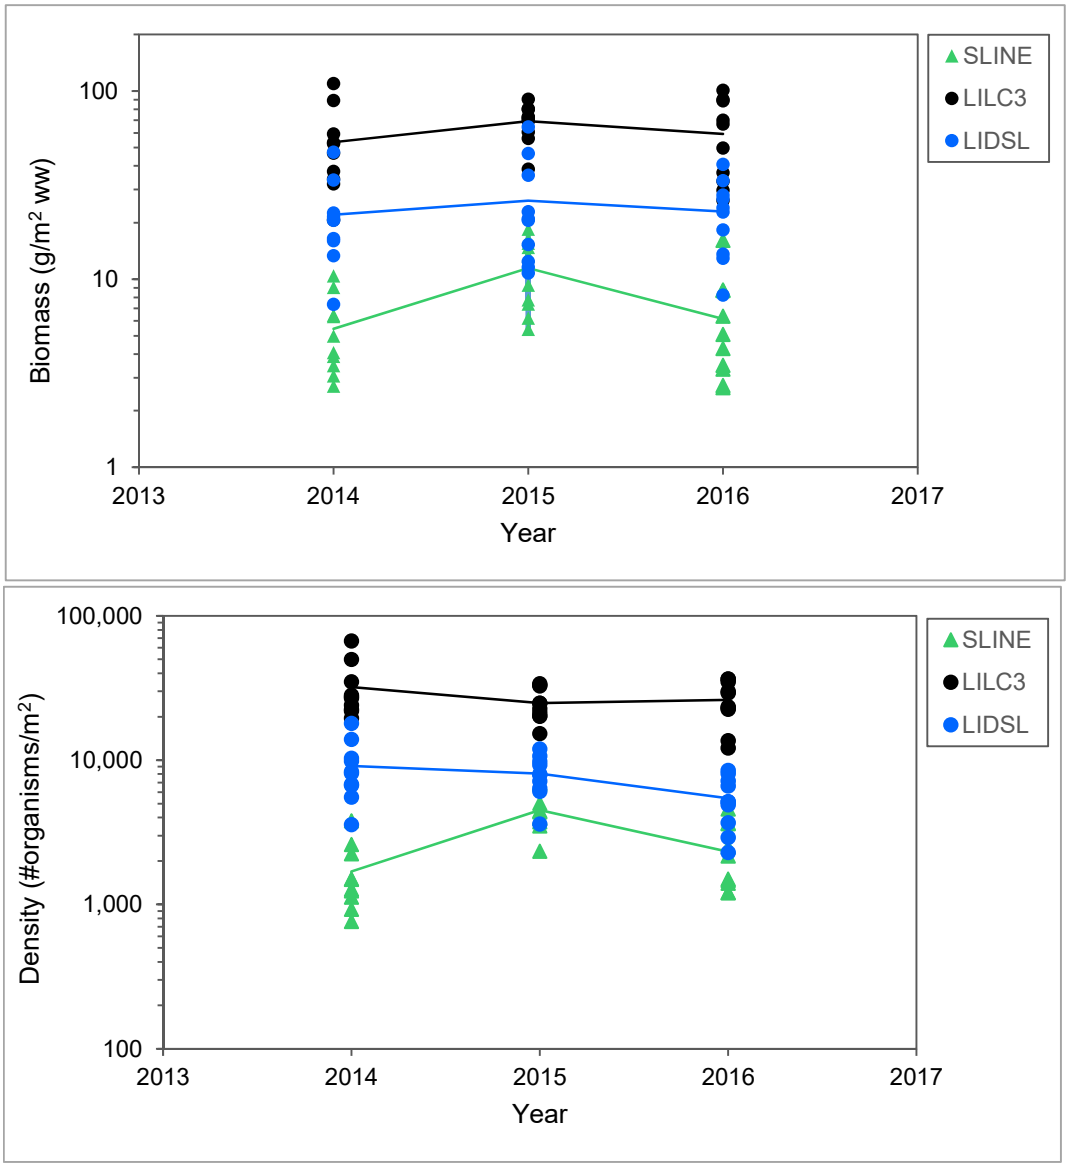

Figure 8.9: BACI Plots for Benthic Invertebrate Biomass and Density in Line Creek from 2014 - 2016

Note: Y-axes are on a log scale

invertebrates represent the first level of consumers and a key food source for aquatic and aquatic-dependent vertebrates (e.g., fish, amphibians, birds).

Dietary uptake steps in the food web are characterized by trophic transfer factors or functions (TTF) that describe the relationship between tissue selenium concentrations in consumers and their prey. TTFs from the base of the food web to invertebrates are typically in the range of 1 to 3 (Presser and Luoma 2010), meaning concentrations in invertebrates are usually 1 to 3 times

higher than those in the algae and other microorganisms they consume. However, TTFs up to about 10 have been observed in the Elk Valley, chiefly in areas with lowest aqueous selenium concentrations (Orr et al. 2012) where organisms actively take up selenium to maintain internal concentrations to support physiological functions (Stewart et al. 2010). Selenium accumulation in food webs tends to be greater in lentic than lotic or semi-lentic systems with similar concentrations of selenium in water (Hillwalker et al. 2006, Orr et al. 2012, USEPA 2016, Deforest et al. 2017). Although such a pattern was not strongly evident for periphyton samples collected in the Elk Valley in 2012 and 2015 (Figure 7.12), differences in accumulation between lotic and lentic areas are indicated by selenium concentrations in benthic invertebrate samples collected in the same areas and years (Figure 8.10). The tissue data collected since 2013 are being incorporated into an update of the Elk Valley bioaccumulation model.

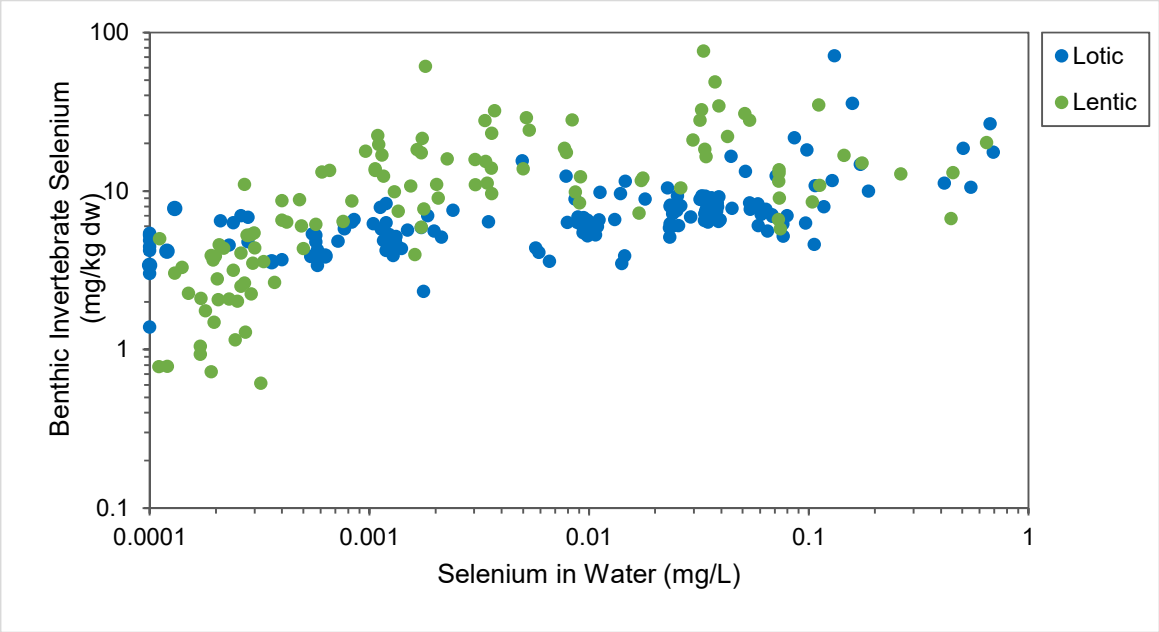

Figure 8.10: Scatterplot of Selenium Concentrations in Benthic Invertebrate Tissue versus Selenium Concentrations in Water in the Elk Valley for Lotic and Lentic Habitats, 2012 and 2015

8.4.2 Comparison to Predictions

Benthic invertebrate tissue selenium concentrations measured in 2015 and 2016 were compared to predictions that were derived from water modelling (Golder 2014a,b) and tissue bioaccumulation models developed for the EVWQP (Teck 2014) (Table 8.4). Observed concentrations were similar to or lower than predicted mean concentrations for 2013 and 2017, except at Swift Creek (SWCK; 2015); LCO Dry Creek (LC_DC1; 2016), lower

[a] Approximate 95% prediction interval for invertebrate tissue selenium concentrations (mg/kg dw) (±2 RMSD) of 2-step, water to invertebrate, bioaccumulation model that used predictions from regional water quality model.

[b] Result was verified with the laboratory, but is suspect.

[c] Maximum concentration reported from replicate samples

Bold values are >50% higher than the mean of predicted means for 2013 and 2017

observed value is greater than upper limit of the prediction interval

Greenhills Creek (GHCKD; 2015), Line Creek immediately downstream from the AWTF (LILC3; 2016), Thompson Creek (THCK), Harmer Creek (HACKDS; 2016), Bodie Creek (BOCK; 2015 and 2016) and the lower Elk River (ELEKO and ELH93; 2015 and 2016), where tissue selenium concentrations were more than 20% higher than the mean predictions for 2013 and 2017 (Table 8.4). However, all observed concentrations except those at Bodie Creek (BOCK) were less than the upper prediction interval (i.e., within the range of model uncertainty). The benthic invertebrate community in Bodie Creek has been affected by mining, so the taxa collected for tissue selenium analysis at Bodie Creek (mainly aquatic worms) differ from those comprising tissue samples at most other areas (EPT).

The elevated tissue selenium concentration at LILC3 in 2016 was associated with discharge of selenium from the AWTF that was in a chemical form (i.e., predominantly selenite) that is more readily accumulated by aquatic organisms than the form that is normally found in other parts of the watershed (i.e., selenate) (Minnow 2017b). Teck is currently pilot testing an active oxidation process to convert most of the selenium discharged by the AWTF back to selenate, which is expected to result in less tissue selenium accumulation in Line Creek after it becomes operational at full-scale.

8.4.3 Comparisons to Normal Reference Ranges

The distributions of reference area benthic invertebrate selenium concentrations were similar for lotic and lentic areas and resulted in 97.5th percentiles that were not significantly different (Appendix Tables G.48 and G.49). Therefore benthic invertebrate tissue selenium concentrations measured at both lotic and lentic reference areas sampled since 1996 were combined (n=176 samples) to characterize the reference normal range (Appendix Table G.49; Appendix Figure G.13). The upper limit of the normal range was defined as 7.82 mg/kg dw of selenium in tissue.

Of samples collected among 59 mine-exposed lotic areas in September 2015, 16 (27%) had selenium concentrations greater than the upper limit of the normal range, resulting in NRQs >1.0 (Figure 8.11; Appendix Table G.43). Highest NRQs were found in tributaries, but NRQs greater than 1.0 were also observed in the Fording River downstream from GHO (FODGH) and in the lower Elk River (ELELKO, ELH93; Figure 8.11; Appendix Table G.50). Of mine-exposed lotic areas having benthic invertebrate selenium concentrations within the normal range, all but eight had NRQs of 0.7 or more, indicating concentrations near the upper limit of the reference area normal range (Figure 8.11). Samples collected from a sub-set of areas in 2016 produced similar results with NRQs of 0.7 or more at 23 of 27 (85%) mine-exposed areas (Appendix Table G.50).

minnow environmental inc.
Figure 8.11

Mean invertebrate tissue selenium concentrations among lentic areas were greater than the reference normal range in 14 of 18 areas, resulting NRQs up to 4.1 (at R5-1, a side channel of the Fording River downstream from Greenhills Creek; Appendix Table G.51).

8.4.4 Comparisons to Site-Specific Benchmarks

Benthic invertebrate tissue selenium concentrations measured in lotic habitats of the watershed since 2006 have typically been less than the EVWQP Level 1 benchmark for effects to invertebrates (13 mg/kg dw), as well as benchmarks for dietary effects to juvenile fish (11 mg/kg dw) and birds (15 mg/kg dw; Figure 8.12). Figure 8.13 expresses the concentrations observed in 2015 as HQs based on the most sensitive EVWQP benchmark of 11 mg/kg dw for dietary effects to fish. Most (7 of 58 = 88%) areas sampled in 2015 had invertebrate tissue selenium concentrations less than the lowest benchmark. HQs > 1 occurred mainly in tributaries (e.g., Swift, Greenhills, Line, Wolfram, Thompson, and Bodie), as well as the most downstream Elk River area (ELH93). In 2016, 6 of 32 (19%) benthic invertebrate tissue samples collected in mine-exposed areas had concentrations greater than the benchmark of 11 mg/kg dw (Appendix Table G.43).

Benthic invertebrate tissue selenium concentrations in lentic areas have frequently been greater than Level 1 benchmarks (Figure 8.12). In 2015, at least one sample exceeded the benchmark in 13 of 18 (72%) mine-exposed areas and one of five (20%) reference areas (Appendix Table G.47). Maximum invertebrate tissue selenium concentrations (of replicate values among areas) exceeded the Level 1 benchmark for potential dietary effects to fish (i.e., HQ > 1) in 11 of 18 mine-exposed lentic areas (Appendix Table G.44).

8.4.5 Temporal Changes

Potential changes in benthic invertebrate tissue selenium concentrations over time were evaluated for all areas having at least two years of data. Significant increases were identified at LILC3 (Line Creek downstream from the AWTF) after 2015 and at BOCK (Bodie Creek) after 2012 (Figure 8.14; Appendix Table G.42a,b). The increase at LILC3 was due to discharge of selenium from the AWTF in a chemical form (i.e., predominantly selenite) that is more readily accumulated by aquatic organisms than the form that predominates in other parts of the watershed (i.e., selenate) (Minnow 2017b). Teck is currently pilot testing an active oxidation process to convert most of the selenium discharged by the AWTF back to selenate, which is expected to result in less tissue selenium accumulation in Line Creek after it becomes operational at full-scale

The cause of elevated tissue selenium concentrations at BOCK in 2015 and 2016 relative to 2012 and predicted values is uncertain. These samples could reflect altered invertebrate

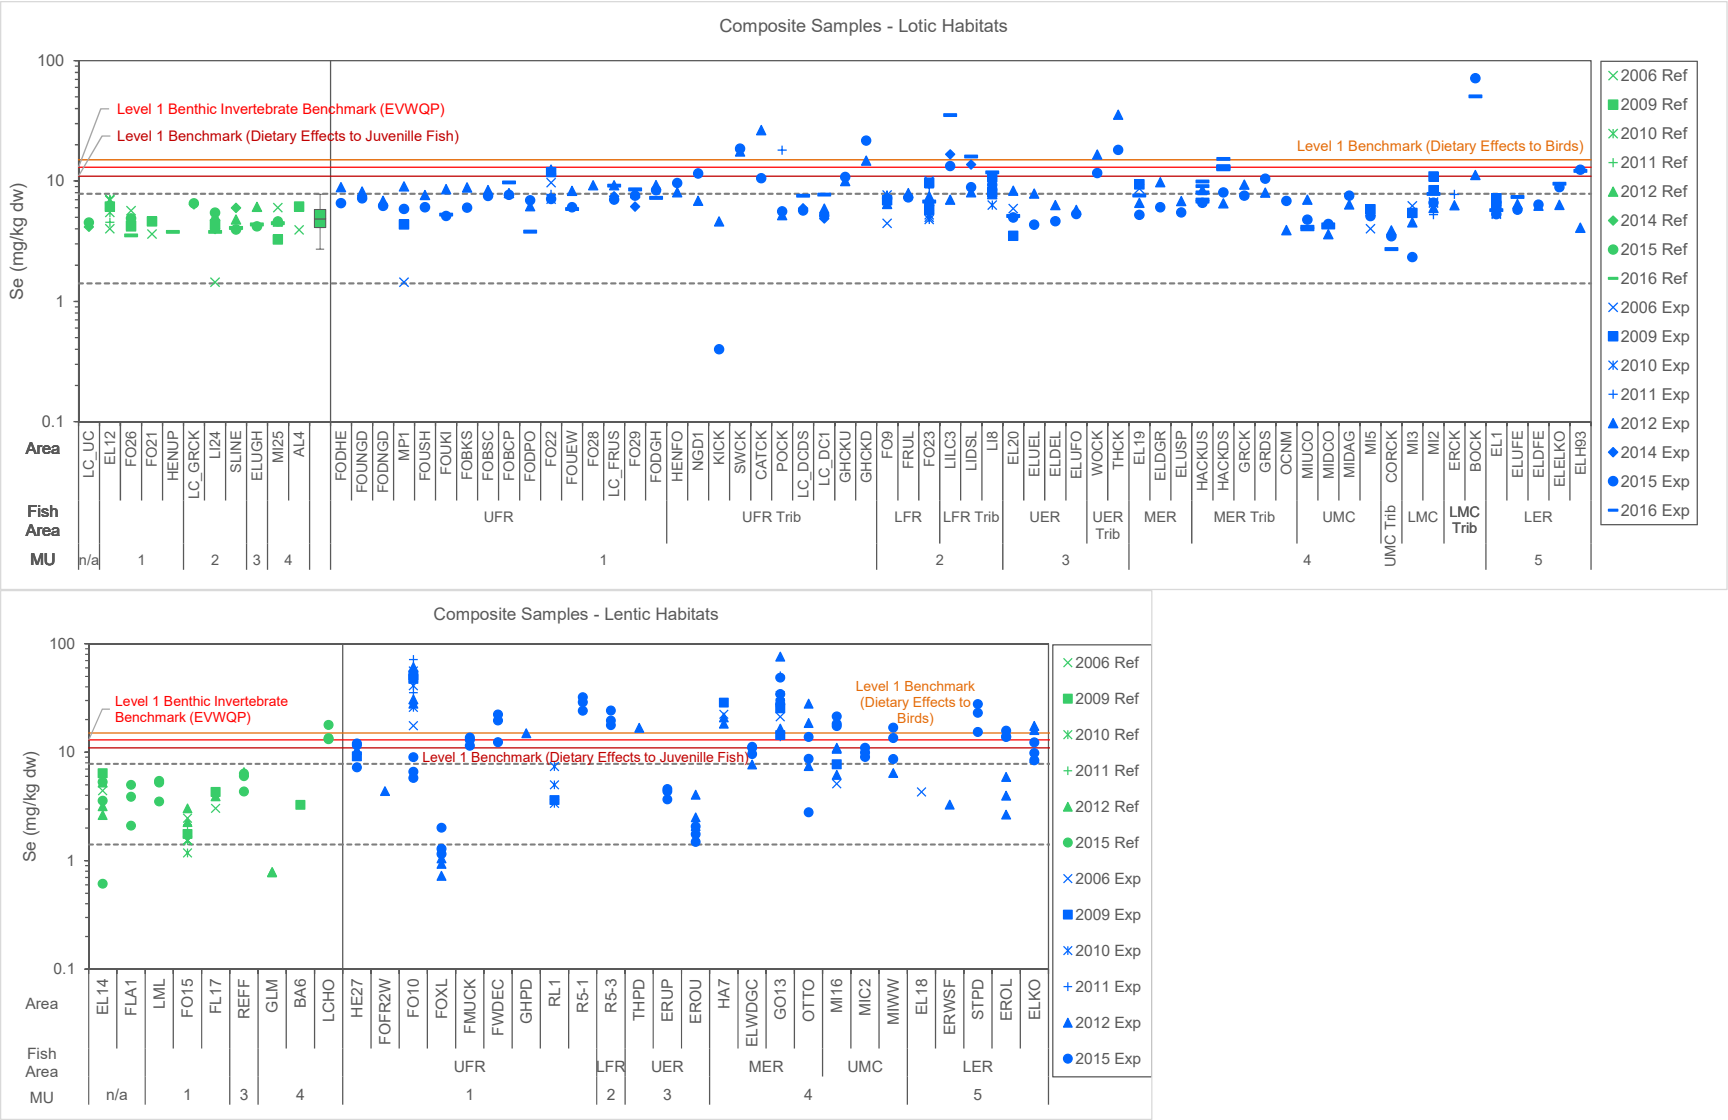

Figure 8.12: Selenium Concentrations in Benthic Invertebrate Samples Collected in Lotic and Lentic Habitats, 2006 - 2016

Notes: UFR = Upper Fording River; LFR = Lower Fording River; UER = Upper Elk River; MER = Middle Elk River; UMC = Upper Michel Creek; LMC = Lower Michel Creek; LER = Lower Elk River; Trib = Tributaries. Normal Range limits are displayed by grey dashed lines. Samples were not collected in 2016 in lentic areas.

Figure 8.13

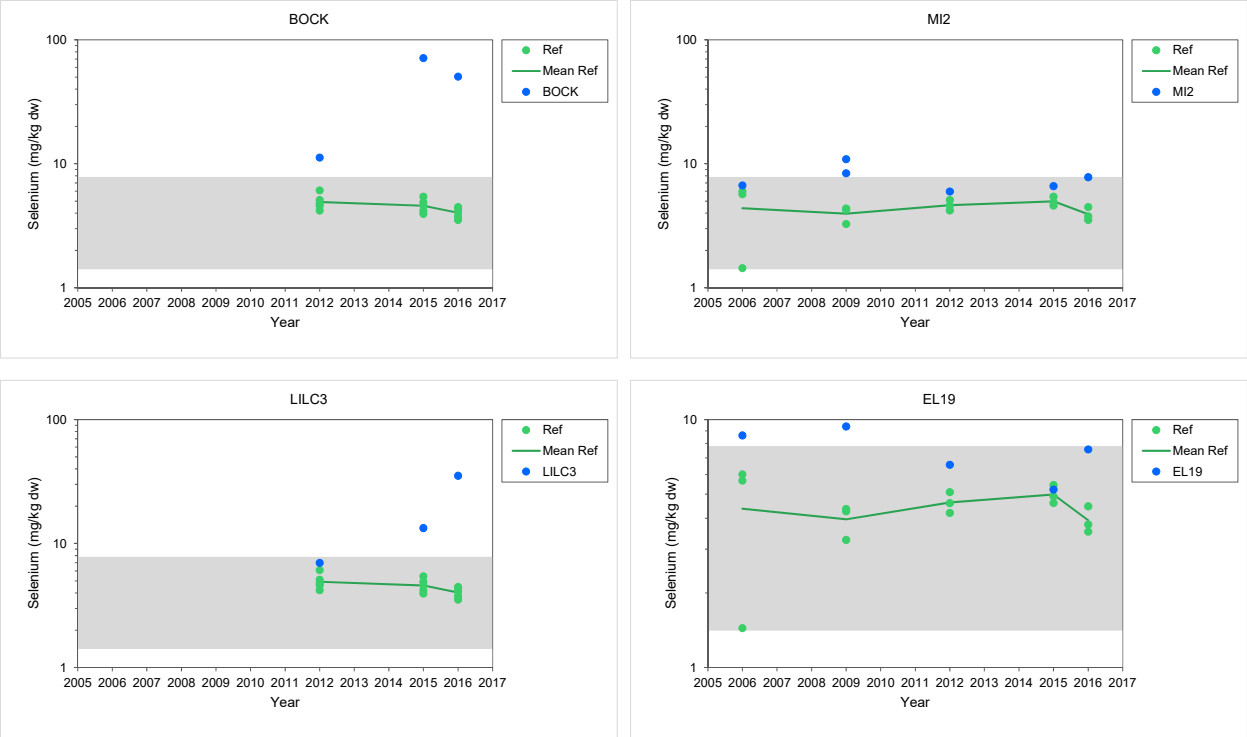

Figure 8.14: Scatterplot of Selenium Concentration in Benthic Invertebrate Tissue versus Year for Lotic Mine-exposed Areas with a Significant Temporal Change Relative to the Mean Reference Area Temporal Change

Notes: Shaded region represents the reference area normal range. The reference area data in each plot represent the reference data used in that specific contrast. Reference data sets included any reference areas having data for the same years as the mine-exposed area.

communities due to exposure to mine-influenced water downstream of the sediment ponds, or some other factor related to proximity to the point of discharge. Locations close to sediment ponds also have a greater potential influence of mine water management practices (e.g., pit dewatering) that could expose these locations to mine-influenced water from a range of sources.

Decreasing step changes were observed at EL19 (Elk River downstream from Fording River) and MI2 (lower Michel Creek after 2006 (Figure 8.14). At all other areas, concentrations observed in 2015 were similar to those observed in one or more previous years (Appendix Table G.42a,b).

Among lentic monitoring areas, a decreasing trend in tissue selenium was observed at the former Fording River Oxbow (FO10) in 2015 compared to previous years (Figure 8.15; Appendix Table G.42c). The record flood in 2013 altered this area from a lentic oxbow habitat to a flow-through side-channel. Tissue selenium concentrations were reduced in a manner consistent with the relative differences in food web accumulation of selenium between lotic and

lentic habitats (Figure 8.10). The tissue selenium concentrations in 2015 were less than EVWQP Level 1 benchmarks (Appendix Table G.51).

A decreasing trend in invertebrate tissue selenium concentrations was also observed at Otto Ponds (OTTO), where the concentrations in 2015 ranged from less than the upper limit of the normal reference area range to greater than Level 1 benchmarks for effects to invertebrates and juvenile fish among the three replicate samples (Appendix Tables G.47 and G.51). This was supported by a decreasing trend for selenium in water at the Otto Creek monitoring station (EV_OC1).

Increasing trends for invertebrate tissue selenium concentrations were evident for the Michel Creek wetland (MI16) downstream from CMO. However, concentrations in water were low at the time of sampling (i.e., < 2 µg/L) and no trends were found for aqueous selenium concentrations downstream from CMO (CM_MC2; Appendix Table C.29). An increase was also observed for the lower Elk River Oxbow (EROL), but this result was based on only two years of data and should be interpreted with caution (Figure 8.15).

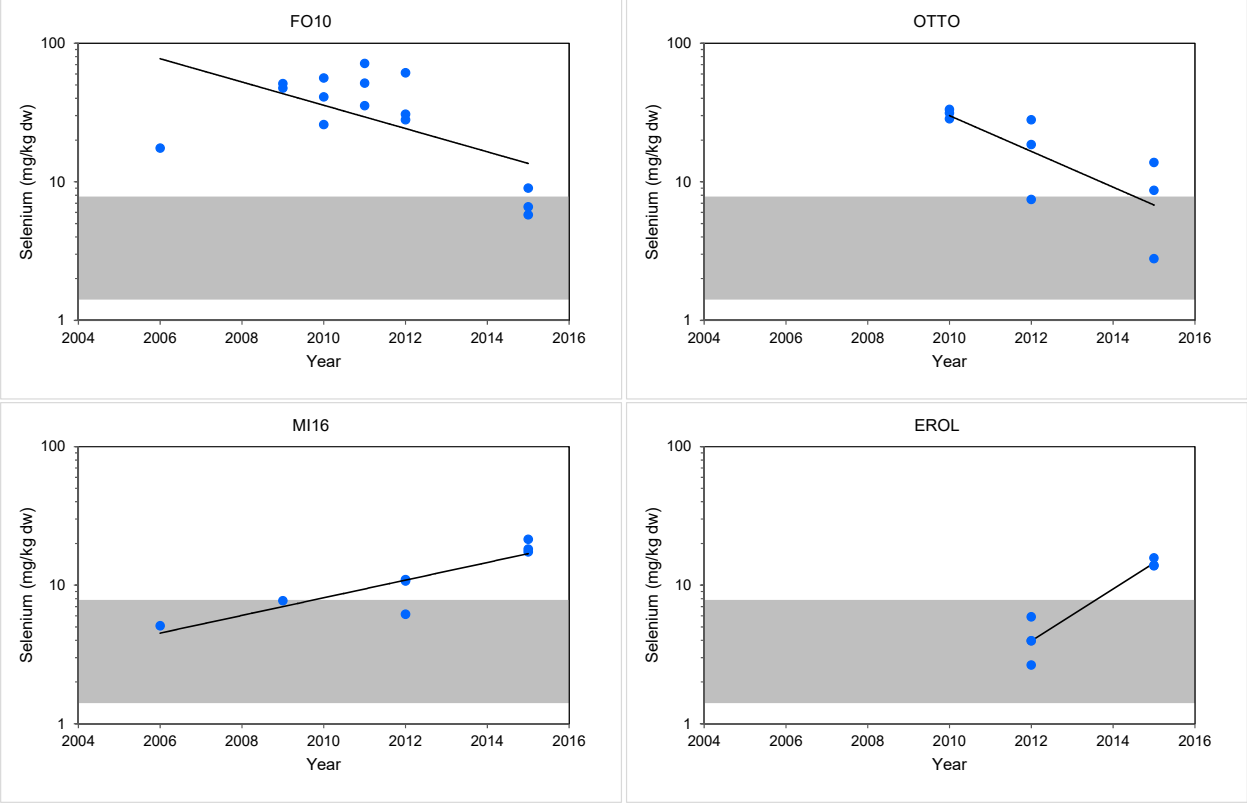

Figure 8.15: Scatterplots and Linear Regression of Benthic Invertebrate Tissue Selenium for Lentic Areas with a Significant Linear Trend over Time, 2006 – 2015

Notes: Shaded region represents the reference area normal range.

8.5 Meta-Analysis

PCA was used to evaluate relationships between benthic invertebrate community endpoints, natural habitat variation, and mine-related constituents (e.g., water quality and calcite) (Figure 8.16; Appendix Tables G.52 to G.54[32]). As noted above, differences in benthic invertebrate community structure (as summarized by NMDS) were directly related to %EPT, particularly %Ephemeroptera, and these community endpoints were inversely related to the summary variables for water quality (expressed as either concentrations [PC1] or HQs for key constituents nitrate, selenium, sulphate) and calcite index). Natural habitat variables explained little of the variation in conditions among areas ($r < 0.5$ for habitat PC1 and PC2; Appendix Table G.51). Benthic invertebrate richness was not related to any of the measured habitat or mine-related variables (Figure 8.16).

8.6 Summary

Benthic invertebrate communities sampled in reference areas were composed mainly of Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies), collectively referred to as EPT. Of the 59 mine-exposed areas sampled in 2015, almost half (27 of 59) had proportions (%) of EPT and/or Ephemeroptera that were less than the reference area normal ranges for those endpoints. % EPT and % Ephemeroptera were inversely related to increasing gradients of mine-related influence on water quality and calcite.

More significant temporal changes were observed for % Ephemeroptera than the other benthic invertebrate community endpoints. Declines were observed in 2015 and 2016 relative to 2012 at main stem areas of the upper Fording River upstream from Ewin Creek (FOUKI, FOBKS, FOBCP, FODPO, and FOUEW) and at the Elk River mouth (ELH93). The other areas (Fording downstream from Greenhills [FODGH] and upstream [FRUL] and downstream [FO23] from Line Creek, as well as mid [MI3] and lower [MI2] Michel Creek showed a pattern of decreased (lowest) % Ephemeroptera in 2013 compared to 2012, followed by increases in 2015 and 2016, with 2016 values being near the reference mean.

The pattern of lower % Ephemeroptera over a distance of about 12 km in the upper Fording River was identified in the FRO LAEMP report submitted in May 2017 (Minnow 2017a). The response appears to be chiefly attributable to declines in abundances of the mayfly families

[32] A second PCA was completed that included benthic invertebrate tissue selenium concentrations, but it depicts results only 5 reference areas. This is because tissue selenium concentrations were not measured at all reference areas in 2015 based on a large existing data set for reference tissue selenium concentrations. The results were similar to those depicted in Figure 8.8 with tissue selenium concentrations correlating strongly with other abiotic mine-related variables (Appendix Figure G.15: Tables G.55 to G.57).

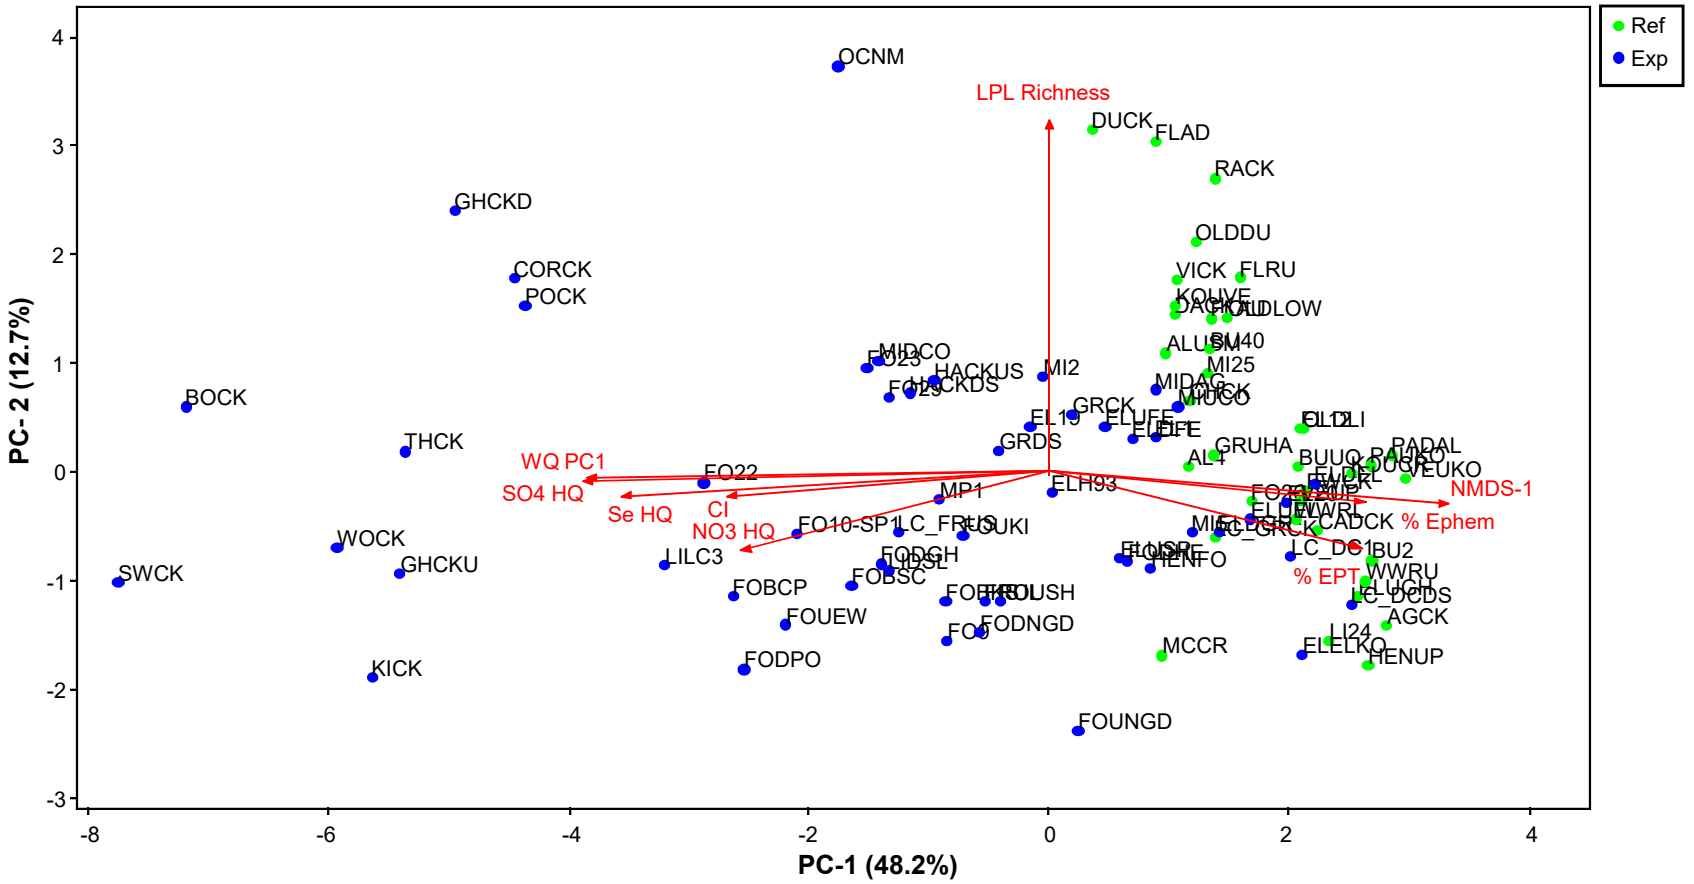

Figure 8.16: Overall Principal Components Analysis Biplot of Biological and Abiotic Summary Variables Based on Data from 36 Reference and 54 Mine-exposed Areas, September 2015, Elk Valley

Note: Direct correlation vectors are displayed for variables having an absolute Pearson's correlation coefficient (r) greater than 0.6 with PCA axis scores. Vector length is proportional to correlation strength. Note that PC-2 is not a significant axis (Monte carlo simulation p > 0.05).

Ephemerellidae and Heptigeniidae. Several factors (e.g., elevated nitrate concentrations increased temperature, variation in annual flow regimes, seasonal dewatering, and/or calcite deposition) may be influencing benthic invertebrate communities. In consideration of these findings, the FRO LAEMP design was adjusted to allow for further investigation of the cause(s) of benthic invertebrate community changes in September 2017 (Minnow 2017e).

Benthic invertebrate tissue selenium concentrations observed in lotic monitoring areas in 2015 and 2016 were compared to predictions that were derived from water modelling and tissue bioaccumulation models developed for the EVWQP. Tissue selenium concentrations were less than the upper prediction interval (i.e., within the range of model uncertainty for individual observations) at all areas except at Bodie Creek (BOCK), although additional areas reflected tissue selenium concentrations that were more than 20% greater than predicted mean concentrations in 2015 and/or 2016. Tissue selenium concentrations measured among mine-exposed areas in 2015 and 2016 were generally at the upper end of, or greater than, the normal range for reference areas (51 of 58 areas = 88%).

Benthic invertebrate tissue selenium concentrations measured in lotic habitats of the watershed since 2006 have typically been less than the EVWQP Level 1 benchmark for effects to invertebrates (13 mg/kg dw), as well as benchmarks for dietary effects to juvenile fish (11 mg/kg dw) and birds (15 mg/kg dw). Most (89%) of the areas sampled in 2015 had invertebrate tissue selenium concentrations less than the lowest benchmark. HQs > 1 occurred mainly in tributaries (e.g., Swift, Greenhills, Line, Wolfram, Thompson, and Bodie), as well as the most downstream Elk River area (ELH93). In 2016, 6 of 32 (19%) benthic invertebrate tissue samples collected in mine-exposed areas had concentrations greater than the benchmark of 11 mg/kg dw. By comparison, benthic invertebrate tissue selenium concentrations in lentic areas have frequently been greater than Level 1 benchmarks, and in 2015, at least one replicate sample exceeded the benchmark in 13 of 18 (72%) mine-exposed areas and one of five (20%) reference areas.

Potential changes in benthic invertebrate tissue selenium concentrations over time were evaluated for all areas having at least two years of data. Significant increases were identified at LILC3 (Line Creek downstream from the AWTF) and at BOCK (Bodie Creek) in 2015 and 2016 compared to 2012. The elevated tissue selenium concentration at LILC3 in 2016 was associated with discharge of selenium from the AWTF that was in a chemical form (i.e., predominantly selenite) that is more readily accumulated by aquatic organisms than the form that is normally found in other parts of the watershed (i.e., selenate). Teck is currently pilot testing an active oxidation process to convert most of the selenium discharged by the AWTF into selenate, which is expected to result in less tissue selenium accumulation in Line Creek

after it becomes operational at full-scale. Increases at BOCK compared to predictions and past observations may be related to altered invertebrate communities due to exposure to mine-influenced water downstream of the sediment ponds, exposure to pit dewatering, or some other factor related to proximity to the point of discharge.

Decreasing step changes in benthic invertebrate tissue selenium concentration were observed at EL19 (Elk River downstream from Fording River) and MI2 (lower Michel Creek) after 2006. At all other areas, concentrations observed in 2015 were similar to those observed in one or more previous years.

Among lentic monitoring areas, a decreasing trend in tissue selenium was observed at the former Fording River Oxbow (FO10) in 2015 compared to previous years which is consistent with the transformation of that area from a stagnant lentic habitat to a flowing side-channel after the record storm event in June 2013. The invertebrate tissue selenium concentration at this area in 2015 was less than EVWQP Level 1 benchmarks.

A decreasing trend in invertebrate tissue selenium concentrations was also observed at Otto Ponds (OTTO), where the concentrations measured in 2015 ranged from less than the upper limit of the normal reference area range to greater than Level 1 benchmarks for effects to invertebrates and juvenile fish among the three replicate samples. This trend was supported by a decreasing trend for selenium in water at the Otto Creek monitoring station (EV_OC1). An increasing trend was observed for the Michel Creek wetland (MI16) downstream from CMO; however, no trends were found for aqueous selenium downstream from CMO (CM_MC2).

The observed spatial and temporal effects on benthic invertebrates are discussed further in Section 12, which compiles and integratively evaluates all the monitoring data for each area within each MU. Teck is working with the EMC to develop a formalized approach for evaluating monitoring data on a weight of evidence basis, as well as triggers for management responses based on biological data, and these approaches will be implemented in future cycles of the RAEMP.

9 LONGNOSE SUCKER

9.1 Overview

In 2004, a dwarf form of longnose suckers (LSU; Photo 9.1) was reported to be inhabiting lentic areas of the Elk River watershed (Minnow 2005). Further study indicated that dwarf LSU populations are widespread in the Elk River watershed, being most abundant in small, cool, lentic water bodies that contain vegetative cover and few other fish species (LePage 2014). The normal-sized phenotype is also found in larger, deeper water bodies in the region (e.g., Grave Lake, Koocanusa Reservoir; LePage 2014). LePage (2014) concluded that, in addition to having smaller body size and different habitat preferences from the normal form, dwarf adults have a shorter head length and snout, larger mouth and eyes, and a more slender body than the normal form, suggesting that the adult dwarf sucker have retained some of the morphological characteristics of juveniles. The dwarf form also shows smaller home range size, younger age-at-maturity, lower maximum age, slower growth rate, lower fecundity, and smaller but proportionally larger egg size compared to normal sucker (LePage 2014). Slight, but significant, genetic differences were indicated between Elk River watershed dwarf and normal longnose sucker forms, and compared to the endangered Salish sucker. The study concluded that the dwarf form may have evolved to opportunistically expand into lentic areas subjected to seasonal flow disturbances and reduced oxygen levels, especially where predators and other interspecific competitors are few or lacking (LePage 2014).

Photo 9.1: Longnose Sucker Collection in Lentic Areas

Although the distribution of LSU is patchy and limited to lower elevations of the Elk River watershed (LePage 2014; Lotic 2014b), this species is an important biological component of some lentic areas. Therefore, it was chosen to serve as one of two "sentinel fish species"[33] in the RAEMP to support assessment of the aquatic ecosystem in the Elk River watershed downstream from Teck's coal mines (Minnow 2015a). Two reference and ten mine-exposed areas were sampled[34] in May 2015[35] (Figure 9.1; Appendix Table HLSU.1) for evaluation of LSU density, population size, health indicators, and tissue selenium concentrations. Although not stipulated in the study design (Minnow 2015a), mine-exposed areas with the most abundant LSU were revisited in September 2015, to determine if the timing of sampling affected LSU catch success and population estimates.

9.2 Fish Catches and LSU Population Estimates

Among the areas targeted for LSU population monitoring, LSU was the dominant species captured in minnow traps in both May and September, 2015 (Table 9.1). Low numbers of redside shiner, longnose dace, juvenile cutthroat trout, and/or juvenile mountain whitefish were also captured at seven of the ten mine-exposed areas in May and/or September, but were not found at either of the two reference areas in minnow traps (Table 9.1). No LSU were captured at the REFF reference area or at the MI16 mine-exposed area, and only low numbers (<10) were captured at ELWDGC, MIC2, MIWW, and EROL mine-exposed areas sampled in May (Table 9.1). Greater numbers of LSU were captured in September than May at each of the four mine-exposed areas that were re-sampled using comparable fishing effort (i.e., consecutive nights until a minimum of 10% of marked fish were recaptured or a maximum of four nights).

LSU population estimates varied widely among the twelve study areas in May 2015. Largest population sizes were estimated for mine-exposed areas Goddard Marsh (GO13), Otto Ponds (OTTO) and Stanford Pond (STPD), where populations were greater than at the reference areas (Table 9.2). The LSU population at the mine-exposed Elk River Upper Ponds (ERUP) was comparable to the FLA1 reference population, whereas relatively small LSU populations were estimated for ELWDGC, MIC2, MIWW, and EROL mine-exposed areas during the May sampling event (Table 9.2). Confidence limits for the LSU population estimates were wide, especially in May. Longnose sucker population estimates did not show consistent numbers

[33] The use of this term is consistent with Gray et al. (2002) and Environment Canada (2012a). The other sentinel species chosen was westslope cutthroat trout, which is discussed in Section 10.

[34] The study design indicated two reference areas and seven mine exposed areas would be targeted from a list of three reference and 10 mine-exposed candidate areas.

[35] Limited information indicates that dwarf longnose sucker spawn in late May or early June, but the timing likely varies among years based on water flows and/or temperature.

[b] Upper population range could not be calculated due to few fish recaptures.
[c] Area was not re-sampled in September.

In 2013, a study of LSU presence/absence, abundance (density) and health was implemented at a variety of lentic areas to inform the design of the RAEMP (Lotic Environmental 2014b). Similar to this study, low densities were reported at a number of oxbows on the Elk River and Michel Creek, although the study was potentially confounded by reduced catch success associated with lower temperatures (mid-September to early October).

9.3 LSU Health Indicators

9.3.1 Comparisons to Reference Area

Potential differences in LSU fork length, body weight, and condition between mine-exposed and reference areas were tested for areas sampled in 2015 using ANOVA followed by *post hoc* comparisons. Mean fork length and body weight were significantly lower for LSU captured at OTTO and STPD compared to the reference area (Figure 9.2; Appendix Table HLSU.8). A significant increase in mean fork length was observed at ERUP, and significant increases in body weight were observed at ERUP and GO13, compared to the reference area.

Potential differences among areas were tested for LSU length-frequency distributions using two-sample KS tests, which compare the cumulative relative frequency distributions between areas (Appendix Table HLSU.8; Appendix Figures HLSU.3 and HLSU.4). The K-S test compares the maximum vertical distance (displayed as a percentage in Appendix Figure HLSU.4) between two cumulative relative frequency distributions to a critical value (based on α and sample size). These plots help demonstrate the size at which differences in length frequency distributions are observed and the magnitude of the differences. For example, 71% of fish at FLA1 were < 10 cm in length and 47% of fish at UNWNMO were < 10 cm in length (a difference of 25% between these two areas). The length frequency distributions were compared between mine-exposed areas and the FLA1 reference area. Differences of 39% and 32% at ERUP and GO13, respectively, indicated significantly fewer small fish were captured at these areas compared to the reference area, whereas differences of -34% and -46% for OTTO and STPD, respectively, indicated a greater proportion of small fish captured at these areas compared to the reference area. The differences in cumulative frequency distribution detected for OTTO and STPD support the test results shown in Figure 9.2 of shorter mean length at those areas compared to the reference areas. The reason for fewer small fish at ERUP and GO13 has not yet been determined, but could be linked to reduced recruitment. This will be investigated in future studies associated with the RAEMP.

9.3.2 Temporal Changes

Based on input from the EMC, evaluation of potential changes over time focused on LSU condition. No differences in LSU condition were found between fish captured in May versus September 2015 among four mine-exposed areas, so fish from both months were used in comparisons among years (Appendix Table HLSU.9). Increases in condition were observed at three of six areas in 2015 compared to earlier years (Appendix Table HLSU.10). Condition was increased by 6.8% at the Elk River upper ponds (ERUP) in 2015 compared to 2005. Increases of 5.4% and 6.2% were also observed for the Flathead reference area (FLA1) and mine-

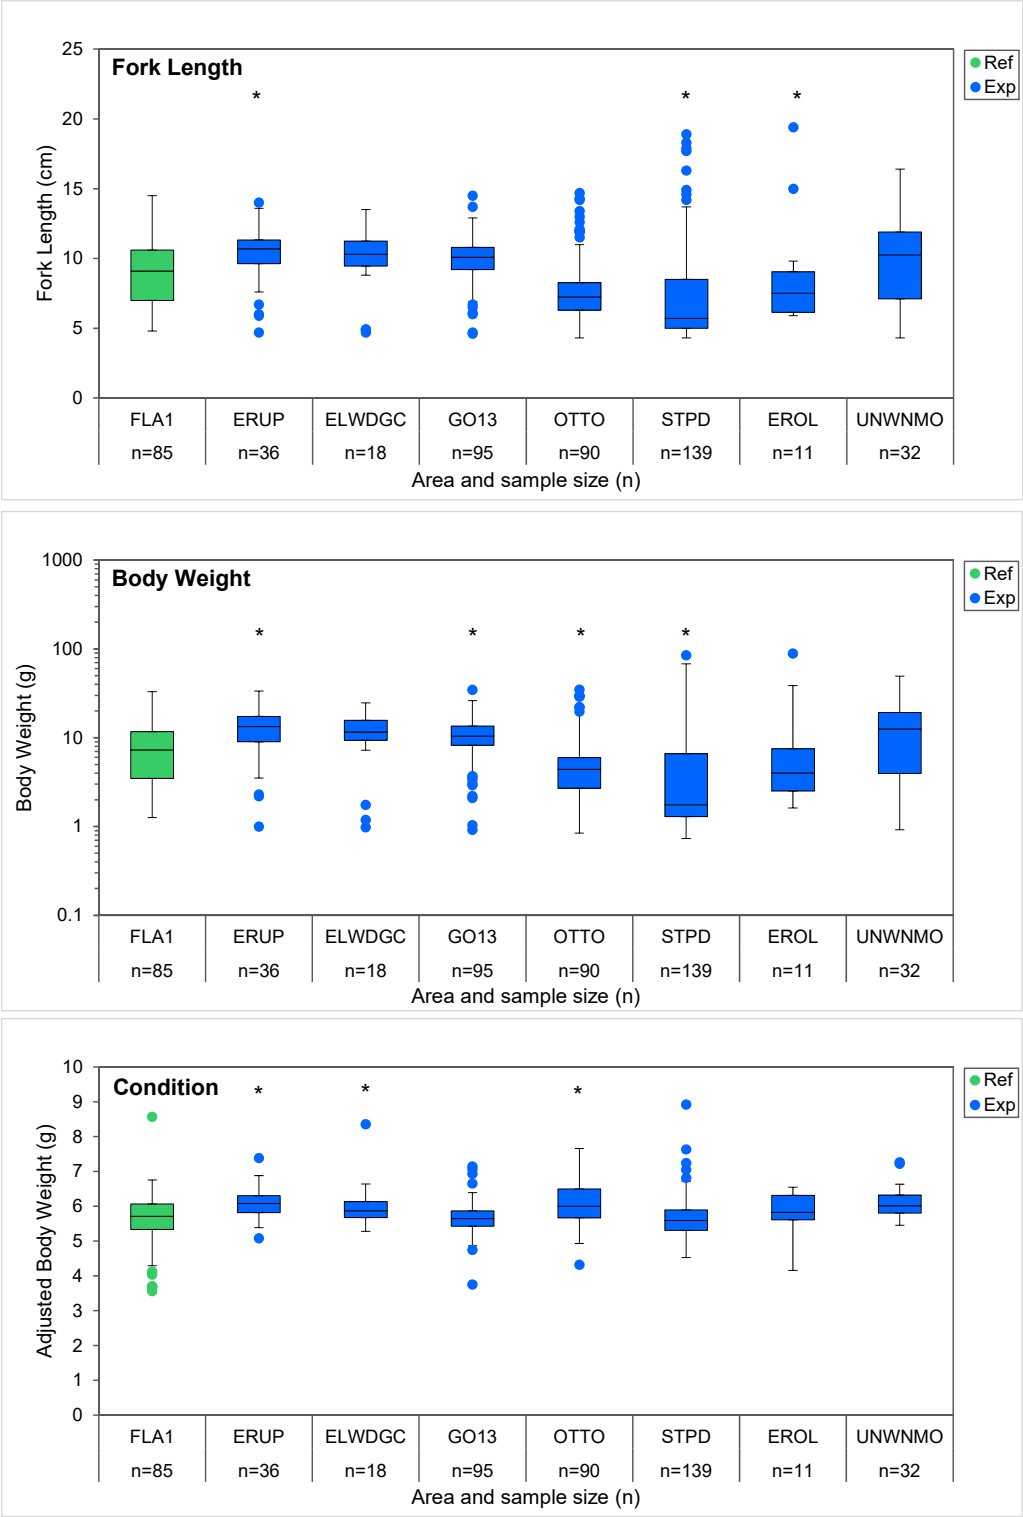

Figure 9.2: Boxplots of Fork Length, Body Weight, and Condition for Longnose Sucker Among Reference and Mine-exposed Areas, May 2015

Notes: * = significantly different from FLA1 (Dunn's Test for Fork Length and Body Weight; Dunnett's test for Condition; α = 0.1). For condition, body weight was adjusted to a fork length of 8.19 cm based on the parallel slope ANCOVA model.

exposed Otto Ponds (OTTO), respectively. These changes are less than what Environment Canada (2012b) defines as a "critical effect size" of 10% for fish condition and the observation of similar magnitude change between reference and mine-exposed areas also suggests the observed differences are not ecologically meaningful.

9.4 Tissue Selenium

9.4.1 Overview

Tissue sampling in May 2015 targeted ovaries and whole bodies of LSU, consistent with the RAEMP study design (Minnow 2015a). However, sampling revealed that the females at some areas had already spawned, possibly because limited winter snow pack and warm weather caused the freshet to be small and earlier than normal. Longnose sucker ovary selenium concentrations tend to be similar to muscle selenium concentrations in the pre-spawning period (Figure 9.3); therefore, muscle samples were collected from spent females to serve as a surrogate for ovary selenium concentration evaluation. A muscle selenium benchmark for LSU was estimated by converting the EVWQP Level 1 benchmark for fish ovary selenium (18 mg/kg dw) to a muscle benchmark (18 mg/kg dw) based on the aforementioned relationship (Figure 9.3).

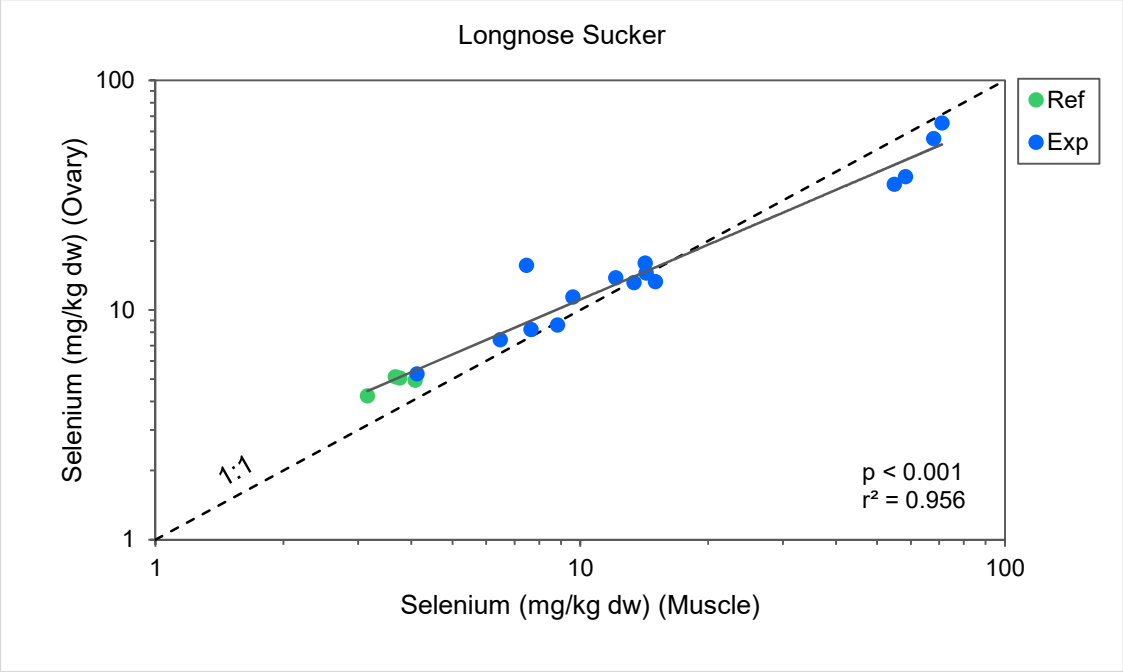

Figure 9.3: Linear Regression of Selenium Concentrations in Ovary Versus Selenium Concentrations in Muscle for Longnose Sucker

9.4.2 Comparisons to Normal Reference Range

LSU tissue samples collected at reference areas from 2002 to 2015 were used to characterize normal ranges for muscle, ovary, and whole body selenium concentrations (Appendix Tables HLSU.14 to HLSU.16; Appendix Figure HLSU.10). Upper normal range limits were defined as 5.71, 6.09, and 6.64 mg/kg dw for ovary, muscle, and whole body selenium concentrations, respectively, based on these data. All LSU captured in mine-exposed areas in 2015 had tissue selenium concentrations greater than the normal reference ranges, except at the Elk River Upper Ponds (ERUP), where ovary selenium concentrations, and one muscle selenium concentration exceeded the normal range, but not whole body selenium concentrations (Figure 9.4; Appendix Table HLSU.17). One fish each had ovary and muscle selenium concentrations greater than the normal range at UNWNMO in 2015. NRQs were calculated by dividing the maximum concentrations observed for each LSU tissue in each area by the respective upper normal range limit (Appendix Table HLSU.18). NRQs were near or above one for muscle and whole body samples at the reference area and at all seven mine-exposed areas. However, ovary selenium concentrations were within the normal range at the reference area and at ERUP and UNWNMO, near the upper end of the normal range at ELWDGC and MIWW, and greater than the normal range at GO13 and STPD.

The LSU tissue selenium concentrations observed in 2015 were generally consistent with those observed in previous years in terms of being greater than the reference area normal ranges in most mine-exposed areas (Figure 9.4).

A Spearman correlation between LSU health endpoints and tissue selenium concentrations identified significant correlations between whole body selenium concentrations and both fish length and body weight, but correlation coefficients were low ($r \leq |0.32|$), indicating that selenium explained little of the variance in fish size (Appendix Table HLSU.20; Appendix Figure HLSU.12). No relationships were found between ovary or muscle selenium concentrations and the various fish health measurements. No significant correlations were detected between tissue selenium concentrations and condition factor, gonadosomatic index or liversomatic index.

9.4.3 Comparisons to Site-Specific Benchmarks

Ovary and muscle selenium concentrations were above site-specific Level 1 benchmarks for all LSU captured at Goddard Marsh (GO13), for some LSU captured at the Elk River wetland downstream from Grave Creek (ELWDGC), and at Stanford Pond (STPD) in 2015 (Figure 9.4; Appendix Table HLSU.17). Whole body selenium concentrations exceeded the BC guideline of 4 µg/g dw for all LSU captured at UNWNMO, ELWDGC, OTTO, MIWW, and STPD even though most or all muscle and ovary selenium concentrations were less than respective site-specific

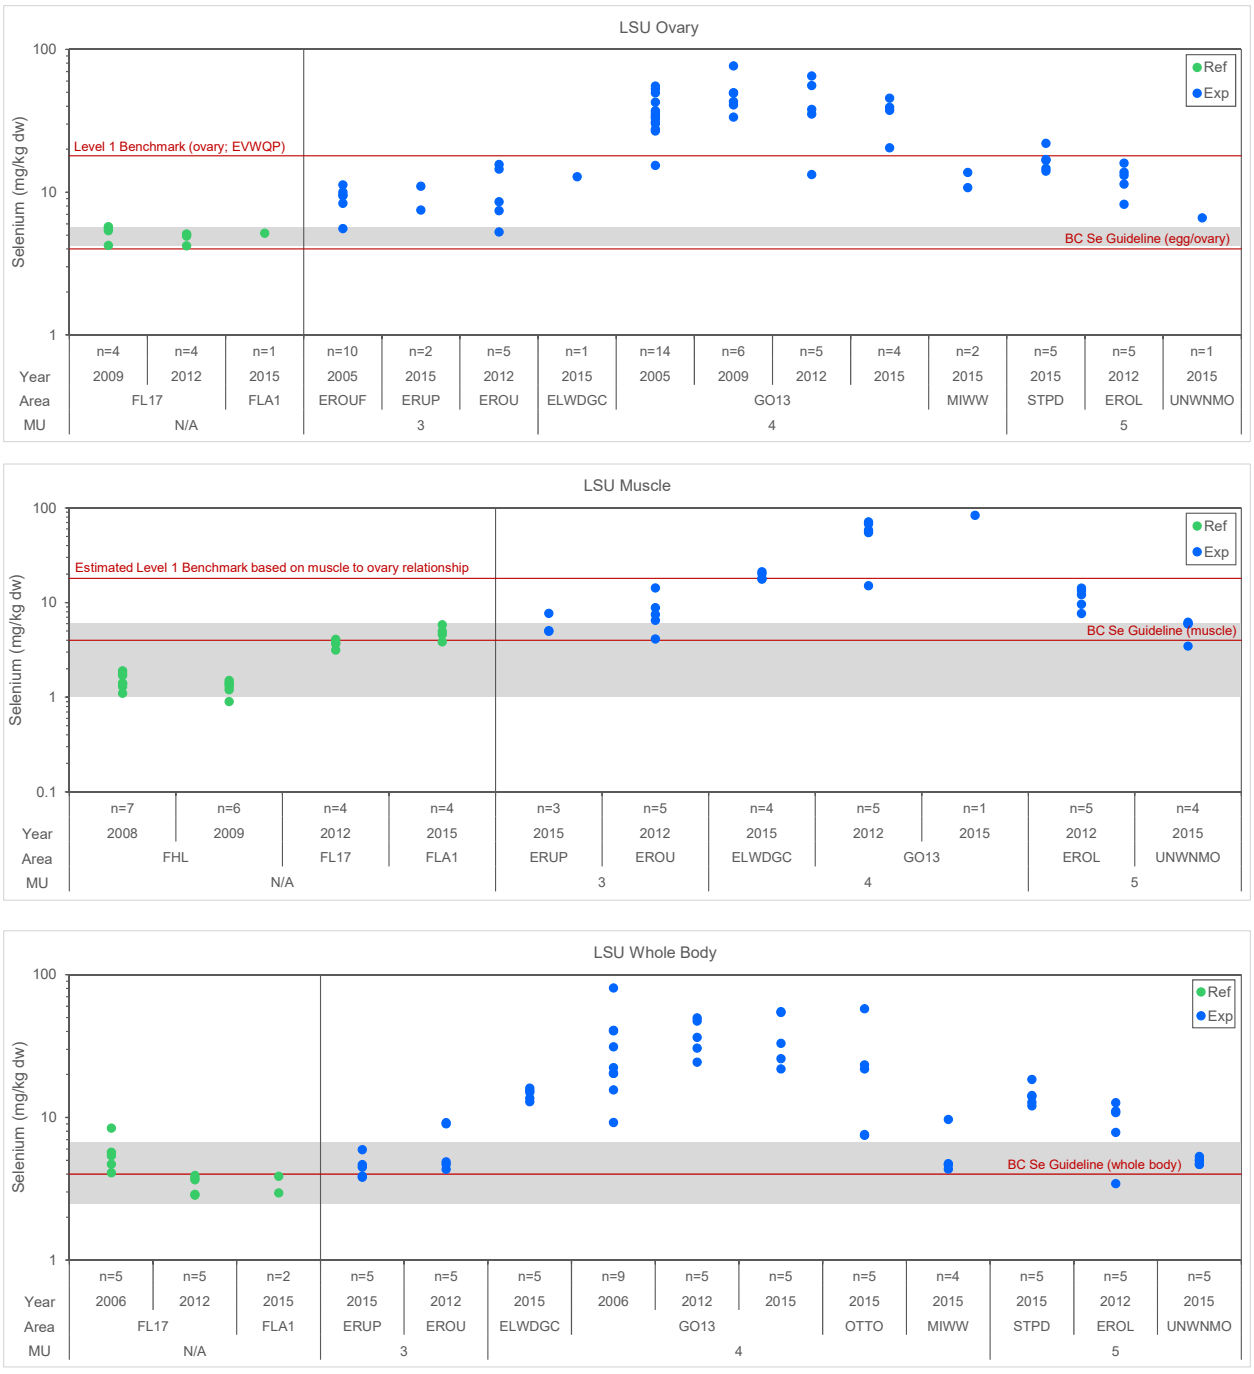

Figure 9.4: Selenium Concentrations in Longnose Sucker Ovary, Muscle, and Whole Body Samples Collected 2005 – 2015

Notes: Shaded region represents the reference area normal range

benchmarks in the areas where muscle and ovary selenium concentrations were also measured in 2015 (Appendix Table HLSU.17). Eggs/ovaries are considered the most relevant tissue type for evaluating the potential for reproductive effects (USEPA 2012).

The LSU tissue selenium concentrations observed in 2015 were generally consistent with those observed in previous years in terms of concentrations being most elevated compared to the Level 1 tissue benchmarks at GO13. Elevated whole body selenium concentrations were also observed at OTTO in 2015, but ovary or muscle selenium data, which would provide a better estimation of potential risk for reproductive effects, are currently lacking for this area (Figure 9.4).

9.4.4 Temporal Changes

Potential changes over time were evaluated for areas having at least three years of LSU tissue data using ANOVA or Kruskal-Wallis tests followed by *post hoc* pairwise comparisons (Appendix Table HLSU.19; Appendix Figure HLSU.11). The only significant difference detected was for the Flathead wetland reference area, where the mean whole body selenium concentration was slightly lower in both 2012 and 2015 (3-4 mg/kg dw) than in 2006 (5 mg/kg dw). There were no differences among years for mine-exposed areas.

9.5 Summary

Two reference and ten mine-exposed areas were sampled in May 2015 for evaluation of density, population size, morphometrics, and tissue selenium concentrations. Although not stipulated in the study design (Minnow 2015a), selected areas were revisited in September 2015, to determine if the timing of sampling affects catch success and population estimates.

LSU population estimates varied widely among the twelve study areas in May 2015. Largest population sizes were estimated for Goddard Marsh (GO13), Otto Ponds (OTTO) and Stanford Pond (STPD), where populations were greater than at the reference area. Confidence limits for the LSU population estimates were wide, especially in May. LSU population estimates were not consistent between May and September 2015; however, narrower confidence limits were obtained using September data.

Mean fork length and body weight were significantly lower for LSU captured at OTTO and STPD than at the reference area. Based on input from the EMC, evaluation of potential changes over time focused on LSU condition. Increases in condition were observed at three of six areas in 2015 compared to earlier years but the changes were small (<10%) and comparable in magnitude between the reference area and the two mine-exposed areas where the increases were observed.

All LSU captured in six of eight mine-exposed areas where tissues were collected had tissue selenium concentrations greater than the tissue-specific reference normal ranges. The exceptions were the most northerly mine-exposed area, Elk River upper ponds (ERUP) and the unnamed wetland near Morrissey (UNWNMO), where ovary selenium concentrations (2 of 2 at

ERUP and 1 of 1 at UNWNMO) and one muscle selenium concentration (of 3 at ERUP and 4 at UNWNMO) exceeded the normal range in each area, but not whole body selenium concentrations (n=5 in both areas). Ovary and muscle selenium concentrations were also above site-specific Level 1 benchmarks for all LSU captured at Goddard Marsh (GO13) and for some of the LSU captured at the Elk River wetland downstream from Grave Creek (ELWDGC) and at Stanford Pond (STPD).

10 WESTSLOPE CUTTHROAT TROUT

10.1 Overview

Westslope cutthroat trout (WCT) are widely distributed throughout the watershed and are the only fish present in the Fording River upstream of Josephine Falls. Josephine Falls has prevented upstream movement of fish, which has protected the population upstream from the falls from hybridization with non-native rainbow trout (and competition with non-native species in general). Consequently, the upper Fording River population is considered to be one of a limited number of populations that remains genetically pure, thus making it important in the context of WCT conservation (Cope et al. 2016). In 2010, the Province of British Columbia closed the upper Fording River to angling due to uncertainty regarding the WCT population status.

Fish population monitoring requires multiple years of study to understand and quantify basic population characteristics sufficiently to then monitor potential changes over time relative to stressors (e.g., mining, angling, extreme weather events, water chemistry, and habitat fragmentation). A three-year study (40 months of 2012 - 2015) was recently completed to determine if the upper Fording watershed WCT population is healthy, robust and sustainable, and to assess movement and critical habitat to help inform fish habitat management decisions (Cope et al. 2016). Results of the study are summarized in Section 10.2.

WCT muscle samples were collected non-lethally from main stem areas of the watershed in 2015 as part of the RAEMP to evaluate tissue selenium concentrations relative to predictions, normal ranges, and site-specific effect benchmarks developed in the EVWQP (Teck 2014). Representative photographs of WCT sampling in the Elk River watershed are shown in Photo 10.1. Sampling areas are shown in Figure 10.1.

10.2 Upper Fording River WCT

A 40-month study by Cope et al. (2016), completed in 2012 to 2015, employed a review of previous studies within the upper Fording River in combination with field methods that included telemetric methods, snorkel mark-recapture, Floy and PIT (Passive Integrated transponder) tag mark-recapture, juvenile density estimates (representative closed-station removal-depletion locations), and habitat mapping (review of high resolution [10 cm] aerial photography and ground-truthing). These methods characterized the fluvial population of WCT and their habitat within the upper Fording River watershed in terms of abundance, genetic differentiation, mortality rates, condition factors, age class structure, growth rates, life history strategies (home ranges, movement patterns and seasonal distribution by life stage), and habitat (available and critical [e.g., over-wintering, rearing, spawning and migration corridors]).

The use of telemetric methods confirmed both resident and migratory life history forms of WCT within the upper Fording River population. The study concluded that the upper Fording River population metrics of sub-adult and adult abundance (2,552 to 3,874 fish > 200 mm fork length), habitat availability (57.5 km of main stem river plus approximately 59 km of tributary habitat), and genetic integrity (pure strain) represent a viable WCT population. Population characteristics such as condition factor (weight to length relationships), growth rates, von Bertalanffy growth model estimates and population age structure indicate the population appears to be in good condition and robust, compared to similar upper Kootenay River populations.

Continued monitoring and evaluation were recommended to address outstanding statistical uncertainties and perceived threats to population resilience and sustainability. Plans to address some of the identified threats are being developed by Teck in collaboration with the Elk Valley Fish and Fish Habitat Committee and the EMC (i.e., Regional Fish Habitat Management Plan, Regional Offsetting Strategy, EVWQP, Tributary Evaluation, and Management Plan). In 2016, habitat rehabilitation (offsetting) measures were constructed to address some of the identified threats and additional offsetting measures are planned to be constructed over the next five years. Snorkel surveys of sub-adults and adults, as well as 3-pass closed-station electrofishing removal-depletion of fry and juveniles will occur in 2017, 2019, and 2021 to monitor trends in population characteristics.

10.3 Tissue Selenium

10.3.1 Comparison to Predictions

WCT tissue selenium concentrations measured in 2015 were compared to predictions derived from water modelling (Golder 2014a,b) and tissue bioaccumulation models developed for the EVWQP (Teck 2014). All observed concentrations were less than predicted mean concentrations (Table 10.1).

10.3.2 Comparisons to Normal Reference Ranges

WCT muscle samples collected in reference areas since 1996 were combined (n=210 samples) to characterize the reference normal range (Appendix Table HWCT.4; Appendix Figure HWCT.1). The upper limit of the normal range was defined as 5.98 mg/kg dw. All 90 WCT muscle samples collected in 2015 had selenium concentrations near or exceeding the upper normal range limit as reflected by NRQs of 0.7 or more (Table 10.2). Spearman correlations between WCT health endpoints and tissue Se concentrations did not identify any significant correlations (Appendix Table HWCT.7).

10.3.3 Comparisons to Site-Specific Benchmarks

All WCT muscle samples collected from lotic main stem areas in May or August 2015 (i.e., total of 80 samples) were less than the Level 1 benchmark for reproductive effects, as were most samples (98%) collected in three-year monitoring cycles beginning in 2006 (Figure 10.2). The results indicate low potential for reproductive effects of selenium to WCT.

The only lentic area where WCT muscle samples were collected in 2015 was Henretta Lake (MU1), where one of five fish had a muscle selenium concentration slightly greater than the Level 1 benchmark. WCT samples collected historically in lentic areas typically had concentrations less than the Level 1 benchmark, except at the Fording River Oxbow (FO10), where fish have not been sampled since 2009 and which was transformed from a lentic habitat to a lotic habitat during the record flood in June 2013. Selenium concentrations in benthic invertebrates collected at FO10 have been much lower since the flood (e.g., 7.1 mg/kg dw in 2015 compared to ≥ 28 mg/kg dw in 2006 to 2012; Minnow et al. 2011, Minnow 2014a), which is consistent with the expected behaviour of selenium in lotic versus lentic habitats (Figure 8.10).

10.3.4 Temporal Changes

Potential changes in WCT tissue selenium concentrations over time were evaluated using ANOVA followed by *post hoc* pairwise comparisons among years (Appendix Tables HWCT.8 and HWCT.9). Of all the areas sampled in 2015, differences among years were evident only for

Good (Quotient < 0.7)
Marginal (Quotient between 0.7 and 1.0)
Poor (Quotient > 1.0)

[a] Quotient was calculated as the tissue selenium concentration divided by the upper limit of the normal range (97.5th percentile of reference area selenium concentrations)

[b] Hazard quotient was caclulated as ovary selenium concentration divided by 15.5 mg/kg, derived from Level 1 egg/ovary benchmark (Golder 2014c) and converting to muscle equivalent value based on ovary-muscle relationship (Nautilus and Interior Reforestation, 2011)

[c] LER-WCT-05 lost during freeze drying.

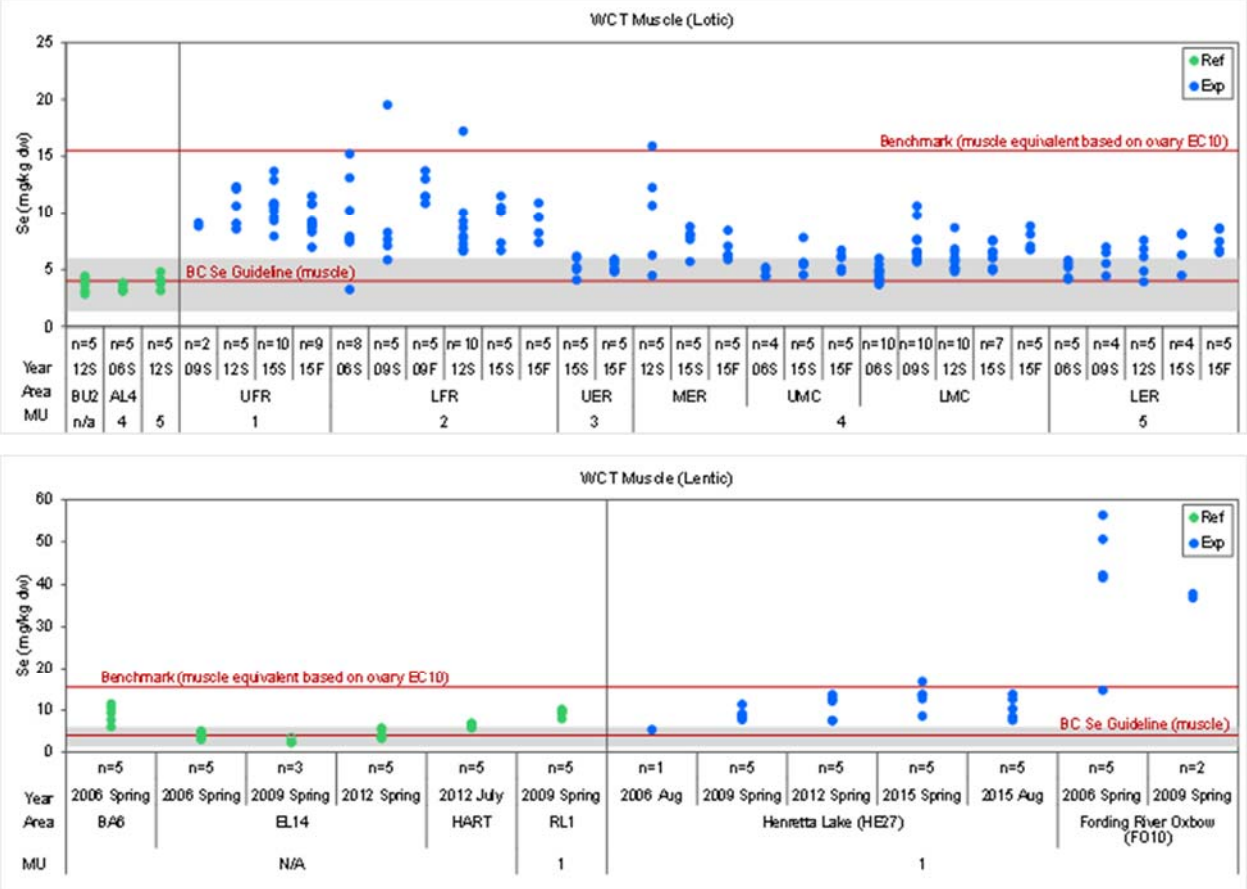

Figure 10.2: Selenium Concentrations in Westslope Cutthroat Trout Muscle Samples Collected in Lotic and Lentic Habitats, 2006 - 2015

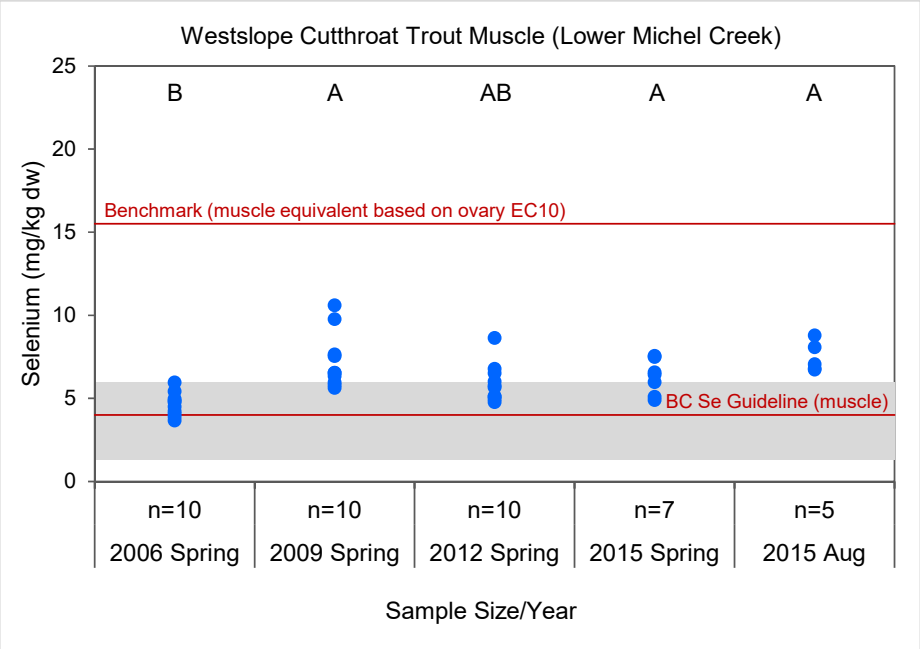
Notes: Shading represents Normal Range. The first two digits of the year were truncated for plotting purposes; S = Spring (i.e. April – June) and F = Fall (August and September); UFR = Upper Fording River; LFR = Lower Fording River; UER = Upper Elk River; MER = Middle Elk River; UMC = Upper Michel Creek; LMC = Lower Michel Creek; LER = Lower Elk River. Concentrations reported below the LRL are plotted as open symbols at the LRL.

lower Michel Creek and the lower Elk River (Figure 10.3; Appendix Figure HWCT.2). Muscle selenium concentrations in lower Michel Creek were variable over time, and did not indicate a trend. Concentrations in WCT from the lower Elk River suggest a potential increasing trend that warrants further investigation.

10.4 Summary

A four-year study (2012 - 2015, inclusive) by Cope et al. (2016) characterized the fluvial population of WCT and their habitat within the upper Fording River watershed. The use of telemetric methods confirmed both resident and migratory life history forms of WCT within the



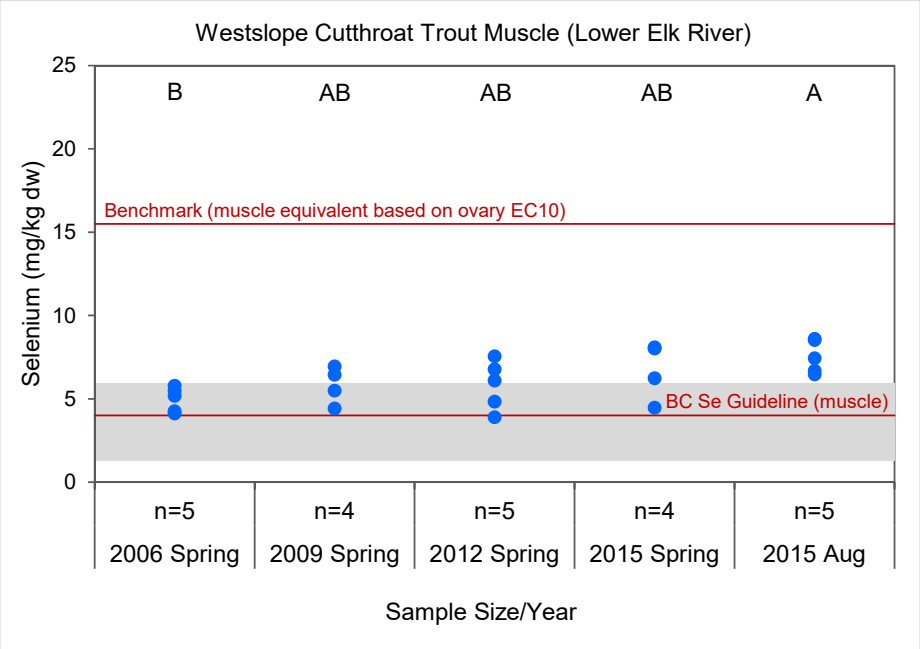


Figure 10.3: Areas with Significant Changes in Westslope Cutthroat Trout Muscle Selenium Concentration Over Time

Notes: time periods that do not share a letter are significantly different (p-value < 0.1)

upper Fording River population. The study concluded that the upper Fording River population metrics of sub-adult and adult abundance (2,552 to 3,874 fish > 200 mm fork length), habitat availability (57.5 km of main stem river plus approximately 59 km of tributary habitat), and

genetic integrity (pure strain) represent a viable WCT population. Population characteristics such as condition factor (weight to length relationships), growth rates, von Bertalanffy growth model estimates, and population age structure indicate the population appears to be in good condition and robust compared to similar upper Kootenay River populations.

WCT muscle samples were collected non-lethally from main stem areas of the watershed in May and August 2015 to evaluate tissue selenium concentrations relative to predictions, normal ranges, and site-specific effect benchmarks developed in the EVWQP. Although all 90 fish had concentrations near or above the normal range for reference area fish, only one muscle sample (from one of the 10 fish collected in Henretta Lake), exceeded the Level 1 benchmark for reproductive effects. Tissue selenium concentrations were also within prediction intervals derived from water quality and tissue selenium bioaccumulation models developed in the EVWQP.

11 MOUNTAIN WHITEFISH TISSUE SELENIUM

11.1 Overview

Mountain whitefish (*Prosopium williamsoni)* is a species native to the Elk River basin, where it is found mainly along the main stem of the Elk River and in lower reaches of larger tributaries such as the Fording River, Line Creek, Alexander Creek, and Michel Creek (Photo 11.1; Wilkinson 2009, Interior Reforestation 2011). Mountain whitefish is an important species to recreational and subsistence fishers in the Elk River valley. As such, whitefish were sampled as part of the RAEMP mainly to support evaluation of human health risks related to whitefish consumption (evaluated outside of the RAEMP; Ramboll Environ 2016). Tissue selenium concentrations were also evaluated relative to normal ranges and Level 1 benchmarks from the EVWQP.

A photograph of a mountain whitefish collected in the Elk River watershed is shown in Photo 11.1. Figure 11.1 depicts the sampling areas for mountain whitefish in 2015.

11.2 Comparisons to Normal Reference Ranges

Tissue samples collected in reference areas since 2008 were combined to characterize the reference normal ranges for muscle (n=72) and ovary (n=31) selenium concentrations (Appendix Tables HMW.2 and HMW.3; Appendix Figure HMW.1). Selenium concentrations were greater than the reference area normal range for 12 of 20 (60%) muscle samples and 2 of 20 (15%) ovary samples collected in mine-exposed areas of the Elk River, lower Fording River, and lower Michel Creek in 2015 (Figure 11.2; Appendix Table HMW.4 and HMW.5).

Compared to most other fish species, mountain whitefish collected throughout the Elk River watershed have unusually high selenium concentrations in eggs/ovaries relative to muscle concentrations (Table 11.1). On average, selenium concentrations in MW ovaries are about 7 times those in muscle, although there is considerable variability in the relationship (Figure 11.3). In most other fish species, ovary selenium concentrations are 1 to 2 times those in muscle.

Spearman correlations between MW health endpoints and tissue selenium concentrations identified a number of significant correlations (Appendix Table HMW.6; Appendix Figure HMW.2 and HMW.3). Ovary and muscle selenium concentrations both correlated with mountain whitefish length and body weight, but not condition factor or gonadosomatic index (Appendix Table HMW.6). Muscle selenium concentrations also correlated with liversomatic index. This may be because whitefish captured in mine-exposed areas, where selenium exposure was higher, were also slightly longer and heavier, on average (Appendix Figures HMW.2 and HMW.3).

11.3 Comparisons to Site-Specific Benchmarks

A site-specific study of selenium effects to mountain whitefish estimated the effect threshold for selenium to be 29.3 mg/kg dw or higher in eggs/ovaries (Nautilus 2017). Ovary selenium concentrations were greater than the BC ovary selenium guideline among most reference and mine-exposed mountain whitefish, and 6 of the 20 (30%) individual mine-exposed whitefish (from lower Michel Creek and the lower Elk River in 2015) had ovary selenium concentrations greater than the lower bound of the estimated effect threshold for this species (Figure 11.2; Table 11.2; Appendix Table HMW.4). Highest whitefish ovary selenium concentrations were observed in 2006 and 2009 when sampling was completed in late August or early September, instead of in October (2012, 2015). The effects of sample timing on tissue selenium concentrations are discussed further in Section 11.4.

For LSU and WCT, ovary selenium benchmarks could be converted to an equivalent benchmark for muscle samples based on strong relationships between muscle and ovary selenium concentrations, but this was not done for whitefish due to the high variability in the relationship

Good (Quotient < 0.7)
Marginal (Quotient between 0.7 and 1.0)
Poor (Quotient > 1.0)

[a] Quotient was calculated as the tissue selenium concentration divided by the upper limit of the normal range (97.5 th percentile of reference area concentrations)
[b] Hazard quotient was calculated as the tissue selenium concentration divided the site-specific benchmark of 29.3 mg/kg, a conservative estimate of lower bound for potential effects (Nautilus 2017)

shown in Figure 11.3. Therefore, mountain whitefish muscle values were compared only to the BC guideline for selenium in fish muscle. Most mountain whitefish captured in mine-exposed areas (20 of 26 = 77%) had muscle selenium concentrations greater than the BC guideline of 4 mg/kg dw, whereas most whitefish collected in reference areas (21 of 22 = 95%) had muscle selenium concentrations below the guideline (Figure 11.2; Table 11.2). Ovary selenium concentrations measured in pre-spawning fish are more relevant for interpreting potential reproductive effects than muscle, when data for both tissue types are available.

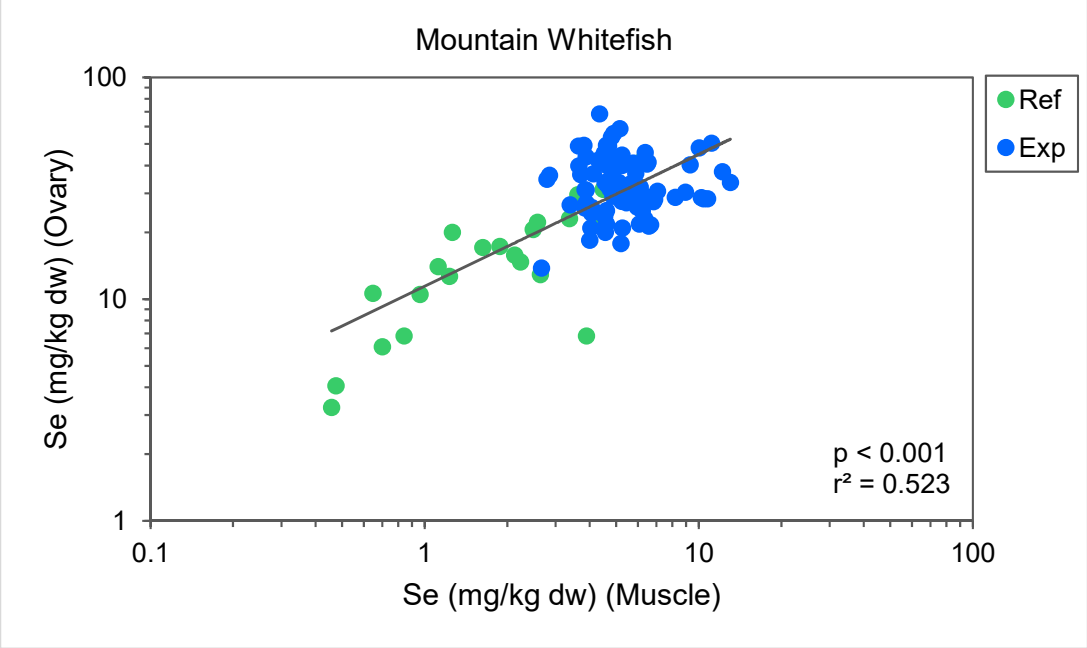

Figure 11.3: Scatterplot and Linear Regressions of Selenium Concentrations in Ovary Versus Selenium Concentrations in Muscle for Mountain Whitefish (2006 - 2015)

11.4 Temporal Changes

Monitoring of mountain whitefish in 2006 and 2009 was completed in August/September (pre-spawning) and yielded numerous female whitefish with egg/ovary selenium concentrations more than the site-specific effect threshold of 29.3 mg/kg dw, with a maximum egg/ovary selenium concentration of 68.4 mg/kg dw (Minnow et al. 2007, 2011) (Figure 11.4). In the site-specific study in which the reproductive effects of selenium to mountain whitefish were evaluated, the fish were sampled in late October and early November (2010, 2011, and 2013), closer to spawning, yielding a maximum egg/ovary selenium concentration of 33.2 mg/kg dw (Nautilus 2017). This suggests a potential shift in whitefish diet or selenium metabolism in the months approaching spawning that affects ovary selenium concentrations. To ensure

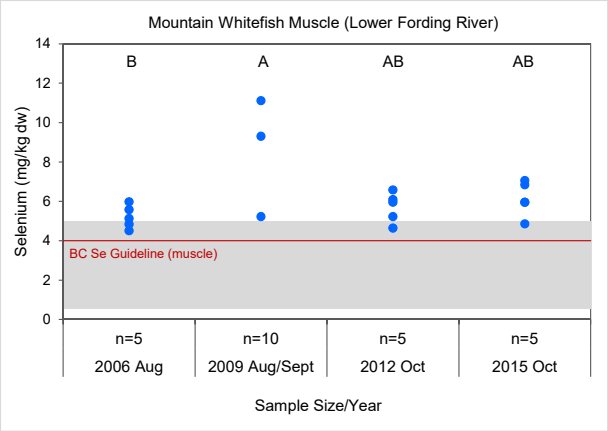
monitoring data were more representative of potential reproductive effects associated with selenium, mountain whitefish samples were collected in October for the 2012 and 2015 regional monitoring cycles. The concentrations observed in October sampling (2012, 2015) were significantly lower than those collected in August/September in earlier study years (2006, 2009; Appendix Figure HMW.4).

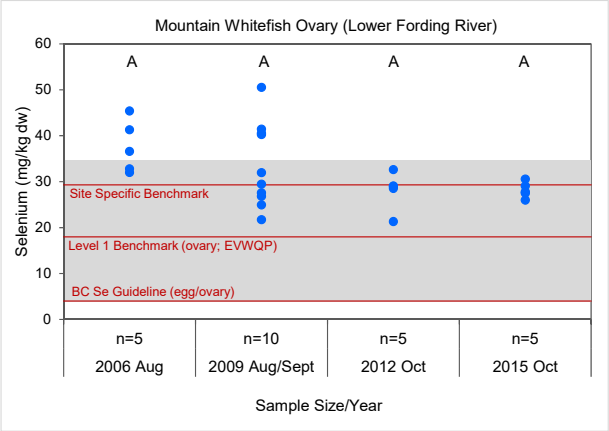
Muscle and ovary samples from mountain whitefish captured in the lower Fording River in 2015 did not differ from previous years (Figure 11.4). Whitefish collected in lower Michel Creek have had variable tissue selenium concentrations over time, with levels observed in 2015 being similar to those in 2012 and 2006. Mountain whitefish captured in the lower Elk River in 2015 also had similar selenium concentrations to those observed in 2012, but muscle selenium concentrations in 2015 were higher, and ovary selenium concentrations were lower, than those observed in 2006. At all areas, ovary selenium concentrations were significantly lower in 2012 and/or 2015 compared to 2006 and/or 2009, which is likely related to samples being collected later in the year in 2012 and 2015, as described above.

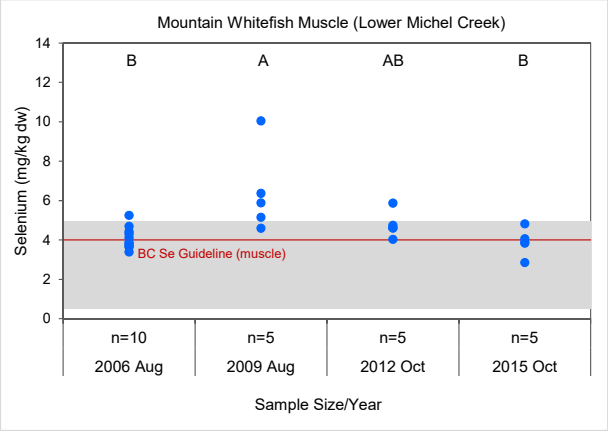
11.5 Summary

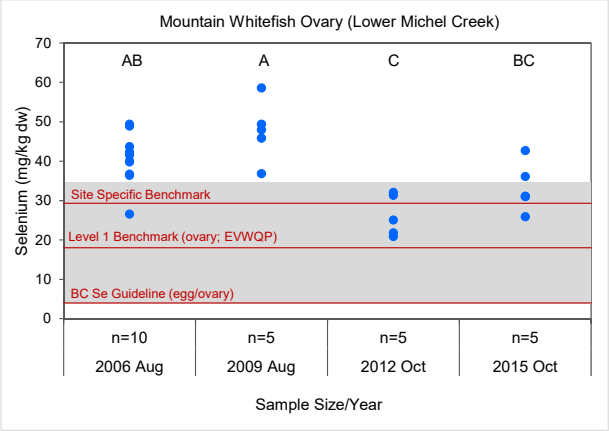
Selenium concentrations in mountain whitefish were greater than the reference area normal range for 12 of 20 (60%) of muscle samples and 2 of 20 (15%) ovary samples collected in mine-exposed areas of the Elk River, lower Fording River, and lower Michel Creek in 2015. Ovary selenium concentrations were greater than the BC ovary selenium guideline among most reference and mine-exposed mountain whitefish, and 6 of the 20 (30%) individual mine-exposed whitefish captured (from lower Michel Creek and the lower Elk River) had ovary selenium concentrations greater than the estimated lower bound of the effect threshold for this species (29.3 mg/kg dw).

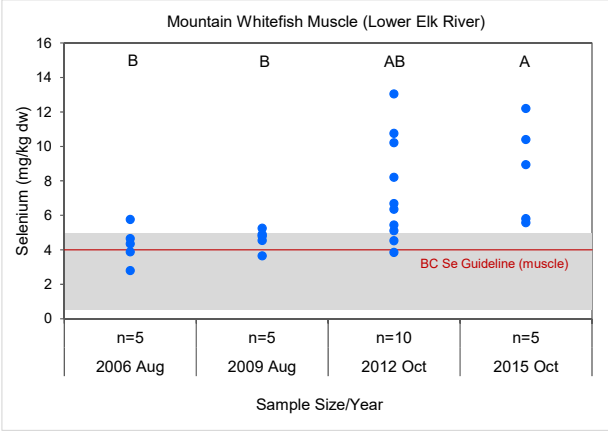
Mountain whitefish have unusually high egg/ovary selenium concentrations relative to muscle compared to other fish species. On average, mountain whitefish ovary selenium concentrations are about 7 times those in muscle, whereas in most other fish species, ovary selenium concentrations are 1 to 2 times those in muscle. Monitoring data since 2006 show that whitefish ovary selenium concentrations tend to be higher in late August or early September than in October, closer to spawning. Therefore, the timing of monitoring was shifted from August-September (2006, 2009) to October (2012, 2015). Ovary samples collected in October 2015 had similar selenium concentrations to those collected in October 2012.











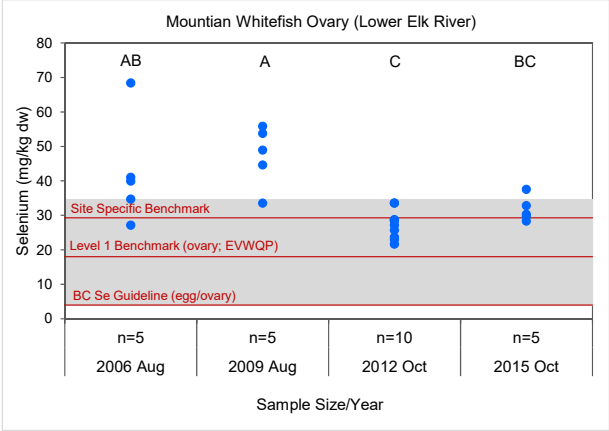


Figure 11.4: Boxplot/Individual Value Plot for Selenium Concentrations in Muscle and Ovary of Mountain Whitefish Over Time

Notes: time periods that do not share a letter are significantly different (p-value < 0.1). Results of statistical comparisons are in Appendix Table HMW.5.

12 MANAGEMENT UNIT EVALUATIONS

12.1 Overview

This section summarizes and evaluates the data to address the original questions posed in the RAEMP study design (Minnow 2015a), and presented in Section 1.3.2, above. The evaluation focuses mainly on the questions related to identifying the portions of the watershed that have been influenced by mining, where effects have occurred, and how conditions have been changing over time. The questions were addressed separately for each of MU1 through MU5. MU6 consists of the Canadian portion of Koocanusa Reservoir, which was evaluated as part of a separate program (Minnow 2018; Appendix J). The main objective of the first cycle (2014 to 2016) of monitoring in Koocanusa Reservoir was to assess conditions near and downstream from the Elk River compared to upstream, to identify differences that may be attributable to influences from the Elk River. Results from the 2014 to 2016 study will also serve as baseline relative to which future changes can be measured. Since the program was not designed to answer the same questions as the RAEMP, the evaluation of data for MU6 within this section simply provides a summary of the findings from the 2014 to 2016 study.

The integrated interpretation presented for each MU (below) compiles the information used to answer the original RAEMP study design questions, to present an overview of the conditions within each MU. The future approach to integrated evaluation of data is currently being discussed with the EMC. It is anticipated that a systematic weight of evidence (WOE) approach will be implemented to provide a clearer link between results, triggers for biological monitoring (currently under development) and adaptive management. The WOE approach will be structured to answer the following revised RAEMP study design questions:

1. Has there been a change in condition since previous monitoring cycle(s), or over time, with respect to fish and benthic invertebrate population/community indicators, water quality, sediment quality, calcite, and/or tissue selenium concentrations?
2. Were the changes identified in Question 1 unexpected (i.e., inconsistent with model predictions or general expectations[36])?
3. Does the weight of evidence indicate the unexpected changes are mine-related?

[36] "General expectations" may include predictions that were presented in approved plans in a narrative or semi-quantitative form. General expectations also include biological characteristics that are considered to be consistent with expectations based on observed chemical concentrations and calcite conditions relative to site-specific effect benchmarks.

4. Does the weight of evidence indicate current or future[37] mine-related effects to the aquatic ecosystem that are of concern, considering the observed type, magnitude, spatial extent, and rate of change?

It is anticipated that the WOE approach to integrated evaluation will be finalized prior to completion of the next cycle of the RAEMP (i.e., before September 2020), such that results/findings can be presented accordingly.

This section has numerous large figures (maps) and tables relative to the amount of text. To minimize disruption for readers, the maps showing lotic and lentic sampling areas within each MU, and data tables summarizing monitoring results for each MU, are all presented at the end of Section 12. Data included in the summary tables are mainly from 2015[38], except in temporal evaluations which included historical data and data from 2016, if available, as presented in previous sections of this report.

12.2 Management Unit 1 – Upper Fording River

12.2.1 Mine-Related Chemical and Physical Changes in Comparison to Normal Reference Ranges

12.2.1.1 Lotic Habitats

Monitoring in MU1 includes areas along the main stem Fording River, as well as numerous tributaries (Figure 12.1). Aqueous concentrations of one or more of the key mine-related constituents were elevated above the normal reference area ranges in all lotic, mine-exposed, main stem and tributary areas of MU1 (i.e., NRQs > 1; Table 12.1). Of all mine-exposed main stem and tributary areas, LCO Dry Creek had the lowest NRQs, consistent with the relatively early stages of mine development in the upper portion of that watershed. Nitrate concentrations at the upper Henretta Creek (FR_HC3) reference area were at or slightly greater than the upper normal range limit in all months of 2015 with the highest monthly mean concentration being observed in June (NRQ of 1.3) (Appendix Table C.18). By definition, 2.5% of values among reference areas will exceed the upper limit of the reference normal range (97.5th percentile) in each month.

Highest NRQs for water quality were in tributaries, especially Kilmarnock, Swift, and Cataract creeks. Calcite index values greater than the normal range were observed in the same three tributaries, as well as Porter and Greenhills creeks, and in the Fording River between Swift and

[37] Although the monitoring data reflect existing conditions, evaluation of trends may indicate a pattern of unexpected degradation indicative of potential future concern.

[38] Some exceptions are noted on the tables.

Porter creeks. No calcite was observed in LCO Dry Creek. Tissue selenium concentrations were close to or exceeded the normal range limits for benthic invertebrates and westslope cutthroat trout muscle at all mine-exposed areas.

Overall, the data showed widespread chemical and physical changes in the aquatic ecosystem of MU1 relative to reference conditions (the latter being presumed to approximate pre-mining conditions).

12.2.1.2 Lentic Habitats

Two reference and five mine-exposed lentic areas were sampled in MU1 (Figure 12.1; Table 12.2). Varying degrees of mine-related disturbance were observed among the mine-exposed lentic areas (Table 12.2). NRQs greater than one for selenium and PAHs in sediment collected at reference area Lake Mountain Lake (LML) indicated that concentrations of these substances in sediment are naturally high in some areas of the watershed[39]. Slightly elevated PAHs in sediment at FOXL may also be natural, because all other data collected in that area resulted in NRQs < 1 (i.e., FOXL is located downstream from mining but appears not to be hydrologically connected to the Fording River). However, mine-related influence was evident at lentic areas FWDEC (downstream from Ewin Creek) and R5-1 (downstream from Greenhills Creek), based on NRQs > 1 for selenium in both sediment and benthic invertebrate samples and concentrations greater than those observed at LML. NRQs greater than one for selenium and sulphate in water and for selenium in benthic invertebrate tissues (Table 12.2) and WCT tissue at Henretta Lake (HE27; Table 10.2), also reflect mine influence.

FMUCK is an area of the main stem Fording River upstream from Chauncey Creek that is slower flowing, deeper, and has finer sediments than other areas of the Fording River, so data from this location were tabulated with lentic areas. FMUCK had NRQs > 1 for aqueous nitrate, selenium, and sulphate, consistent with other lotic habitats of the Fording River (indicating concentrations above normal reference ranges). Benthic invertebrate tissue selenium was also greater than the reference area normal range, but NRQs for sediment were less than one.

12.2.2 Comparisons to Predictions

Selenium and sulphate concentrations in water were greater than the modelled concentrations at the FRO Compliance Point (FR_FRCP1) in the Fording River in 2016 (Golder 2017a). The data indicated that water collected at this location during the winter low flow period is predominantly discharge from Cataract Creek, which explained the high concentrations of

[39] Lake Mountain Lake is on mine property upstream from mining. The lake is not accessible by road so it is not influenced by public use (i.e., motorized vehicles).

selenium and sulphate observed in winter samples. Nitrate concentrations at the FRO Compliance Point, as well as nitrate and sulphate concentrations at the GHO Fording River Compliance Point (GH_FR1) were considered to match the model predictions reasonably well. Selenium concentrations observed at the GHO Fording River Compliance Point were less than those estimated by the model (Golder 2017a). Tissue selenium concentrations in invertebrates and WCT were within predicted ranges (Tables 8.1 and 10.1). Therefore, concentrations of mine-related constituents in water and tissues in MU1 are generally consistent with expectations based on models developed in support of the EVWQP and based on SPOs and compliance limits established in Permit 107517.

12.2.3 Mine-Related Biological Effects

12.2.3.1 Lotic

Benthic invertebrate communities sampled in main stem areas of the Fording River in 2015 generally had characteristics within normal reference area ranges, except % Ephemeroptera (mayflies), which was reduced at sampling areas from Cataract Creek (FOBCP) to downstream from Chauncey Creek (FOUEW; Table 12.3; Figure 8.7). In the same portion of the Fording River, maximum monthly average HQs for water quality variables were greater than one for nitrate (with selenium and sulphate also exceeding HQs at one or more locations), and calcite index HQs were also near or greater than one, indicating potential for mine-related effects. Chronic toxicity tests completed on samples collected at the two Fording River Compliance Points in MU1 also provided some evidence of effects, although the results shown in Table 12.3 for *C. dubia* and *P. subcapitata* at FR_FRCP1 were from samples collected in the first quarter of 2015 when surface water at that location comes mainly from Cataract Creek (Golder 2016, 2017c).

A similar pattern of reduced % Ephemeroptera between Cataract Creek and Chauncey Creek was identified in the first (2016) cycle of the FRO LAEMP (Minnow 2017a). The LAEMP report also identified a potential pattern of decreasing benthic invertebrate abundance and % EPT over time among areas in the same section of the Fording River downstream from Kilmarnock Creek. The study concluded that elevated nitrate concentrations (but not as likely selenium or sulphate concentrations) may have contributed to the spatial pattern of decreasing % Ephemeroptera with distance downstream, but did not explain the apparent change in benthic invertebrate community structure over time. Conversely, increased temperature trends (and/or associated variation in annual flow regimes) were identified as potentially contributing to the temporal changes in community structure, but did not fully explain the spatial pattern of reduced % Ephemeroptera observed in the Fording River in 2016. Seasonal dewatering and/or calcite deposition in portions of the Fording River are additional factors potentially influencing benthic

invertebrate communities. In consideration of these findings, the FRO LAEMP design was adjusted to allow for further investigation of the cause(s) of benthic invertebrate community changes in September 2017 (Minnow 2017e).

Of tributaries in MU1, Kilmarnock (KICK), Swift (SWCK), Cataract (CATCK), Porter (POCK), and Greenhills Creek (GHCKU, GHCKD) were each associated with benthic invertebrate communities having % EPT and % Ephemeroptera less than reference area normal ranges in 2015. These areas also had HQs > 1 for two or more of the following: aqueous nitrate, selenium, and sulphate concentrations, calcite, and/or tissue selenium concentrations. Benthic invertebrate community data were not available for Clode Creek, which also had aqueous nitrate and selenium concentrations greater than the respective benchmarks in most months in 2015. These tributaries have been heavily influenced by historical mining, and at least 30% of each creek has been permanently altered or destroyed (Minnow 2016e).

Of all four reference and 25 mine-exposed tributary and main stem areas in MU1, a total of three (10%; mine-exposed) areas had benthic invertebrate community total abundance and taxa richness outside of normal reference area ranges. Two areas, Kilmarnock and Greenhills Creek, had abundance less than the normal range and Cataract Creek had taxa richness less than normal range.

At least one sample each from Swift and Cataract creeks resulted in acute toxicity to *Daphnia magna* in 2015 (Table 4.1; Appendix Table C.18), which may have been due to effects of precipitate formation within the laboratory test vessels (see Section 4). Henretta Creek, Kilmarnock Creek, Swift Creek, and Cataract Creek each contribute 5% or more of the nitrate, selenium, or sulphate loads to the watershed, with Kilmarnock being the single largest load source for all three constituents (Zajdlik and Minnow 2013). All water from Swift and Cataract, as well as a portion of the water from Kilmarnock, will be directed to a future AWTF that is expected to reduce concentrations of nitrate and selenium in the Fording River downstream from Kilmarnock Creek.

Of 19 and 10 WCT muscle samples collected in lotic and lentic areas of MU1 in 2015, only one fish from the lentic area (Henretta Lake) had a tissue selenium concentration slightly over the EVWQP Level 1 benchmark (HQ > 1) (=3% of all fish).

A four-year study (2012 - 2015, inclusive) by Cope et al. (2016) characterized the fluvial population of WCT and their habitat within the upper Fording River watershed. The use of telemetric methods confirmed both resident and migratory life history forms of WCT within the upper Fording River population. The study concluded that the upper Fording River population metrics of sub-adult and adult abundance (2,552 to 3,874 fish > 200 mm fork length), habitat availability (57.5 km of main stem river plus approximately 59 km of tributary habitat), and

genetic integrity (pure strain) represent a viable WCT population. Population characteristics such as condition factor (weight to length relationships), growth rates, von Bertalanffy growth model estimates, and population age structure indicate the population appears to be in good condition and robust compared to similar upper Kootenay River populations.

12.2.3.2 Lentic

Most lentic areas in MU1 had HQs < 1 for nitrate, sulphate, and selenium in water samples collected concurrently with other RAEMP samples in 2015 (Table 12.4). The exception was FMUCK on the main stem Fording River, where nitrate concentrations were consistent with other lotic habitats of the Fording River. HQs > 1 were also observed for sediment selenium and PAHs at FMUCK, even though NRQs were within normal reference area ranges (i.e., normal ranges exceed SQGs). Benthic invertebrate tissue selenium concentrations at FMUCK were at the Level 1 benchmark for effects to invertebrates, but slightly greater than the benchmark for effects to juvenile fish (Table 12.4).

Mine influence was also evident at lentic areas FWDEC (downstream from Ewin Creek), R5-1 (downstream from Greenhills Creek), and HE27 (Henretta Lake) based on elevated selenium concentrations in both sediment and benthic invertebrate samples. Sediment from R5-1, which had the highest concentrations of selenium and PAHs of lentic areas in MU1, had a toxic response in laboratory tests (Section 6.3). Sediment from reference area LML also had PAH concentrations greater than normal ranges and sediment quality guidelines, but was not toxic in laboratory tests. One of five WCT captured in Henretta Lake (HE27) in May 2015 had HQs > 1 for muscle and ovary selenium concentrations, but all other samples (n=5 muscle samples in both May and August) had concentrations less than Level 1 effect benchmarks (Table 10.2).

12.2.4 Changes over Time

There were many decreasing step changes or linear trends for nitrate and selenium among water monitoring stations in MU1 (Table 12.5). However, as noted in Section 3, this is usually the result of increasing trends in reference areas rather than decreases at mine-exposed areas. When temporal changes were evaluated without accounting for reference areas changes, most areas showed either no change over time or increasing concentrations. Only Swift Creek (GH_SC1 and GH_SC2) still showed decreases for nitrate and lower Lake Mountain Creek (FR_NGD1) and lower Greenhills Creek (GH_GH1) showed decreases for selenium (Appendix Tables C.36 and C.37).

Statistically significant increases in nitrate concentrations were observed at Clode Ponds decant (FR_CC1 99% after 2015) and upper LCO Dry Creek (LC-DC3 83% after 2015), whereas increases in selenium were observed at Kilmarnock Creek (FR_KC1 22% after 2012) and upper

Dry Creek stations LC_DC3 (38% after 2015) and LC_DCDS (27% after 2015). No significant increases in sulphate concentrations were observed over the period 2012 to 2016 (Table 12.5).

Significant increases in calcite deposition were observed at two locations in the main stem Fording River (FORD5 and SPSE1) and four tributaries (Clode, Kilmarnock, Swift, and Greenhills upstream of the settling pond; Table 12.5). The two main stem locations showing increasing temporal trends were separated by four other monitoring locations showing either no change over time, or a significant decrease (Table 12.5). All of the significant increases were due to step changes after 2013 or 2014, which may have been related to accumulation after the record flood event in 2013.

Significant reductions in % Ephemeroptera occurred relative to reference areas between 2012 and 2015 at main stem areas of the Fording River. This pattern extended about 12 km from downstream of Cataract Creek (FOBCP) to downstream from Chauncey Creek (FOUEW; Table 12.5; Figure 8.7) and was evaluated as part of the FRO LAEMP report (Minnow 2017a; results also summarized in the previous section). This change was not corroborated by increases in mine-related stressors over the same time period. As noted above, investigation will continue as part of the 2017 FRO LAEMP (Minnow 2017e).

A reduction in % Ephemeroptera was also identified in the Fording River downstream from Greenhills Creek after 2012 (FODGH; Table 12.5). However, the proportion of Ephemeroptera at FODGH in all study years was still within the reference normal range (Figure 8.7). Mine-related stressors at FODGH were less than site-specific benchmarks for water quality and tissue selenium concentrations and no temporal trends were detected that would account for the observed change since 2012.

A decrease in % EPT was evident in lower Swift Creek (SWCK; Table 12.5), but the analysis was based on only two years of data (2012 and 2015) which is not sufficient to confidently identify a temporal trend. This creek has been heavily influenced historically by mining (Minnow 2016e) and water from Swift Creek will be directed to an AWTF in the future.

No temporal changes were found for tissue selenium concentrations in benthic invertebrates. Most tributary and main stem locations within MU1 did not have any significant changes for benthic invertebrate total abundance or taxa richness.

Significant decreases in invertebrate abundance were identified for lower Cataract Creek (CATCK) and for Greenhills Creek upstream from the sediment pond (GHCKU), but the analysis was based on only two years of data (2012 and 2015) for both areas, which is not sufficient to confidently identify temporal trends. Both creeks have also been heavily influenced historically

by mining (Minnow 2016e). Water from Cataract Creek will also be directed to the future FRO AWTF.

Historical data were limited for evaluating temporal changes in lentic areas of MU1 (Table 12.6). Sediment chemistry at HE27 and FMUCK did not change between 2013 and 2015.

12.2.5 Integrated Interpretation

Conditions in MU1 in 2015-2016 were largely as expected based on the long history of mining, projections from the EVWQP and monitoring results. Most tributaries in MU1 have been both physically and chemically altered by mining (Minnow 2016e). The upper Fording River WCT population study (Cope et al. 2016) indicated that the fish are in good condition and the population is viable. This is an important finding because it suggests that mine-related effects on WCT are unlikely in other MUs where main stem concentrations of mine-related stressors are lower, and there is greater access to main stem and tributary habitats with minimal or no disturbance from mining. Teck continues to work with the Regional Fish and Fish Habitat Committee to identify, prioritize, and implement aquatic habitat improvements, with particular focus on MU1 where historical mining has had more effect on the amount and quality of tributary habitat than in other MUs. A Tributary Management Plan is also under development to protect or rehabilitate aquatic ecosystems in tributaries that flow into the Fording River, Michel Creek, and the Elk River (Teck 2017b).

The main, unexpected observation for MU1 was a reduction in the proportion of Ephemeroptera relative to normal reference area values over a distance of about 12 km of the Fording River main stem since 2012. Minnow (2017a) concluded that several factors (e.g., elevated nitrate concentrations increased temperature, variation in annual flow regimes, seasonal dewatering, and/or calcite deposition) may be influencing benthic invertebrate communities. In consideration of these findings, the FRO LAEMP design was adjusted to allow for further investigation of the cause(s) of benthic invertebrate community changes in September 2017 (Minnow 2017e).

Reduced % EPT at lower Swift Creek (GH_SC1 and GH_SC2), and reduced invertebrate abundance at lower Cataract Creek (GH_CC1) have no long-term ecological consequence, because water from these streams will be directed to the future FRO AWTF. Increasing selenium concentrations at Kilmarnock Creek (FR_KC1) will also be addressed by directing a portion of the flow to the future AWTF. Increasing concentrations of nitrate at Clode Ponds decant [FR_CC1] warrant on-going monitoring since concentrations of nitrate already exceed Level 1 benchmarks in much of the Fording River.

Twenty two of 25 mine-exposed tributary and main stem monitoring areas in MU had benthic invertebrate community total abundance and taxa richness within normal reference area ranges. Of 19 and 10 WCT muscle samples collected in lotic and lentic areas of MU1 in 2015, only one fish from the lentic area (Henretta Lake) had a tissue selenium concentration slightly over the EVWQP Level 1 benchmark (HQ > 1) (=3%).

Increasing nitrate and selenium concentrations in upper LCO Dry Creek [LC_DCDS, LC_DC3]) are the expected consequence of advancement of mining into that catchment based on the approved plan for LCOII. The concentrations of mine-related constituents in LCO Dry Creek remain well below levels of concern at the present time (Table 12.3, Minnow 2017c).

12.3 Management Unit 2 – Lower Fording River

12.3.1 Mine-Related Chemical and Physical Changes in Comparison to Normal Reference Ranges

12.3.1.1 Lotic

Monitoring in MU2 includes areas on the main stem Fording River and in two tributaries to the Fording River (Grace Creek [reference] and Line Creek [reference and mine-exposed]) (Figure 12.2). Aqueous concentrations of one or more of the key mine-related constituents were elevated above the normal reference area ranges in all lotic, mine-exposed, main stem and tributary areas of MU2 resulting in NRQs > 1 (Table 12.1). The maximum monthly mean for aqueous sulphate was also greater than the normal range at the upper Line Creek reference area (LI24). By definition, 2.5% of monthly means among reference areas will exceed reference normal ranges in each month. Tissue selenium concentrations were also above normal ranges in the lower Fording River (WCT and MW muscle) and in mine-exposed areas of Line Creek (benthic invertebrates). Calcite index values were within normal ranges at all areas. Overall, the data for MU2 indicated mine-related chemical changes in mine-exposed areas of Line Creek and the lower Fording River.

12.3.1.2 Lentic

A single mine-exposed lentic area was sampled in MU2, situated adjacent the Fording River downstream from Josephine Falls (R5-3; Figure 12.2). NRQs > 1 for aqueous nitrate, sulphate, and selenium were indicative of mine influence on water quality, as was the benthic invertebrate tissue selenium NRQ of 2.5 (Table 12.2). Selenium and PAH concentrations in sediment were within normal ranges (i.e., NRQs ≤ 1).

12.3.2 Comparisons to Predictions

Aqueous nitrate concentrations at the LCO Compliance Point in 2016 were greater than the modelled concentrations due to greater than anticipated loads from Line Creek upstream from West Line Creek (Golder 2017a). Observed aqueous selenium and sulphate concentrations at the LCO Compliance Point (LC_LCDSSLCC) corresponded reasonably well to model predictions, as did selenium, nitrate, and sulphate concentrations at the Order station in the lower Fording River (LC_LC5; Golder 2017a). Tissue selenium concentrations in invertebrates at LILC3 (LC_LC3) were near the predicted mean in 2015, but were well (130%) above the predicted mean in 2016 (Table 8.1). While the results were within the uncertainty bounds of the model in both years, the large increase in 2016 was unexpected. Tissue selenium predictions for invertebrates and WCT in the Fording River were consistent with model predictions (Tables 8.4 and 10.1). Overall, concentrations of mine-related constituents in water and tissues in MU2 were generally consistent with expectations based on models developed in support of the EVWQP, except for higher than anticipated aqueous nitrate and tissue selenium concentrations in Line Creek in 2016, the latter of which was due to the change in form of aqueous selenium (due to AWTF effluent) in Line Creek immediately downstream of the AWTF (more discussion below).

12.3.3 Mine-Related Biological Effects

12.3.3.1 Lotic

No effects to benthic invertebrates were evident at 6 of 9 monitoring areas in MU2 having invertebrate community data (Table 12.3). Strongest evidence of effects was at LILC3, located downstream from the Line Creek rock drain and the discharge from the West Line Creek AWTF, where proportions of EPT and Ephemeroptera were reduced relative to normal ranges. At this area, maximum monthly HQs for nitrate and selenium were greater than one, and values for both the invertebrate tissue selenium HQ and the calcite HQ were one (i.e., on the verge for potential effects). Water samples collected a bit farther downstream at the LCO Compliance Point provided some evidence of effects in laboratory toxicity tests with *C. dubia* and *P. subcapitata*, but based on evaluation of supporting data, it remained uncertain if these results indicated an adverse response or variance in test organism performance related to background water quality (Golder 2016). Benthic invertebrate community characteristics were within normal ranges at the LCO Compliance Point and in lower Line Creek (LI8), and invertebrate tissue selenium concentrations were within normal ranges in spite of a maximum monthly HQ > 1 for selenium in water (2015, prior to AWTF operation).

Of the three reference and six tributary and main stem monitoring areas in MU2, all had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges. All 10 WCT captured in MU2 in 2015 had muscle selenium concentrations less than the Level 1 benchmark for reproductive effects.

12.3.3.2 Lentic

At R5-3, HQs > 1 for nitrate and selenium in water, as well as selenium in sediment and benthic invertebrate tissues suggested potential for mine-related effects (Table 12.4). At reference area LCHO and mine-exposed area MI16 (in MU4; Table 12.4), HQs for selenium and PAHs in sediment were comparable or greater than those observed at R5-3 and did not cause toxicity in laboratory tests with standard invertebrate test species, suggesting sediment toxicity would not likely be observed at R5-3.

12.3.4 Changes over Time

A significant decrease in % Ephemeroptera occurred at the Fording River monitoring area downstream from Line Creek (FO23) after 2012 (perhaps associated with the record flood in 2013), but consecutive increases in 2015 and 2016, resulted in % Ephemeroptera being within the normal range in 2016 (Table 12.5).

Increasing temporal trends for calcite were observed at one location in Line Creek (in the vicinity of the AWTF discharge; LINE4), and one location in the Fording River (upstream of Line Creek; FORD4) (Table 12.5). Both were related to a significant step change after 2014, which may have been due accumulation after the record flood event in 2013. A slight increase in sulphate (15%) was also observed on Line Creek upstream of the AWTF outfall (Table 12.5), but concentrations remained below the site specific benchmark (Appendix Figure C.9).

Line Creek, including the discharge from West Line Creek, was previously identified as a major load source of mine-related constituents to the Fording River and the Elk River watershed overall (Zajdlik and Minnow 2013). The West Line Creek AWTF was commissioned in late 2015 (commencing full scale operation in early 2016) to reduce loads of selenium and nitrate. Although decreases in nitrate concentrations were detected in Line Creek downstream from the AWTF, decreases of similar magnitude were observed in previous years (i.e., after 2013 and 2014) and were also observed widely among mine-exposed areas (i.e., related to reference area increases, not decreases at mine-exposed areas). However, monthly mean total selenium concentrations decreased at LC_LC3, particularly in 2016. A significant increase in benthic invertebrate tissue selenium concentrations was observed at LILC3 (LC_LC3), immediately downstream from the West Line Creek AWTF, for the period 2012 to 2016 (Table 12.5). As noted above, the benthic invertebrate tissue selenium concentration observed at LILC3 in 2016

was greater than that observed in 2015 and substantially greater than the predicted mean concentration for Line Creek (Table 8.4). This increase was a result of discharge of selenium from the AWTF that was in a chemical form (i.e., predominantly selenite) that is more readily accumulated by aquatic organisms than the form that is normally found in other parts of the watershed (i.e., selenate) (Minnow 2017b). Teck is currently pilot testing an active oxidation process to convert most of the selenium discharged by the AWTF into selenate, which is expected to result in less tissue selenium accumulation in Line Creek after it becomes operational at full-scale. No temporal changes in invertebrate tissue selenium concentrations were found at monitoring areas farther downstream in Line Creek (LIDSL, LI8), or in the lower Fording River. Also no changes were found for benthic invertebrate abundance, richness, or % ETP among the 10 monitoring areas in MU2.

Potential temporal changes could not be evaluated for MU2 lentic area R5-3 due to lack of historical data (Table 12.6).

12.3.5 Integrated Interpretation

Concentrations of mine-related constituents in water and tissues in MU2 were generally consistent with expectations based on models developed in support of the EVWQP. Exceptions included higher than anticipated aqueous nitrate concentrations due to greater loading than anticipated from Line Creek upstream from West Line Creek, which will be taken into account in the next update of the Regional Water Quality Model (Golder 2016a). Also, despite significant reductions in total aqueous selenium concentrations, tissue selenium concentrations were elevated in Line Creek immediately downstream from the AWTF in 2016 (compared to predictions and values observed in 2015). This was the result of discharge of selenium from the AWTF that was in a chemical form (i.e., predominantly selenite) that is more readily accumulated by aquatic organisms than the form that is normally found in other parts of the watershed (i.e., selenate) (Minnow 2017b). Teck is currently pilot testing an active oxidation process to convert most of the selenium discharged by the AWTF back to selenate, which is expected to result in less tissue selenium accumulation in Line Creek after it becomes operational at full-scale.

All six mine-exposed tributary and main stem monitoring areas in MU2 had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges. All 10 WCT captured in MU2 in 2015 had muscle selenium concentrations less than the Level 1 benchmark for reproductive effects.

A significant temporal reduction of % Ephemeroptera in the lower Fording River (FO23) occurred after 2012 and then showed consecutive increases in 2013, 2015, and 2016. The 2016 value was within the reference area normal range.

12.4 Management Unit 3 – Upper Elk River

12.4.1 Mine-Related Chemical and Physical Changes in Comparison to Normal Reference Range

12.4.1.1 Lotic

Management Unit 3 includes the main stem Elk River and its tributaries to the west of GHO and downstream to the mouth of the Fording River (Figure 12.3). Nitrate concentrations were elevated in water at two of four mine-exposed stations in the Elk River downstream from GHO in 2015, resulting in maximum monthly NRQs of 2.2 and 2.5, and selenium concentrations in mountain whitefish muscle exceeded the normal range (NRQ = 1.4), but all other samples types had values within reference area normal ranges (Table 12.1). Mine influence was evident in all mine-exposed tributaries in MU3, except the south branch of Willow Creek, based on NRQs > 1. Highest NRQs were associated with tributaries to the south (i.e., Mickelson, Leask, Wolfram, and Thompson) which drain the areas where mining activities have historically been most intense, compared to the tributaries to the north (e.g., Branch F, Wolf, Willow).

12.4.1.2 Lentic

Lentic areas sampled in MU3 included two reference areas (REFF and LOLA) and two mine-exposed areas (ERUP and EROU; Figure 12.3). Water constituents, sediment selenium, and benthic invertebrate selenium concentrations resulted in NRQs less than 1, indicating conditions within normal reference area ranges. The high NRQ for sediment PAHs at the Lost Lake (LOLA) reference area provides further evidence (along with LML in MU1) that PAH concentrations in sediments are naturally elevated in some parts of the watershed (Table 12.2). Longnose sucker from the upper Elk River ponds (ERUP) had muscle and ovary selenium concentrations above reference area normal ranges (i.e., NRQs >1), providing some evidence of mining influence even though selenium concentrations in water and sediment were within normal ranges.

12.4.2 Comparisons to Predictions

Water quality models developed for the EVWQP overestimated selenium concentrations observed at the GHO Elk River Compliance Point (GH_ERC), as well as selenium and nitrate concentrations observed at the Elk River Order Station upstream of the Fording River in 2016 (Golder 2017a). Observed values corresponded reasonably well to modelled values for nitrate and sulphate at the GHO Elk River Compliance Point and for sulphate at the Elk River Order station upstream of the Fording River (GH_ER1). Benthic invertebrate and WCT tissue selenium concentrations in MU3 were consistent with model predictions.

12.4.3 Mine-Related Biological Effects

12.4.3.1 Lotic

HQs were less than one for samples collected in MU3 from the main stem Elk River in 2015 (Table 12.3). A chronic toxicity test with rainbow trout performed on a sample from the GHO Compliance Point in 2015 (GH_ERC) resulted in significant reduction in fish survival and length, but thorough evaluation of supporting data resulted in a conclusion that evidence for adverse mine-related effects was equivocal (Golder 2016). Reduced % EPT and % Ephemeroptera at the monitoring area on the Elk River upstream from the Fording River (ELUFO) was contrary to low HQs for water quality and tissue selenium concentrations at that location, but calcite index was at the estimated threshold for effects to invertebrates in these taxonomic orders (Section 5). However, no effects were observed at EL20, ELDEL, and ELUEL, farther upstream closer to GHO, where HQs were similarly less than one for mine-related stressors. These results suggest benthic invertebrate community effects at ELUFO are not mine-related.

Of the seven tributary and main stem monitoring areas in MU3, including one reference area, all had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges. All 10 WCT captured in MU3 in 2015 had muscle selenium concentrations less than the Level 1 benchmark for reproductive effects.

HQs for water quality were less than one for the most northerly tributaries (Branch F to Cougar) to the Elk River in MU3 (Table 12.3), but greater than one for the more southerly tributaries (Mickelson to Thompson). Benthic invertebrate communities have only been sampled at two of the southern tributaries in MU3 (Wolfram and Thompson), and in both cases, effects were evident as reductions in both % EPT and % Ephemeroptera relative to normal ranges. HQs for calcite and tissue selenium effects to invertebrates were also close to or greater than one for both creeks. Therefore, the observed reductions in % EPT and % Ephemeroptera at Thompson and Wolfram creeks may be associated with one or more mine-related stressors. Many of the tributaries in MU3, especially the northern ones, are steep-gradient and ephemeral, and only Thompson Creek is fish bearing (Minnow 2016e). There has also been active deforestation along the GHO west-side tributaries in recent years.

12.4.3.2 Lentic

HQs for selenium and PAHs in sediment were greater than one at both reference and mine-exposed lentic areas in MU3, but only the concentrations of PAHs at reference area Lost Lake (LOLA) were above normal ranges (i.e., the upper limit of the distribution of reference area concentrations exceeds the upper guideline for several PAHs; Table 12.4). Mine-related constituents in water, as well as tissue selenium concentrations in invertebrates and longnose

sucker resulted in HQs less than one. Also, longnose sucker at ERUP had condition that differed from reference longnose sucker by less than 10%, which is not likely ecological relevant (Environment Canada 2012b) and the direction of change (7.3% increase) was opposite to expectations for an adverse response. Therefore, the data do not suggest potential mine-related effects have occurred in the lentic areas that were sampled downstream from mining in MU3.

12.4.4 Changes over Time

Significant increases in aqueous nitrate (28% after 2015) and sulphate (53% from 2012 to 2016) were observed at the GHO Elk River Order station (GH_ER1) but no changes to benthic invertebrate communities were observed. No significant changes to benthic invertebrate communities were observed for the other main stem monitoring areas in MU3 or in the two tributaries having biological monitoring data.

Increases in aqueous concentrations of mine-related constituents were observed at 3 of 12 tributaries where no biological monitoring occurred[40]: Cougar Creek (GH_COUGAR, 377% for nitrate after 2014), Mickelson Creek (GH_ MC1, 1,539%, 186%, and 407% for nitrate, selenium, and sulphate after 2014), and Leask Creek (GH_LC2, 142% for sulphate after 2013; Table 12.5). The maximum monthly mean concentrations were greater than EVWQP Level 1 benchmarks at GH_MC1 and GH_LC2, but not at GH_COUGAR. A significant temporal increase in calcite was also observed in Mickelson Creek, primarily due to a step change after 2015 (Table 12.5).

No temporal changes in invertebrate tissue selenium concentrations or benthic invertebrate community endpoints were found.

Historical data were limited for evaluating temporal changes in lentic areas of MU3. There was no change in sediment chemistry at EROU in 2015 compared to 2013, and only a slight increase (6.8%) in longnose sucker condition at ERUP in 2015 compared to 2005 (Table 12.6).

12.4.5 Integrated Interpretation

Conditions in MU3 in 2015 to 2016 were generally consistent with expectations based on comparisons of observed conditions to EVWQP predictions and past monitoring results. The exceptions were reduced % EPT and % Ephemeroptera at the monitoring area on the Elk River

[40] Temporal changes were evaluated in mine-exposed stations relative to the mean change in reference stations from 2012 to 2016. The analysis was conducted using ANOVA on the difference in monthly mean concentrations (log_{10}-transformed) between the mine-exposed station and the monthly mean reference station, with Year as a factor (see Section 2.2.3 for further details).

upstream from the Fording River (ELUFO). No benthic invertebrate community effects were observed at EL20, ELDEL, and ELUEL, closer to GHO sources and HQs for mine-related stressors were also less than one at all four Elk River areas downstream from GHO, suggesting the cause of effects at ELUFO was not mine-related.

Cougar Creek (GH_COUGAR), for which an increasing trend in nitrate concentrations was observed, flows only intermittently which accounts for the limited data set depicted in Figure 3.11. As it is dry much of the year it has low habitat value within the broader spatial context of MU3.

Step increases in concentrations of nitrate, selenium, and sulphate were observed at Mickelson Creek (GH_ MC1) in all years after 2012, but especially after 2014 (Table 12.5; Figure 3.12; Appendix Tables C.36 to C.38). Maximum monthly mean concentrations of both nitrate and sulphate were greater than EVWQP Level 1 benchmarks in 2015. Calcite deposition also increased over time, particularly after 2015. It is not considered to be fish bearing, but western toads have been observed within the catchment (Minnow 2016e). The area around Mickelson Creek has been extensively deforested in recent years. This information bears consideration in future cycles of RAEMP or GHO LAEMP study design development.

Sulphate concentrations increased at Leask Creek (GH_LC2) in all years, particularly after 2013 (Figure 3.12) and were above the Level 1 benchmark in 2013. The stream is considered to be non-fish-bearing and the catchment has also been disturbed by logging.

All six mine-exposed tributary and main stem monitoring areas in MU3 had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges. All 10 WCT captured in MU3 in 2015 had muscle selenium concentrations less than the Level 1 benchmark for reproductive effects.

MU3 is very large and includes the Elk River up to its headwaters (Figure 1.2). The mine-disturbed tributaries have small catchments relative to other mine-disturbed and undisturbed tributaries in MU1-MU4 (Minnow 2016e). Therefore the mine-disturbed tributaries represent a small proportion of the total tributary habitat in MU3 and in the watershed as a whole.

12.5 Management Unit 4 – Michel Creek and Middle Elk River

12.5.1 Mine-Related Chemical and Physical Changes in Comparison to Normal Reference Range

12.5.1.1 Lotic

Management Unit 4 is large and encompasses Michel Creek and its tributaries as well as the middle portion of the Elk River and its tributaries (Figure 12.4). Reference areas in MU4 had

NRQs < 1 for all samples, except for slightly elevated nitrate in water at Andy Good Creek (Table 12.1). Mine-exposed areas in Michel Creek, the MU4 portion of the Elk River, as well as mine-exposed tributaries all had NRQs > 1 for nitrate, selenium and/or sulphate, except Harmer Creek upstream from Harmer Pond (EV_HC6). Calcite index values and benthic invertebrate tissue selenium concentrations were within normal ranges at all areas except at Corbin Creek (for calcite) and Bodie and Grave creeks (for tissue) (Table 12.1). The maximum NRQ for WCT muscle (of n=5 replicate fish per area) was greater than one in the Elk River and both upper and lower Michel Creek, but some individual fish (11 of 32 = 34%) had selenium concentrations within normal ranges (Appendix Table HWCT.6). The maximum selenium concentration in mountain whitefish ovaries also exceeded the normal range in lower Michel Creek (Table 12.1).

12.5.1.2 Lentic

Lentic areas in MU4 included three reference areas and six mine-exposed areas (Table 12.2). NRQs > 1 for aqueous sulphate at five of six mine-exposed lentic areas provided evidence of mine-related influence, as did NRQs > 1 for benthic invertebrate tissue selenium at all six mine-exposed lentic areas, and NRQs > 1 for longnose sucker tissues, where sampled (Table 12.2). Influence from mining was greatest at Goddard Marsh (GO13) based on highest NRQs for selenium in water (30), sediment (5.6), and tissues (3.6 for invertebrates and 8.0 for LSU ovaries, respectively), as well as for PAHs in sediment (38; Table 12.2). PAH concentrations were also above the reference normal range in sediment at Otto Ponds (OTTO; NRQ = 33), Michel Creek Wetland (MI16; NRQ = 2.6), and Lower Michel Wetland (MIWW; NRQ = 1.2).

12.5.2 Comparisons to Predictions

Aqueous concentrations of selenium, nitrate, and sulphate agreed with predictions from EVWQP models at the Order Station in the Elk River downstream from the Fording River (EV_ER1) in 2016 (Golder 2017a). At the CMO Michel Creek Compliance Point (CM_MC2), observed values corresponded reasonably well to modelled values for sulphate; however, selenium and nitrate concentrations were greater than modelled concentrations, which also occurred during the EVWQP model calibration period and may relate to overestimation of flows at that location.

Observed values also corresponded reasonably well to modelled values for selenium at the EVO Michel Creek Compliance Point (EV_MC2). However, monitored selenium and nitrate concentrations at the CMO Compliance Point were greater than modelled concentrations, which also occurred during the EVWQP model calibration period and may relate to overestimation of flows or lack of integration of pumping data at that location.

Nitrate concentrations were greater than the modelled concentrations at the EVO Harmer Creek Compliance Point (EV_HC1), but both monitored and modelled concentrations were less than water quality guidelines. Aqueous selenium and sulphate concentrations were consistent with predictions for EVO Harmer Creek (Golder 2017a).

Tissue selenium concentrations in benthic invertebrates were consistent with predicted values, except at Bodie Creek, where observed values were outside of the predicted range in both 2015 and 2016.

12.5.3 Mine-Related Biological Effects

12.5.3.1 Lotic

Of the Elk River portion of MU4, effects to benthic invertebrate communities were suggested by reduced % EPT at EL19 (Elk River downstream from Fording River), Harmer Creek downstream from the settling pond (HACKDS), and at Otto Creek (OTTO; Table 12.3). HQs greater than one were indicated for nitrate at EL19 and selenium at HACKDS, which may account for the response observed for % EPT. HQs for the other water quality constituents, calcite, and tissue selenium concentrations were less than one, except for an HQ of 1.4 for selenium in water at Grave Creek (GRDS) where the benthic invertebrate community had characteristics within normal reference area ranges, an HQ of 2.5 for selenium in Goddard Creek. Low HQs for mine-related stressors in Otto Creek suggest that low proportions of EPT and Ephemeroptera are due to factors other than mining. For example, the habitat in Otto Creek is slower-flowing and more depositional than the habitats preferred by those taxonomic orders.

In the Michel Creek portion of MU4, effects to benthic invertebrates were evident downstream from Corbin Creek (MIDCO), although HQs for mine-related stressors were less than one, except for aqueous nitrate (HQ of 1.1). A toxicity test with *C. dubia* completed on a water sample from the same area (CM_MC2 Compliance Point) resulted in a significant adverse response but, after evaluation of supporting data, it remained uncertain if this indicated an adverse response or normal variability in test organism performance (Golder 2016). Therefore, the cause of benthic invertebrate effects at MIDCO is uncertain. Sampling areas farther downstream on main stem Michel Creek (MIDAG, MI5, MI3, MI2) had benthic invertebrate communities with characteristics in the normal range for reference areas and HQs < 1 for mine-related stressors. Water samples at the EVO Michel Creek Compliance Point (EV_MC2), located between RAEMP sampling areas MI3 and MI2 had maximum HQs for nitrate and selenium above 1, but chronic toxicity tests did not provide compelling evidence of mine-related effects. The maximum HQ for WCT muscle selenium concentrations was less than one, but the

maximum HQ for mountain whitefish ovaries was greater than one, suggesting potential for effects.

HQs were greater than one for at least two of the three key mine-related constituents in all mine-influenced tributaries, except Aqueduct Creek (Table 12.3). Effects to benthic invertebrate communities were indicated for the two tributaries that were sampled in 2015 (Corbin [CORCK] and Bodie [BOCK]) based on reduced % EPT and % Ephemeroptera. Tissue selenium concentrations also resulted in an HQ of 5.5 for effects to invertebrates at BOCK. Calcite index values were also at or above the threshold for effects to these taxonomic orders at both CORCK and BOCK. Therefore, mine-related stressors may account for the observed biological effects at CORCK and BOCK.

Of the 6 reference and 15 mine-exposed tributary and main stem monitoring areas in MU4, all had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges. All 22 WCT captured in MU4 in 2015 had muscle selenium concentrations less than the Level 1 benchmark for reproductive effects (Table 10.2).

12.5.3.2 Lentic

Water samples had HQs < 1 for nitrate, sulphate, and selenium except at Goddard Marsh (GO13). HQs for tissue selenium concentrations were greater than one at four of six mine-exposed areas and at one reference area in MU4. HQs were also greater than one for selenium and/or PAHs in sediment at all reference and mine-exposed lentic areas in MU4 (Table 12.4), but at four of the areas both selenium and PAHs were within normal ranges (Table 12.2). The normal range for 2-methylnaphthalene exceeds both the lower and upper SQG (Appendix Figure E.1), so HQs were typically higher, but NRQs were lower for this PAH than those for other PAHs (Appendix Tables E.8 to E.11). Sediment samples collected at Goddard Marsh (GO13) and Otto Ponds (OTTO) caused significant effects to survival and/or growth of invertebrates in laboratory toxicity tests (see Section 6.3), consistent with these areas having highest HQs for selenium and PAHs. However, GO13 and OTTO continue to support two of the largest populations of LSU identified to date in the Elk River watershed (Table 12.4). Longnose sucker condition did not differ from reference (GO13), or differed from reference by less than 10% (OTTO, ELWDGC), suggesting low ecological relevance. On the other hand, based on very large differences in area size, habitat characteristics, and longnose sucker population sizes among reference and mine-exposed areas, the relative health of the populations in Goddard Marsh and Otto ponds is uncertain.

Sediment samples collected at MI16 and at reference area LCHO were not toxic in spite of HQs ≥ 4 for selenium (and for PAHs in the case of MI16), suggesting that the sediment quality guidelines may overestimate site-specific effects of these substances. HQs for the other mine-

exposed areas (ELWDGC, MIC2, MIWW) were less than HQs observed at reference areas in MU4.

Overall, the existing information suggests potential for mine-related effects at GO13 and OTTO where highest HQs for mine-related variables, as well as sediment toxicity, were observed.

12.5.4 Changes over Time

There were many decreasing step changes or linear trends for nitrate and selenium among water monitoring stations in MU4 (Table 12.5). However, as noted in Section 3, this was usually the result of increasing trends in reference areas rather than decreases at mine-exposed areas. When temporal changes were evaluated without accounting for reference area increases, decreases were still evident for nitrate at EV_OC1, EV_SP1, EV_MG1, and EV_BC1; for selenium at EV_OC1, EV_GT1, and EV_BC1, and for sulphate EV_BC1 (Appendix Tables C.36 to C.38). In analyses that accounted for increased concentrations at reference areas, increasing concentrations of mine-related constituents (specifically nitrate and sulphate) were observed only in Michel Creek upstream from EVO (EV_MC3).

Significant increases in calcite index were observed at both Corbin Creek and Bodie Creek (Table 12.5). The observed increases may be contributing to effects observed on the benthic invertebrate communities in both tributaries.

Benthic invertebrate abundance decreased at the Harmer Creek monitoring area upstream from the settling pond (HACKUS) after 2012, but abundances in all three years were greater than the reference area normal range (Table 12.5). There were also no significant temporal changes in mine-related stressors, so the change in community abundance is not interpreted as an adverse mining effect.

A significant step change decrease in % Ephemeroptera occurred after 2012 at Michel Creek monitoring area MI3 (Table 12.5), which is far downstream from CMO and upstream from tributaries influenced by EVO (Figure 12.4). However, % Ephemeroptera remained within normal ranges in all four years and the value observed in 2016 was near the reference area mean and the value observed at MI3 in 2012. Also, significant increases were observed for nitrate (65%) and sulphate (18%) in water at MI3 (EV_MC3) after 2015 (Table 12.5; Figure 3.12). However, concentrations in 2016 remained near or within normal ranges for reference areas (depending on the month) and below Level 1 benchmarks.

Thirteen of the 17 monitoring areas showed no change in benthic invertebrate community characteristics since 2012. Fifteen of the sixteen monitoring areas evaluated for potential changes in tissue selenium concentration, showed no change or a significant decrease. A significant increase in benthic invertebrate selenium concentrations occurred after 2012 in Bodie

Creek. This did not result in a significant change in benthic invertebrate community characteristics, but the mining-sensitive endpoints of % EPT and % Ephemeroptera were already less than reference area normal ranges in 2012 and continued to be in 2016.

The only statistically significant changes observed for lentic areas in MU4 were increased concentrations of selenium and PAHs in sediment samples collected at GO13 in 2015 compared to 2013, increased selenium concentrations in benthic invertebrate tissues from MI16, and increased condition of LSU in OTTO in 2015 relative to 2013 (Table 12.6). A significant temporal decrease in benthic invertebrate tissue selenium was also noted at OTTO.

12.5.5 Integrated Interpretation

Future adjustments to the Regional Water Quality Model are expected to address the few discrepancies noted between observed and modelled concentrations of nitrate, selenium, or sulphate at some water monitoring stations in MU4.

Tissue selenium concentrations in benthic invertebrates were consistent with predicted values, except at Bodie Creek, where observed values were outside of the predicted range in both 2015 and 2016. Increases in tissue selenium concentrations compared to predictions and past observations (2012) may be related to one or more of a number of factors, such as drift of invertebrates from lentic conditions in the sediment ponds, altered invertebrate communities due to exposure to mine-influenced water downstream of the sediment ponds, exposure to pit dewatering, or some other factor related to proximity to the point of discharge.

The reduction in % Ephemeroptera observed in Michel Creek upstream from EVO occurred after 2012 and was followed by consecutive increases in 2015 and 2016, with all values being within the reference area normal range. In spite of significant increases observed after 2015, concentrations of nitrate and sulphate in water remain near or within normal ranges for reference areas (depending on the month) and well below Level 1 benchmarks. Therefore, no further action is warranted other than on-going monitoring.

Another concern that has emerged from the monitoring data for MU4 is elevated concentrations of selenium and PAHs in sediment at Goddard Marsh (GO13) and Otto Creek ponds (OTTO), and the toxicity response that was observed in laboratory tests of sediment samples from these areas that used standard invertebrate species. There were no significant differences in condition of LSU from GO13 relative to reference, and only a minor increase in condition of LSU from OTTO (6%) but, based on very large differences in area size, habitat characteristics, and LSU population sizes among reference and mine-exposed areas, the relative health of the populations in Goddard Marsh and Otto Ponds is uncertain.

The other monitoring observations for MU4 were consistent with expectations based on past monitoring results. All 15 mine-exposed tributary and main stem monitoring areas in MU4 had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges.

12.6 Management Unit 5 – Lower Elk River

12.6.1 Mine-Related Chemical and Physical Changes in Comparison to Normal Reference Range

12.6.1.1 Lotic

MU5 represents the portion of the Elk River downstream from Michel Creek to its mouth at Koocanusa Reservoir (Figure 12.5). There are no tributaries affected by mining within this MU, but three reference tributaries had water quality, calcite, and benthic invertebrate tissue selenium concentrations within normal ranges, except for elevated sulphate at McCool Creek (Table 12.1). Water quality in the Elk River downstream from mining reflected the influence of mining based on NRQs > 1 for nitrate, selenium, and sulphate. Benthic invertebrates collected between Sparwood and ELDFE (Elk River immediately downstream from Fernie) had selenium concentrations within normal ranges, but selenium concentrations were greater than the normal range in invertebrates collected farther downstream near Elko (ELELKO) and near the Elk River mouth (ELH93). WCT and MW collected in the lower Elk River also had elevated tissue selenium concentrations. Overall, the data show that mine influence continues to be measurable throughout the lower Elk River.

12.6.1.2 Lentic

NRQs > 1 were observed for most of the mine-related constituents in water and sediment samples, as well as benthic invertebrate tissue selenium samples, collected in mine-exposed areas Stanford Pond (STPD), the lower Elk River oxbow (EROL), and Elko Reservoir (ELKO) (Table 12.2). Sediment samples collected in 2013 at wetlands near Sparwood (SPW) and downstream of Fernie (ERWSF), had selenium and PAH concentrations within normal reference area ranges. Water and tissue selenium data are not available for these areas.

12.6.2 Comparisons to Predictions

Aqueous concentrations of selenium, nitrate, and sulphate agreed with EVWQP model predictions at the Order stations in the Elk River downstream from Michel Creek (EV_ER1) and at the Elko Reservoir (EV_ELKORES) in 2016 (Golder 2017a).

12.6.3 Mine-Related Biological Effects

12.6.3.1 Lotic

Sampling areas in the lower Elk River generally had benthic invertebrate communities with characteristics in normal ranges and HQs < 1, with a few exceptions. % EPT was slightly reduced (61%) relative to the lower limit of the normal range (63%) at the sampling area upstream from Fernie (ELUFE; Table 12.3). Mine-related stressors produced HQs less than one, so the cause of reduced % EPT at ELUFE is uncertain. Strongest evidence of effects was near the mouth of the Elk River at ELH93, where both % EPT and % Ephemeroptera were less than normal ranges, and both calcite and tissue selenium concentrations were at their respective thresholds for potential effects (HQ=1). Selenium concentrations in ovaries of mountain whitefish were also above the estimated effect threshold in the lower Elk River.

Of the three reference and five mine-exposed tributary and main stem monitoring areas in MU5, all but one had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges. The exception was the upper Wigwam reference area (WWRU; Table 12.3). All 10 WCT captured in MU5 in 2015 had muscle selenium concentrations less than the Level 1 benchmark for reproductive effects.

12.6.3.2 Lentic

Sediment collected at Stanford Pond (STPD) had the highest HQs for selenium and PAHs of samples collected among lentic areas in MU5, and resulted in effects on growth and/or survival of standard invertebrate species in laboratory toxicity testing (Table 12.4). The pattern of PAH concentrations in sediment at STPD suggested contributions from a source other than, or in addition to, mining. This pond appears to have been constructed for storm water management. HQs for tissue selenium at STPD were also greater than one, suggesting potential for effects. However, of the areas sampled in the RAEMP, STPD supports the largest population of dwarf LSU, and condition of the LSU at STPD did not differ from reference fish. On the other hand, as noted for GO13 and OTTO in MU3, there are large differences in area size, habitat characteristics, and LSU population sizes among reference and mine-exposed areas in the watershed which confound determination of the relative health of the populations in individual areas.

LSU condition at EROL was similar to that of reference LSU in spite of HQs > 1 for selenium in sediment and tissues. Also, HQs for selenium and PAHs in sediment at EROL (and also SPW) were less than those observed among reference areas and concentrations associated with toxicity to invertebrates in laboratory testing.

12.6.4 Changes over Time

A decrease in invertebrate taxa richness was observed at the Elk River Order station (EV_ER1) after 2015 (Table 12.5). The 2016 value was still within the normal range but less than observed in 2015 or 2012 (Figure 8.8). No temporal changes were observed for mine-related stressors and aqueous concentrations were less than Level 1 benchmarks. Also, % EPT and % Ephemeroptera, which appear to be the community endpoints most sensitive to mining influences, were in normal ranges and did not change significantly over time. Therefore, the results appear to reflect normal variability or an influence that is not mine-related.

The low values for % EPT and % Ephemeroptera reported in 2015 and 2016 at ELH93, mentioned in the previous section, represent a significant decrease since 2012 and the cause is currently uncertain.

No temporal changes in benthic invertebrate tissue selenium concentrations were found.

Historical data were limited for evaluating temporal changes in lentic areas of MU5 (Table 12.6). The only significant difference was an increase in benthic invertebrate tissue selenium at EROL from 2012 to 2015, but this trend was based on only two years of data, which is not sufficient to confidently identify a temporal trend. No changes in sediment chemistry were evident at EROL or ELKO in 2015 compared to 2013. Longnose sucker condition was similar to historical observations for both STPD and EROL.

12.6.5 Integrated Interpretation

MU5, aqueous concentrations of selenium, nitrate, and sulphate agreed with EVWQP model predictions at the Order stations in the Elk River downstream from Michel Creek (EV_ER1) and at the Elko Reservoir (EV_ELKORES) in 2016. No tributaries in this MU have been affected by Teck's coal mines. Three reference tributaries had water quality, calcite, and benthic invertebrate tissue selenium concentrations within normal ranges, except for elevated sulphate at McCool Creek. Water quality in the Elk River reflected the influence of mining based on NRQs > 1 for nitrate, selenium, and sulphate. Benthic invertebrates collected between Sparwood and ELDFE (Elk River immediately downstream from Fernie) had selenium concentrations within normal ranges, but selenium concentrations were greater than the normal range in invertebrates collected farther downstream near Elko (ELELKO) and near the mouth of the Elk River (ELH93). The most notable finding was temporal reduction in % EPT and % Ephemeroptera immediately upstream the Elk River mouth (ELH93), where values of these endpoints were well below reference area normal ranges. There were no significant changes detected for mine-related stressors, so the cause of the benthic invertebrate community changes is uncertain. Additional samples were collected in 2017 to further investigate

conditions at this location. All monitoring areas in MU5 had benthic invertebrate community total abundance and taxa richness values within normal reference area ranges.

12.7 Management Unit 6 – Koocanusa Reservoir

Management Unit 6 (MU6) consists of the Canadian portion of Koocanusa Reservoir, which was created when the Libby Dam (Montana) was constructed in 1972. As required under Permit 107517, a three-year study characterizing and comparing chemical and biological conditions downstream from the Elk River relative to upstream was implemented from 2014 to 2016. This section provides a brief summary of the findings from the three-year study (reported in Minnow 2018; Appendix J).

Most of the water column within the reservoir was oxygenated with slightly alkaline pH. *In situ* water quality profiles showed only limited gradients in temperature, oxygen, pH, and conductivity with depth. Findings were consistent with a study completed by Hamilton et al. (1990) which concluded that waters in the Canadian portion of the reservoir remain relatively well-mixed, even during periods of maximum water elevation (May-November), as a result of basin morphometry, continual movement of water from river inputs and reservoir operations, and exposure to strong prevailing winds.

The evaluation of water quality focused on key substances associated with coal mining: nitrate, selenium, and sulphate. Concentrations of these substances were generally similar in water samples collected at middle and bottom depths at all sample locations downstream of the Elk River, but were higher than concentrations measured in samples collected at the surface. Differences between upstream and downstream concentrations were greater in 2016 than 2015 for both nitrate and selenium, but mean concentrations at the downstream areas in 2016 were similar to or less than those observed in 2015. Sulphate concentrations did not differ significantly between downstream and upstream. Site performance objectives for nitrate, selenium, sulphate, and dissolved cadmium were consistently met at the Order station (RG_DSELK).

Sediment samples collected in the reservoir both downstream and upstream from the Elk River were mostly silt (≥60%), with sand and clay comprising smaller fractions. Sediments collected upstream from the Elk River (T2/TN) were significantly sandier (annual means of 2-10%) with less clay (means of 17-19%) than those collected downstream (T4; means of <1% for sand and 26-30% for clay). This may be related to the shallower depths and more fluvial nature of the reservoir upstream of the Elk River (i.e., greater seasonal scour resulting in finer particles accumulating in sediments farther downstream). Total organic carbon content was similar at both areas, ranging from 0.9 to 1.7%.

Concentrations of most metals and polycyclic aromatic hydrocarbons (PAHs) in sediment were higher in sediments collected downstream from the Elk River compared to upstream, but did not increase over the three year study. Concentrations of some metals (upstream and downstream) and PAHs (downstream only) in sediments were above the lower provincial sediment quality guidelines, but none exceeded the higher guidelines. The general pattern of higher concentrations in sediment downstream from the Elk River compared to upstream may be related to a greater proportion of fine sediment particles in the downstream area, providing more surface area for adsorption than larger particles.

The reservoir is considered to be phosphorus limited. Low concentrations of phosphorus and chlorophyll-a, along with low seston and zooplankton biomass, all indicated that the reservoir is oligotrophic. Phytoplankton communities in the reservoir were numerically dominated by diatoms, and to a lesser extent with Chrysophytes. There were no significant differences in overall phytoplankton density, biomass, or richness between downstream and upstream areas over the three years. Community structure was similar between upstream and downstream areas, except for greater Cyanophyte (biomass at the downstream area, which was considered to have low ecological significance because this group represented <1% of the community.

The zooplankton community was numerically dominated by rotifers and copepods, with relatively low numbers of cladocerans. With the exception of abundance and biomass of cladocerans (tended to be lower downstream from the Elk River compared to upstream), no consistent differences were observed between downstream and upstream areas in overall zooplankton community structure (i.e., density, biomass, richness, and absolute or relative density or biomass of copepods or rotifers), over the three year study. Selenium concentrations in zooplankton were also similar between downstream and upstream areas in all three years.

Benthic invertebrate communities upstream (T2/TN) and downstream (T4) from the Elk River were primarily composed of oligochaetes (mostly immature Tubificinae), insects (various species of chironomids), and ostracods in all three study years. Overall community density and richness did not differ significantly between upstream and downstream areas in any of the three study years. However, the densities of ostracods and oligochaetes were higher at the downstream area compared to upstream. Greater abundance of these organisms may be associated with preference for greater depths and finer sediment texture present at the downstream area, and/or avoidance of coarser, compacted sediments that may dry out during low pool in the upstream area.

Mean benthic invertebrate tissue selenium concentrations were significantly higher at the downstream area (6.9 µg/g dw) than the upstream area (5.0 µg/g dw), and were greater than

the BC interim chronic dietary guideline of 4 µg/g dw, but were consistently less than the Level 1 EVWQP benchmarks (based on <10% effect) for growth and reproductive effects to benthic invertebrates (13 mg/kg dw) and for dietary effects to fish (11 mg/kg dw).

Largescale sucker, northern pikeminnow, peamouth chub, redside shiner, and yellow perch were consistently captured in highest numbers at all three fish study areas (i.e., areas within the reservoir in the vicinity of the mouths of Sand Creek, Elk River, and Gold Creek). Other species that were captured included bull trout, burbot, kokanee, longnose sucker, mountain whitefish, pumpkinseed, rainbow trout, slimy sculpin, and westslope cutthroat trout.

Following technical guidance developed by Environment Canada, fish surveys were conducted in April of each study year at each of the three study areas, to assess endpoints indicative of fish survival (mean age), growth (body size-at-age), reproduction (relative gonad weight) and energy storage (relative liver weight and overall condition). Peamouth chub were targeted in 2014 but additional species (northern pikeminnow, redside shiner, yellow perch, and largescale sucker) were also evaluated in subsequent years. Results were statistically compared between the downstream areas (Elk River and Gold Creek) and the upstream area (Sand Creek). No consistent patterns were observed among fish species, sexes, or sampling years that were indicative of influence from the Elk River.

Tissue samples were collected for analysis of metals from all fish species collected over the three-year study. Some fish had concentrations of selenium in muscle or whole body that were greater than the BC guidelines of 4 µg/g dw for both tissue types. All muscle and whole body samples were less than the USEPA criterion of 11.3 µg/g dw in muscle and 8.5 µg/g dw in whole bodies, except for a single yellow perch with a muscle selenium concentration of 15.0 µg/g dw. Similarly, ovary selenium concentrations were frequently greater than the BC chronic guideline of 11 µg/g dw (particularly in peamouth chub, redside shiner, and northern pikeminnow). All species except redside shiner and northern pikeminnow had mean ovary selenium concentrations less than the EVWQP Level 1 benchmark for reproductive effects to fish (18 mg/kg dw), and the 2016 USEPA guideline of 15.1 µg/g dw. Northern pikeminnow had mean ovary selenium concentrations above the Level 1 benchmark at the Elk River area in only one of the three years they were sampled (2014), when ovaries were relatively undeveloped. Mean redside shiner ovary selenium concentrations were above the Level 1 benchmark at both the Elk River and the Sand Creek areas in both years sampled.

Data obtained during the 2014 to 2016 sampling program are being used to design the next phase (2018 to 2020) of chemical and biological monitoring in the Canadian portion of Koocanusa reservoir. Results of all monitoring will be considered in the weight of evidence evaluation of MU6, which is currently under development in consultation with the EMC.

Comments/Notes		Rocks had black algae pucks, some heavily coated. Periphyton very thin but rocks slippery, no calcite	No to slight organic smell, calcite was slight green dots or orange patches	Very fine periphyton, very smooth on rocks, just see a yellowing but rocks are slippery. Calcite, some speckling black calite on most rocks/ quite thin.	Approx. 20 m from 2012 coordinates, but relocated because original coodinates were on a small trib that is created by groundwater flow and a stream entering from the mountains. Rocky shoreline but some slumping on rocky shoreline and where there is grass. Small amount of calcite, orange, flat and patchy on rocks.	Station moved from the confluence with the Wildhorse River, no riffle habitat. This station is u/s from sawmill in the Canal Flats and u/s from pulp mill in Skookumchuck.	-	-	-

Comments/Notes		Samples for periphyton (rocks) were gathered near d/s end of reach in fairly open canopy area (about 40%) cover, whereas kick was completed further u/s	-	Lots of calcite on rocks. Creek braids through forest upstream of sampling location.	Site is upstream of obvious off road crossing in riffle area. Calcite on rocks. Small curled vegetation on most rocks at site, possibly a type of bryophyte.	Hard to judge bankfull width as 2013 flood heavily scoured banks. Slightly fishy, no obvious odor	-	Slight "fishy" smell	More boulders towards the middle of the channel, so CABIN kick was along the edge of the river.

Comments/Notes		Very muddy substrate, very little rocky substrate. Area is a ditch. Difficult overturning rocks for 3 min kick and sweep. Creek is narrow and sides of channel are mud. Calcite flakes off rocks easily in a sheet.	Calcite forming on top of moss. For each sample rock scrapings removed calcite too, not possible to separate surficial matter from calcite. Excavator taking soil samples (see comment). Water samples collected prior to disturbance. No 100 pebble count due to high calcification	dark calcite throughout and covering entire creek. Calcite and periphyton were also dark. Small piece of coal in creek. Calcite incorporated into periphyton, so therefore calcite thickness included the periphyton thickness.	Pool back eddy that flows into river d/s of reach. Cyanobacteria layer (up to about 1 cm thick) present on rocks at the edge of river.	-	highly braided area, chose the middle braid for a good riffle.	very little periphyton growth compared to other sites on the Elk River (for instance d/s of Fernie wastewater outflow)	site located next to highway, wastewater treatment outflow upstream from site.

Comments/Notes		pool/back eddy with a lot of algae growth flowing into river d/s of site. Bankfull width includes the width of the reach and the back eddy. Little periphyton compared to sites u/s and d/s of Fernie and at Lake Koocanusa.	-	All rocks covered in mat of periphyton and calcite/silt that was olive in colour.	-		-	faint wastewater smell at site. Slight fishy smell to periphyton. Thick gelatin like coating on some rocks, about 1 cm thick. Grey in colour under green surface. Very cohesive and gelatin-like sample kept for identification (identified as cyanobacteria)	-	-

Comments/Notes		FODHE coordinates were in a dry channel, it appears they have diverted the watercourse. Moved station about 80m. Mostly rocky boulders, some grasses/shrubs within rocks, some trees upstream and downstream, but not within the reach assesed. Very fine periphyton, faint smell. Calcite both soft/mushy thick areas and light green speckled calcite	calcite hard black specks, orange blotches	-	-	moved station slightly from 2012 location (about 25 m) as old coordinates are no longer part of this channel. Calcite - orange/brown globules and black specks along edge	-	organic smell, calcite - black patch and dots.	at high flow banks are eroded, lower flow banks are boulders. Slight organic smell. Calcite small brown globules/soft (b/w 1 -5 mm). Black speckling of rocks

Comments/Notes		-	Calcite is very hard. Hard to scrape, very different than other sites, thin but tough. Cataract had a lot of thick calcite but still softer than what is here.	small campsite u/s with elk carcass present. Densiometer was left behind and there were concerns about bear safety so was not retrieved.	-	no smell - slightly organic smell. Some bryophytes. Noticeable white/blotchy calcite on rocks d/s of spillway	very slight smell rock (slightly organic). Mainly fine calcite on rocks/looks a bit like lichens (small patchy/tight to rocks)	Periphyton variable size, some globules that were thicker. Some green and some brown. Calcite, soft clumps and hard black and green spots. Faint organic smell.	borderd by rip-rap on each bank, some small failures have occurred. Calcite only on rocks, can't see very much calcite on surface but can't pick up. Bottom of rocks completely covered in calcite. Concreted can't even distinguish beginning and ending of rock (heavy calcited)

Comments/Notes		forest has been cleared nearby for campsite. Slightly fishy smell to periphyton	Difficult to turn rocks during kick and sweep. Two creek beds present (braided stream) within creek channel. Only the more western channel was assessed. Fishy smell to periphyton. Only small amount of periphyton on rocks.	Drainage ditch alongside highway, also flowing towards the creek at sampling site. Small pond/wetland upstream of site, visible from truck parking location. Fishy smell to periphyton layer on some rocks. Thin layer of yellow/olive flaky periphyton. Rocks on edge of creek had larger amounts of moss and filamentous algae, rocks in centre were thin yellow/olive periphyton (slimy) with clumps of filamentous algae	ATV trail nearby which was used to access site but trail does not intersect or cross creek. Slimes/streamers and filamentous algae mixed in with calcite present on rocks.	Rivers edge appears to be recently adjusted with a dozer - cobble/gravel on the left bank, looking upstream. No smell/slightly organic. Calcite - soft globules and black specks. Saw filamentous algae in benthic samples but did not really see it with the pebble count.	Some cut banks from high flows on north side. Coordinates from 2012 were not on creek/diversion. Periphyton had no smell, some filamentous/streaming algae. Calcite mainly thin dots on rocks (black/orange); very few rocks with thicker calcite.	Very muddy, silty area, deadfall over creek, garbage present in creek. Very minor flow. Weir and staff gauge d/s, closer to mouth with Elk River. Habitat d/s is narrower and shallower but with more gravel/cobble and step pools with very little flow. No visible periphtyon, rocks covered in dark brown mud.	-

Comments		-	Lots of chara, sediment had red hues with dark brown to light brown layers.	-	-	Lots of chara, sediment black to dark brown underneath. Beaver dam present.	Substrate predominantly silt/clay with very little organic matter. Slight chemical odor detected.	-	Sediment predominantly silt/clay, with some sandy areas. WCT observed.	Some groundwater inflow. Sediment soft, predominantly silt/clay with some decaying vegetation and algal growth.	Oil sheen	Sediment predominantly soft with sandy/gritty particles present. Redox layer darker to lighter brown. Banks contained eroding rusty-red areas. WCT observed.	-	Very fine sediment along the ban, lots of aquatic vegetation, very muddy (dark brown sediment). GBH observed.	-

		Dominant Substrate	sand	predominantly fines, some gravel patches	fines	fines	clay	fines	predominantly fines, some cobble patches	hard packed fines	fines	fines	fines
		Aquatic Vegetation	thick carpet of mossy vegetation	grasses, thick patches of chara	thick carpet of chara, cattails, horsetails grasses and sedges	thick carpet of chara, cattails	cattails	patches of pondweed, cattails along E shore of upper pond	thick floating filamentous algae, thick carpet of mossy vegetation	patches of grasses	thick carpet of mossy vegetation, grasses and dead bushes	thick carpet of mossy vegetation	thick carpet of mossy vegetation, grasses and sedges, cattails
		Riparian Vegetation	grasses and sedges, conifers	conifers, shrubs, grasses	grasses, conifers	grasses, conifers	conifers, grasses and sedges, shrubs, cattails	grasses and sedges, shrubs	grasses and sedges	grasses and sedges, shrubs	grasses and sedges, shrubs	grasses, deciduous trees	grasses and sedges
		Other Habitat Features	upwelling through sand in a deep pool. lots of woody debris, particularly at the SW end of the pond.	woody debris and thick bryophytes	woody debris throughout the pond.	beaver damn along South shore.	small sections of woody debris found in main pond.	active beaver lodge on SW shore of upper pond.	woody debris at the N end of the wetland. one deep pool (~1 m).	sections of woody debris	small patch of woody debris	boulder riprap along sections of shoreline, deep pool	boulder riprap along west bank. deep pool (>2 m). woody debris along E shoreline.
		Comments	Upstream of a beaver dam, very muddy with some woody debris, very fine detritus and a slight odor	-	Cobble/gravel substrate with fines (black to dark brown to grey) over top. Lots of vegetation and goose scat. Cows nearby. Small trout (7 cm) observed.	Lots of chara present. Sediment black below the surface.	-	-	Cobble substrate covered with fines, detritus, organics with thick vegetation.	Located upstream of a beaver dam. Sediment depth shallow at some areas, and very hard below sediment.	Sediment very black below top 2 cm, lots of vegetation and a slight odor. Juvenile trout observed.	Thick chara covered the entire pond substrate.	Lots of vegetation

APPENDIX B
DATA QUALITY ASSESSMENT

APPENDIX B DATA QUALITY ASSESSMENT

B1 INTRODUCTION

A Data Quality Assessment (DQA) was conducted on data collected as part of the Regional Aquatic Effects Monitoring Program (RAEMP) implemented for Teck's coal mining operations in the Elk River Watershed in 2015. The objective of the DQA is to define the overall quality of the data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions.

B1.1 Background

A variety of factors can influence the chemical and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Inconsistencies in sampling or laboratory methods, use of instruments that are inadequately calibrated or which cannot measure to the desired level of accuracy or precision, and contamination of samples in the field or laboratory are just some of the potential factors that can lead to the reporting of data that do not accurately reflect actual environmental conditions. Depending on the magnitude of the problem, inaccuracy or imprecision have the potential to affect the reliability of any conclusions made from the data. Therefore, it is important to ensure that monitoring programs incorporate appropriate steps to control the non-natural sources of data variability (i.e., minimize the variability that does not reflect natural spatial and temporal variability in the environment) and thus assure the quality of the data.

Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. DQA involves comparison of actual field and laboratory measurement performance to data quality objectives (DQOs) established for a particular study, such as evaluation of method detection limits, blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials).

DQOs were established at the outset of the field program that reflect reasonable and achievable performance expectations (Appendix Table B.1). Programs involving a large amount of samples and analytes usually have some results that exceed the DQOs. This is particularly so for multi-element scans (e.g., ICP scans for metals) since the analytical conditions are not necessarily optimal for every element included in the scan. Generally, scan results may be considered acceptable if no more than 20% of the analytes fail to meet the DQOs. Overall, the intent of comparing data to DQOs was not to reject any measurement that did not meet the DQO, but to ensure any questionable data received more scrutiny to

determine what effect, if any, this had on interpretation of results within the context of this project.

B1.2 Types of Quality Control Samples

Several types of quality control (QC) samples were assessed based on samples collected (or prepared) in the field and laboratory. These samples, and a description of each, include the following:

Blanks are samples of de-ionized water and/or appropriate reagent(s) that are handled and analyzed the same way as regular samples. These samples will reflect any contamination of samples occurring in the field (in the case of field or trip blanks) or the laboratory (in the case of laboratory or method blanks). Concentrations of analytes should not be detectable, although a DQO of twice the method detection limit allows for slight "noise" around the detection limit.

Field Duplicates are replicate samples collected from a randomly selected field station using identical collection and handling methods that are then analyzed separately in the laboratory. The data from field replicate samples reflect natural variability, as well as the variability associated with sample collection methods, and therefore provide a measure of field precision.

Laboratory Duplicates are replicate sub-samples created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.

Spike Recovery Samples are created in the laboratory by adding a known amount/concentration of a given analyte (or mixture of analytes) to a randomly selected test sample previously divided to create two sub-samples. The spiked and regular sub-samples are then analyzed in an identical manner. The spike recovery represents the difference between the measured spike amount (total amount in spiked sample minus amount in original sample) relative to the known spike amount (as a percentage). Two types of spike recovery samples are commonly analyzed. Spiked blanks are created using laboratory control materials, whereas matrix spikes are created using field-collected samples. The analysis of spiked samples provides an indication of the accuracy of analytical results.

Certified Reference Materials are samples containing known chemical concentrations that are processed and analyzed along with batches of environmental samples. The sample results are then compared to target results to provide a measure of analytical accuracy. The results are reported as the percent of the known amount that was recovered in the analysis.

Two additional types of QC, specific to benthic invertebrate community samples, included:

Organism Recovery Checks for benthic invertebrate community samples involve the re-processing of previously sorted material from a randomly selected sample to determine the number of invertebrates that were not recovered during the original sample processing. The reprocessing is conducted by an analyst not involved during the original processing to reduce any bias. This check allows the determination of accuracy through assessment of recovery efficiency.

Sub-Sampling Error is assessed for studies in which benthic invertebrate community samples require sub-sampling (due to excessive sample volume and/or invertebrate density). By comparing the numbers of benthic invertebrates recovered between at least two sub-samples, this measure provides an evaluation of how effective the sub-sampling method was in evenly dividing the original sample. Therefore, sub-sampling error provides a measure of analytical accuracy and precision. The processing of entire benthic invertebrate community samples in representative sample fractions also allows an evaluation of sub-sampling accuracy.

B2 WATER SAMPLES

B2.1 Laboratory Reporting Limits

Laboratory reporting limits (LRLs) that were reported for analysis of water samples were at or below the target concentrations, with the exception of hardness, TSS, aluminum, and calcium in some samples (Appendix Table B.2). The LRLs achieved for aluminum were consistently less than the water quality guideline, and there are no approved guidelines for hardness, TSS, or calcium. Only LRLs for aluminum, copper and zinc (0.005, 0.0005, and 0.003 mg/L respectively) were above or equivalent to the provincial baseline guidance of 0.001, 0.0005, and 0.003, respectively[1]. The low detection limits indicated for aluminum, copper, and zinc apply to water with <1NTU turbidity, which applies to most of the watershed. The LRL for each analyte was, however, below the WQG. The LRLs that were achieved for all substances were suitable for evaluation of observed concentrations relative to guidelines.

B2.2 Laboratory Blank Sample Analysis

Laboratory blank samples all met the DQO, which specified concentrations less than or equal to twice the LRL (Appendix Table B.3). This indicates no inadvertent contamination of samples during laboratory handling and analysis.

B2.3 Data Precision

B2.3.1 Laboratory Duplicate Samples

In general, close agreement was achieved between laboratory duplicate samples indicating reported sample results were associated with excellent analytical precision (Appendix Table B.4(a)). The DQO was met for all samples (Appendix Table B.4(a)).

B2.3.2 Field Duplicate Samples

Eleven sets of field duplicate water samples were collected, which were splits of the same sample. No DQO was established in the RAEMP study design for field split duplicates. The field duplicate samples showed agreement in analyte concentrations for 92% of comparisons (Appendix Table B.4(b)). Half of the duplicate pairs showing RPDs greater than 20% were associated with analysis of total kjeldahl nitrogen and nitrite. Most instances in which RPDs

---

ENV. 2016. Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators. Prepared by the British Columbia Ministry of Environment. June. [1]

were greater than 20%, concentrations were very low (near or less than LRL). Good agreement was achieved between field duplicate samples for selenium. Overall, the data suggest that reported results were reasonably precise representations of conditions at the time of sampling.

B2.4 Data Accuracy

B2.4.1 Blank Spike Recovery Samples

Laboratory blank samples all met the DQO, which specified concentrations less than or equal to twice the LRL (Appendix Table B.3). This indicates no inadvertent contamination of samples during laboratory handling and analysis.

B2.4.2 Matrix Spike Recovery Samples

Analyte recoveries for matrix spike recoveries samples met the DQO in all instances (Appendix Table B.6), indicating excellent analytical accuracy associated with the analysis of water samples.

B2.4.3 Certified Reference Materials

Reference material recoveries were all reported within the target range except for five samples of iron (Appendix Table B.7), one sample of phosphorus and one sample of antimony. In all cases the target range was exceeded by no more than 1% at the upper limit of the DQO for recovery, indicating excellent analytical accuracy.

B3 SEDIMENT SAMPLES

B3.1 Method Detection Limits

LRLs reported by the laboratory were greater than the target LRL for some analytes, but were consistently less than the lower sediment quality guidelines of BCMOE (Appendix Table B.8). Therefore the LRLs were suitable for evaluation of observed concentrations in sediment samples relative to guidelines.

B3.2 Laboratory Blank Sample Analysis

Results for laboratory blanks analyzed concurrent with sediment samples were all less than the DQO (i.e., twice the LRL) (Appendix Table B.9). This indicates no inadvertent contamination of samples during laboratory handling and analysis.

B3.3 Data Precision

B3.3.1 Laboratory Duplicate Samples

The DQO was met for all metals measured in laboratory duplicate sediment samples, indicating excellent analytical precision for those analytes (Appendix Table B.10). The few cases in which particle size fractions did not meet the DQO when fractions comprised a small proportion of the overall sediment sample and absolute differences between samples were small (Appendix Table B.11). All but three PAH results associated with a single set of duplicates met the DQO, and those three cases only slightly exceeded DQO (Appendix Table B.11) Overall, there was good agreement between laboratory duplicate samples indicating reported sample results were associated with satisfactory analytical precision.

B3.3.2 Field Duplicate Samples

There was good agreement between field split-sample duplicate results for sediment, with 94% of comparisons meeting the DQO (Appendix Table B.12). Some PAHs exceeded the DQO in 3 of 11 sets duplicates and some metals exceeded in one set of duplicates. These results may reflect somewhat incomplete homogenization of the sample in the field prior to splitting. Overall, the data suggest that reported results were reasonably precise representations of conditions at the time of sampling.

B3.4 Data Accuracy

B3.4.1 Certified Reference Materials

Recoveries of metals from certified reference samples consistently met the DQO, except in some cases for boron and tin, which were present at low or non-detectable concentrations

(Appendix Table B.13). Recoveries were also good for particle size analyses, except for sand fractions comprising a small proportion of the overall sediment sample for which absolute differences in 170 comparisons (Table B.14). In the 9% of instances in which the recovery targets were not met, all recoveries were at least 61%, compared to the minimum DQO of 70% recovery. Overall, the data indicated satisfactory analytical accuracy associated with sediment samples.

B4 TISSUE CHEMISTRY

B4.1 Periphyton and Benthic Invertebrates

Selenium concentrations were determined for periphyton and benthic invertebrate samples by standard comparison using certified single-element selenium standards traceable to the U.S. National Institutes of Standards and Technology (NIST). Recoveries associated with analyses for periphyton and benthic invertebrate samples were within the DQO range of 70% and 130% (Tables B.15 and B.16)

B4.2 Fish

B4.2.1 Method Detection Limits

Laboratory LRLs associated with fish tissue analysis are shown in Appendix Table B.17. The LRLs for elements measured in fish tissue samples were variable, but were low enough to quantify tissue concentrations for most analytes, except beryllium, boron, cadmium, rhenium, thorium, and yttrium, whereas tissue concentrations of selenium were the main focus of this study (Appendix Table B.17). Element concentrations were generally lower in muscle than egg/ovary samples, so concentrations of silver, bismuth and tin were also frequently less than detection limits in fish muscle.

B4.2.2 Data Precision

Duplicate digestions of muscle samples were prepared and analyzed for four muscle samples (Appendix Table B.18) and five ovary samples (Appendix Table B.19). The DQO was met for 70% and 89% of analytes measured among muscle and ovary duplicate analyses. Duplicate tissue analyses for selenium consistently met the DQO and showed very low RPD of ≤ 6%. Results for other analytes were variable and should be taken into account for uses of the data outside of this study.

B4.2.3 Data Accuracy

Matrix spikes using approximately 3 ppm of two multi-element solutions (together containing many, but not all, analytes) were performed concurrent with analysis of MW muscle and ovary samples (Appendix Table B.20). Given the impracticality of splitting the very small WCT muscle plug samples, no matrix spikes were prepared/analyzed for those samples. Recoveries met the DQO for 90% of analytes yielding a quantifiable result. The spike for selenium was too small relative to the sample concentrations to allow for evaluation of analytical accuracy by this method.

Accuracy of elemental concentration data was also determined by comparing achieved values to either a range (mean ± standard deviation) of literature values or a percent recovery associated with three different certified reference materials - NIST SRM 1577 (bovine liver), NIST SRM 1566b (oyster tissue) and NRC CRM DOLT-4 (dogfish liver) (Appendix Table B.21). Selenium recoveries from certified reference materials met the DQO in eight of nine analyses, and the single exception was only slightly greater than the target value (135%).

Overall, results for analysis of matrix spikes and certified reference materials indicated acceptable analytical accuracy for fish tissue samples, particularly for selenium which is the substance of most relevance to the objectives of this study.

B5 BENTHIC COMMUNITY SAMPLES

The analysis of benthic invertebrate community samples involved concurrent assessment of data quality, including sub-sampling accuracy, precision and percent recovery of organisms. Canadian Aquatic Biomonitoring Network (CABIN) protocols were followed for sub-sampling (i.e., identification of a minimum 300 invertebrates), which often resulted in only 5% of a sample being assessed. Despite this, accuracy and recovery were very good, and generally met (or only slightly exceeded) the corresponding DQOs).

To measure the effectiveness of the sorters, 10% of samples were selected at random for re-sorting analysis by a different sorter from the original sorter. All of the re-sorted samples were above 95% efficiency of invertebrate removal and achieved industry standards (20% of total organism count). Only a single fraction of 5% failed the DQO by 35-40 organisms. This could be due to a piece of debris holding a large number of organisms, and no further action was required to correct sampling.

A detailed report providing discussion related to benthic invertebrate sample processing and QC (prepared by the analytical laboratory, Cordillera Consulting) is included after Appendix Table B.21.

B6 DATA QUALITY STATEMENT

Overall the quality of the data collected for this project was considered acceptable for serving the project objectives.

Table B.1: Data Quality Objectives for Aquatic Ecological Samples in the RAEMP

Quality Control Measure	Quality Control Sample Type/Check	Study Component				
		Water Quality	**Sediment Quality**	**Tissue Quality**	**Benthic Invertebrate Community**	**Fish Morphometrics**

Note: Any highlighted values indicate LRLs that were above the target.

[1] Working guidelines (BCMOE 2006)

[a] A concentration that will protect aquatic life from adverse effects of toxic substances in most situations.

[b] A concentration that if exceeded will likely cause severe effects on aquatic life.

[c] Only a single guideline has been defined.

Shaded values indicate Achieved LRLs which exceed the Target LRL

Zirconium (Zr)	mg/kg dw	77%	77%	82%	65%	59%

Note: Highlighted values did not meet the data quality objective of 70 - 130% recovery.

* Not spiked (the element was not included in the multi-element spike solution).

† Spike too small (the concentration of the element spiked into sample was less than 50% of the average concentration measured in the replicates).

‡ High variability in replicates (the spike level was less than 2x the standard deviation of replicates).

§ Only one unspiked replicate was used for this element because the second replicate was digested in a vessel with known, significantly high background levels of this element. Thus the standard deviation of the replicates could not be accurately determined.

Methods and QC Report for Teck Elk Valley RAEMP (2561) – Minnow Environmental
Benthic Invertebrate Samples processed by Cordillera Consulting

On September 24, 2015, 139 benthic samples were received by Cordillera Consulting from Minnow Environmental.
When samples arrive at Cordillera Consulting they are logged into a proprietary software data base (INSTAR1) and the client generated sample information is recorded along with a Cordillera Consulting number for cross reference. The client representative is notified of the arrival of the shipment. The samples are checked that all sites and replicates recorded on field sheets or packing lists have been delivered intact and with adequate preservative. If there are any missing, mislabelled or extra samples Cordillera Consulting will contact the client immediately to confirm the total numbers and correct names on the sample jars.
Each sample was assigned a distinct Cordillera Consulting code. See table below for summary:

Table 1: Summary of sample information including Cordillera Consulting number.

Sorting Effort

The sorting team at Cordillera Consulting sorted the invertebrates into order/family taxa level vials.

- Using a gridded Petri dish, fine forceps and a low power stereo microscope (Olympus, Nikon, Lieca) the sorting technicians removed the invertebrates and sorted them into family/orders at the same time
- The sorting technician kept a running tally of total numbers as they sorted the invertebrates into family/order specific vials. Excluded organisms from Porifera, Nemata, Platyhelminthes, Ostracoda, Copepoda, Cladocera and terrestrial drop-ins such as aphids were removed and counted but they were not included towards the total count
- Where specimens were broken or damaged, only heads were counted
- The number of organisms removed were recorded manually on a bench sheet. The number of organisms in each family or order were also recorded at this time.
- The groups of invertebrates and numbers of each group were entered into INSTAR1
- They are stored in 80% ethanol in separate vials (according to family/order) and an interior label using heavy laser paper is made using site names, date of sampling, site code numbers and portion subsampled. This information is also recorded on the laboratory bench sheet and on the data base.
- The sorted portion of the debris was preserved and labeled separately from the unsorted portion and was tested for sorting efficiency. The unsorted portion was also labeled and preserved in separate jars.

Percent sub-sampled and total countable invertebrates pulled from the samples are summarized in the table below.

Sorting QC – Sorting Efficiency

10% of samples were selected at random for resorting analysis to measure the effectiveness of the sorters. A different sorter from the original sorter did the resort.
All of the resorted samples were above 95% efficiency of invertebrate removal and so achieved industry standards.

Table 3: Summary of sorting efficiency

CC #	Number of Organisms Recovered (initial sort)	Number of Organisms in Re-sort	Percent Recovery
CC160676	364	2	99%
CC160690	493	17	97%
CC160696	858	3	100%
CC160702	364	10	97%
CC160710	330	7	98%
CC160725	351	9	97%
CC160736	392	8	98%

CC160756	339	1	100%
CC160761	360	5	99%
CC160764	325	10	97%
CC160790	318	5	98%
CC160806	591	5	99%
CC160810	409	2	100%
		Average % Recovery	98%

Sorting QC – SubSample QC

*Results presented in Appendix A
Sub-Sampling efficiency is measured on 10% of the number of sub-sampled samples in a project. Ex. In a project where 50 of 100 total samples were processed through subsampling using a Marchant box, then 10% of 50; or 5 samples will be used for sub sampling efficiency.
Sub-Sampling efficiency is performed by fractioning the entire sample into sub-sample percentages. On each sub-sampled portion, a total organism count is recorded and compared to the rest of the sub-samples. In order to pass, all fractions must be within 20% of total organism count.

Sorting Note: Of all of the subsampling QC conducted, only a single fraction of 5% failed by 35-40 organisms. This could be due to a piece of debris holding a large number of organisms. Other sub-sample QC from the same sorter were checked and passed, no further action was required to correct sampling.

Taxonomic Effort

The next procedure was the identification of invertebrates to genus-species level where possible. According to CABIN criteria[1], identifications were made at the genus/species level for all insect organisms found including Chironomidae. Non-insect organisms (except those not included in count) were identified to genus/species where possible and to a minimum of family level with intact and mature specimens. The Standard Taxonomic Effort lists compiled by SAFIT[2] was used as a guideline for what level of identification to achieve where the condition and maturity of the organism enables.
Appendix 1 lists the major reference texts used for identification, though other online keys and journal publications are also used.

- Organisms from the same families/order were kept in separate vials (unless directed to do otherwise) in 80% ethanol and labeled with an interior label of heavy laser paper. Where numbers of organisms in a family or genus was large (>30) it merited a separate vial.
- Chironomidae will be identified to genus/species level using slide mounts. CMC-10 will be used to clear and mount the slide.
- Oligochaetes were identified to family/genus level with the aid of slide mounts. CMC-10 was used to clear and mount the slide
- Decapoda, Amphipoda and Isopoda were identified at family/genus/species level where possible.
- Nemata remained at the phylum level
- Hydrachnidae were identified at the family/genus level where possible.

Taxonomic QC

The taxonomists for this project were certified by the Society of Freshwater Science (SFS) Taxonomic Certification Program, which is the required certification for CABIN projects:

Sue Salter: Holds 5 SFS certifications - Level 2 Group 1 General Arthropods East/West; Group 2 EPT West; Group 3 Chironomids EPT East/West

Scott Finlayson: Holds 6 SFS certifications **-** Level 2 Group 1 General Arthropods (East/West); Group 2 EPT East/West; Group 3 Chironomids East/West

Adam Bliss: Holds 4 SFS certifications - Level 2 Group 1 General Arthropods (East/West); Group 2 EPT East/West

Rita Avery: Holds 2 SFS certifications - Level 2 Group 2 EPT East/West

Taxonomic QC was performed in house by someone other than the original taxonomist.

CABIN protocol calculates taxonomic efficiency as:

$$\frac{\#\ Incorrect\ Identifications}{Total\ organisms\ found\ in\ audit} * 100\% = \%\ Identification\ Error$$

Error Summary

All samples report errors within the acceptable limits for CABIN Laboratory methods (less than 5% error).

Table 4: Summary of taxonomic error following QC

CC #	# Taxa identified	% Misidentifications
CC160686	354	0.00
CC160698	400	0.00
CC160710	329	0.00
CC160715	358	0.28
CC160727	362	0.00
CC160738	701	0.00
CC160747	314	0.00
CC160753	309	0.65
CC160766	382	0.00
CC160773	672	0.15
CC160782	326	0.00
CC160790	315	1.59

There will always be disagreements between taxonomists regarding the degree of taxonomic resolution in immature specimens and when laboratories make use of different keys for certain groups (Mollusks is an especially disputed group). It is always possible that some taxa found by the original taxonomist were overlooked in QC.

All of the Taxonomic QC samples that were observed passed testing according to the CABIN misidentification protocols. See the tables below for results from taxonomic QC audit.

Taxonomy Note

Misidentification of Drunella flavilinea as Ephemerella dorothea/excrucians occurred in only one sample CC160790, and so the data was changed to reflect this change.

Other errors were examined and no further changes required.

Keys used for Identification of Freshwater Benthic Invertebrates - Cordillera Consulting 2014

Below is a reference list of taxonomic keys utilized by taxonomists at Cordillera Consulting. Cordillera taxonomists routinely seek out new literature to ensure the most accurate identification keys are being utilized. This is not reflective of the exhaustive list of resources that we use for identification. A more complete list of taxonomic resources can be found at Southwest Association of Freshwater Invertebrate Taxonomists. (2015). http://www.safit.org/Docs/SAFIT_Taxonomic_Literature_Database_1_March_2011.enl

APPENDIX C
WATER QUALITY DATA

Raw Data

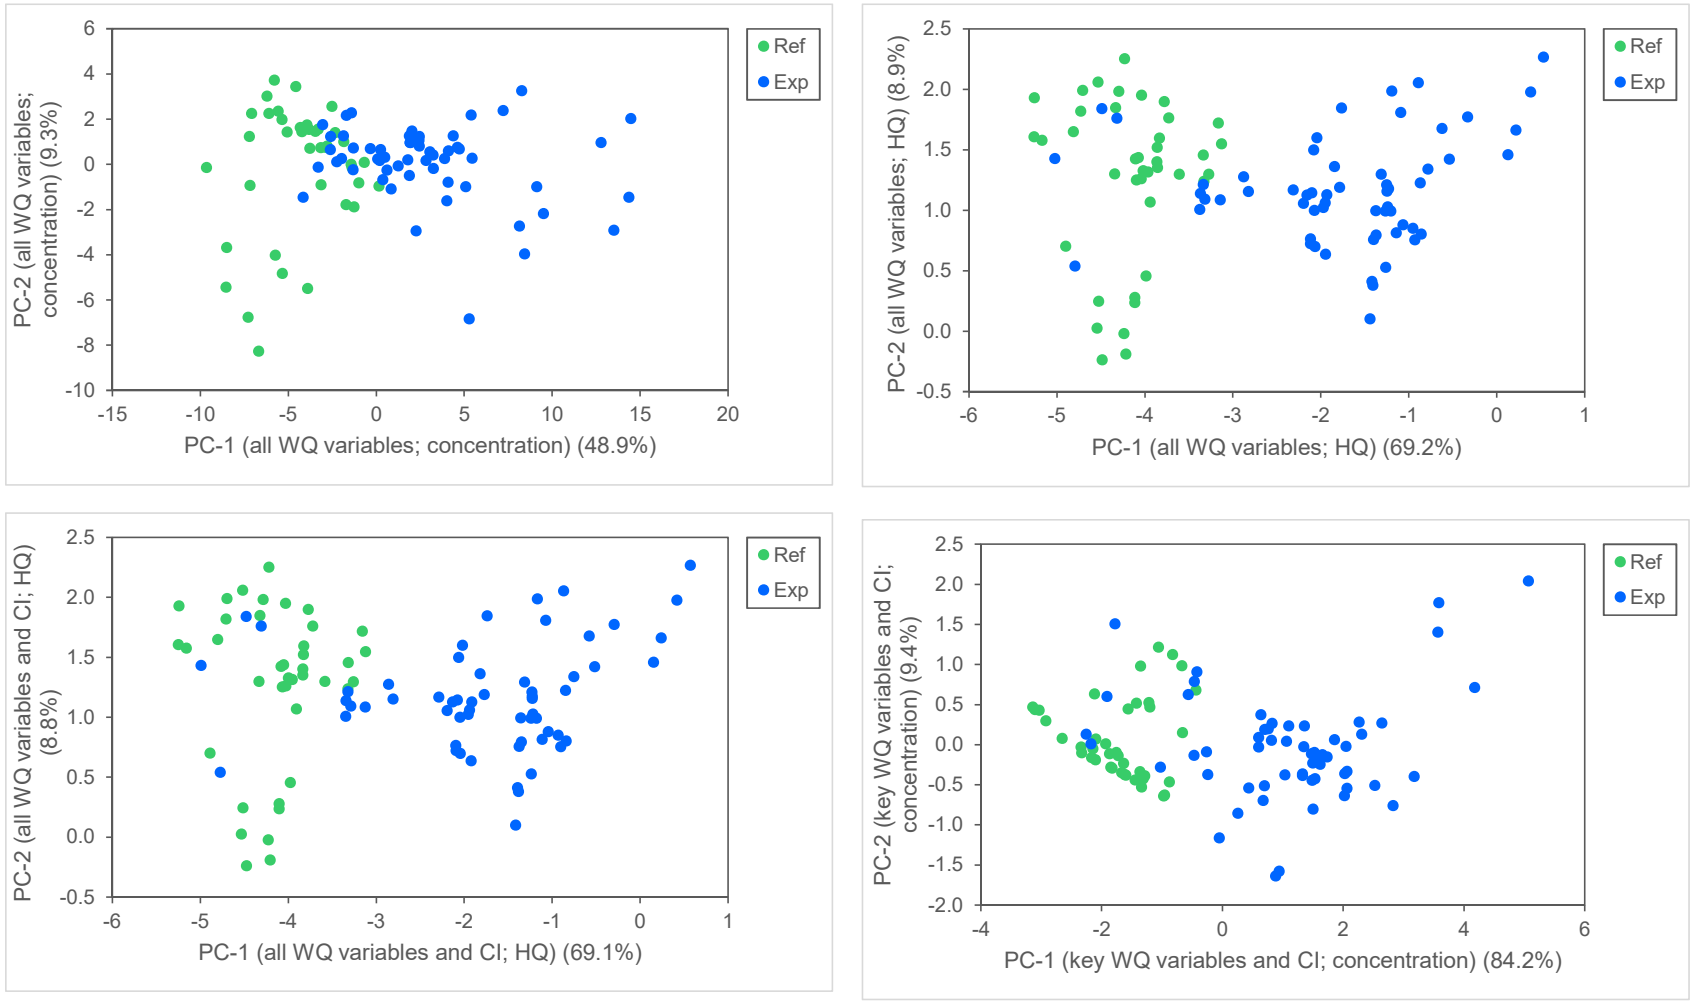

Figure C.1: Scatterplots of PC-2 Versus PC-1 from Five Different PCAs with Variations of Concentrations or Hazard Quotients for Water Quality (WQ) Variables and Calcite Index

Notes: Data are for lotic reference (n = 40) and mine-exposed (n = 59) areas. HQ - hazard quotient. Observed concentration divided by Level 1 effect benchmark defined in the Elk Valley Water Quality Plan (selenium, sulphate, nitrate, cadmium), the upper normal range limit defined by Minnow (2016b; calcite index), or BC water quality guidelines (the other water quality variables), as applicable. Key WQ variables = selenium, sulphate, nitrate.

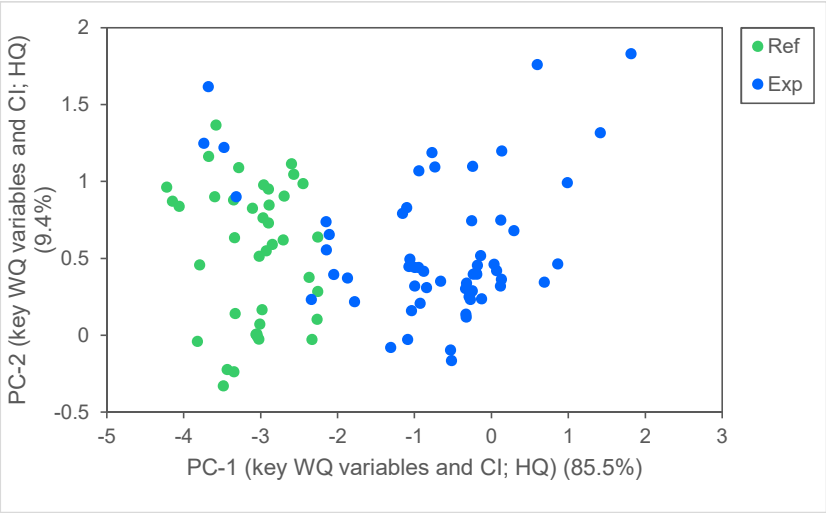

Figure C.1: Scatterplots of PC-2 Versus PC-1 from Five Different PCAs with Variations of Concentrations or Hazard Quotients for Water Quality (WQ) Variables and Calcite Index

Notes: Data are for lotic reference (n = 40) and mine-exposed (n = 59) areas where biological samples were collected in 2015. HQ - hazard quotient. Observed concentration divided by Level 1 effect benchmark defined in the Elk Valley Water Quality Plan (selenium, sulphate, nitrate, cadmium), the upper normal range limit defined by Minnow (2016b; calcite index), or BC water quality guidelines (the other water quality variables), as applicable. Key WQ variables = selenium, sulphate, nitrate.

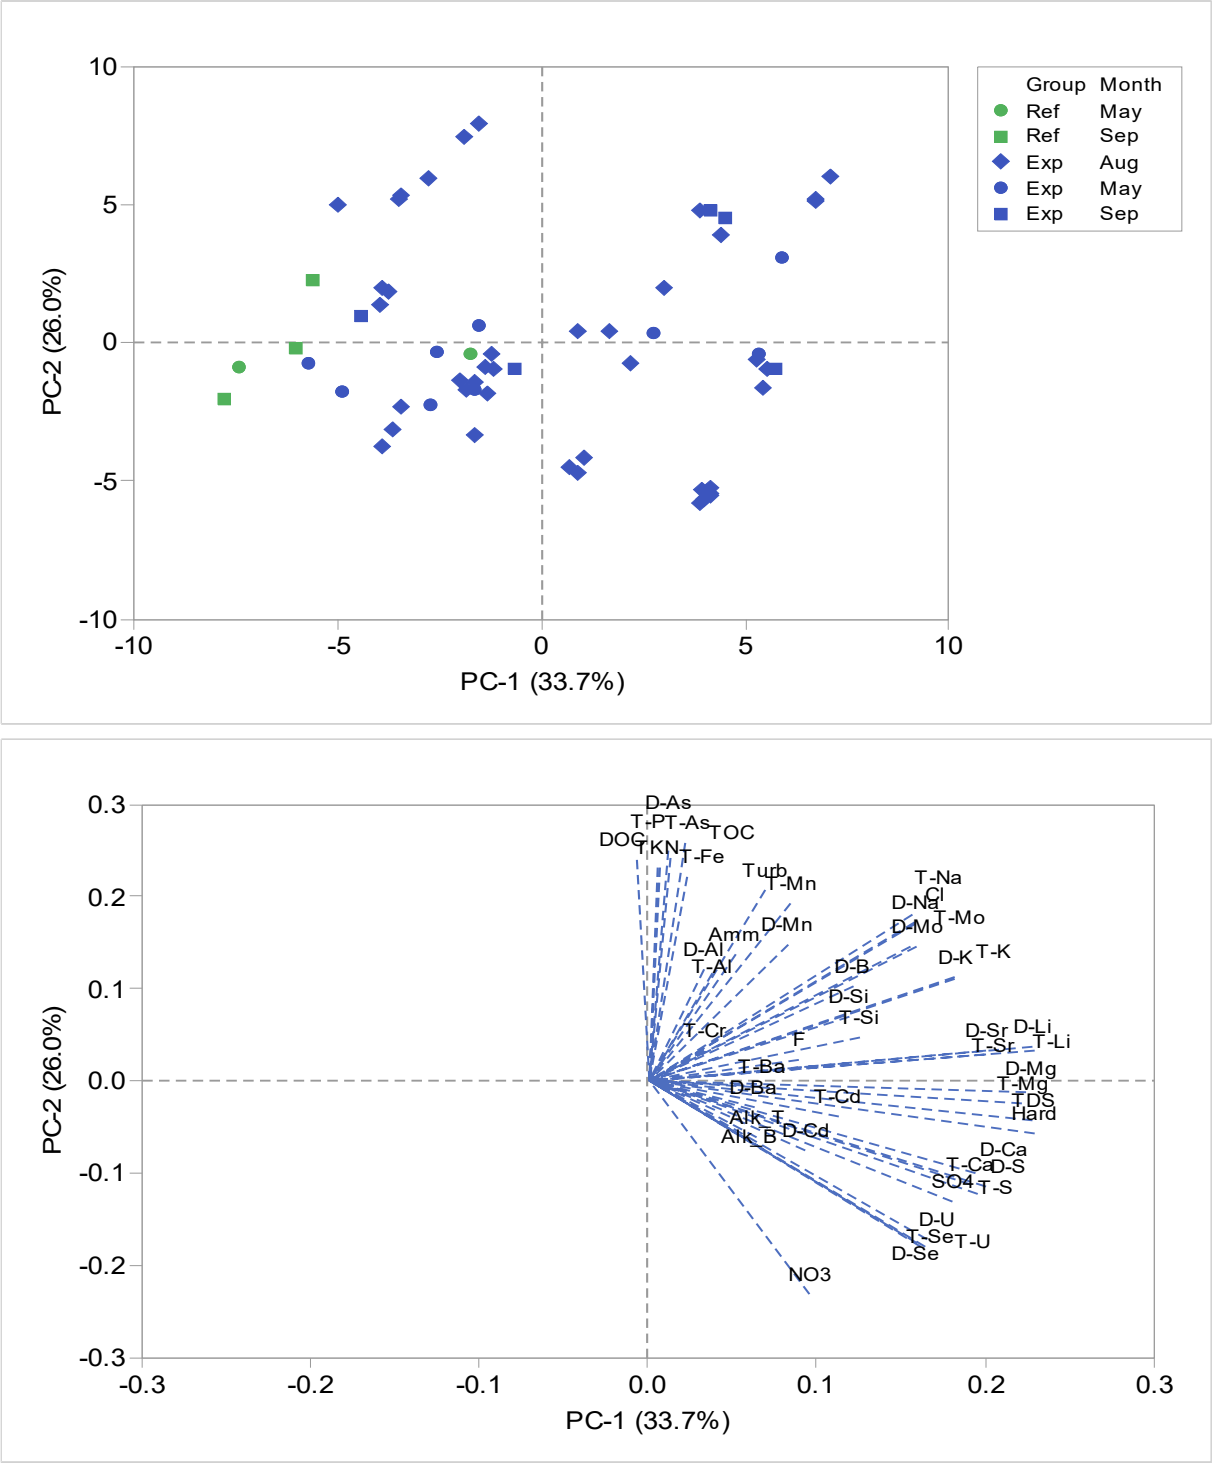

Figure C.2: Scatterplot of PC-2 versus PC-1 from a PCA of Concentrations (log_{10}-transformed) of Water Quality Parameters (Top Panel) and a Scatterplot of Weightings of each Water Quality Parameter to PC-2 and PC-1 (Bottom Panel) for 60 Samples Collected from Lentic Reference (n = 5) and Mine-exposed (n = 55) Areas Where Other Types of Samples were Also Collected in May, August, and September 2015

Notes: "T-" = total; "D-" = dissolved

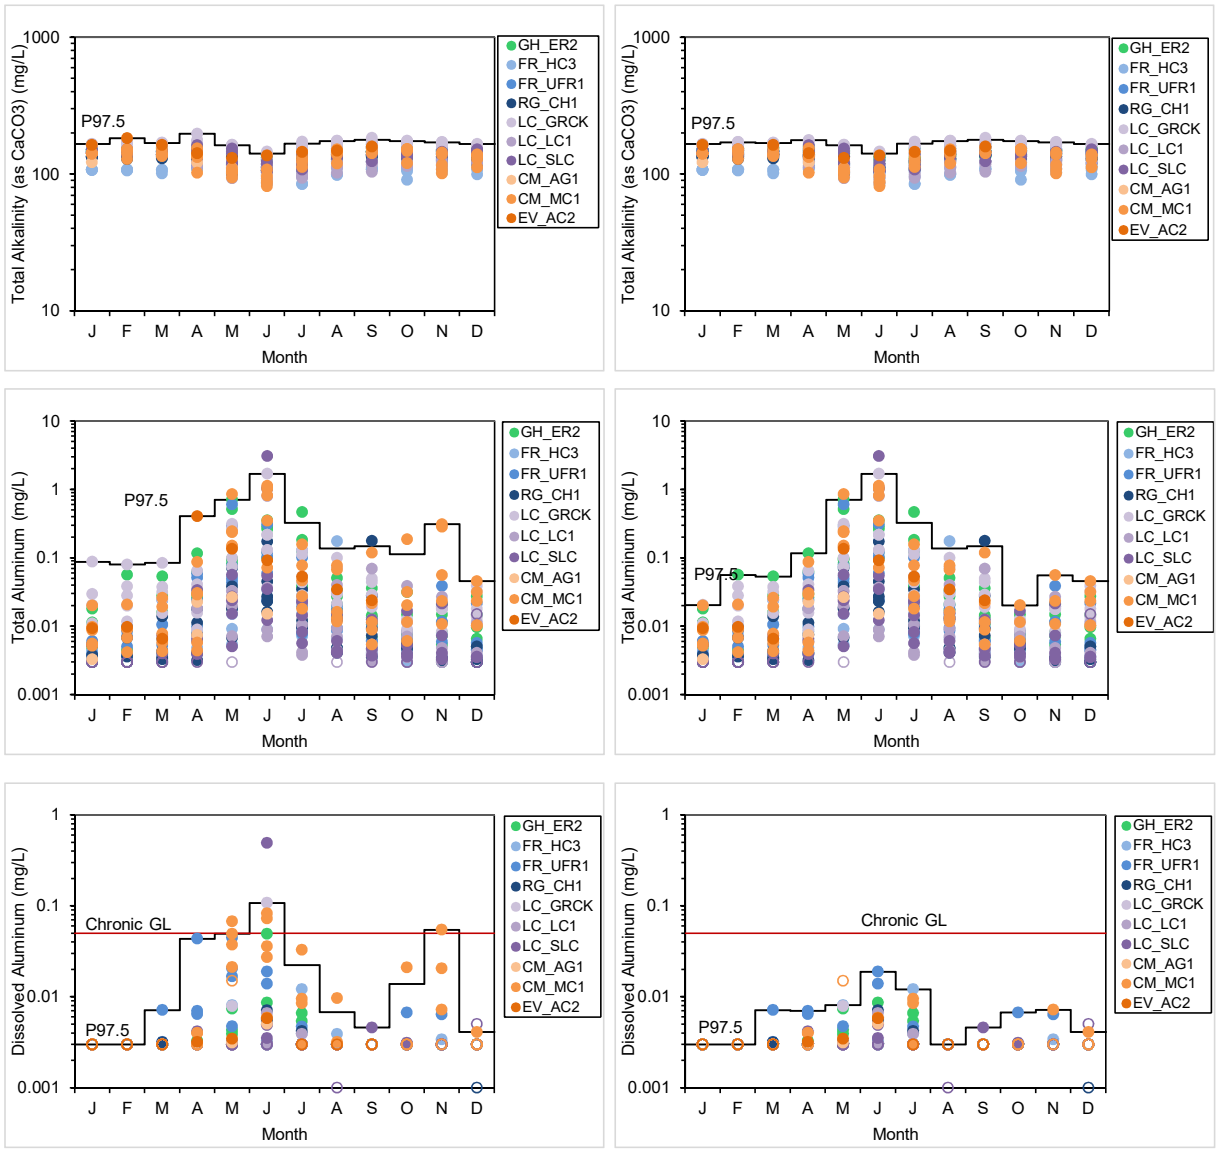

Figure C.3a: Scatterplot of Monthly Normal Ranges Defined using Reference Area Data, 2012-2016

Note: All data (left) and outliers removed (right). Concentrations below the laboratory detection limit (LRL) are plotted as open symbols at the LRL. Elk River areas are plotted in green, Fording River areas are plotted in blue and purple, and Michel Creek areas are plotted in orange. Black lines represent monthly upper normal range values, while red lines represent the water quality guidelines. For analytes with parameter-dependent guidelines (e.g., hardness), then a range of guidelines was calculated using the minimum and maximum monthly mean parameter values. For some months with data below the LRL, the upper normal range was lowered to a lower LRL in order to be more conservative.

GL - guideline; SSBM - Level 1 site-specific benchmark

Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

Figure C.7d: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

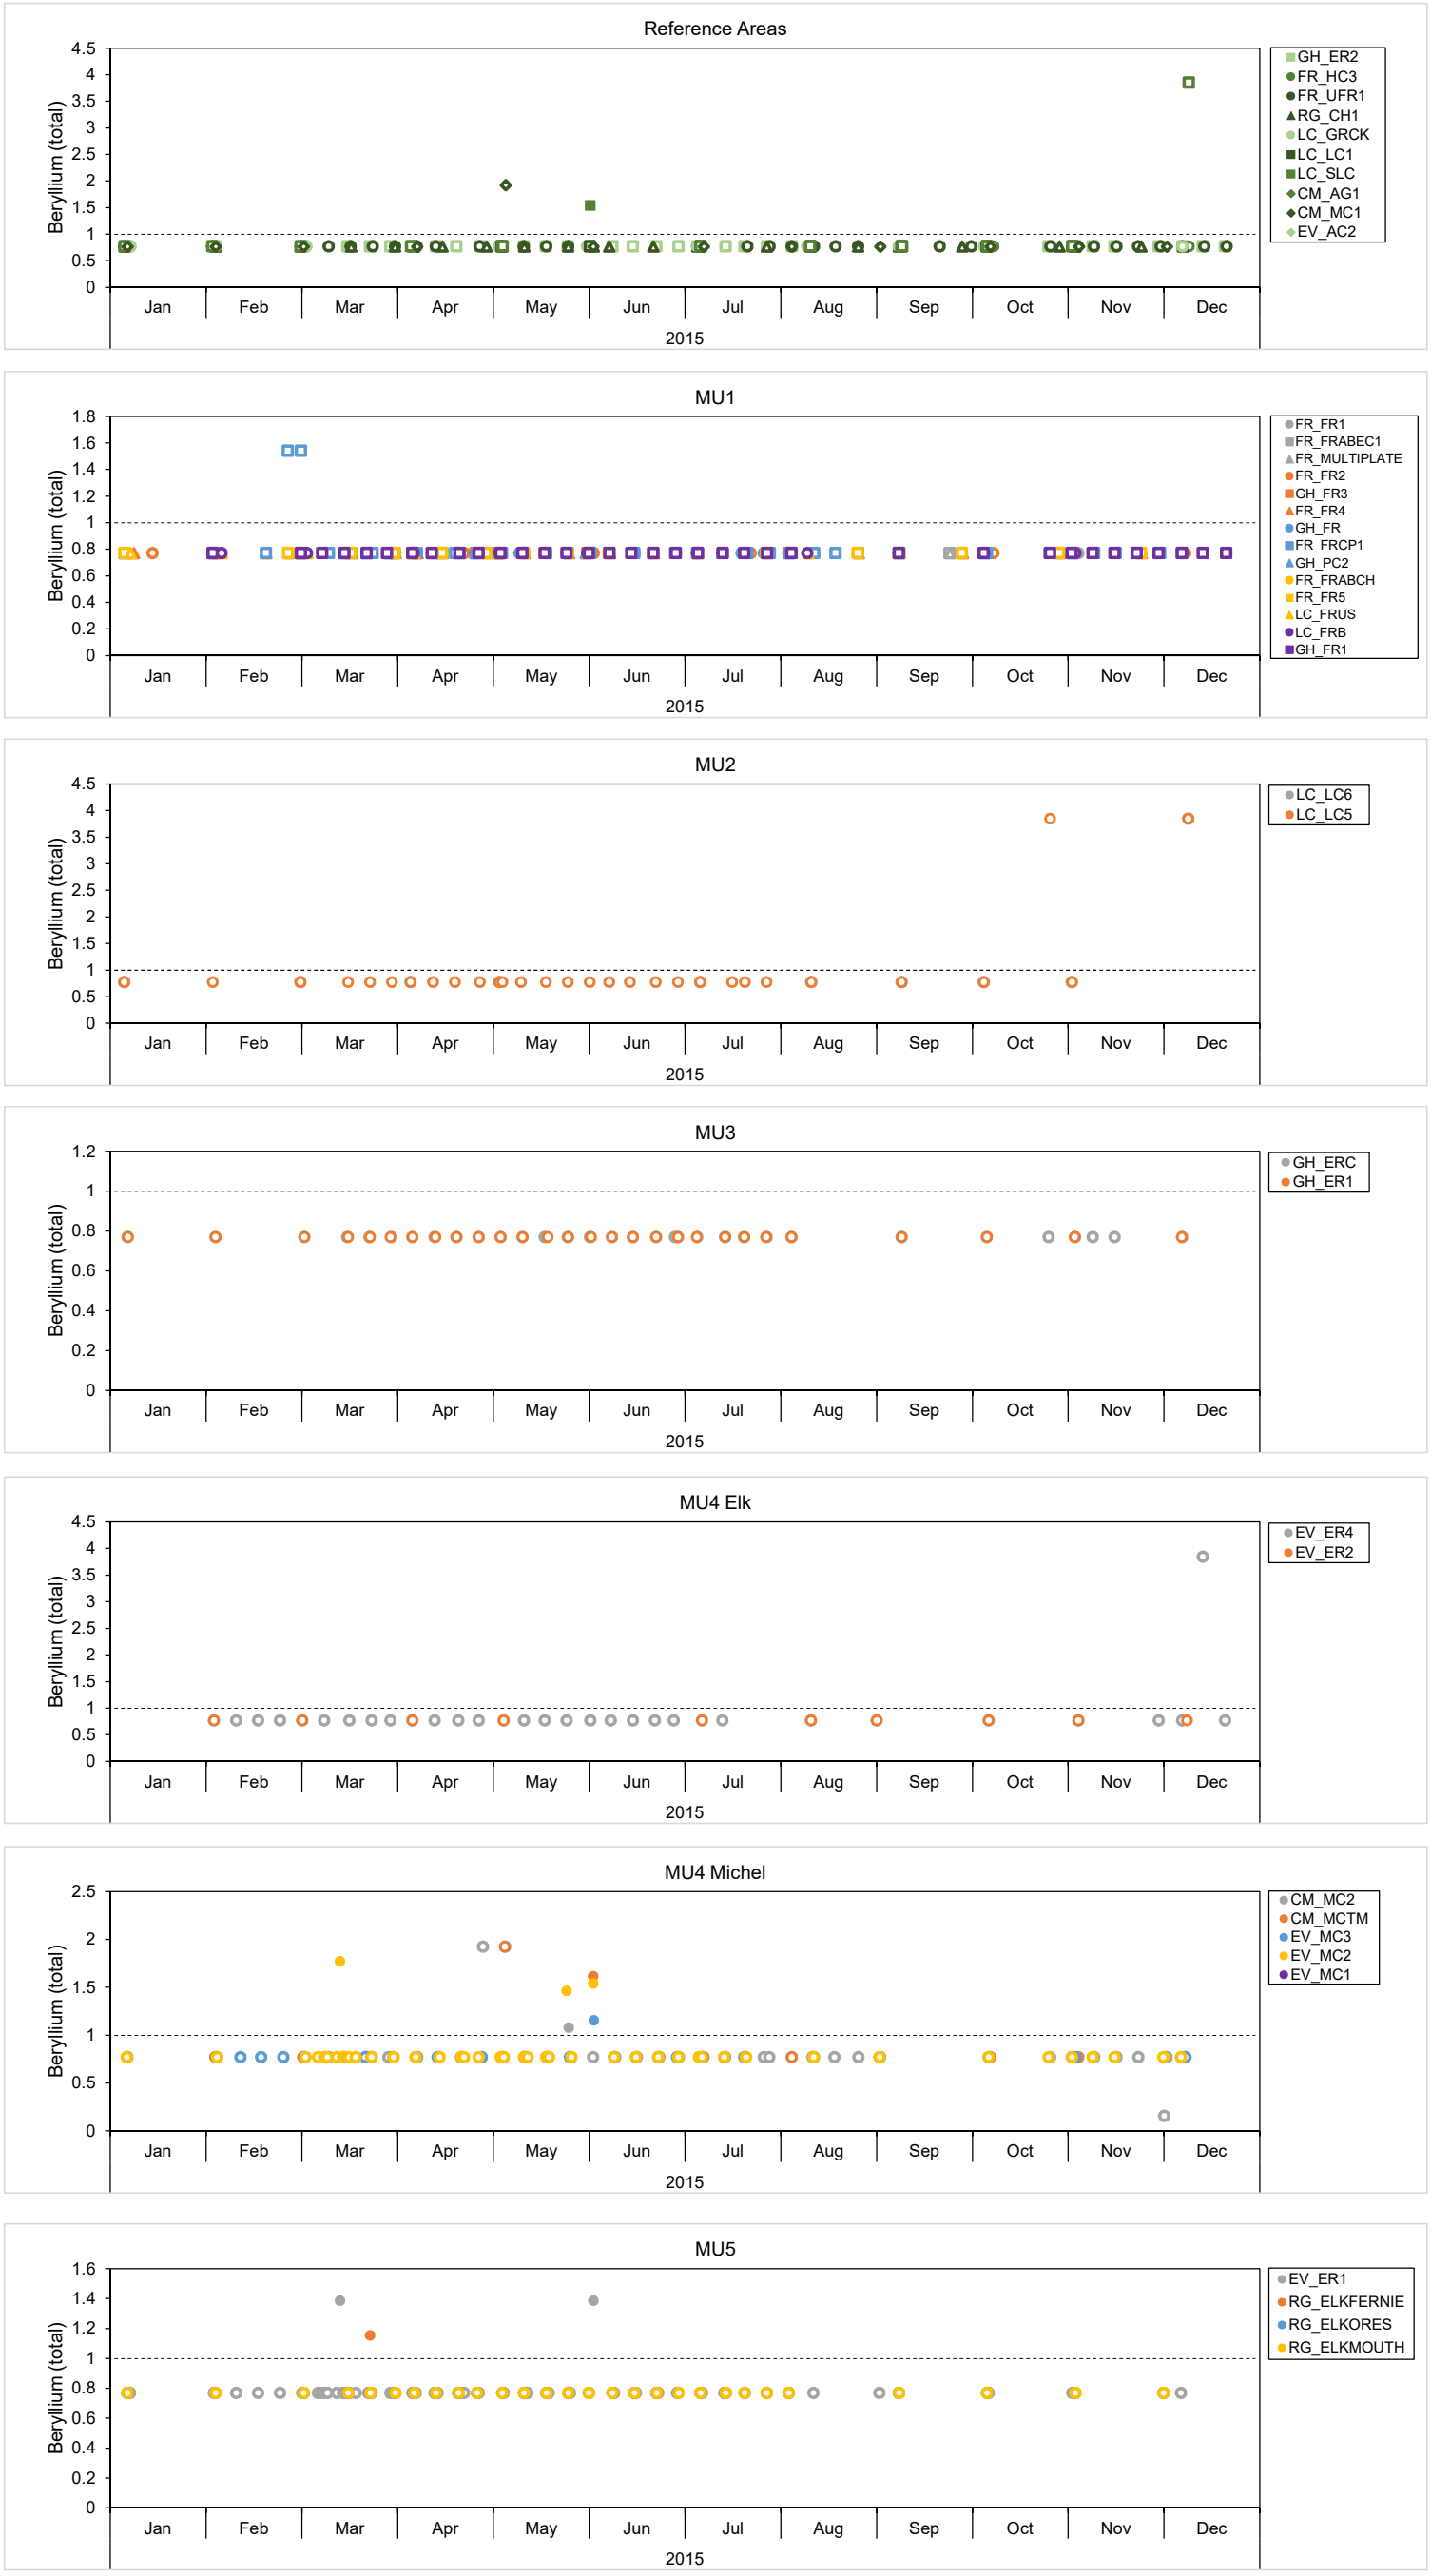

Figure C.7e: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

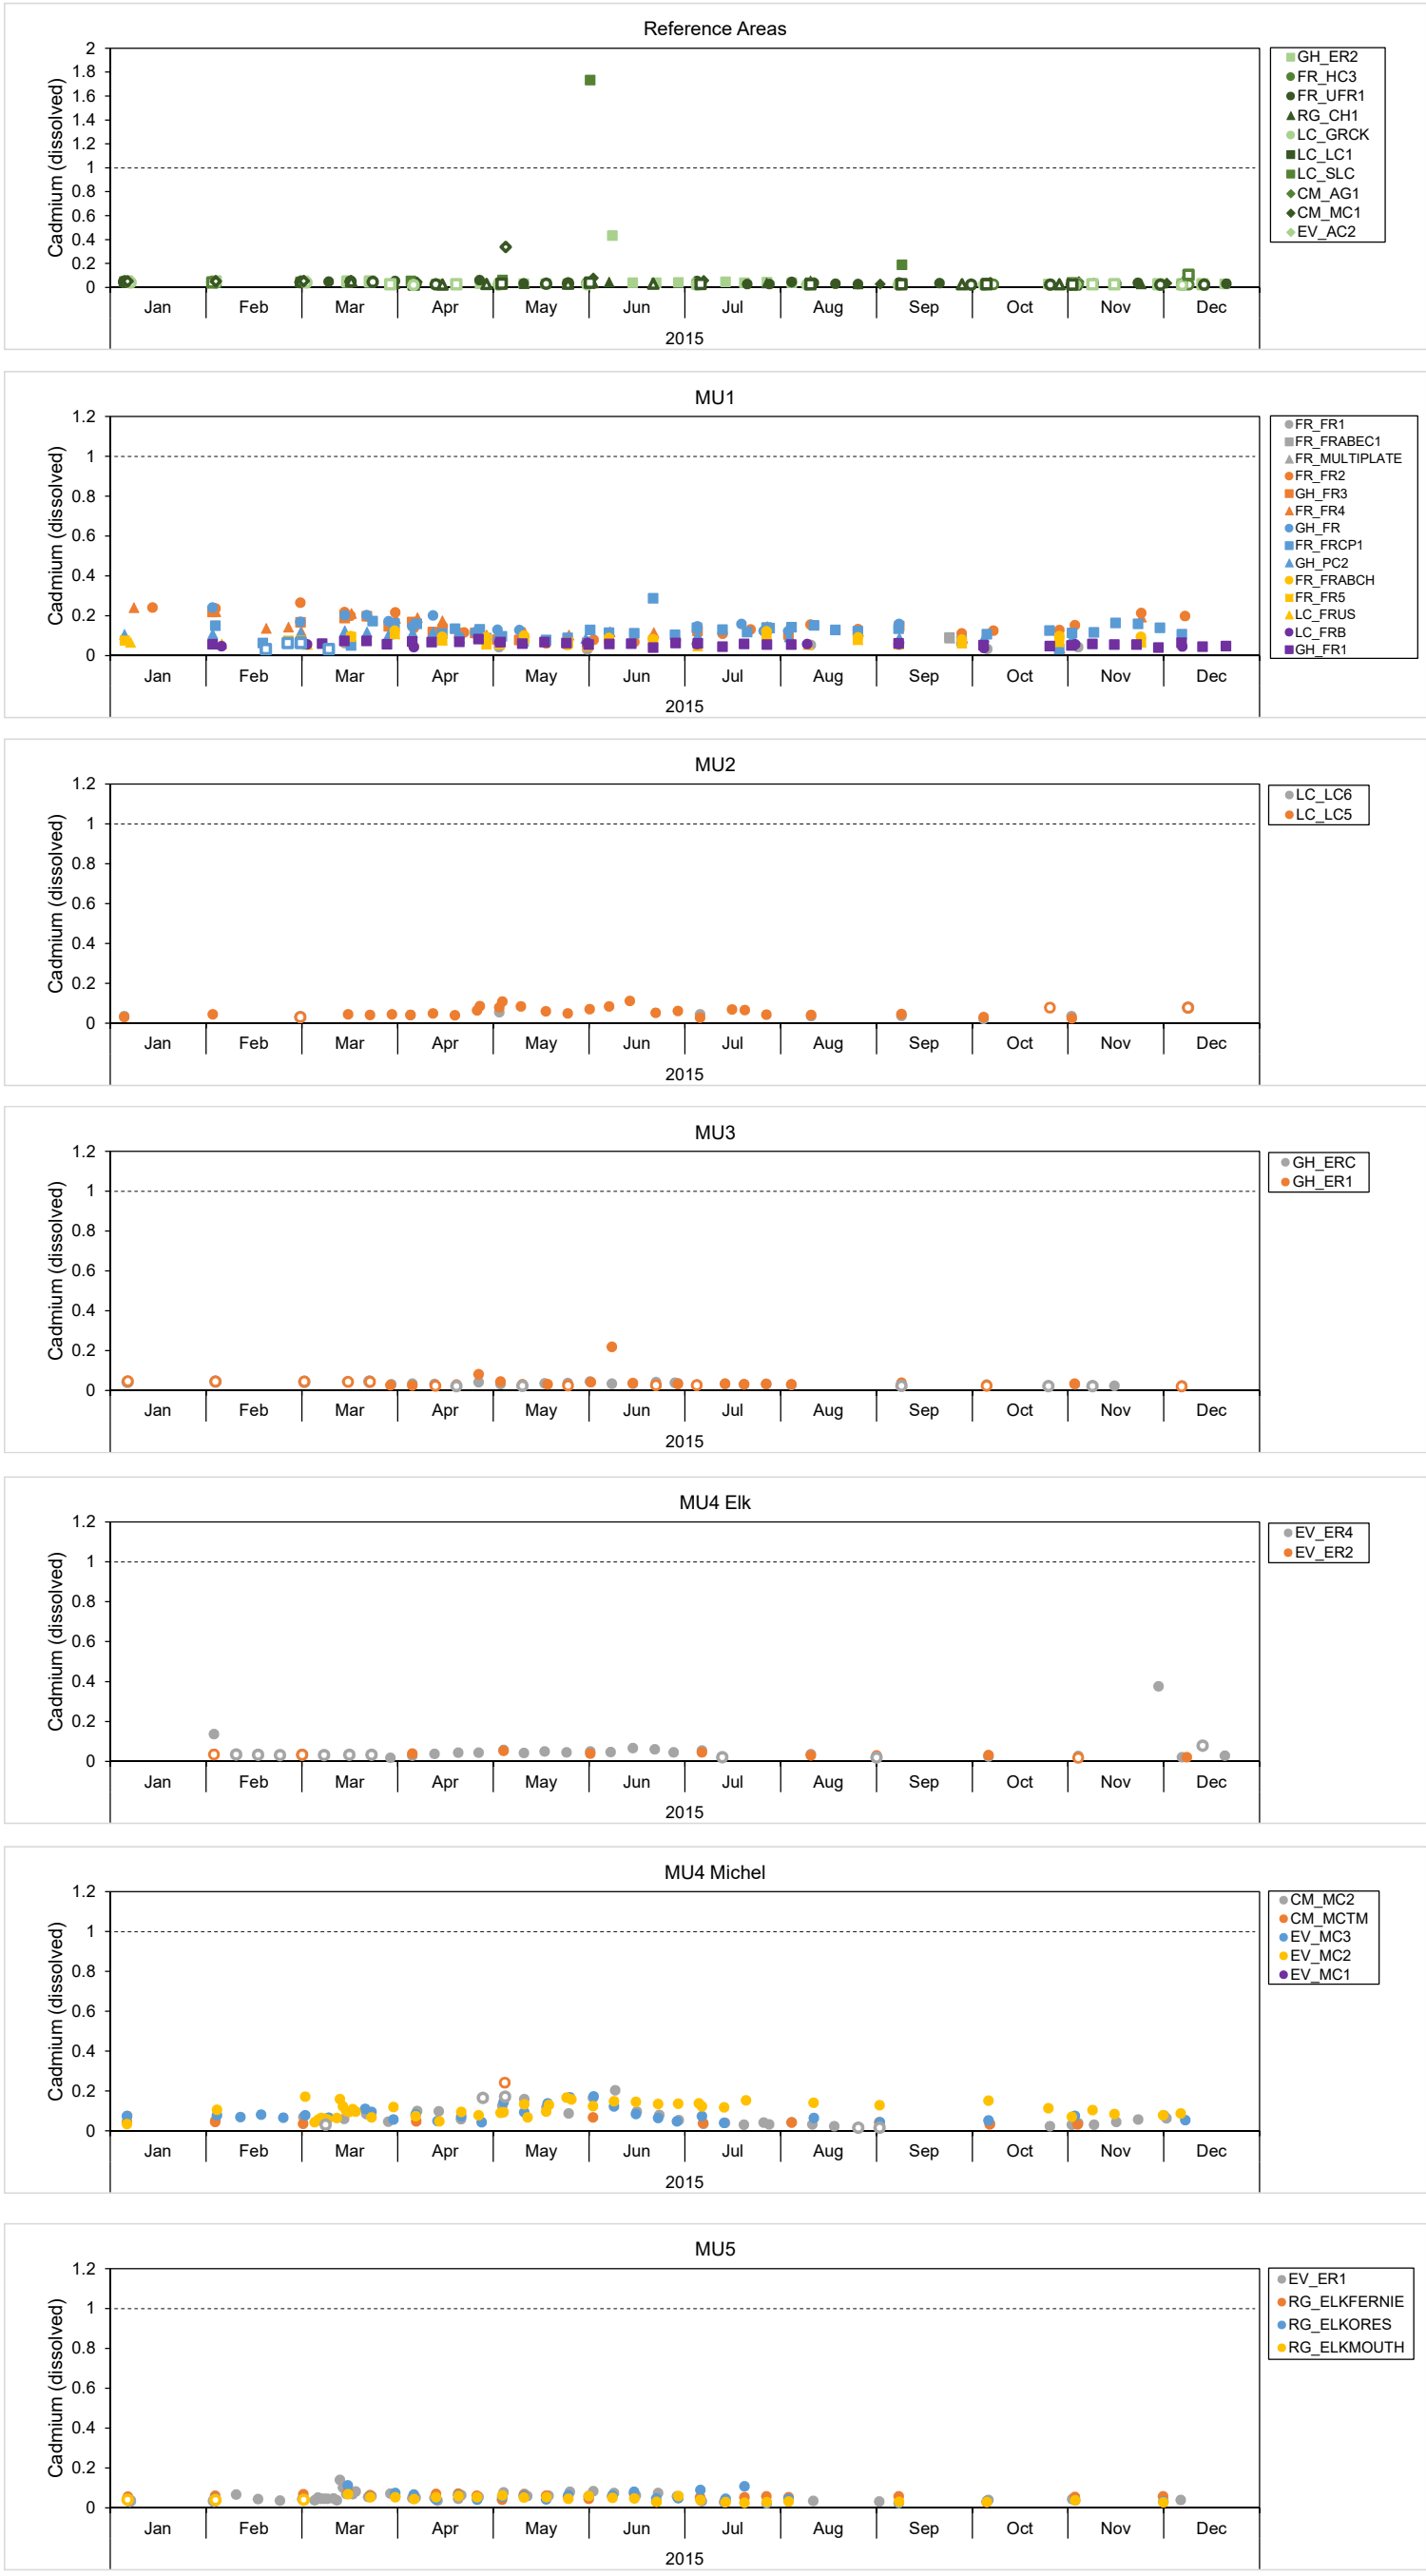

Figure C.7f: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

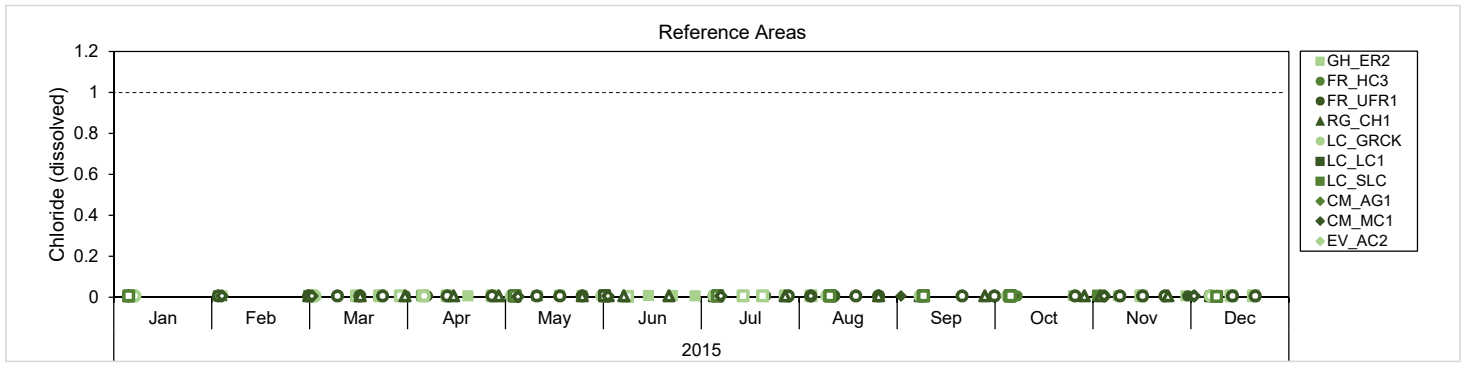
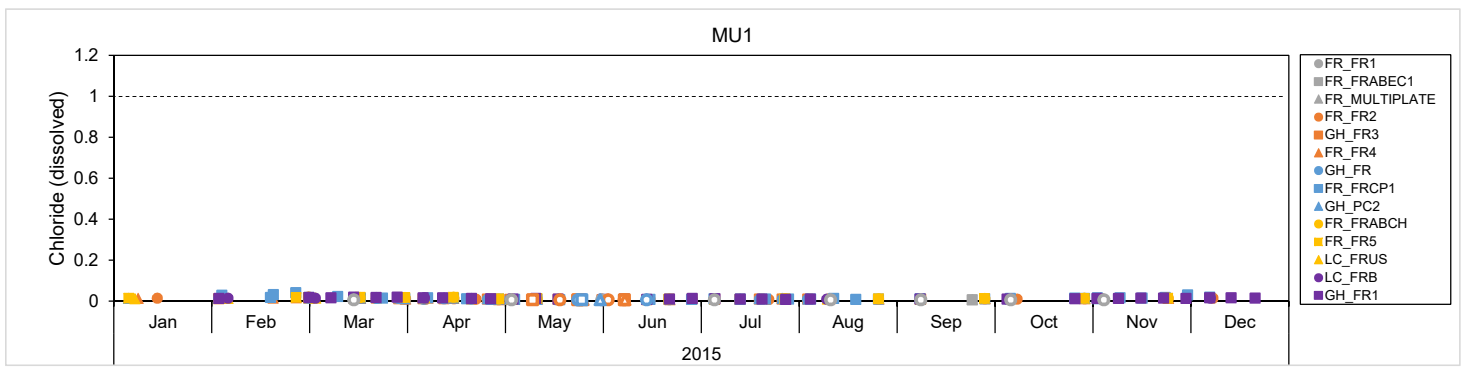
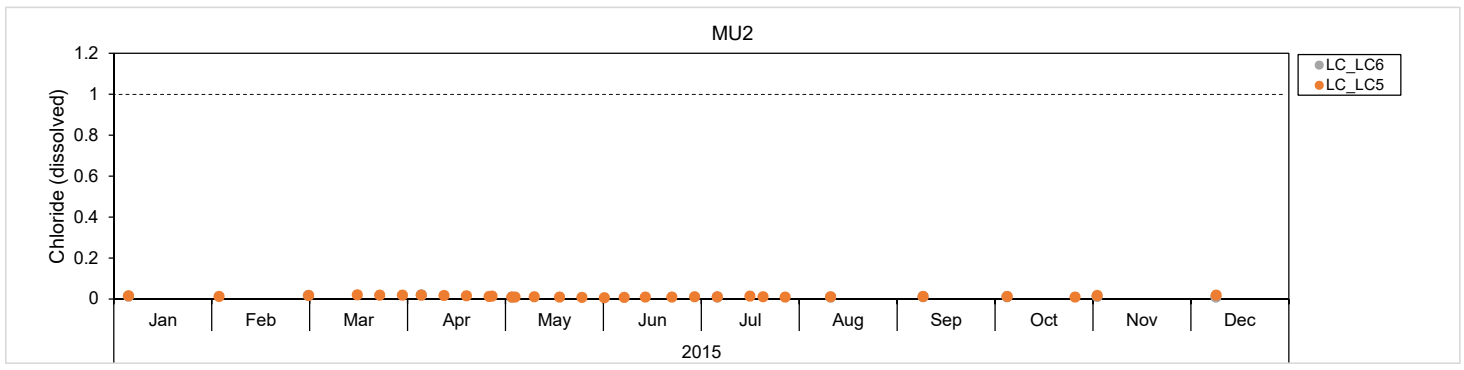
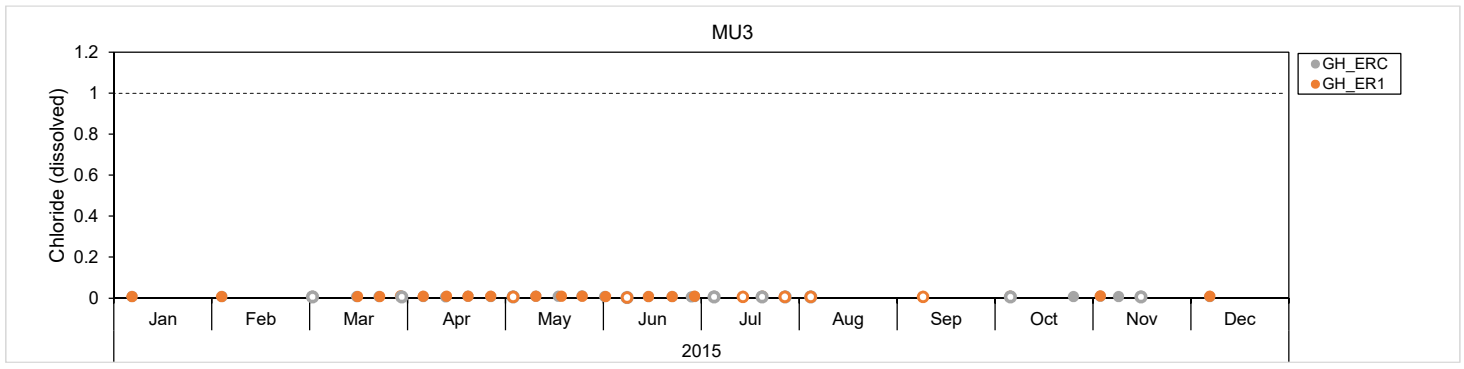
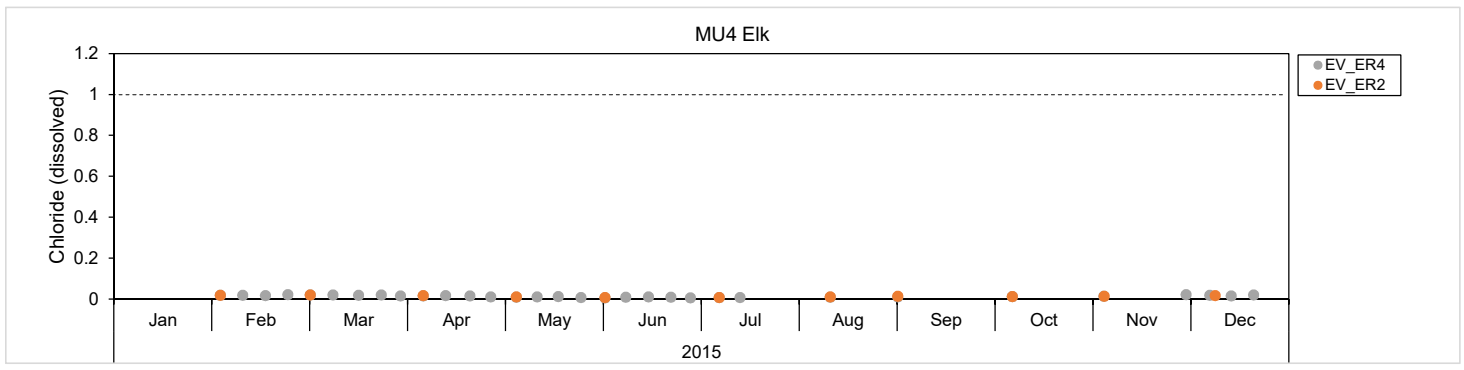
Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

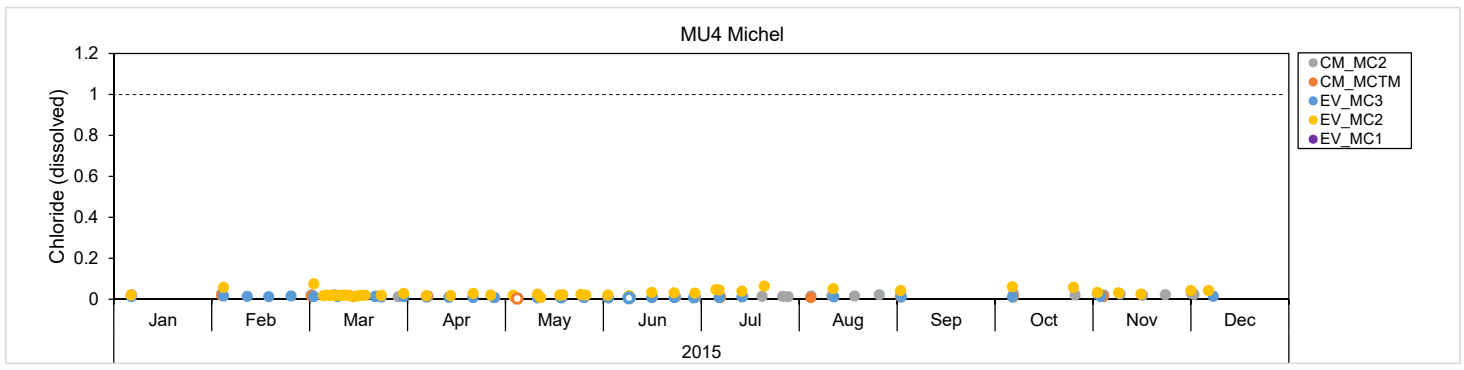












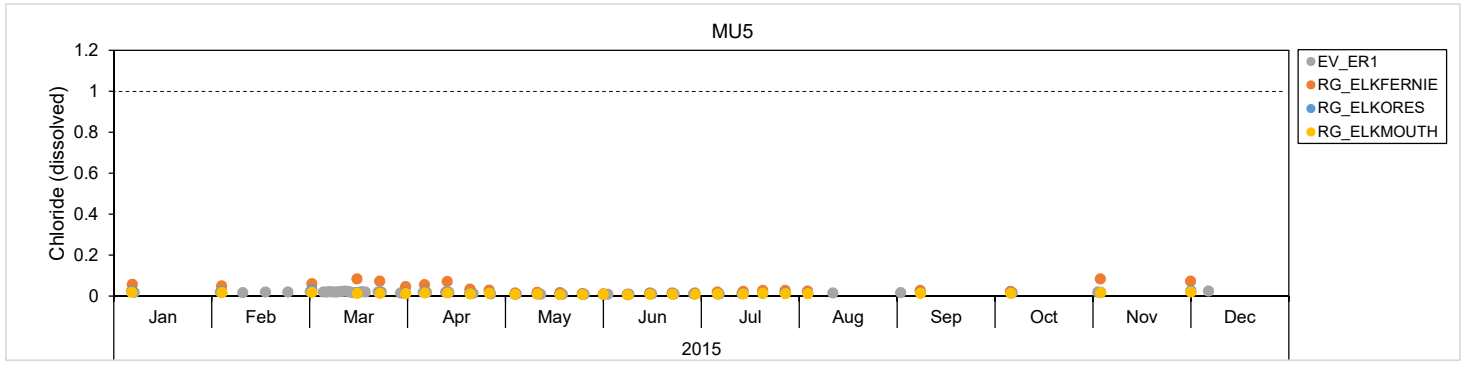


Figure C.7g: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

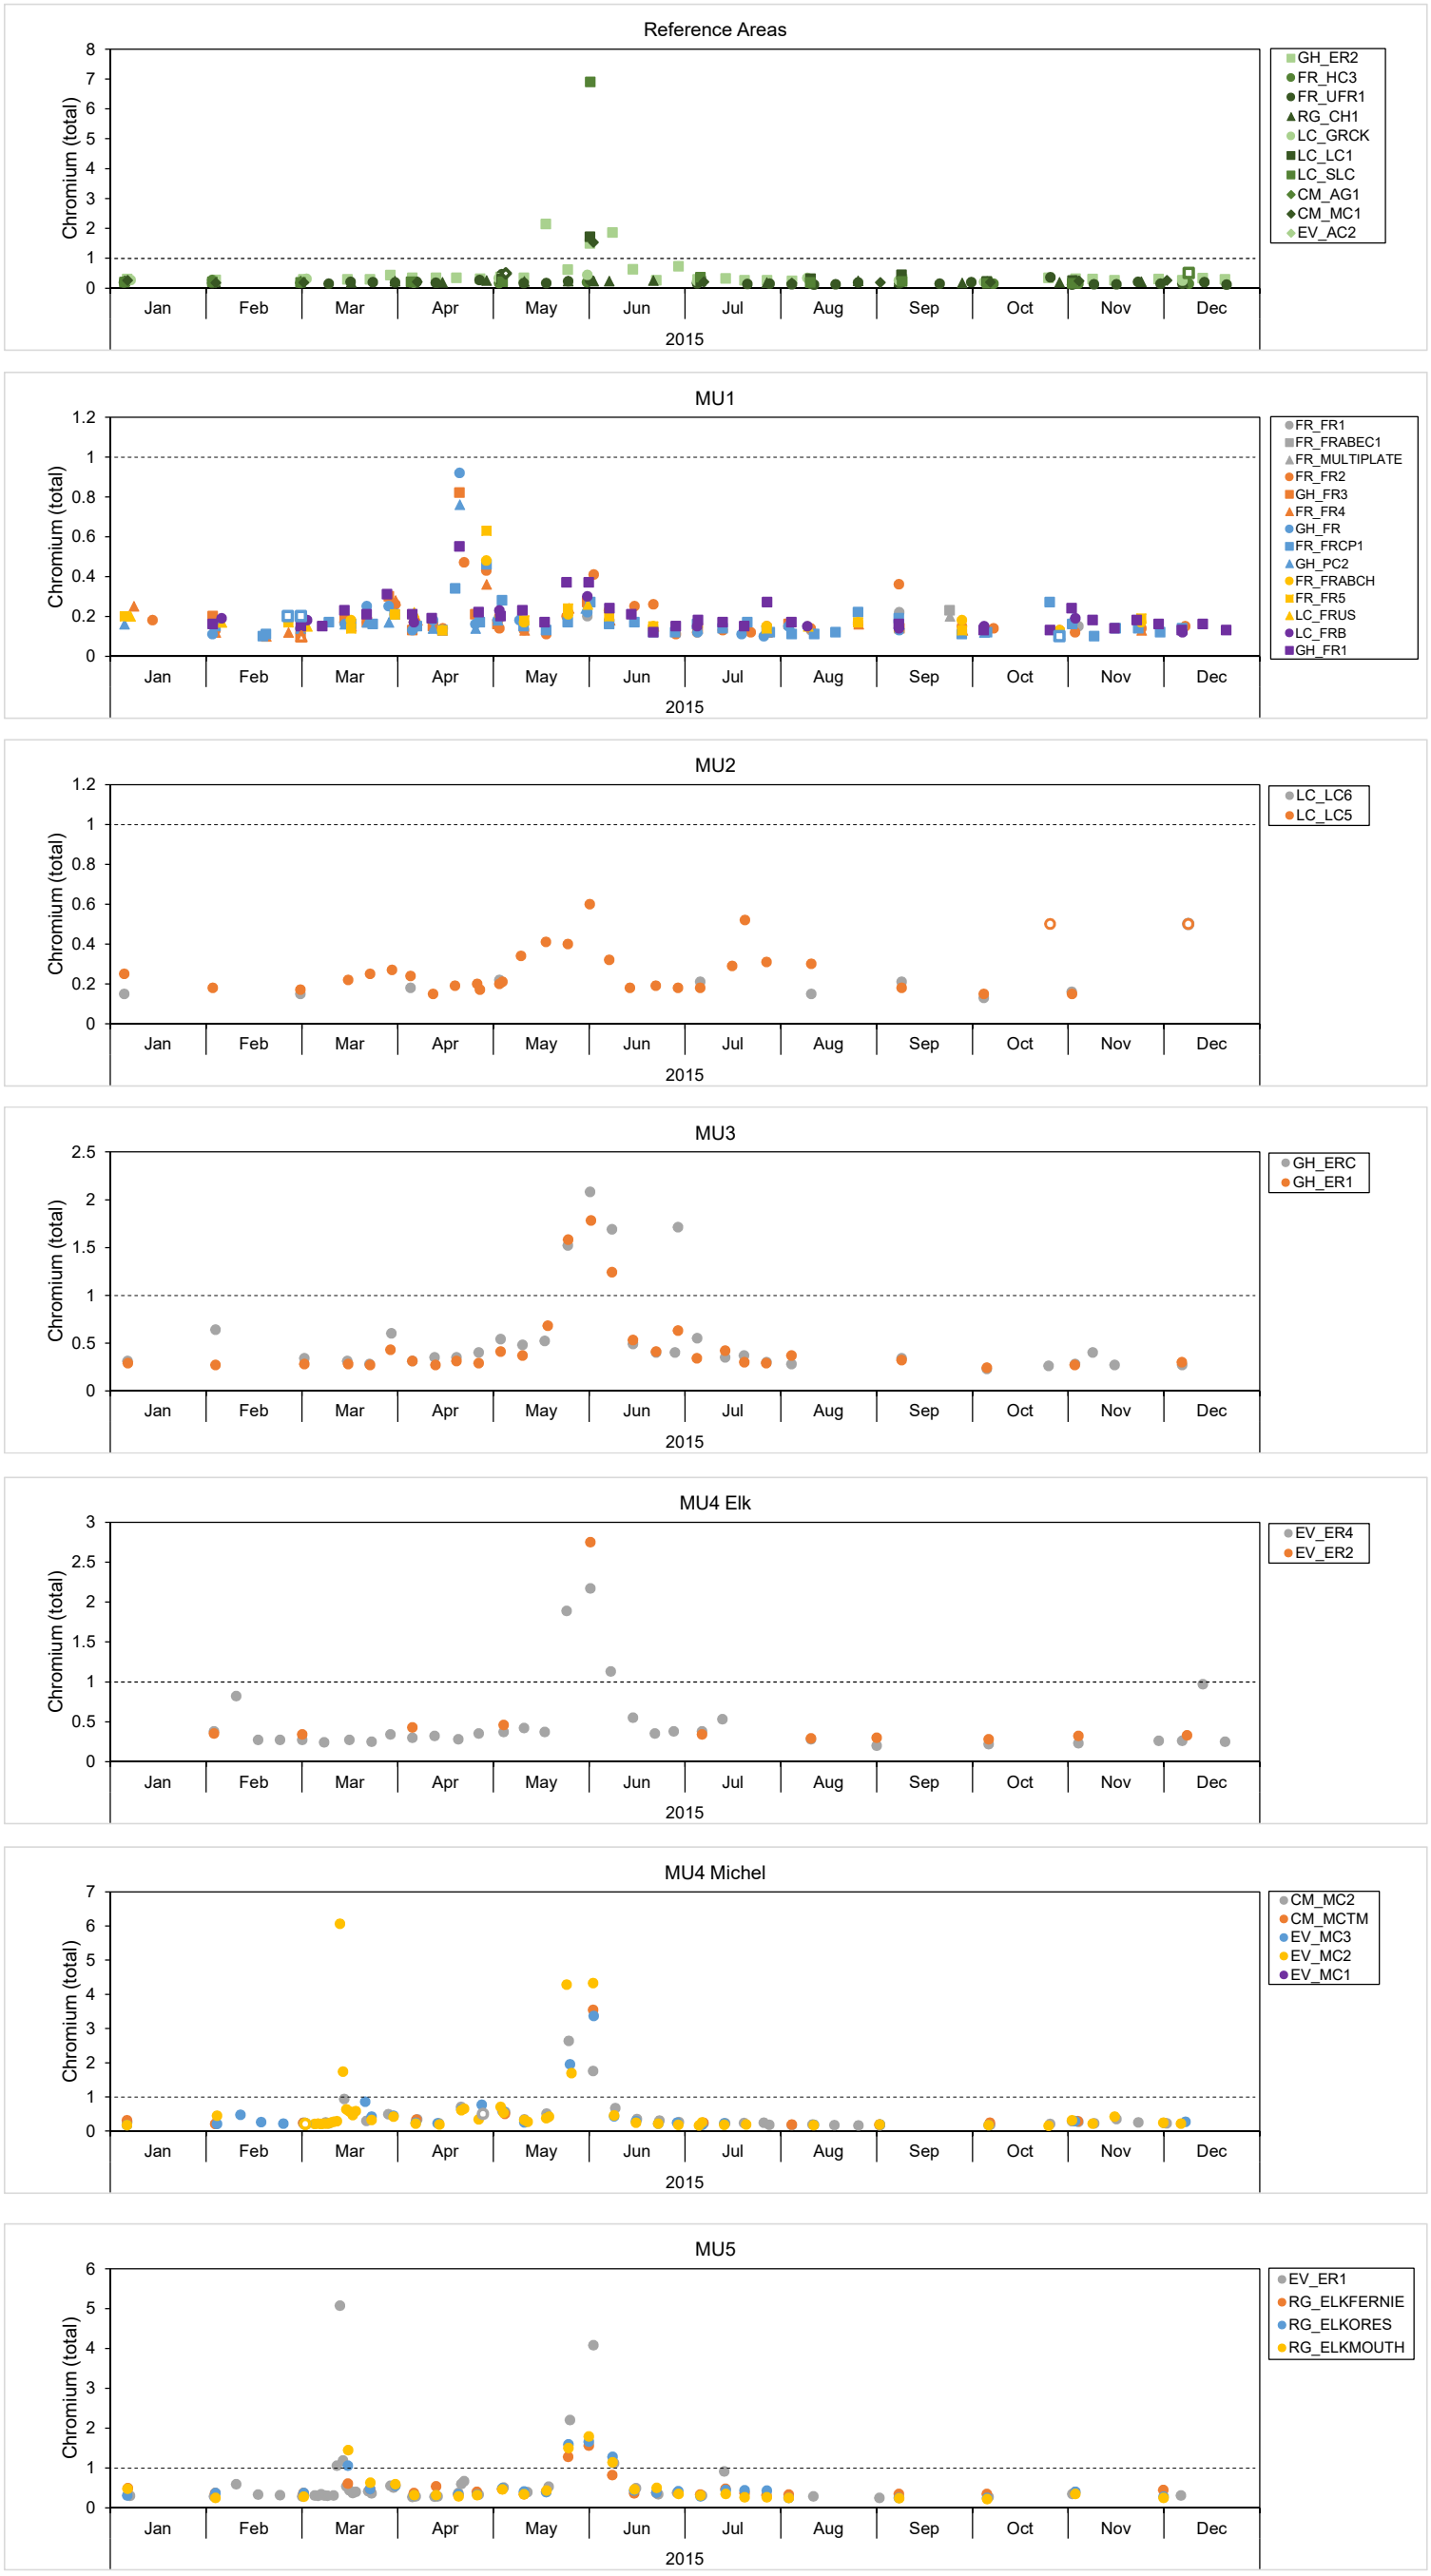

Figure C.7h: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

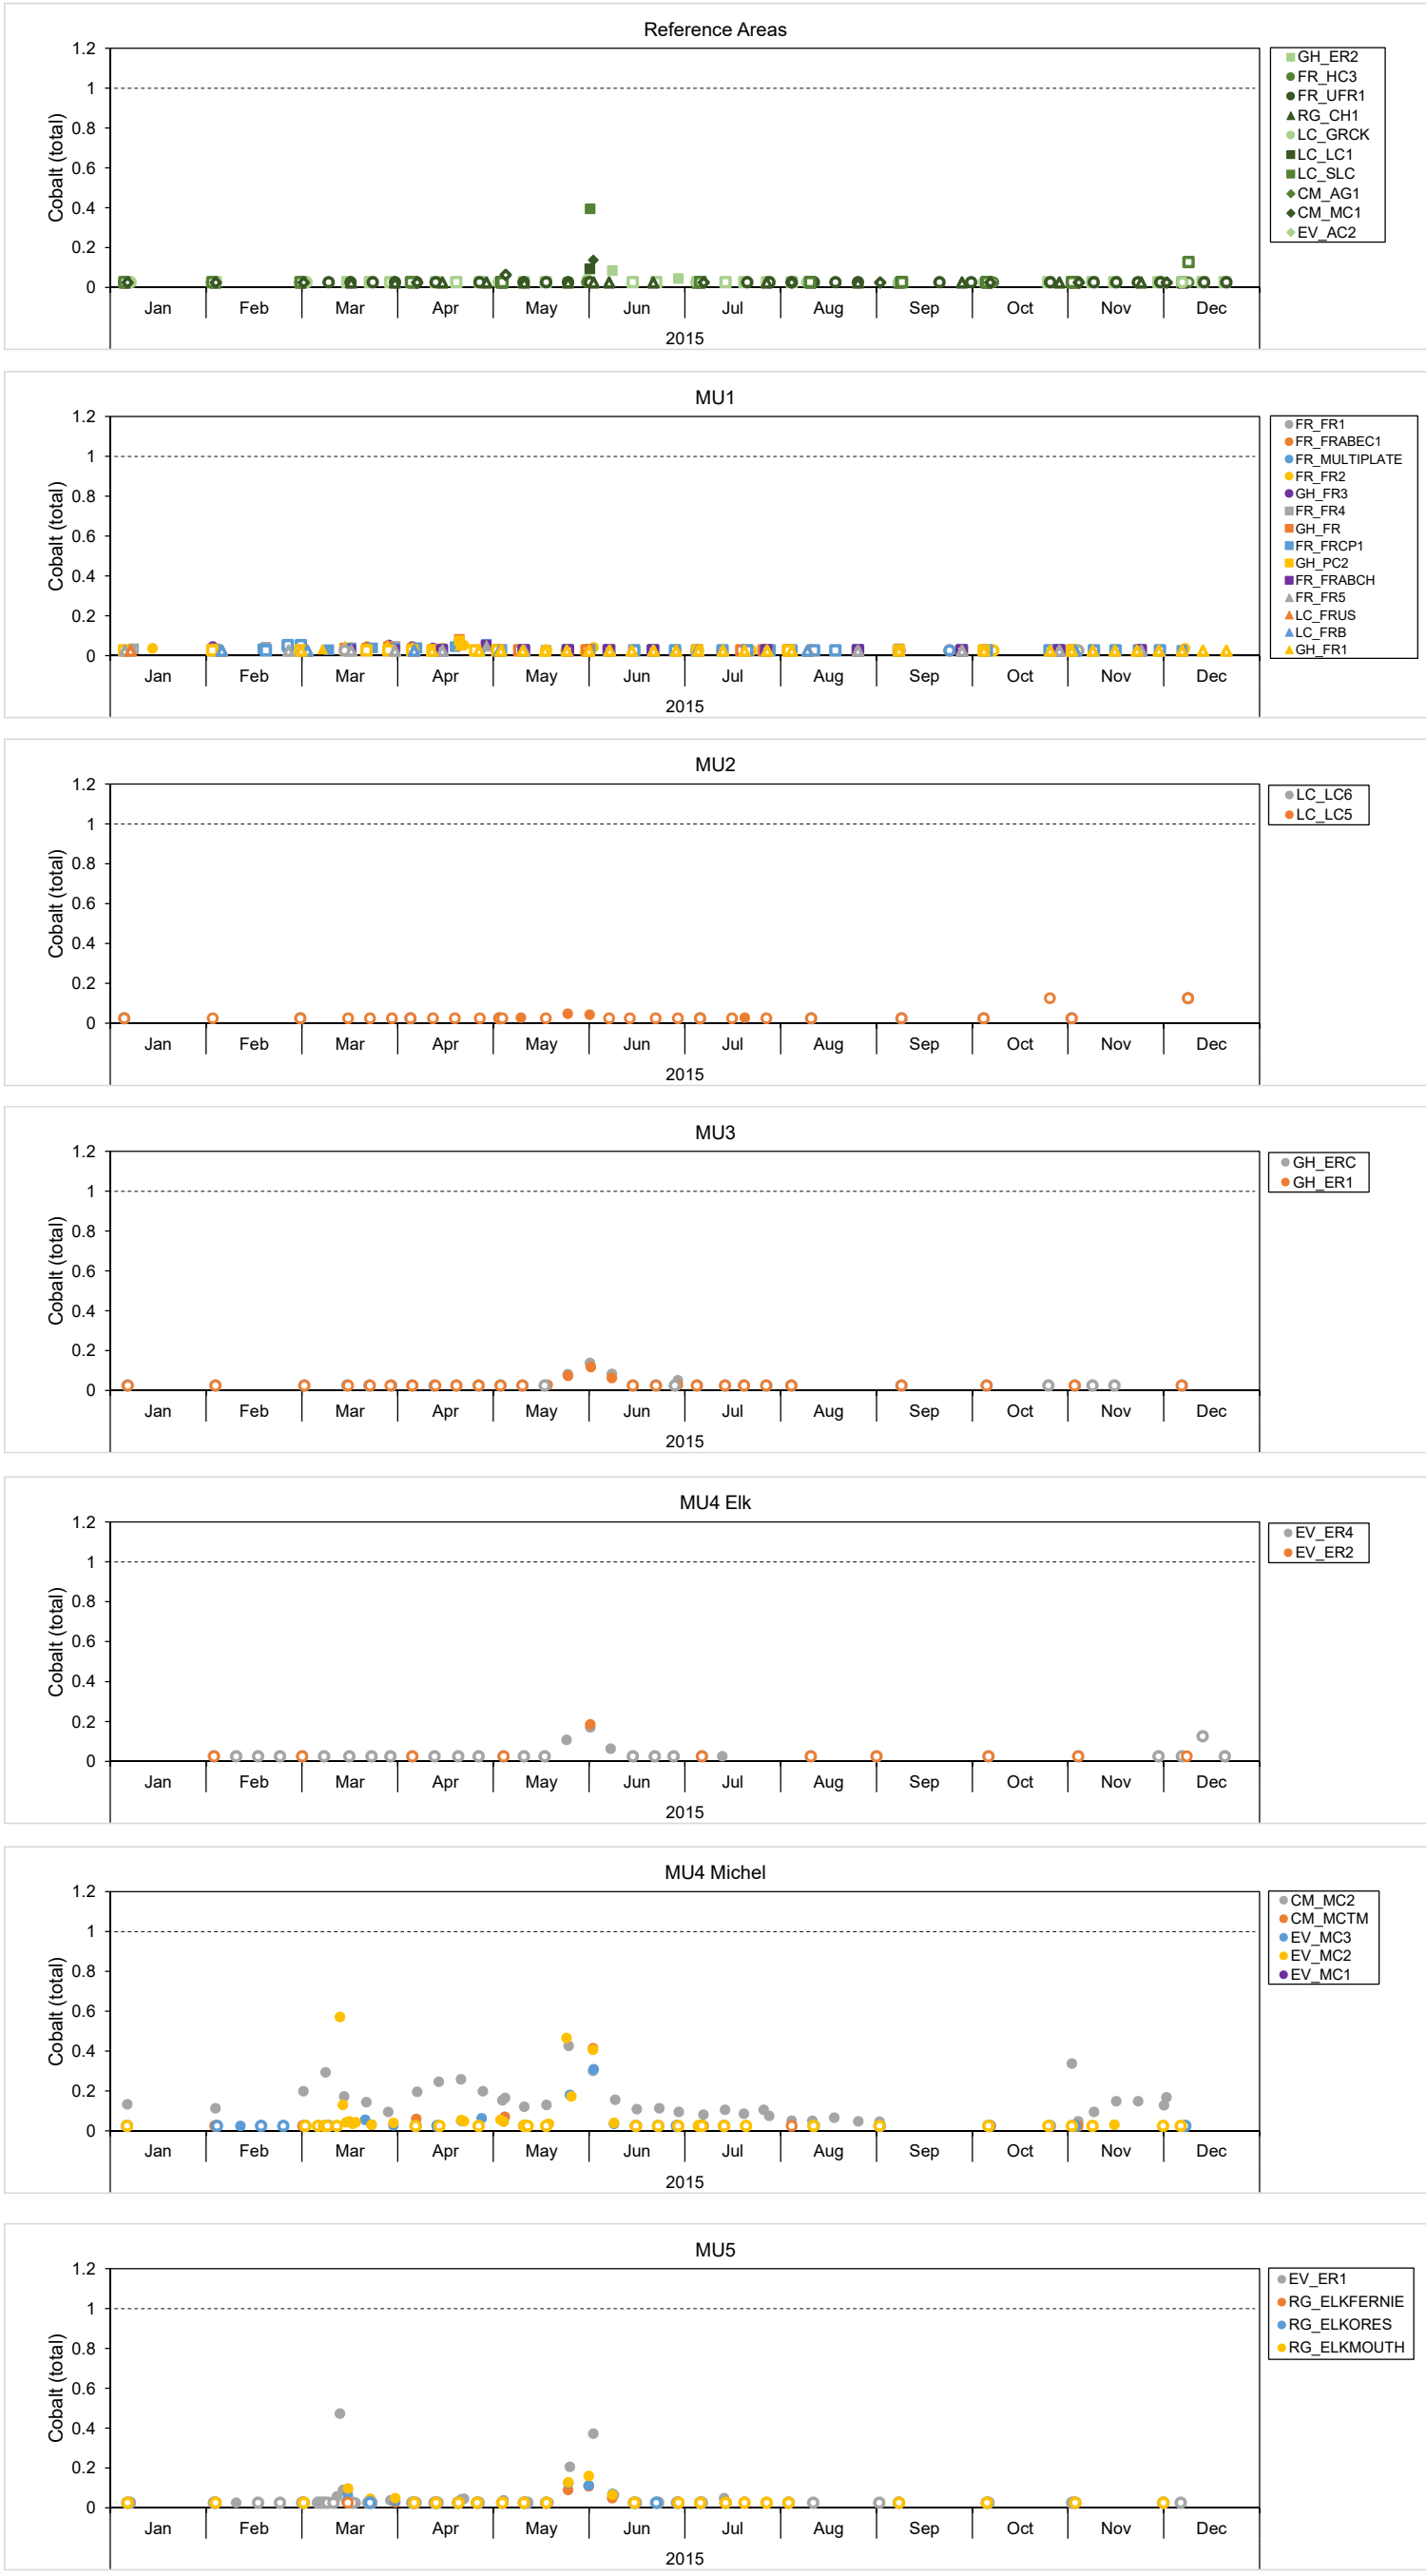

Figure C.7i: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

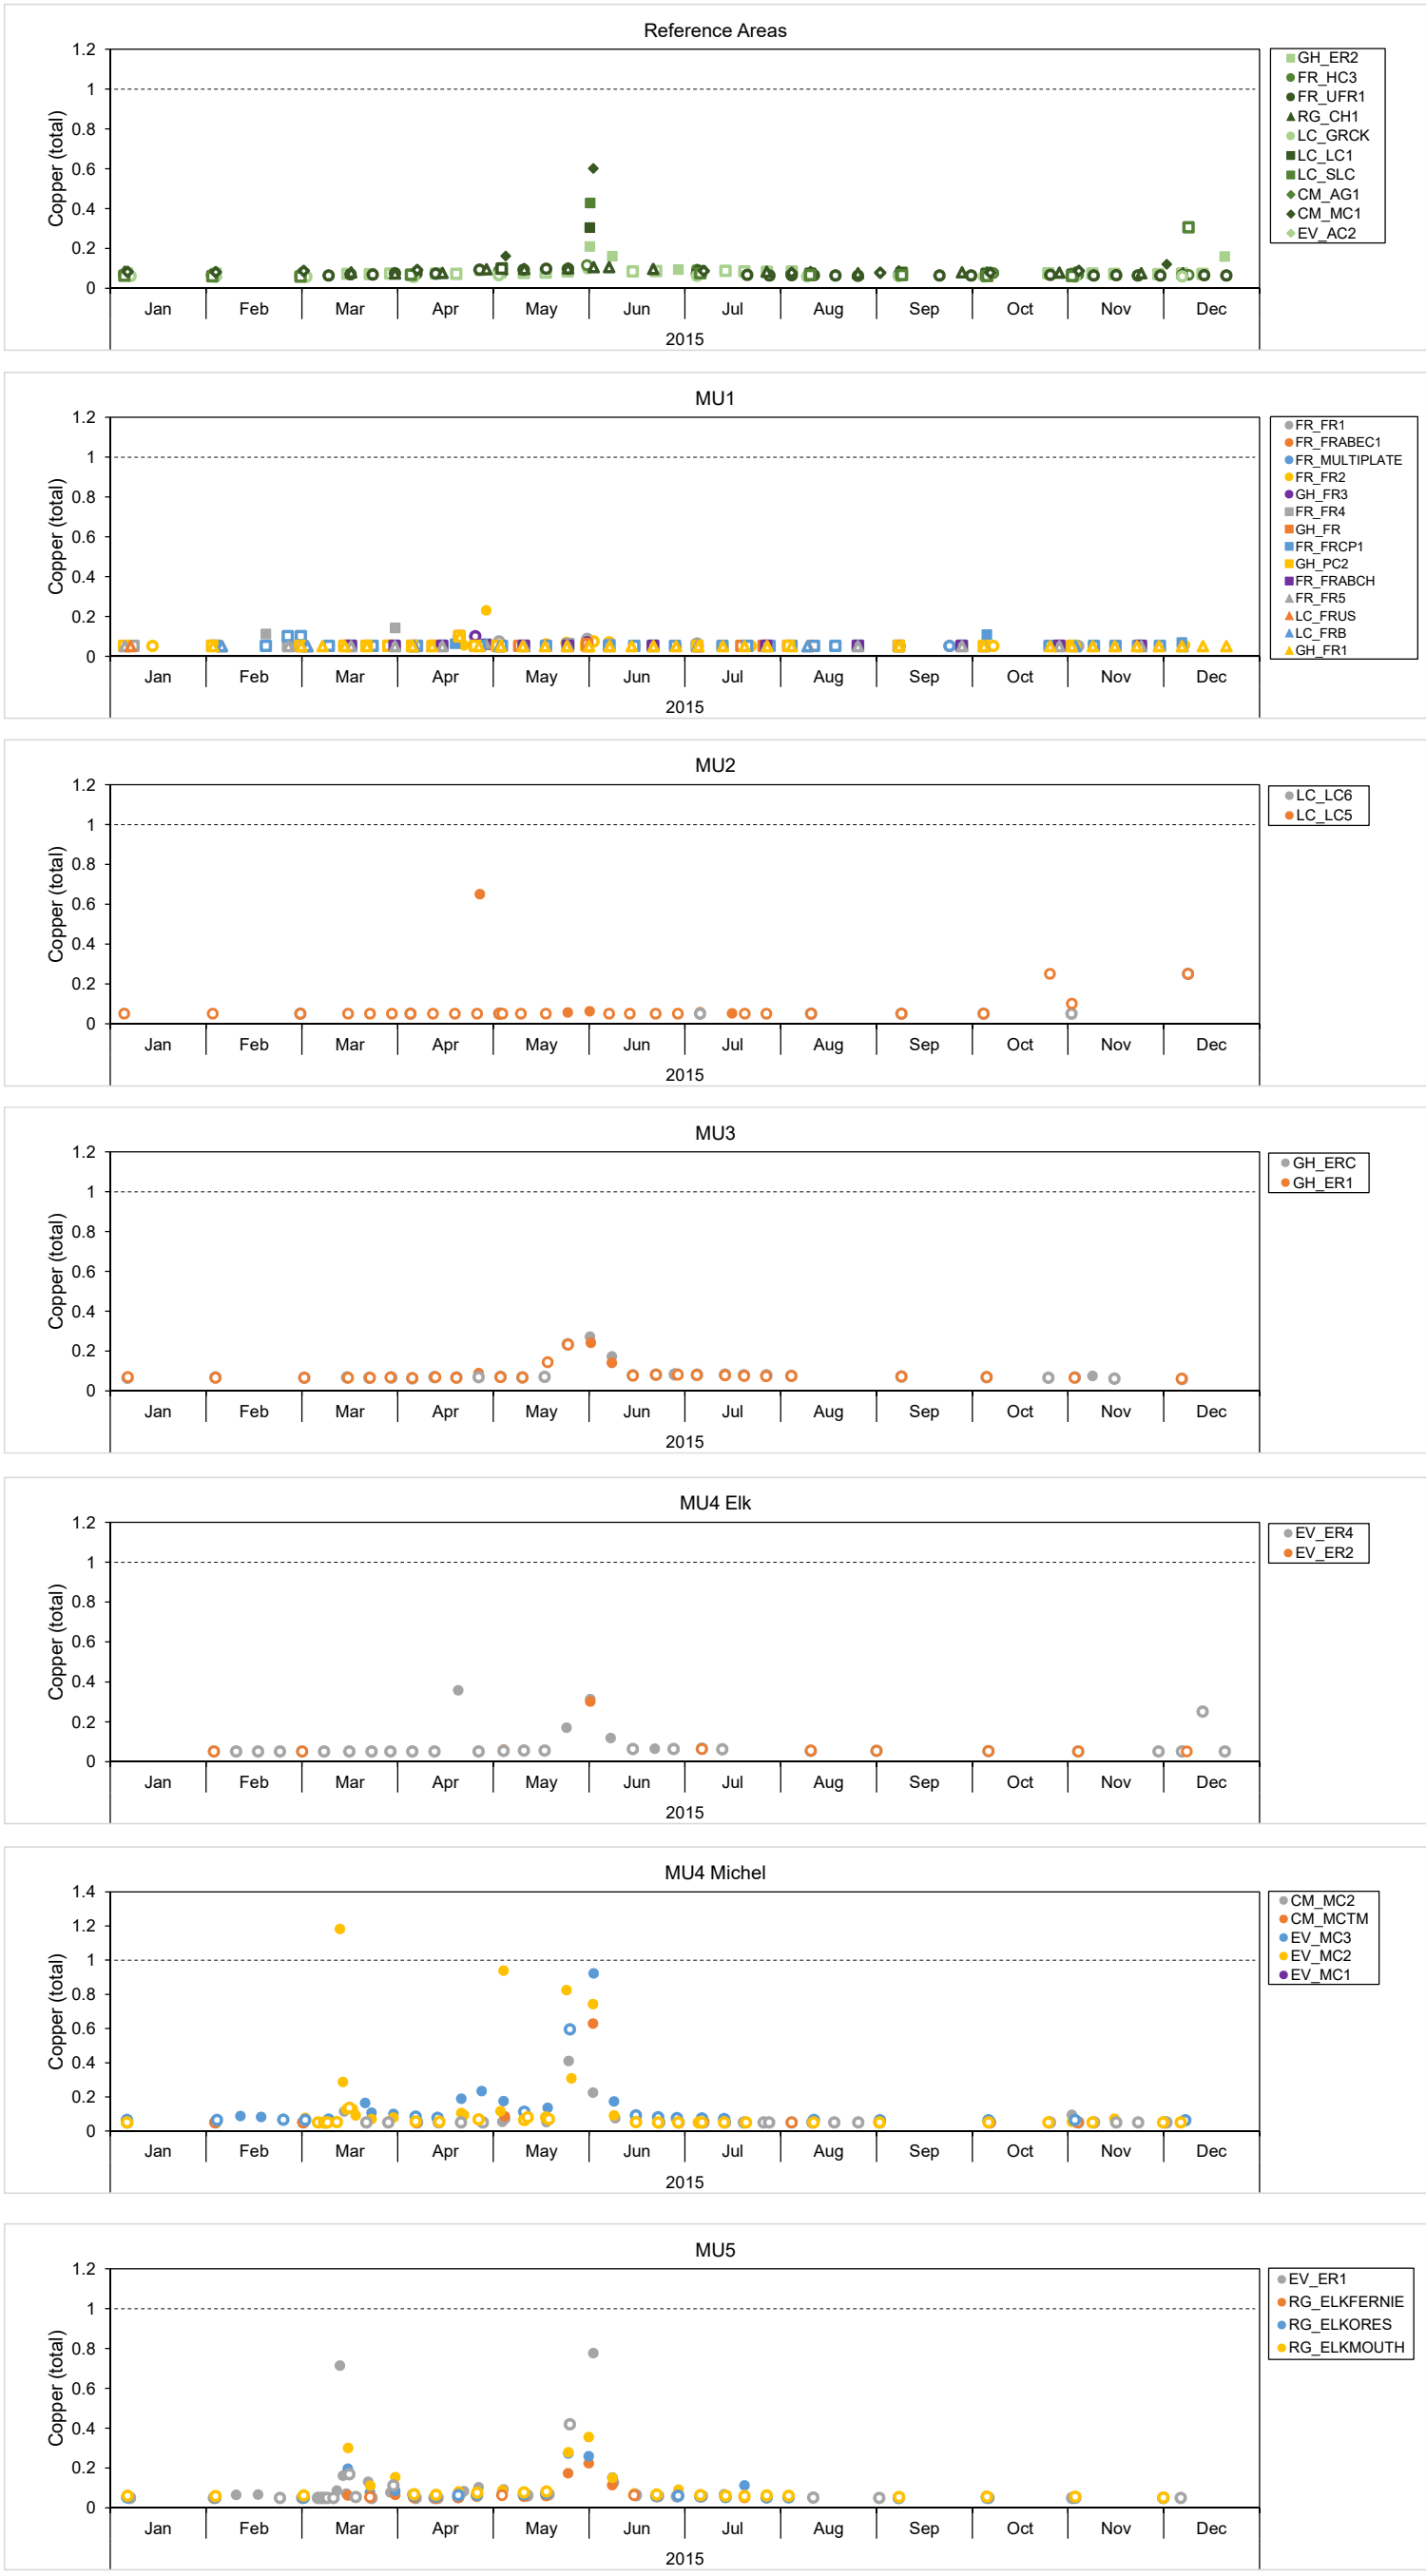

Figure C.7j: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

Figure C.7k: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

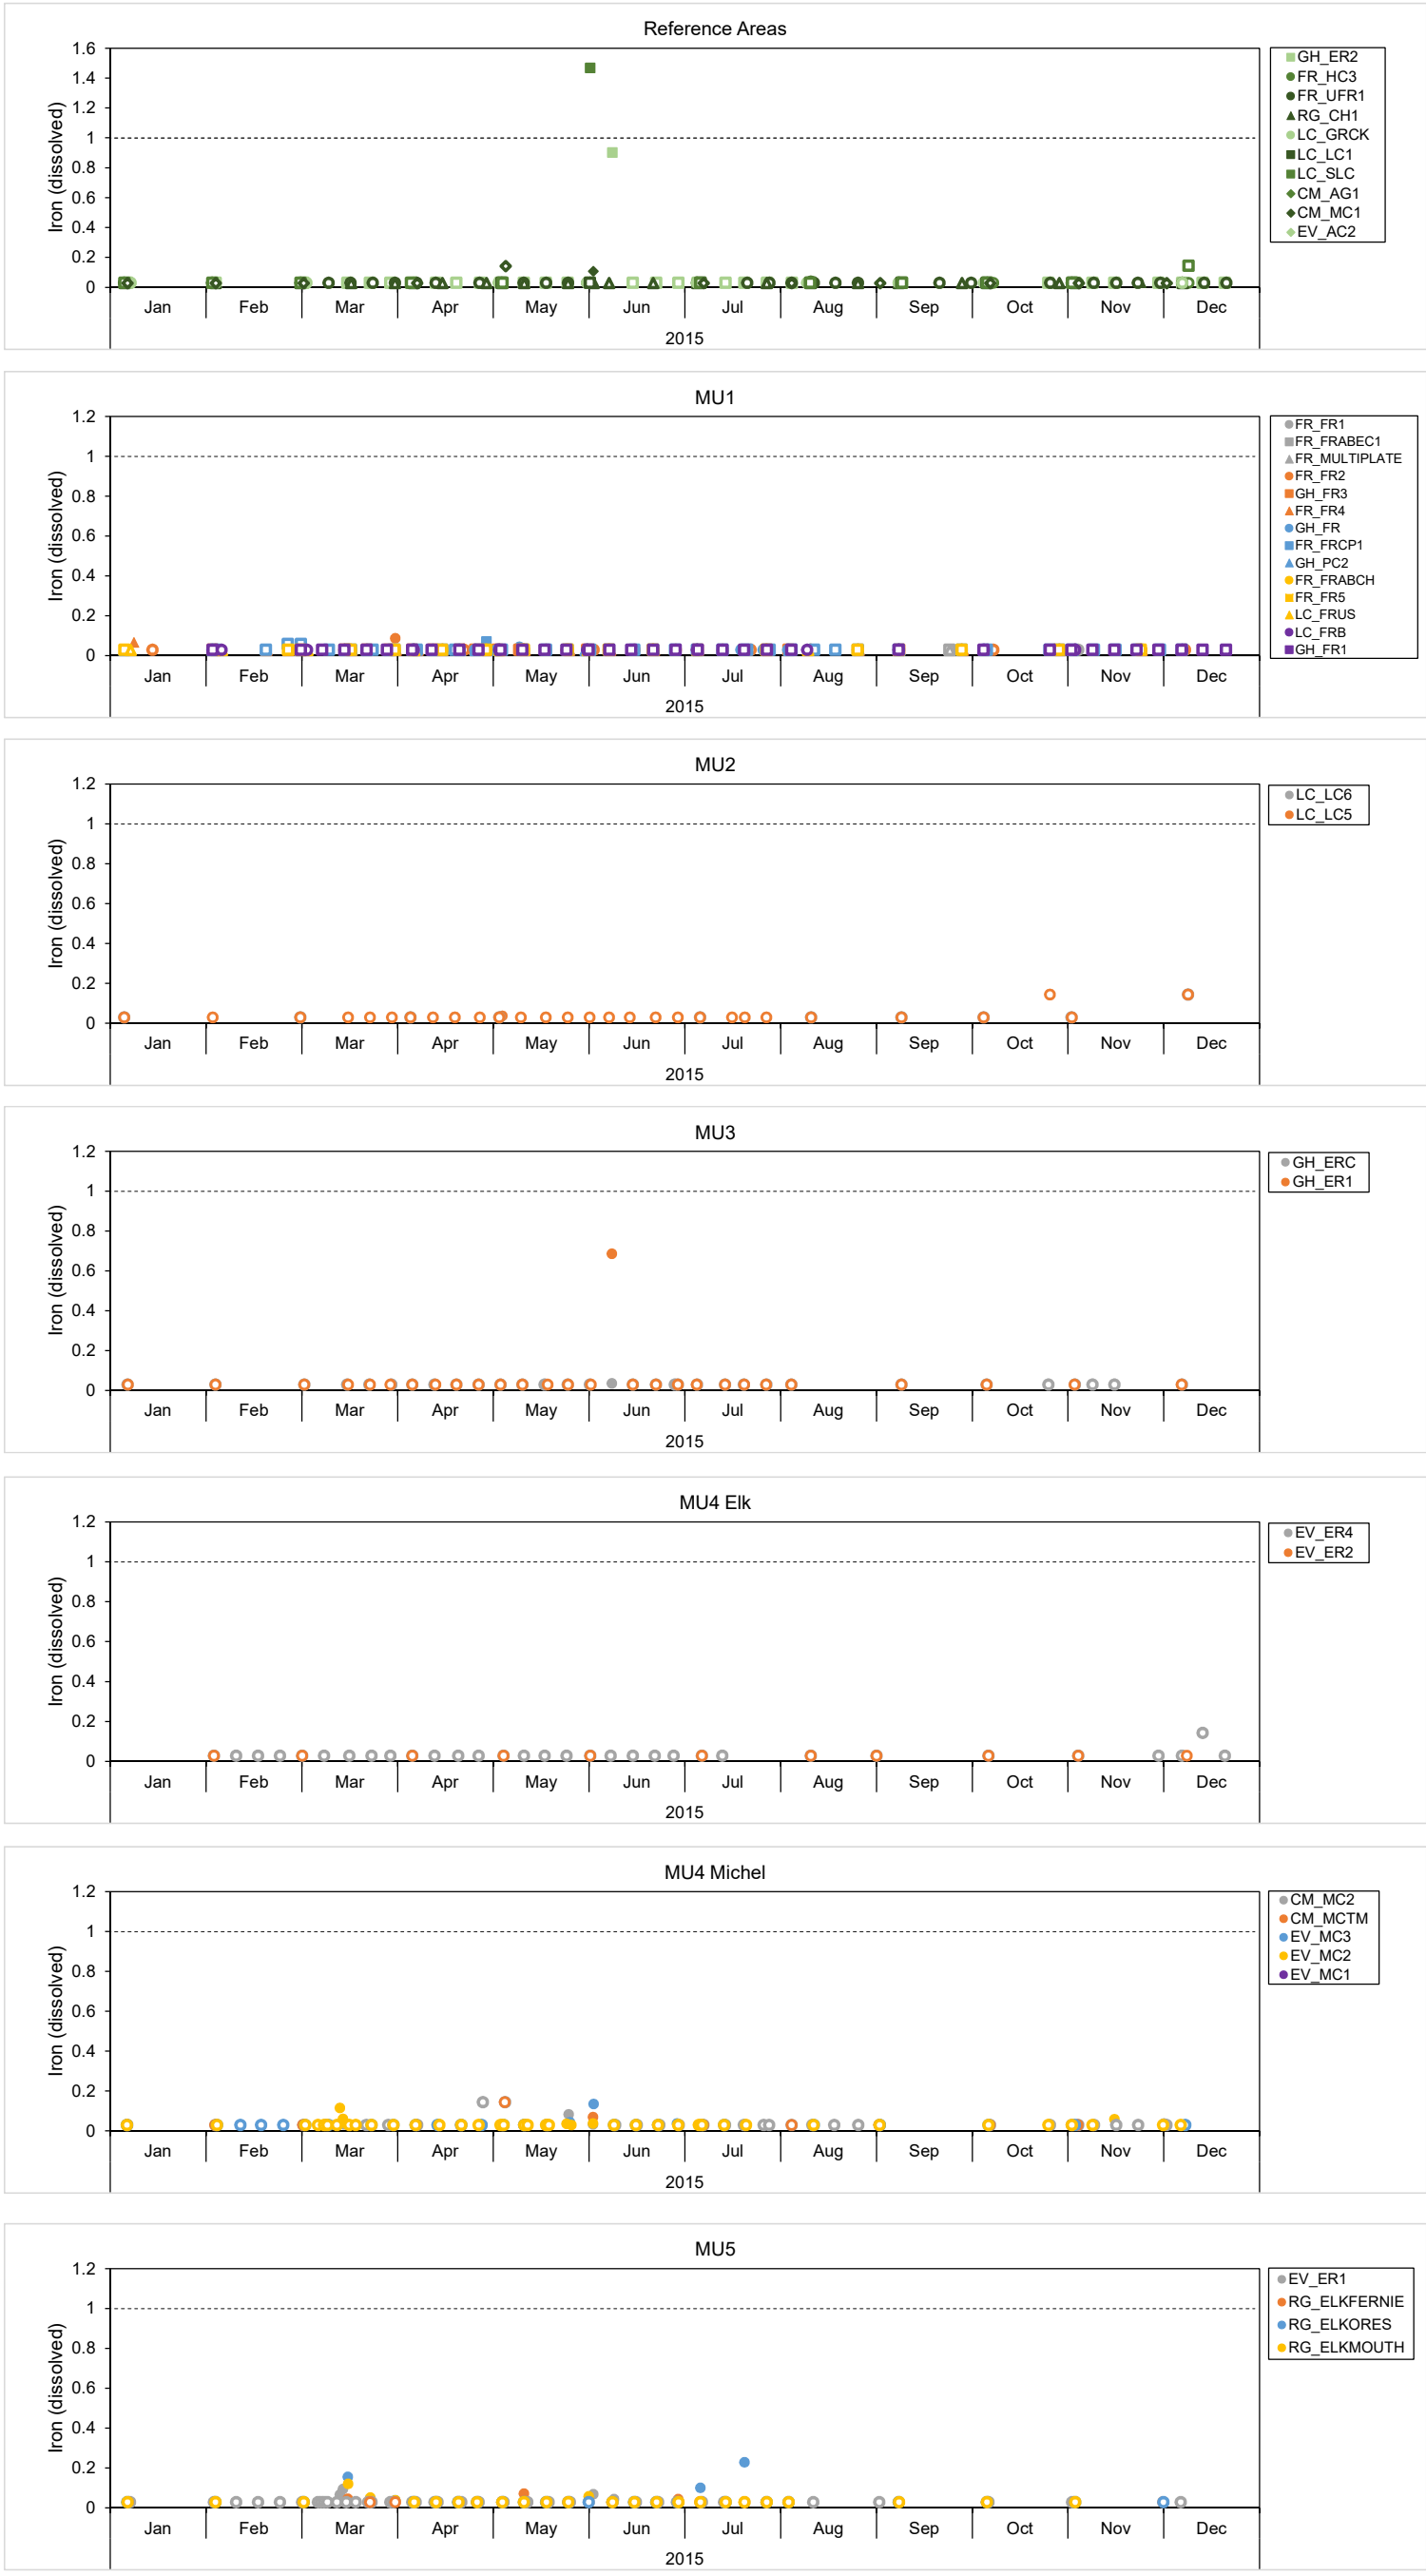

Figure C.7I: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

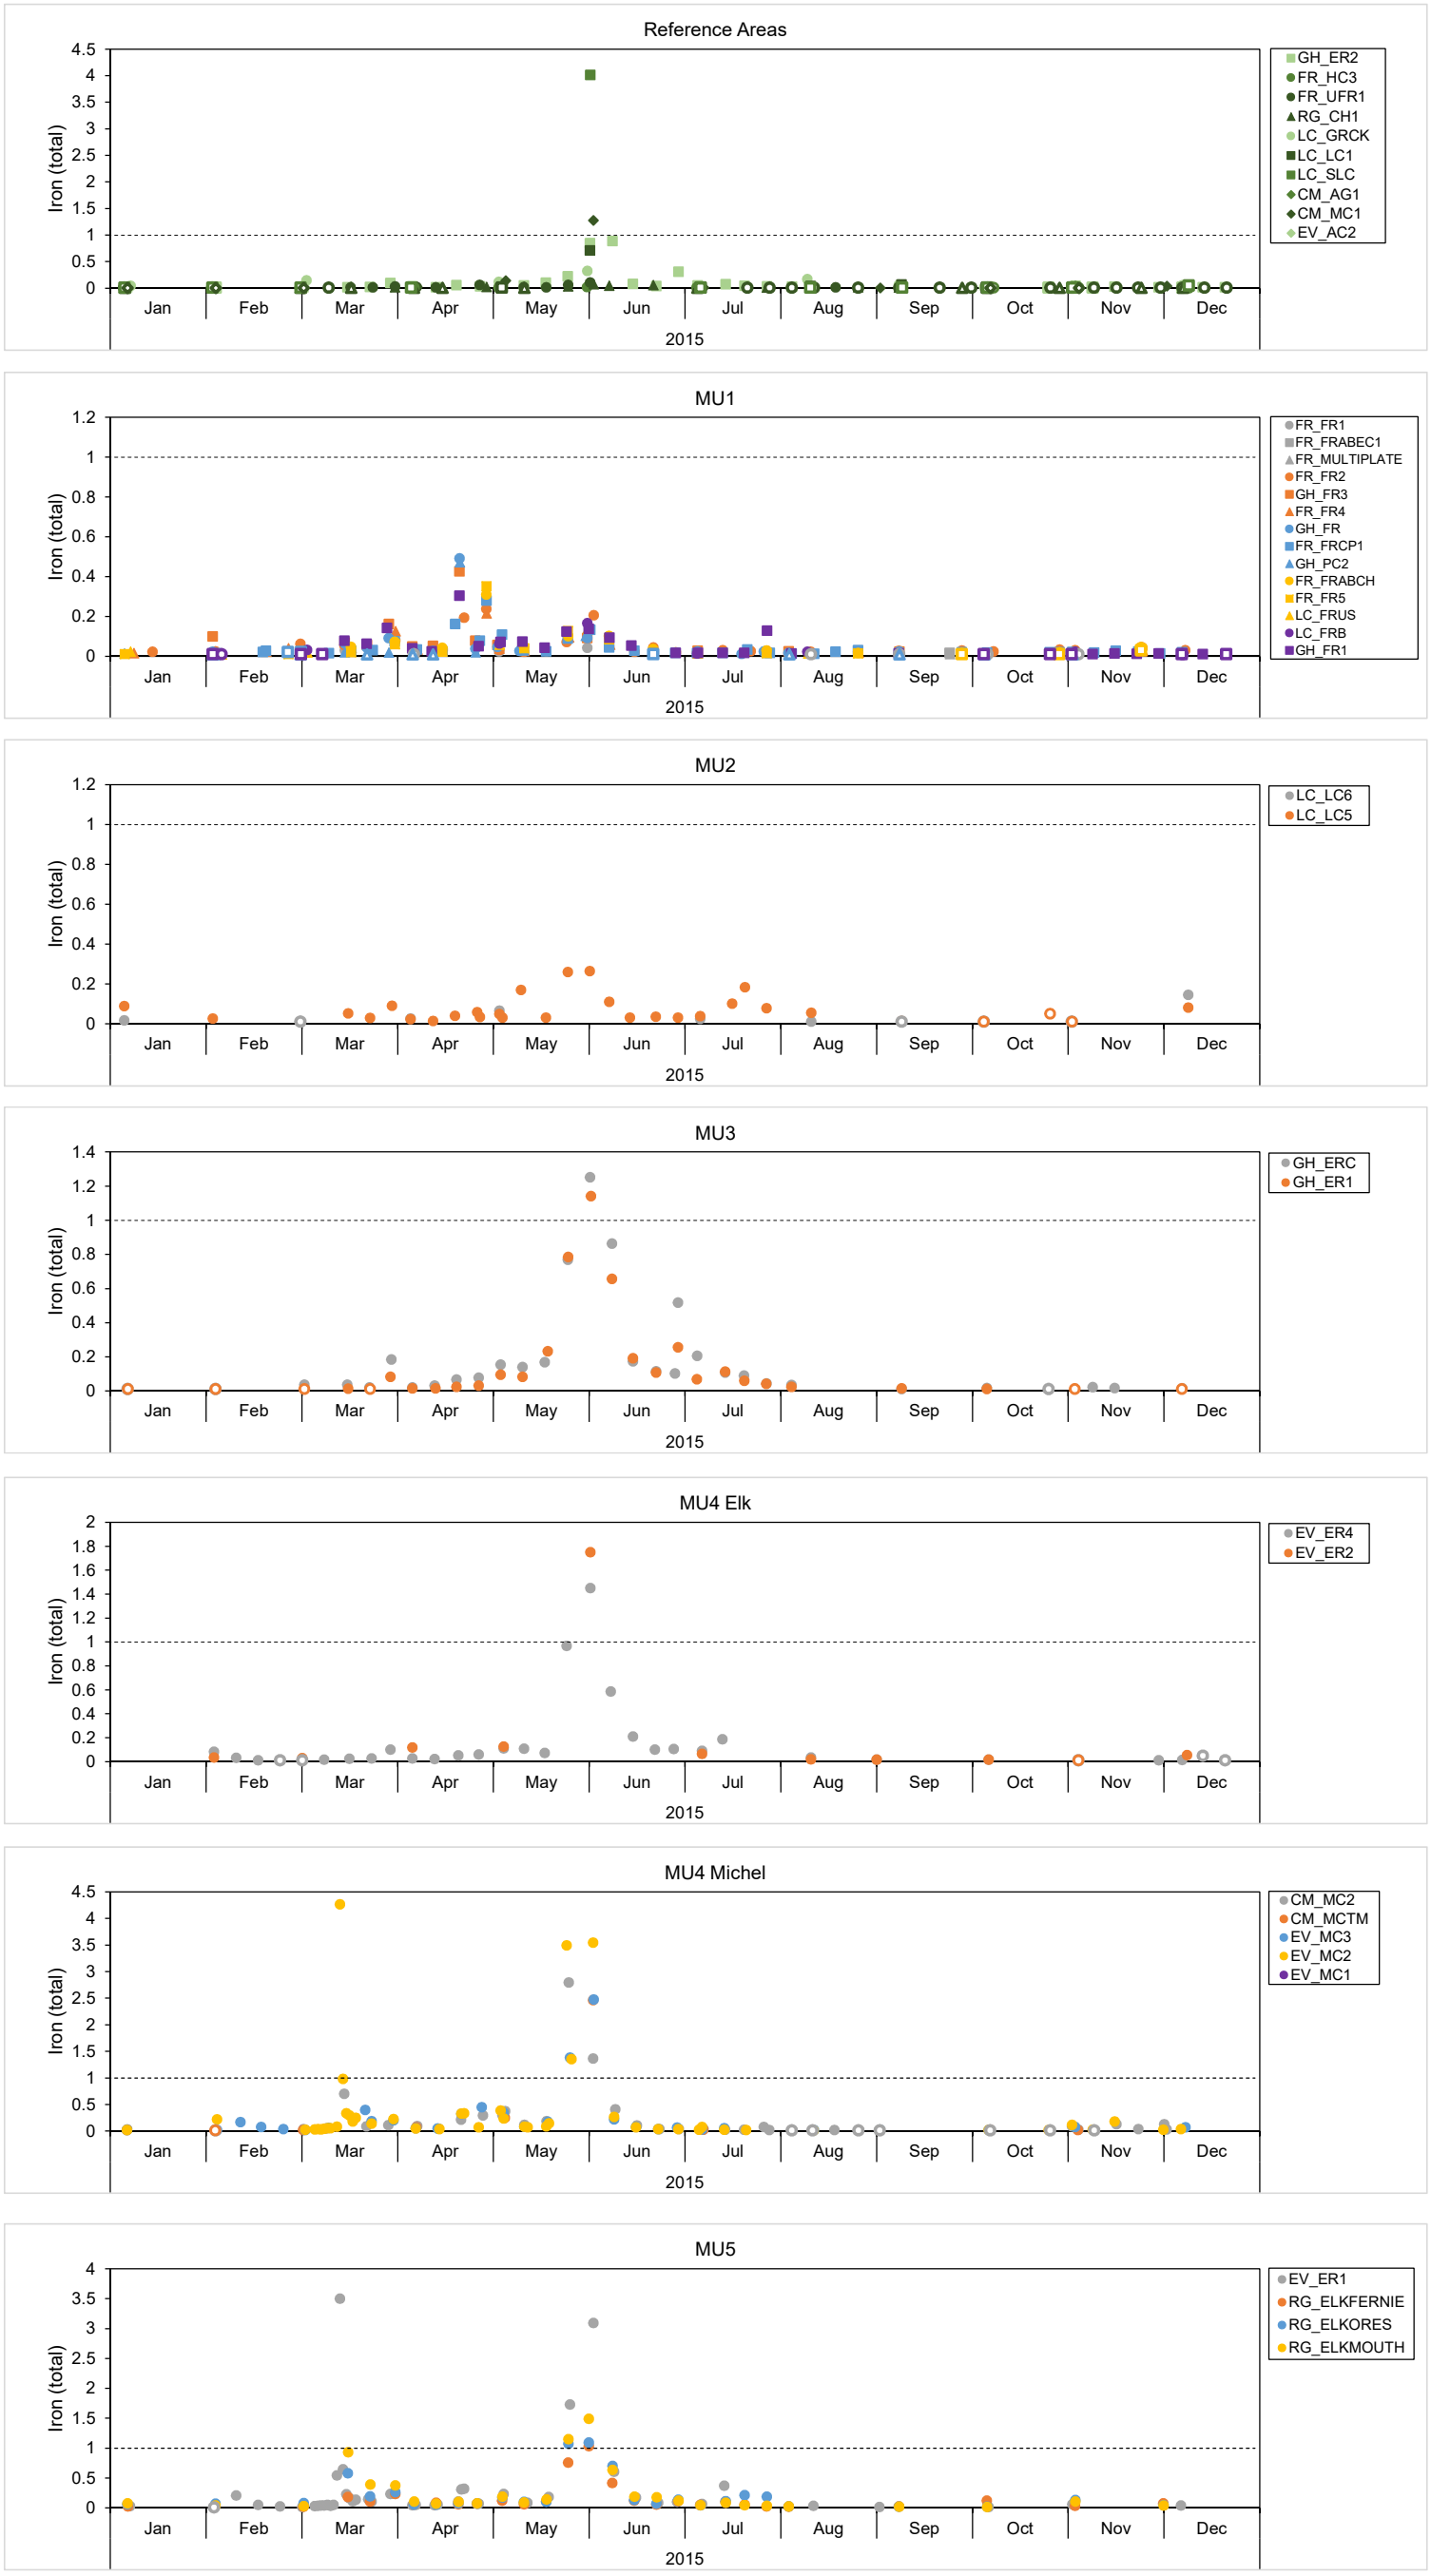

Figure C.7m: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

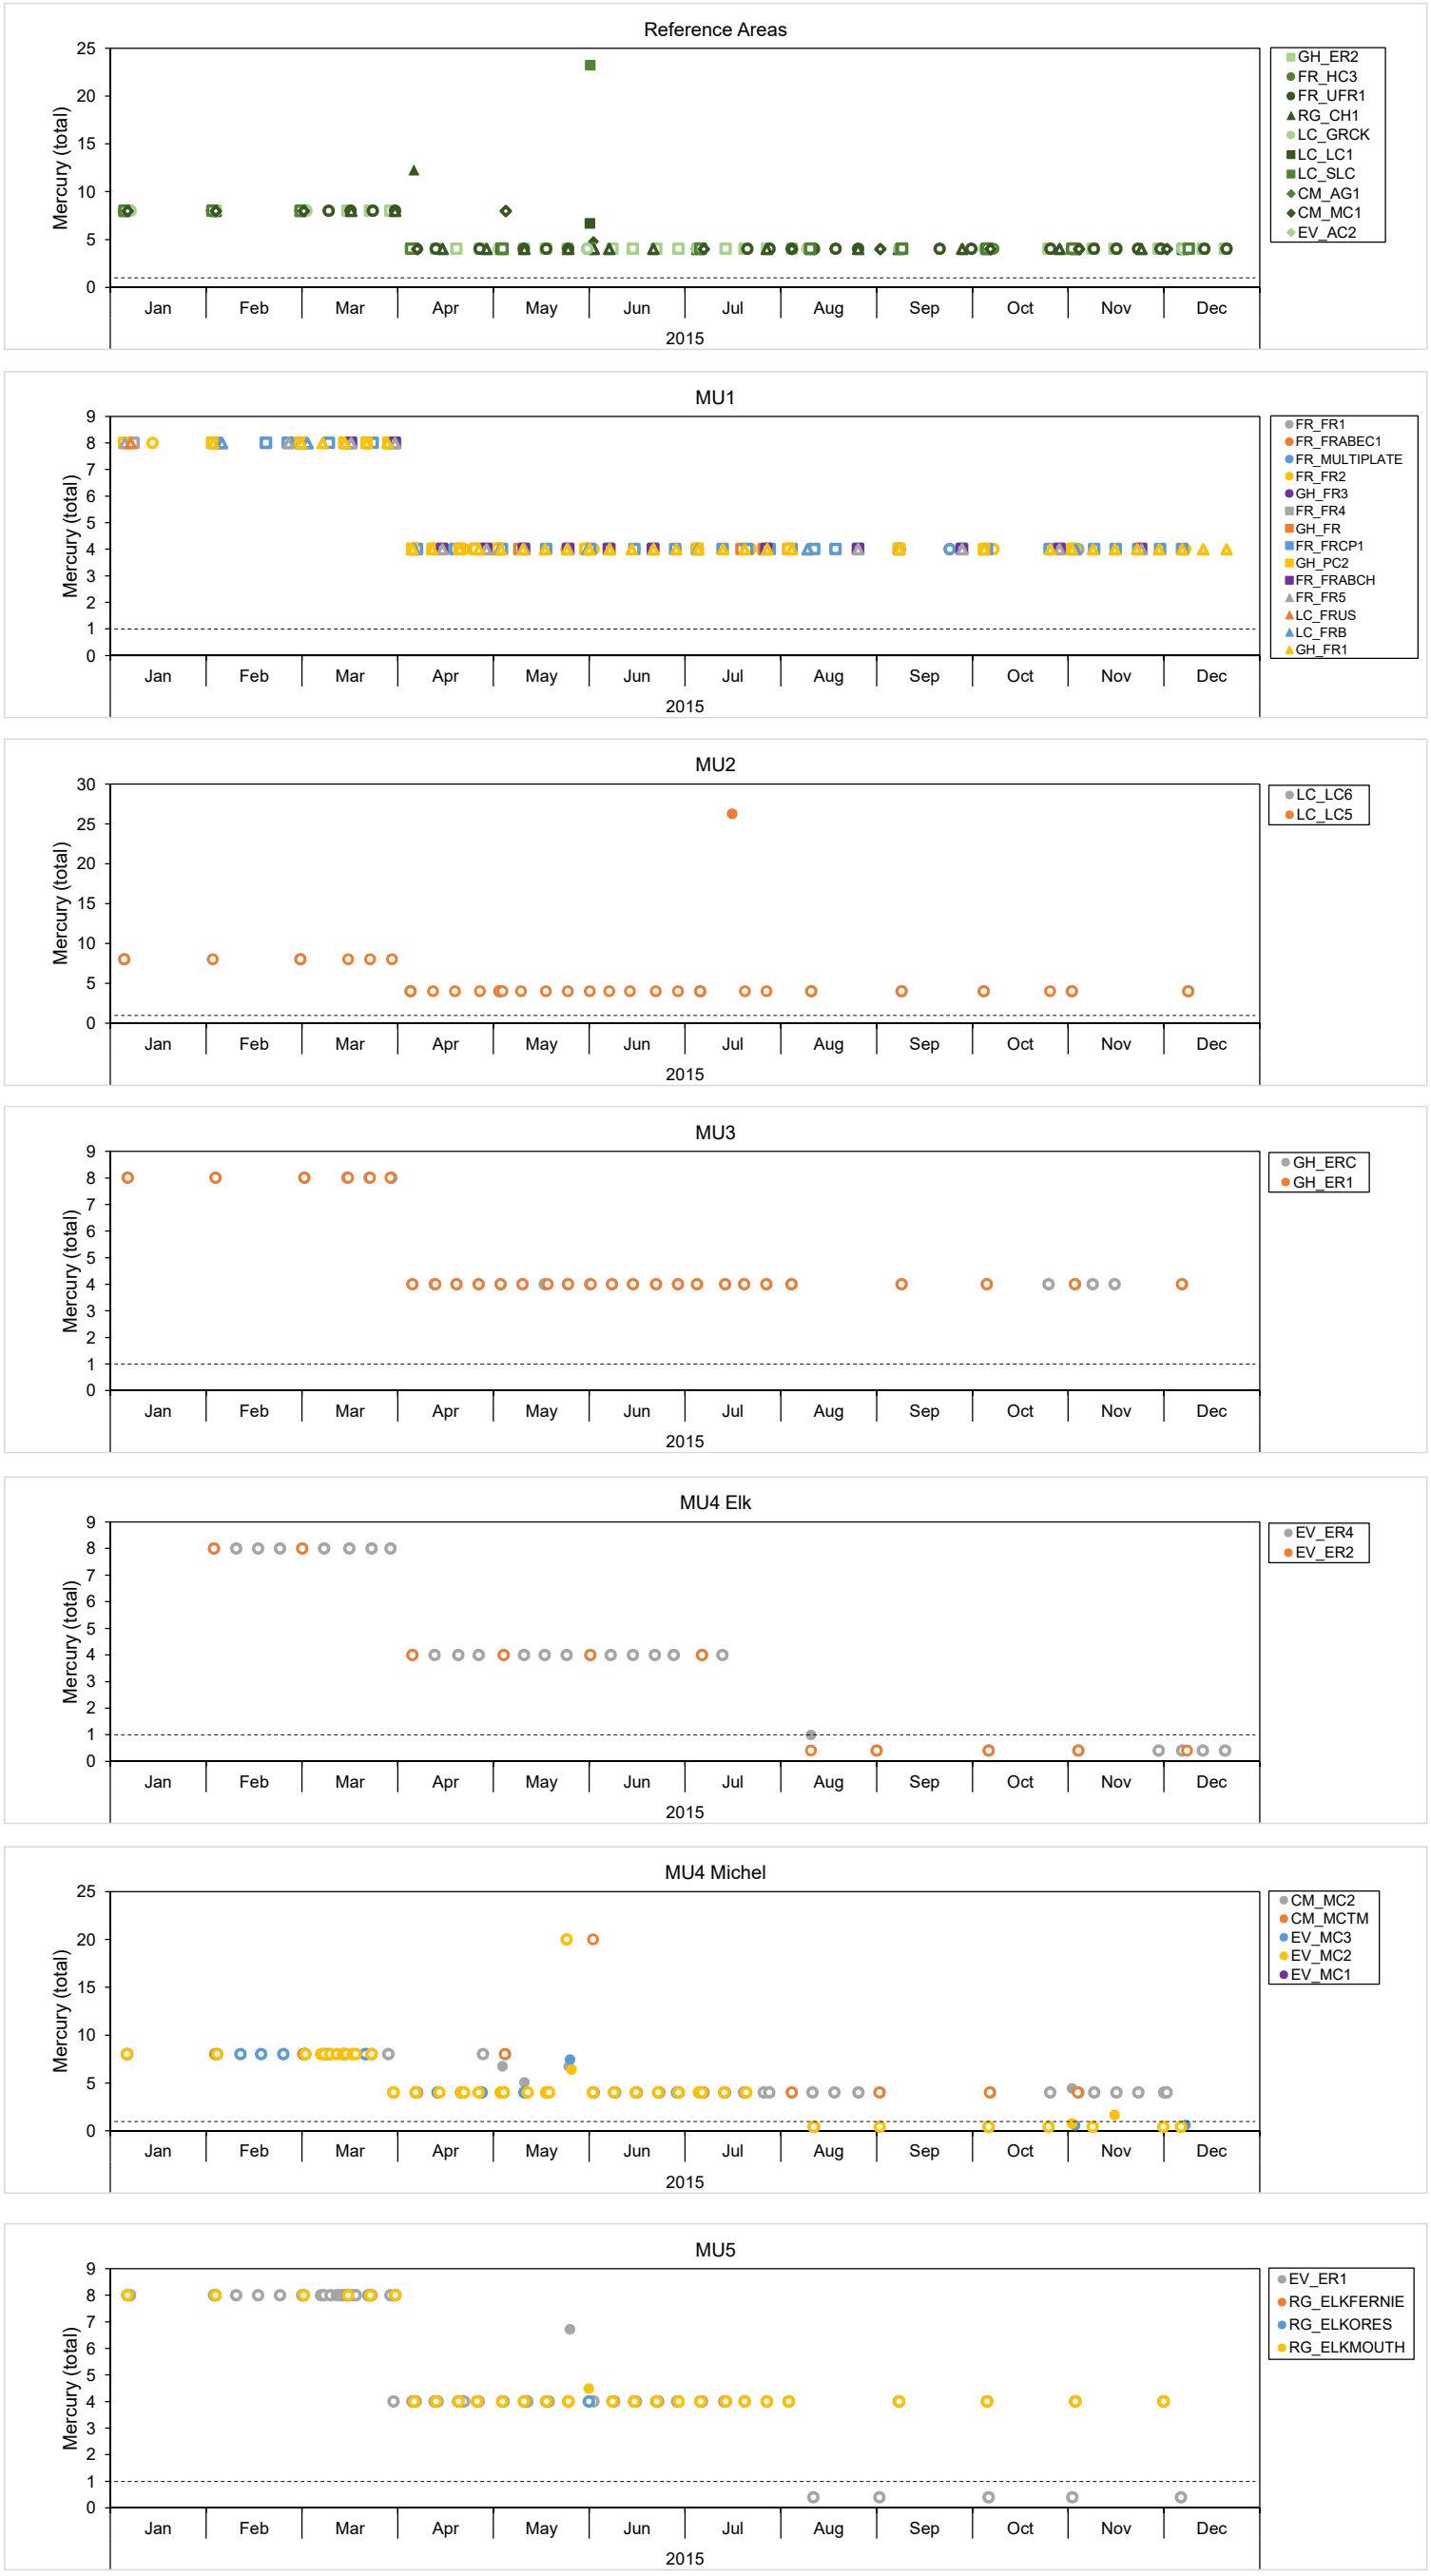

Figure C.7n: Scatterplots of Hazard Quotients for Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), sample-specific values were used to calculate the guideline. Values above the dashed line indicate concentrations observed in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

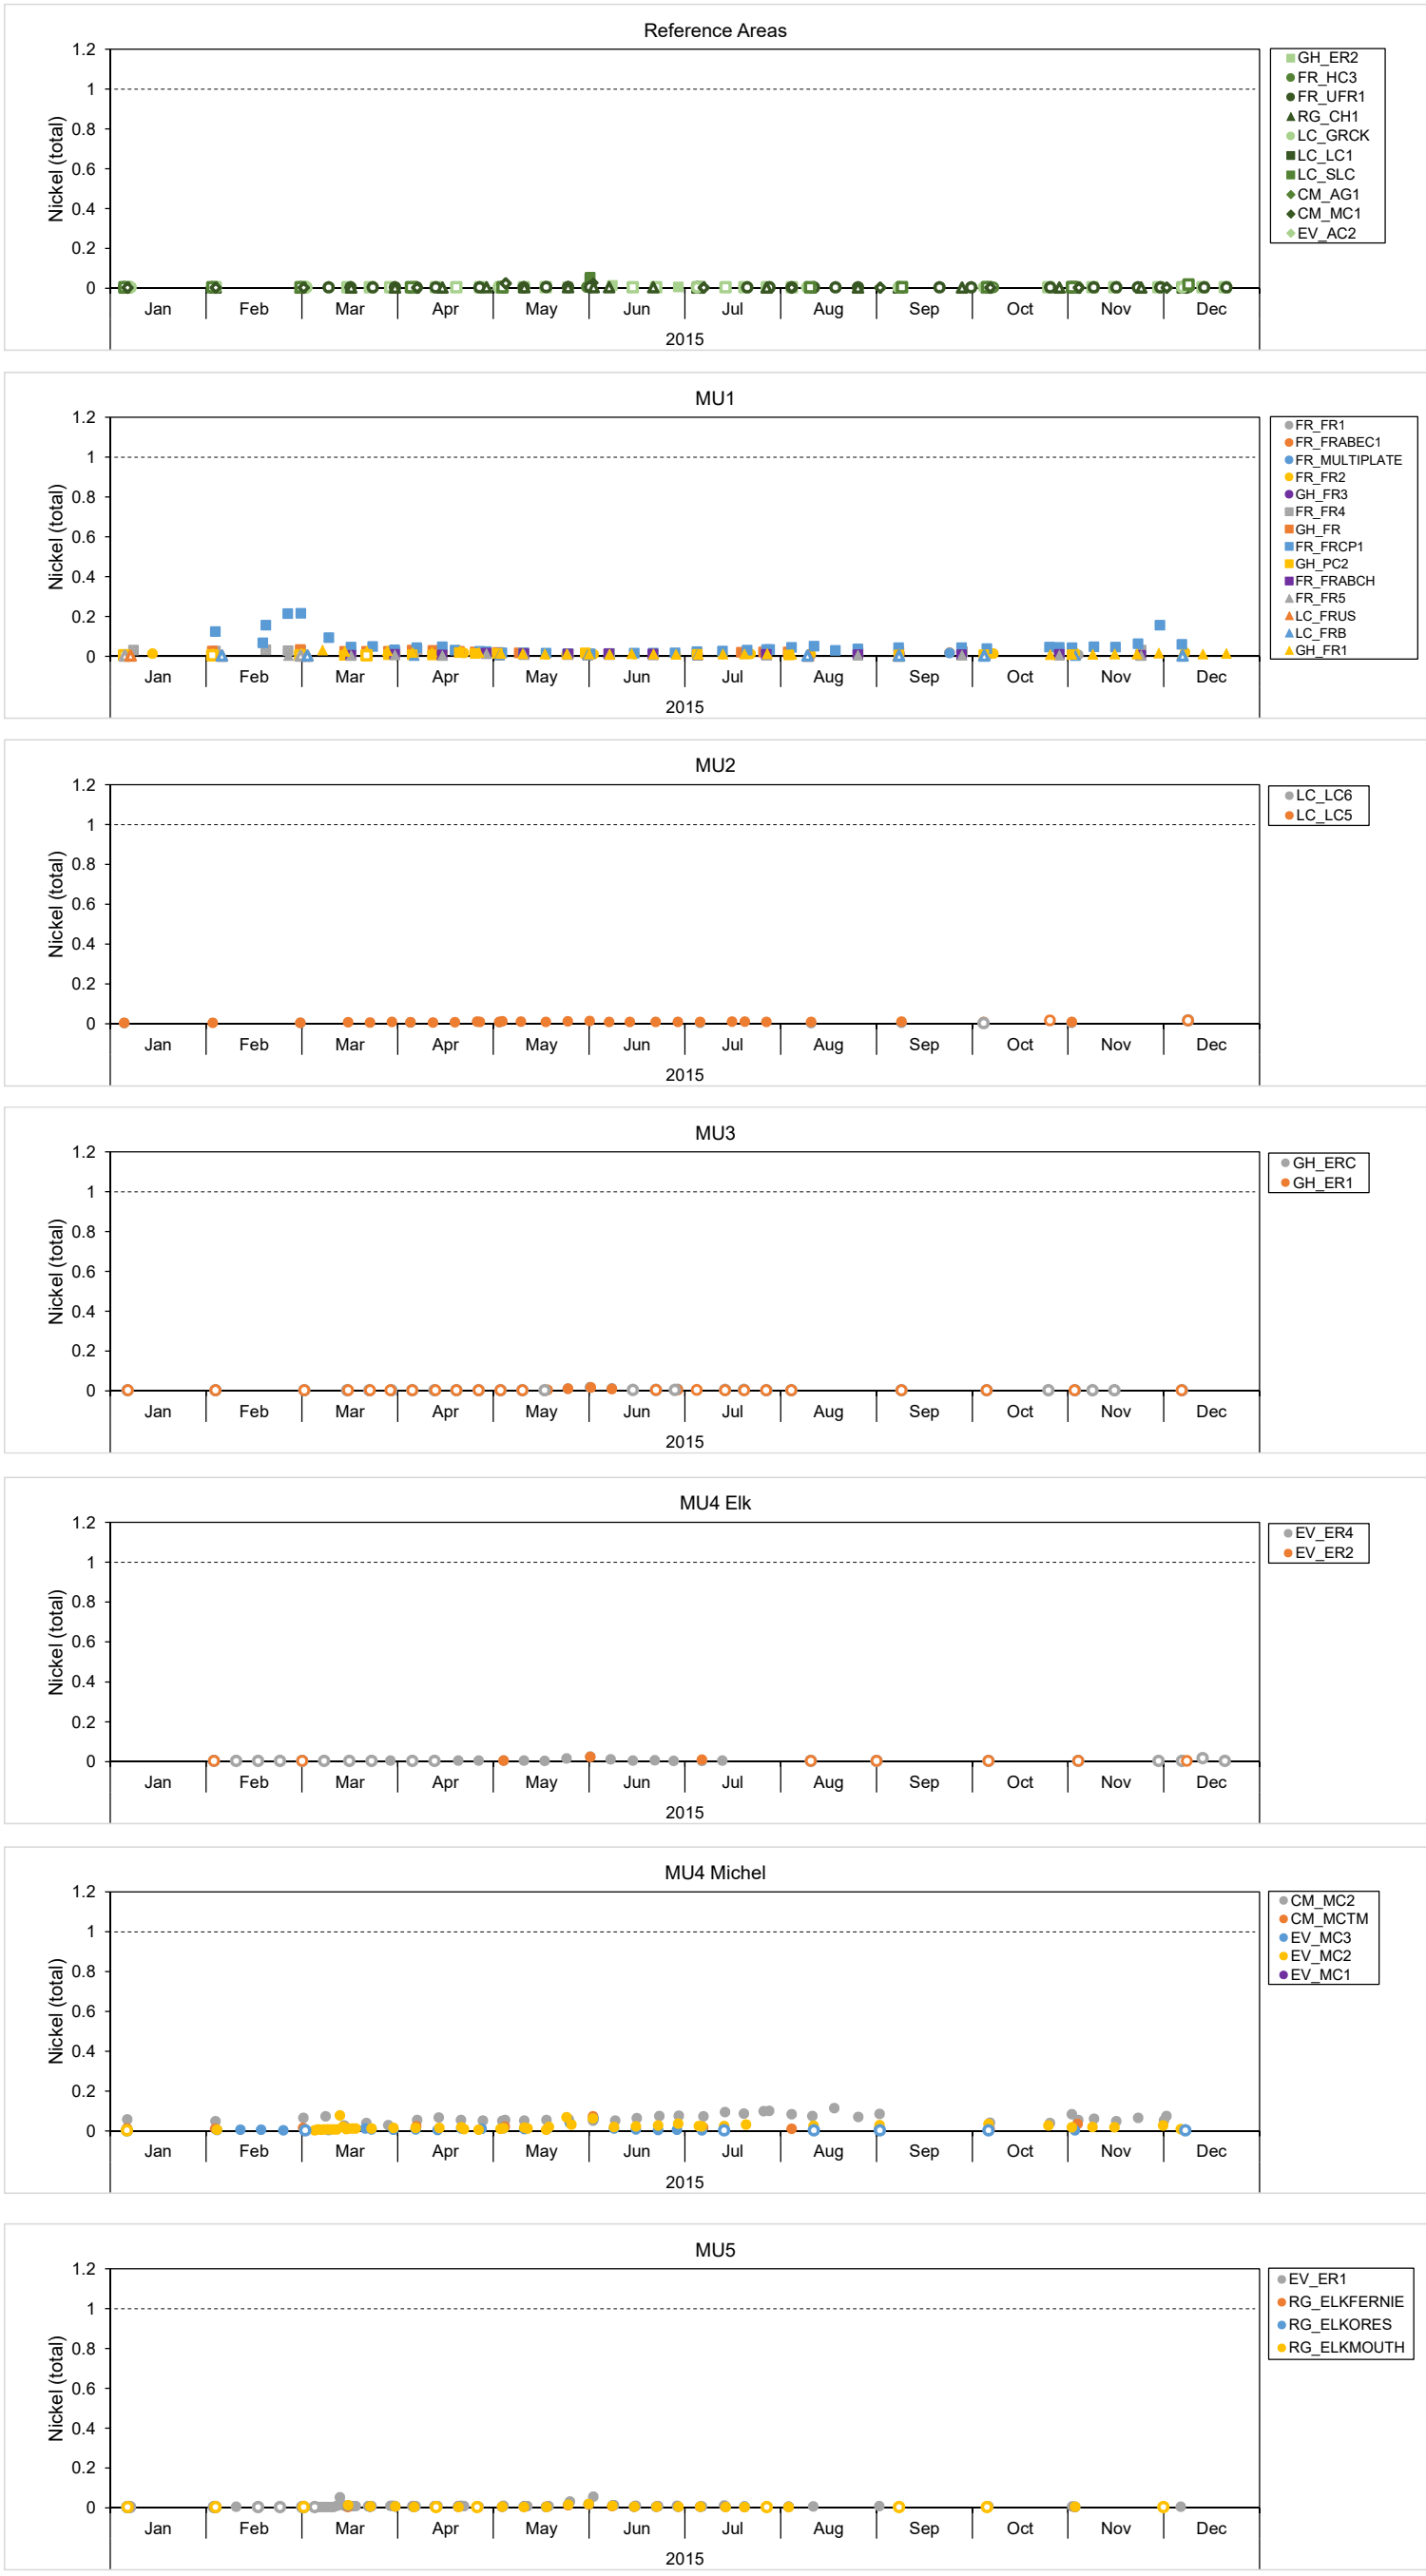

Figure C.7o: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

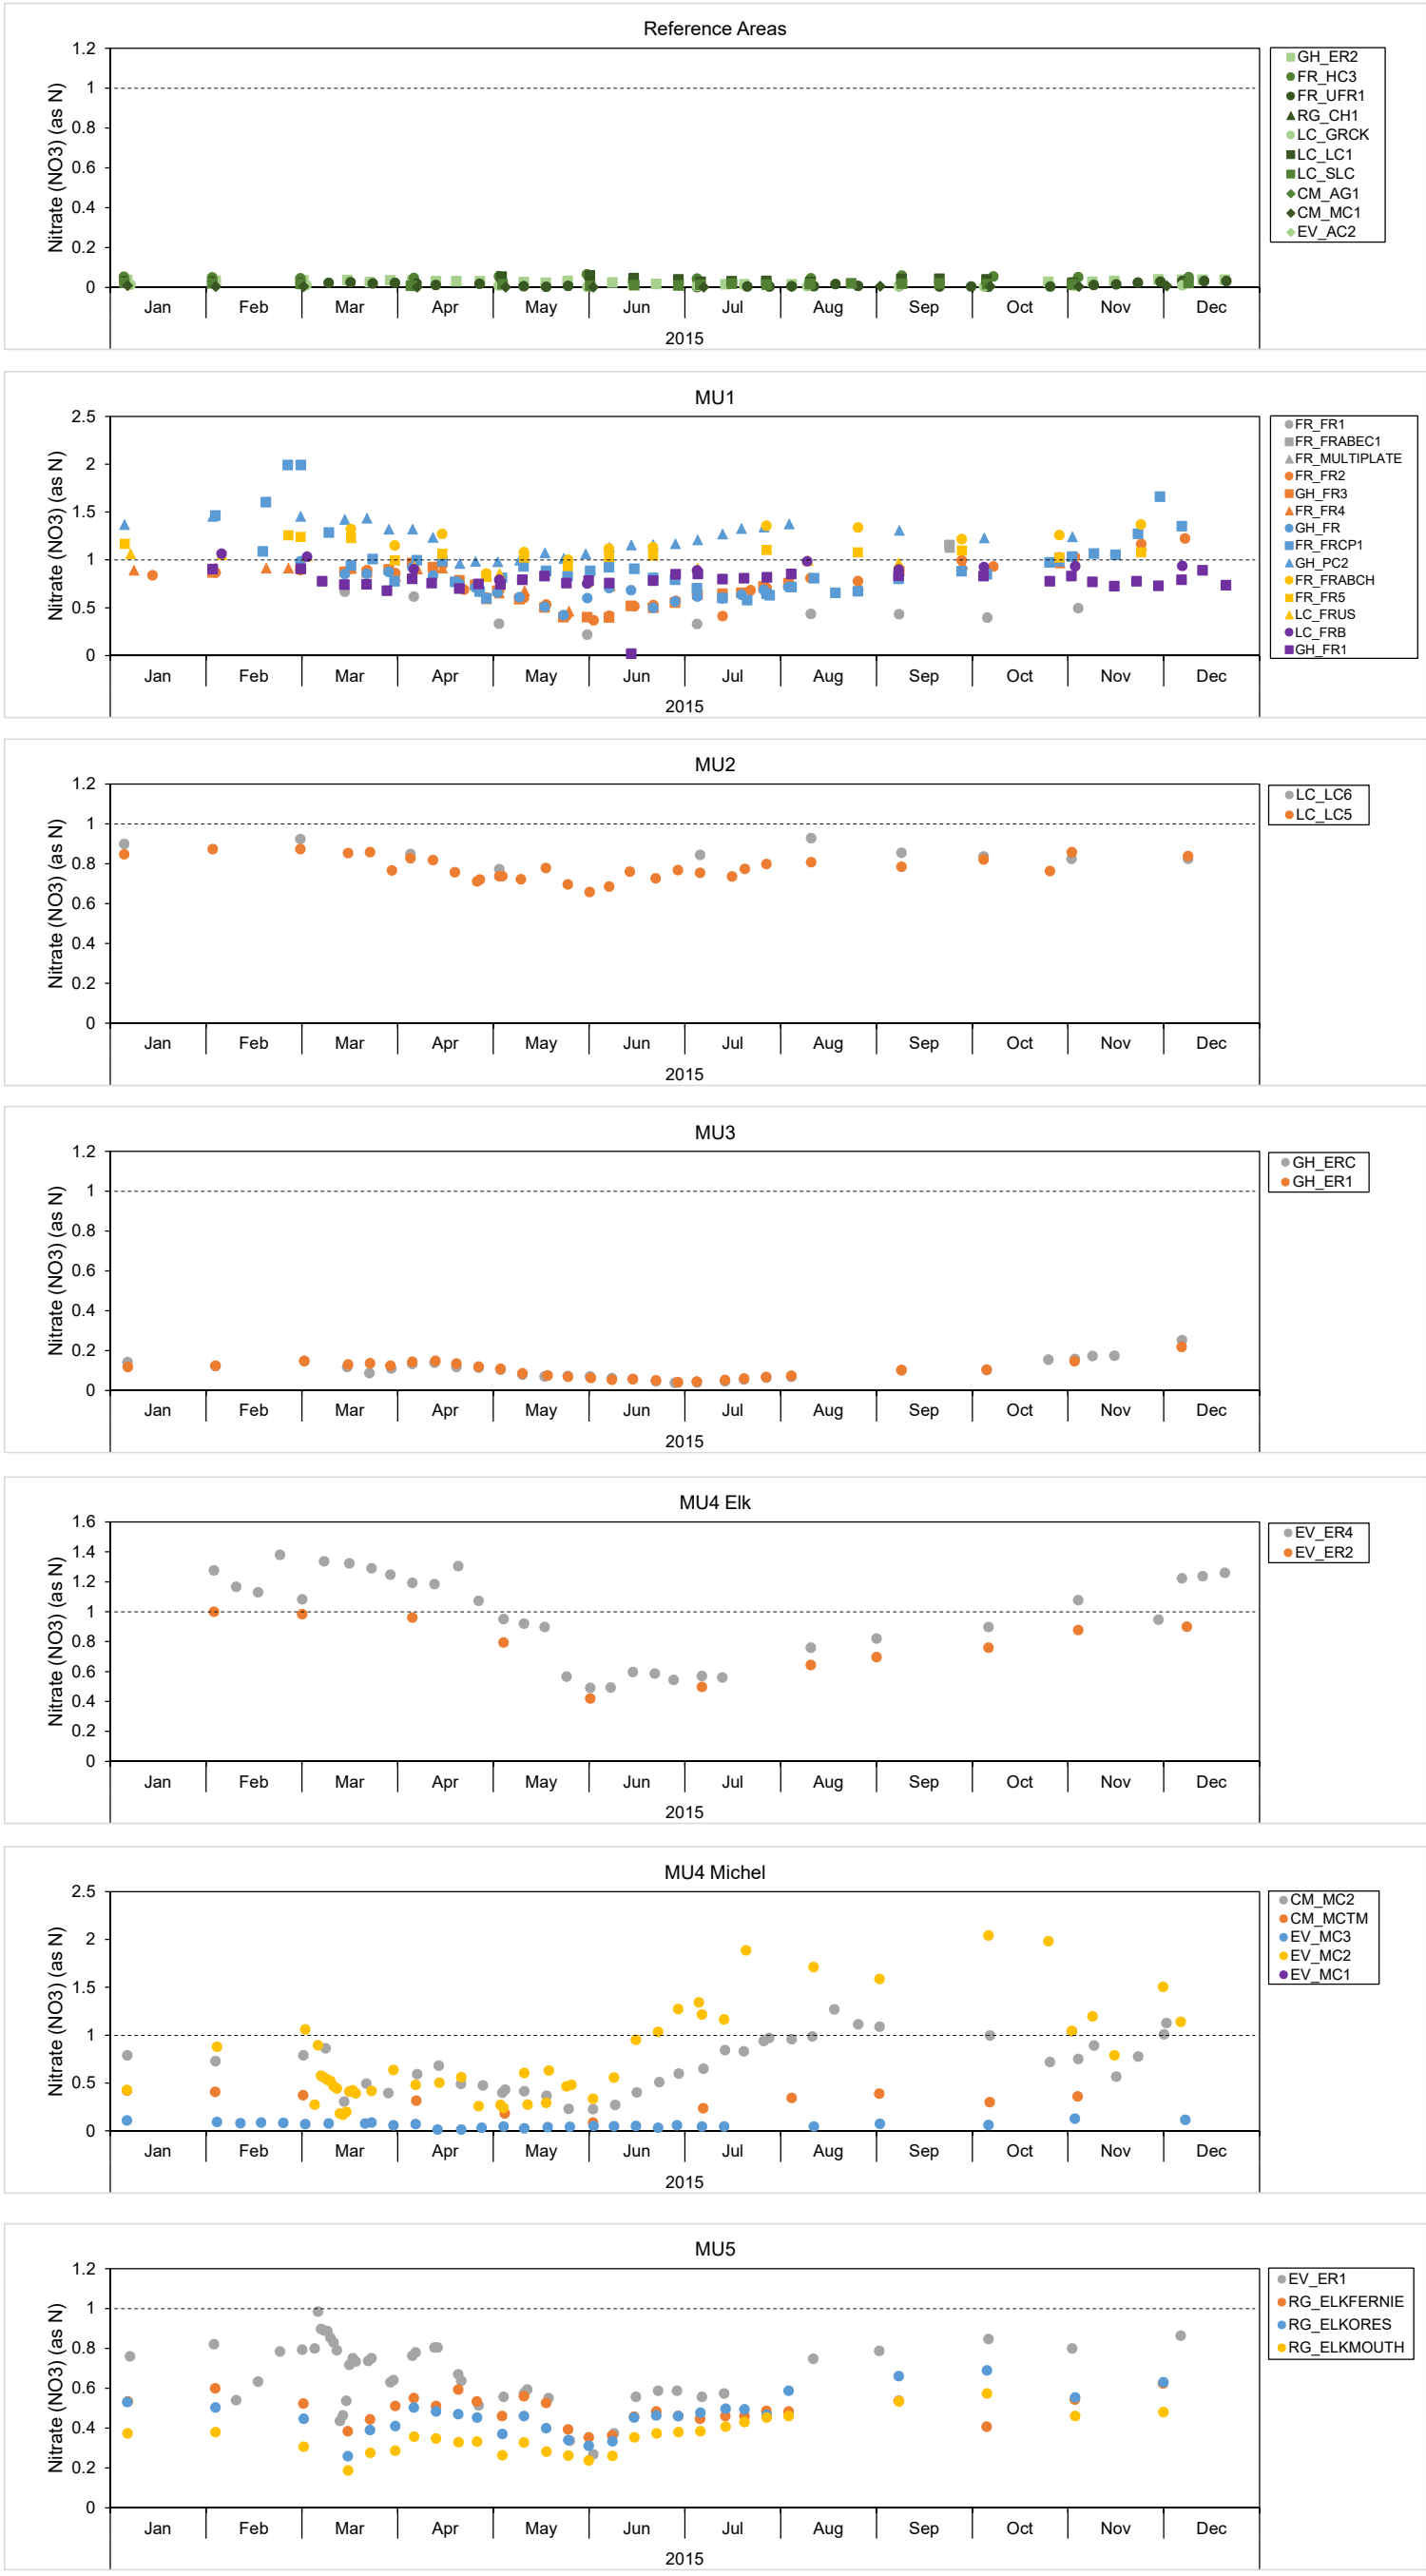

Figure C.7p: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

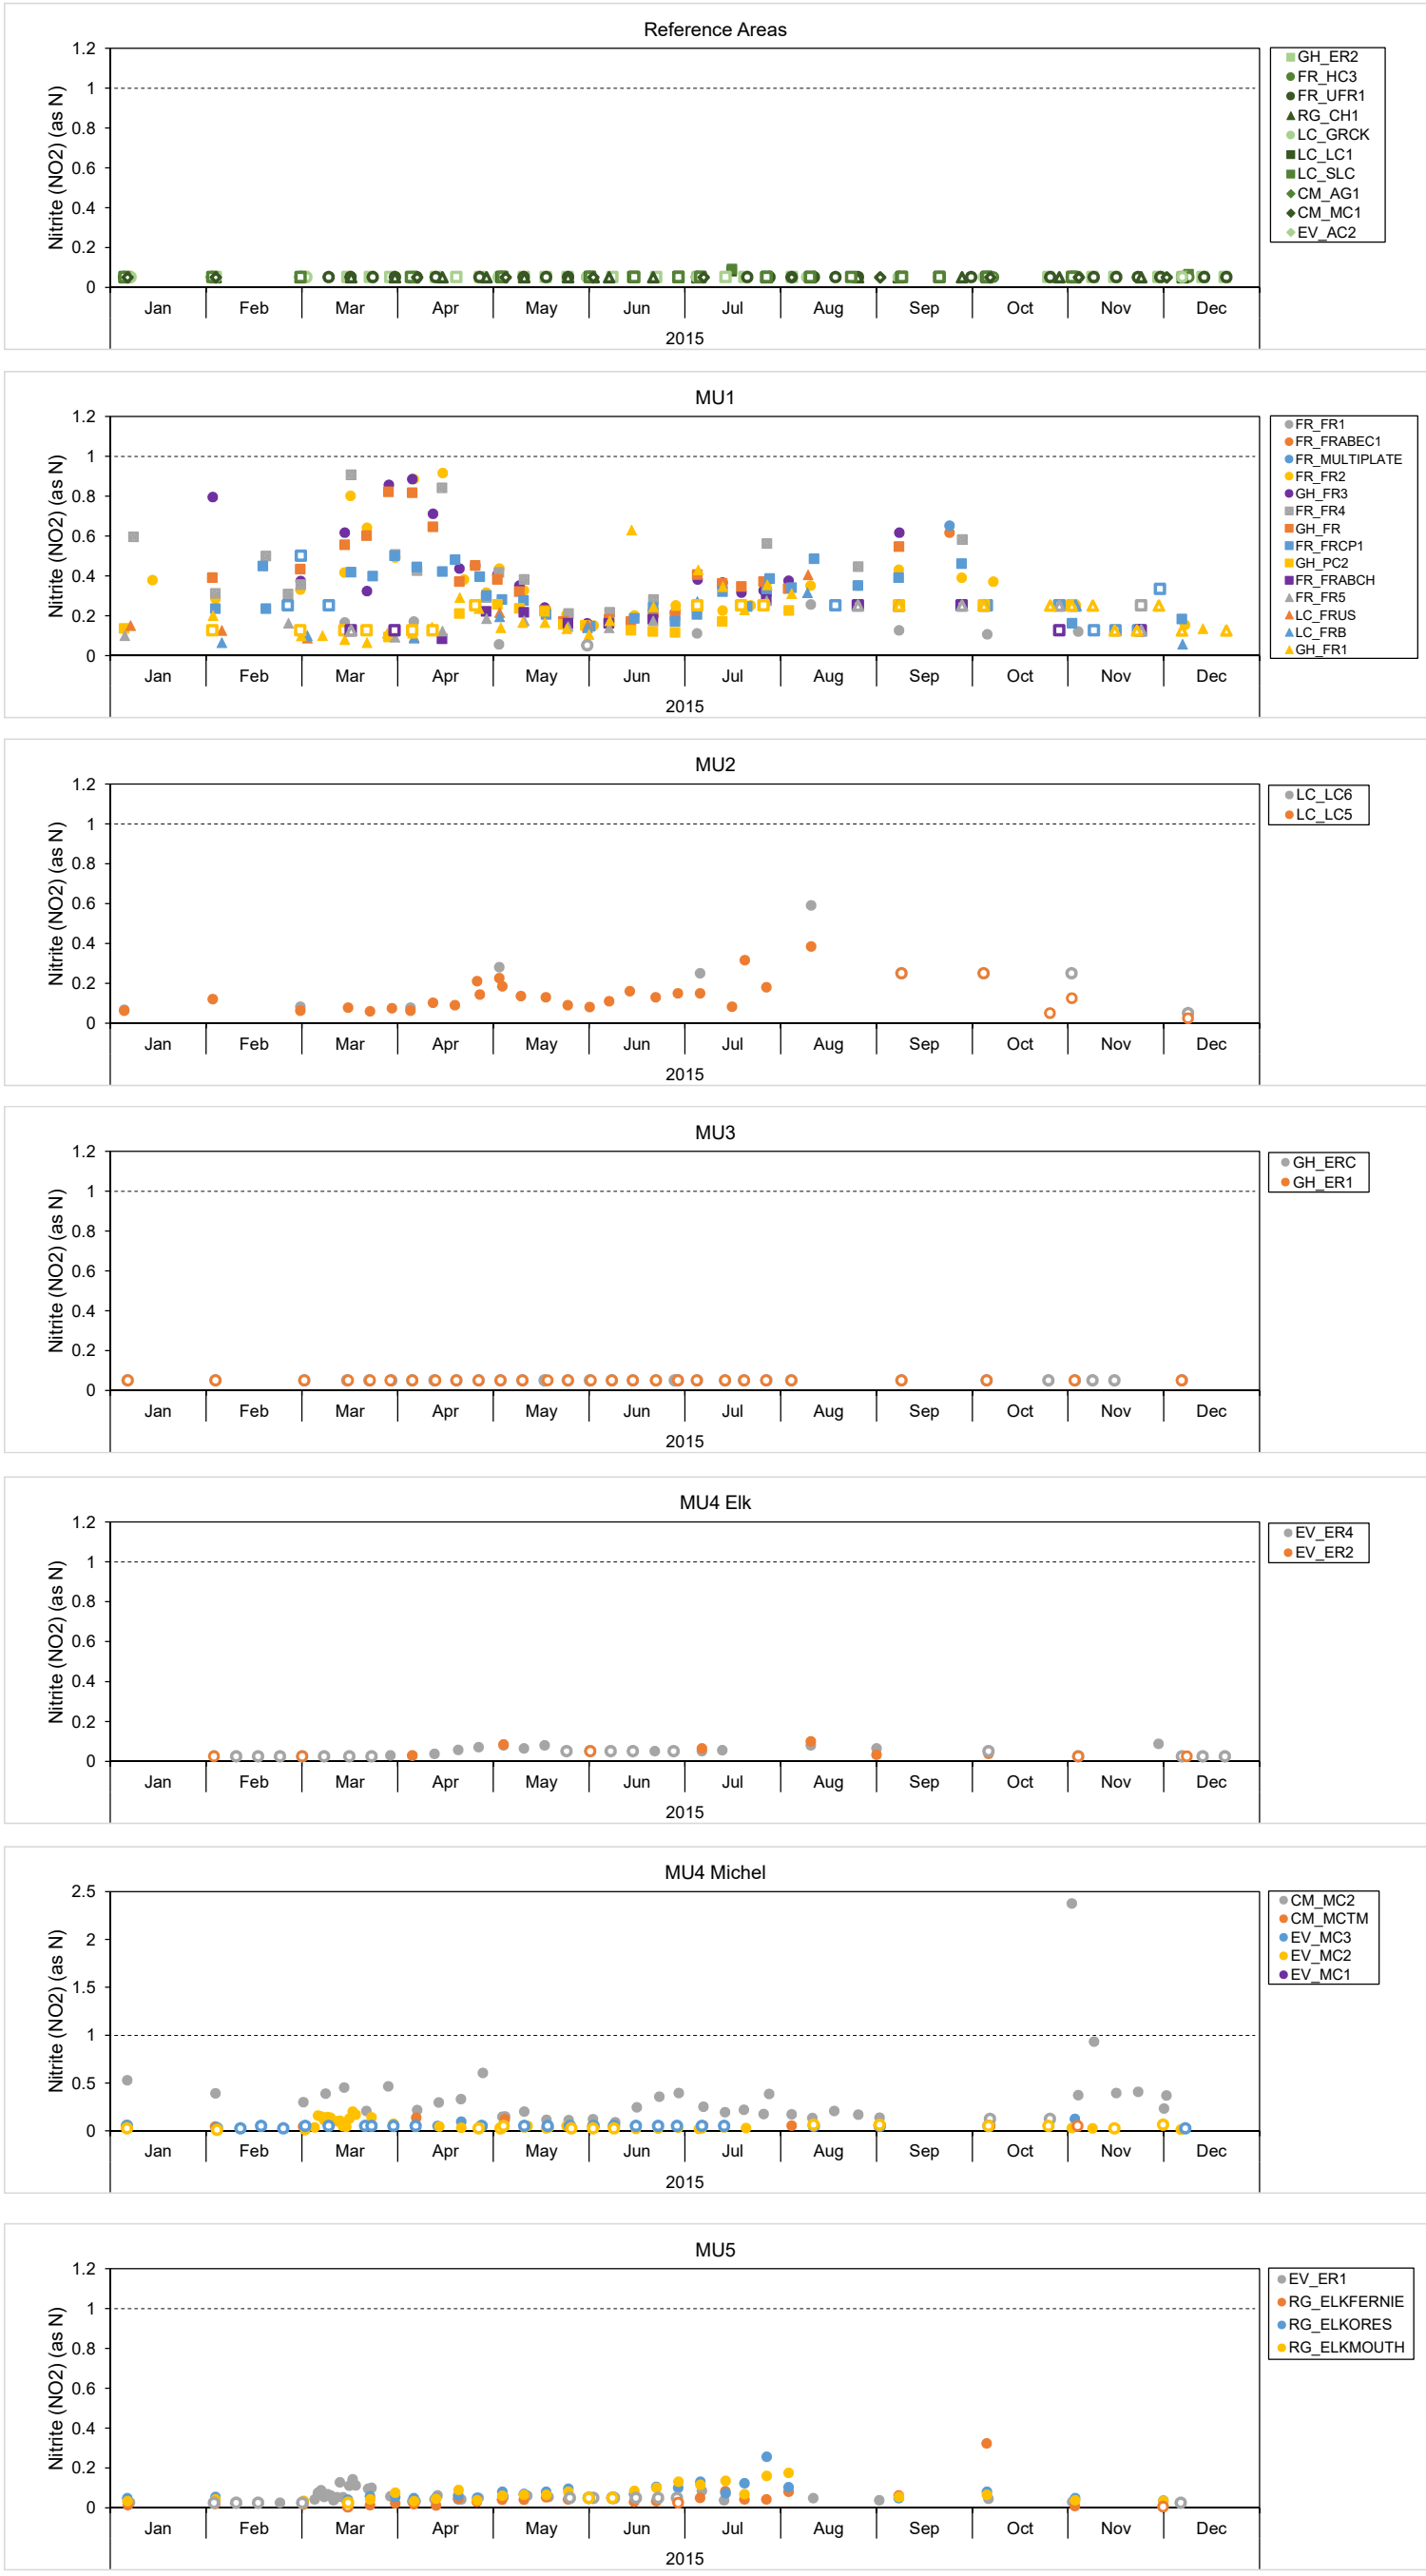

Figure C.7q: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

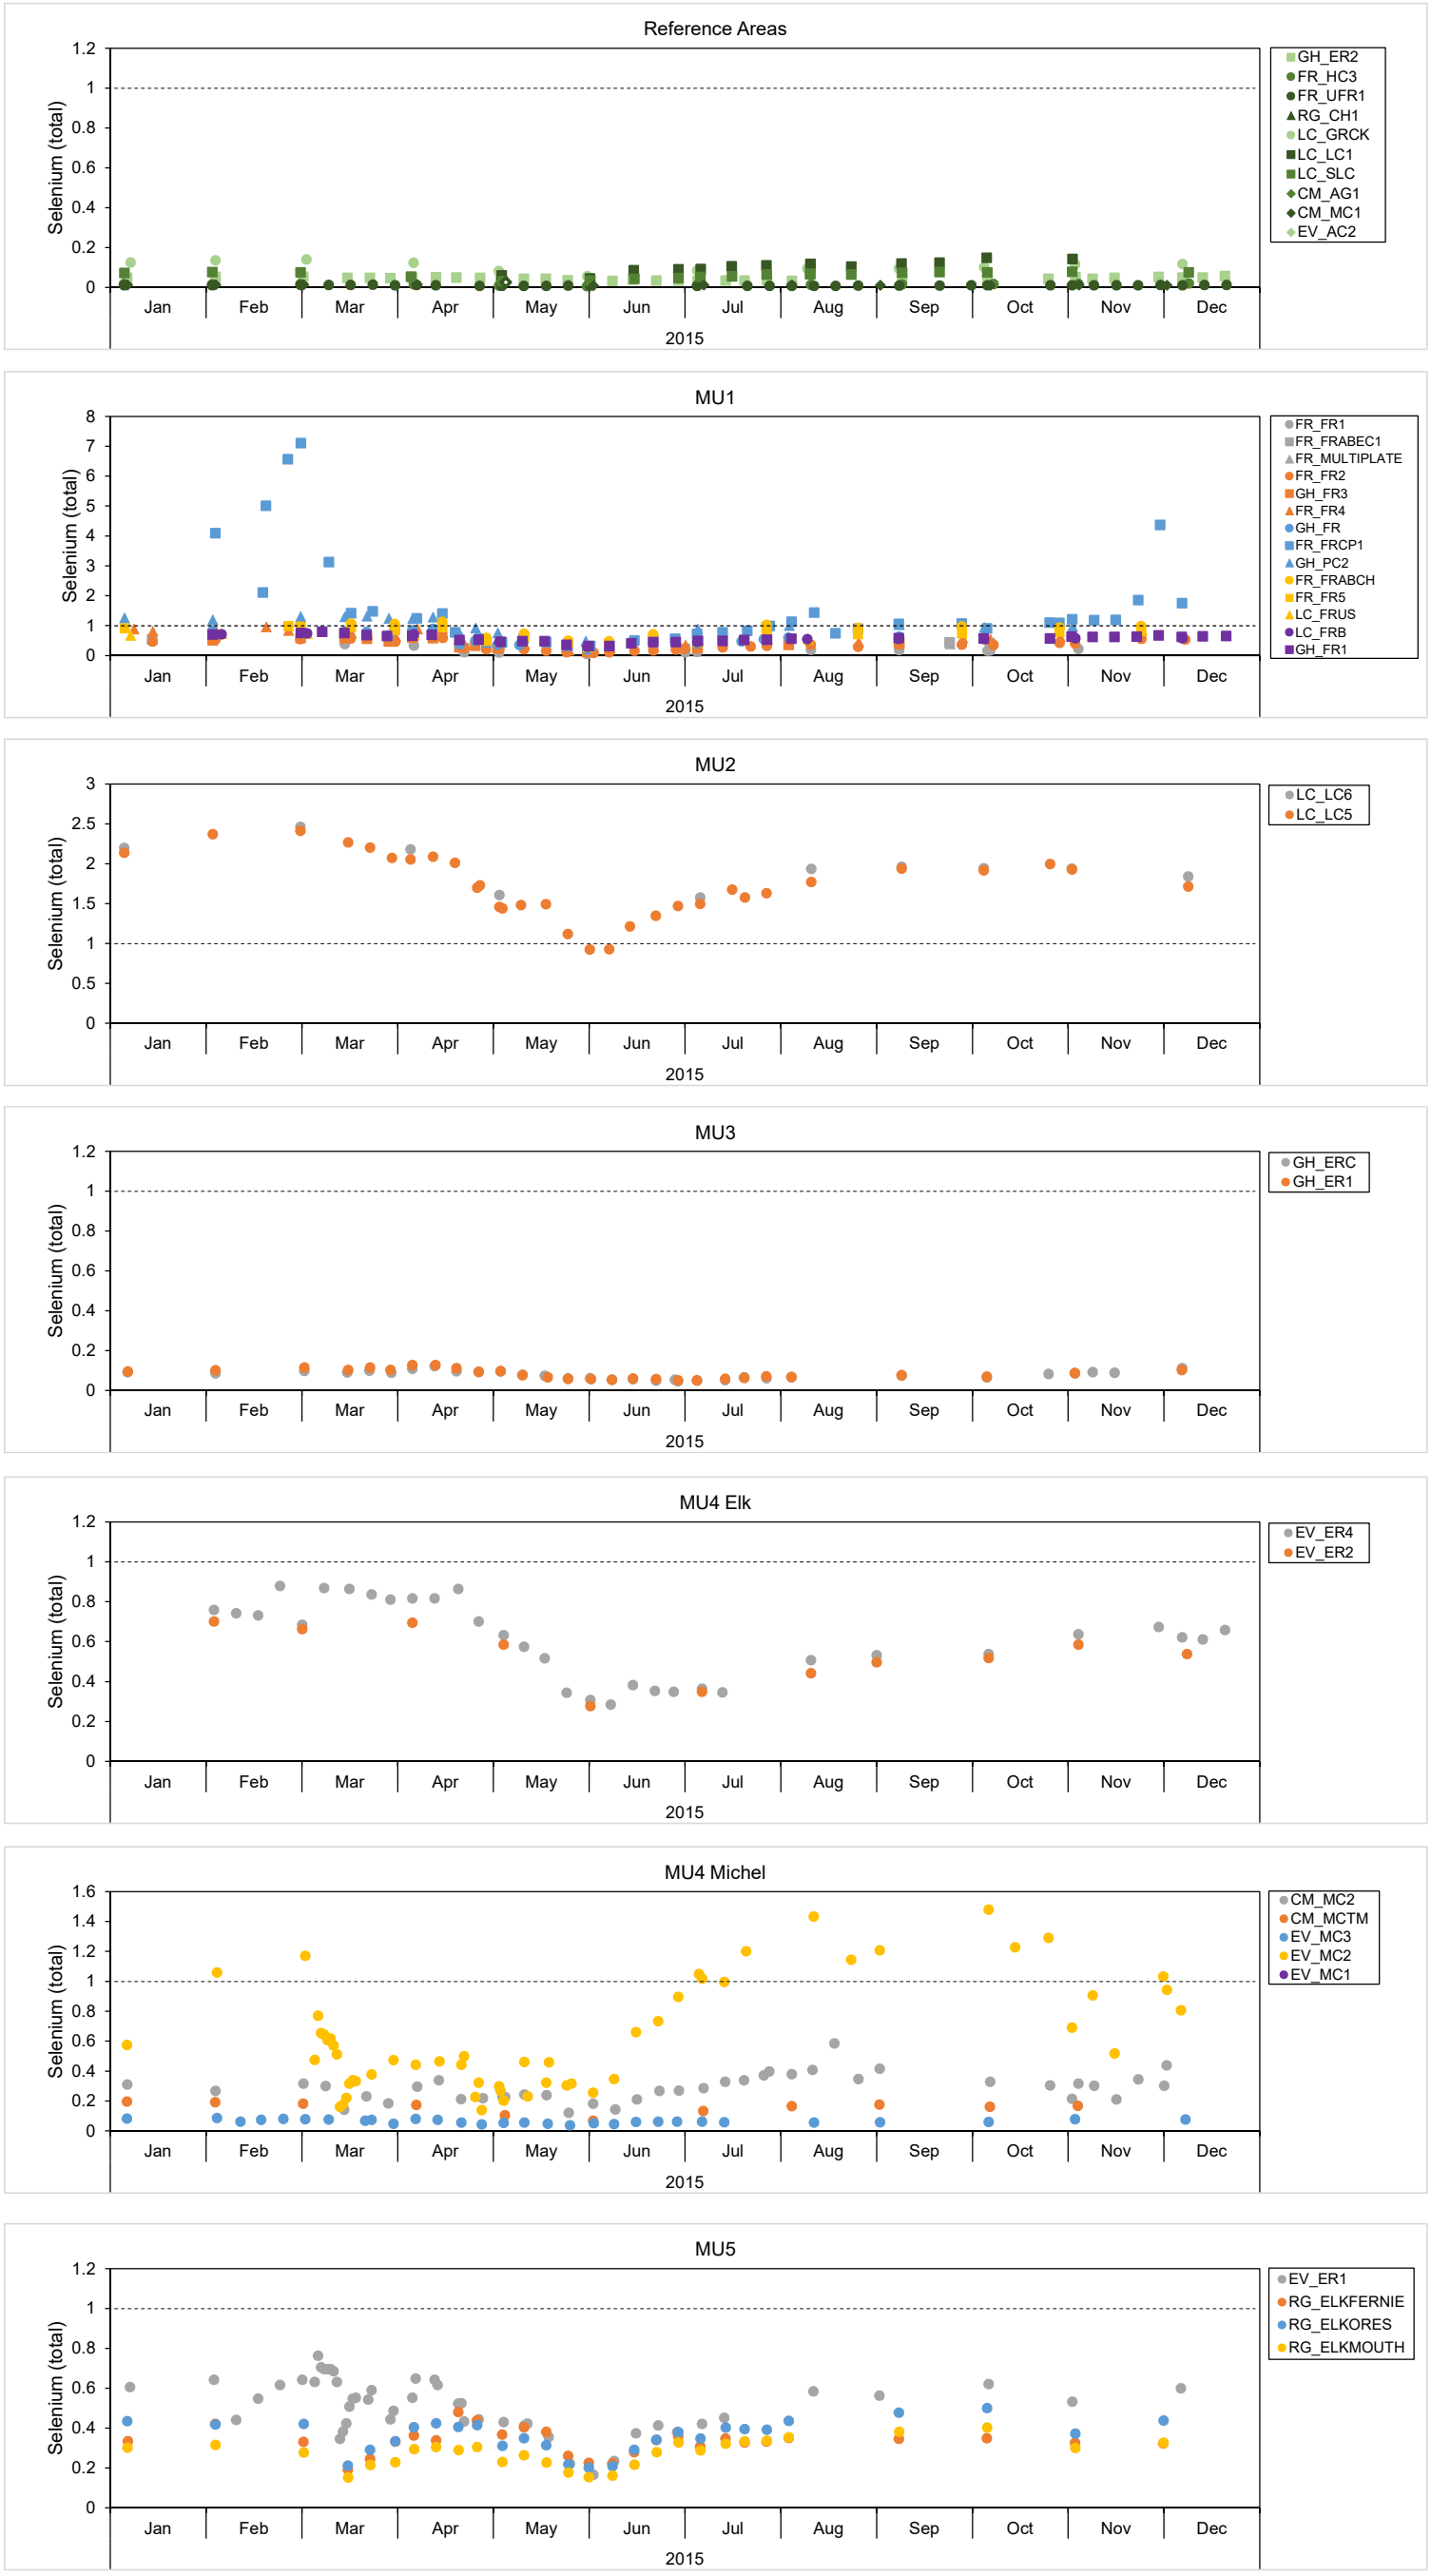

Figure C.7r: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

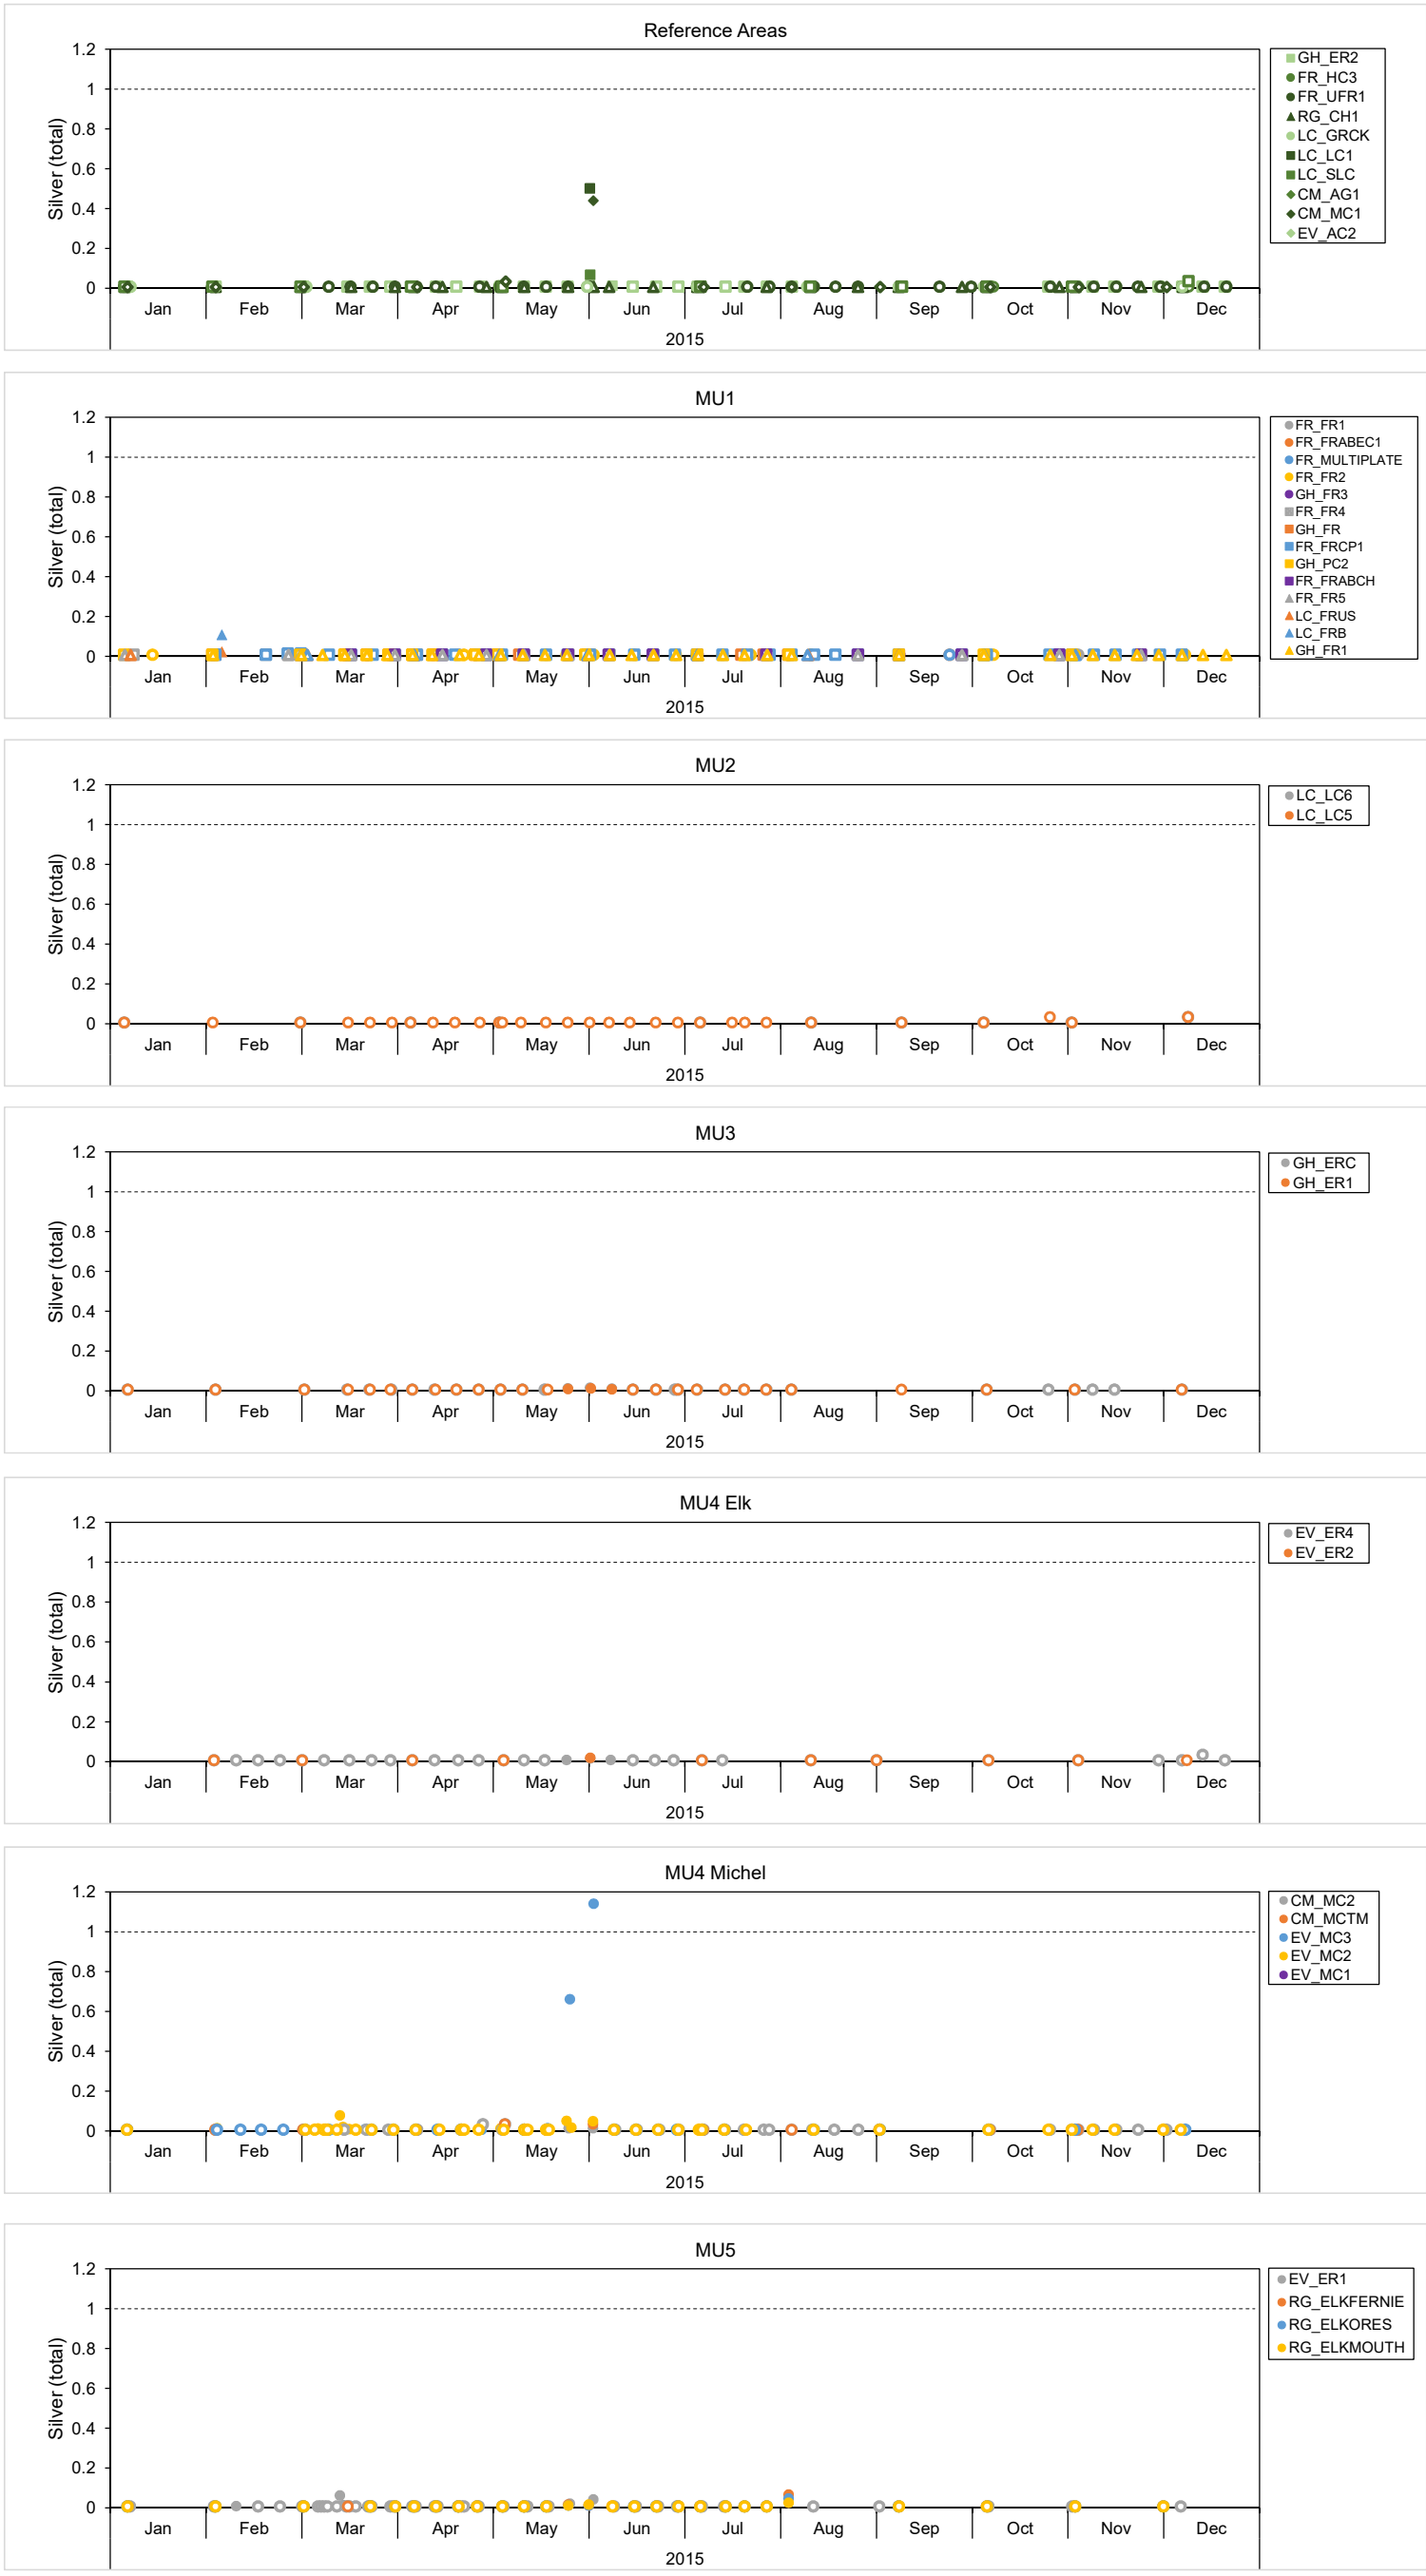

Figure C.7s: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

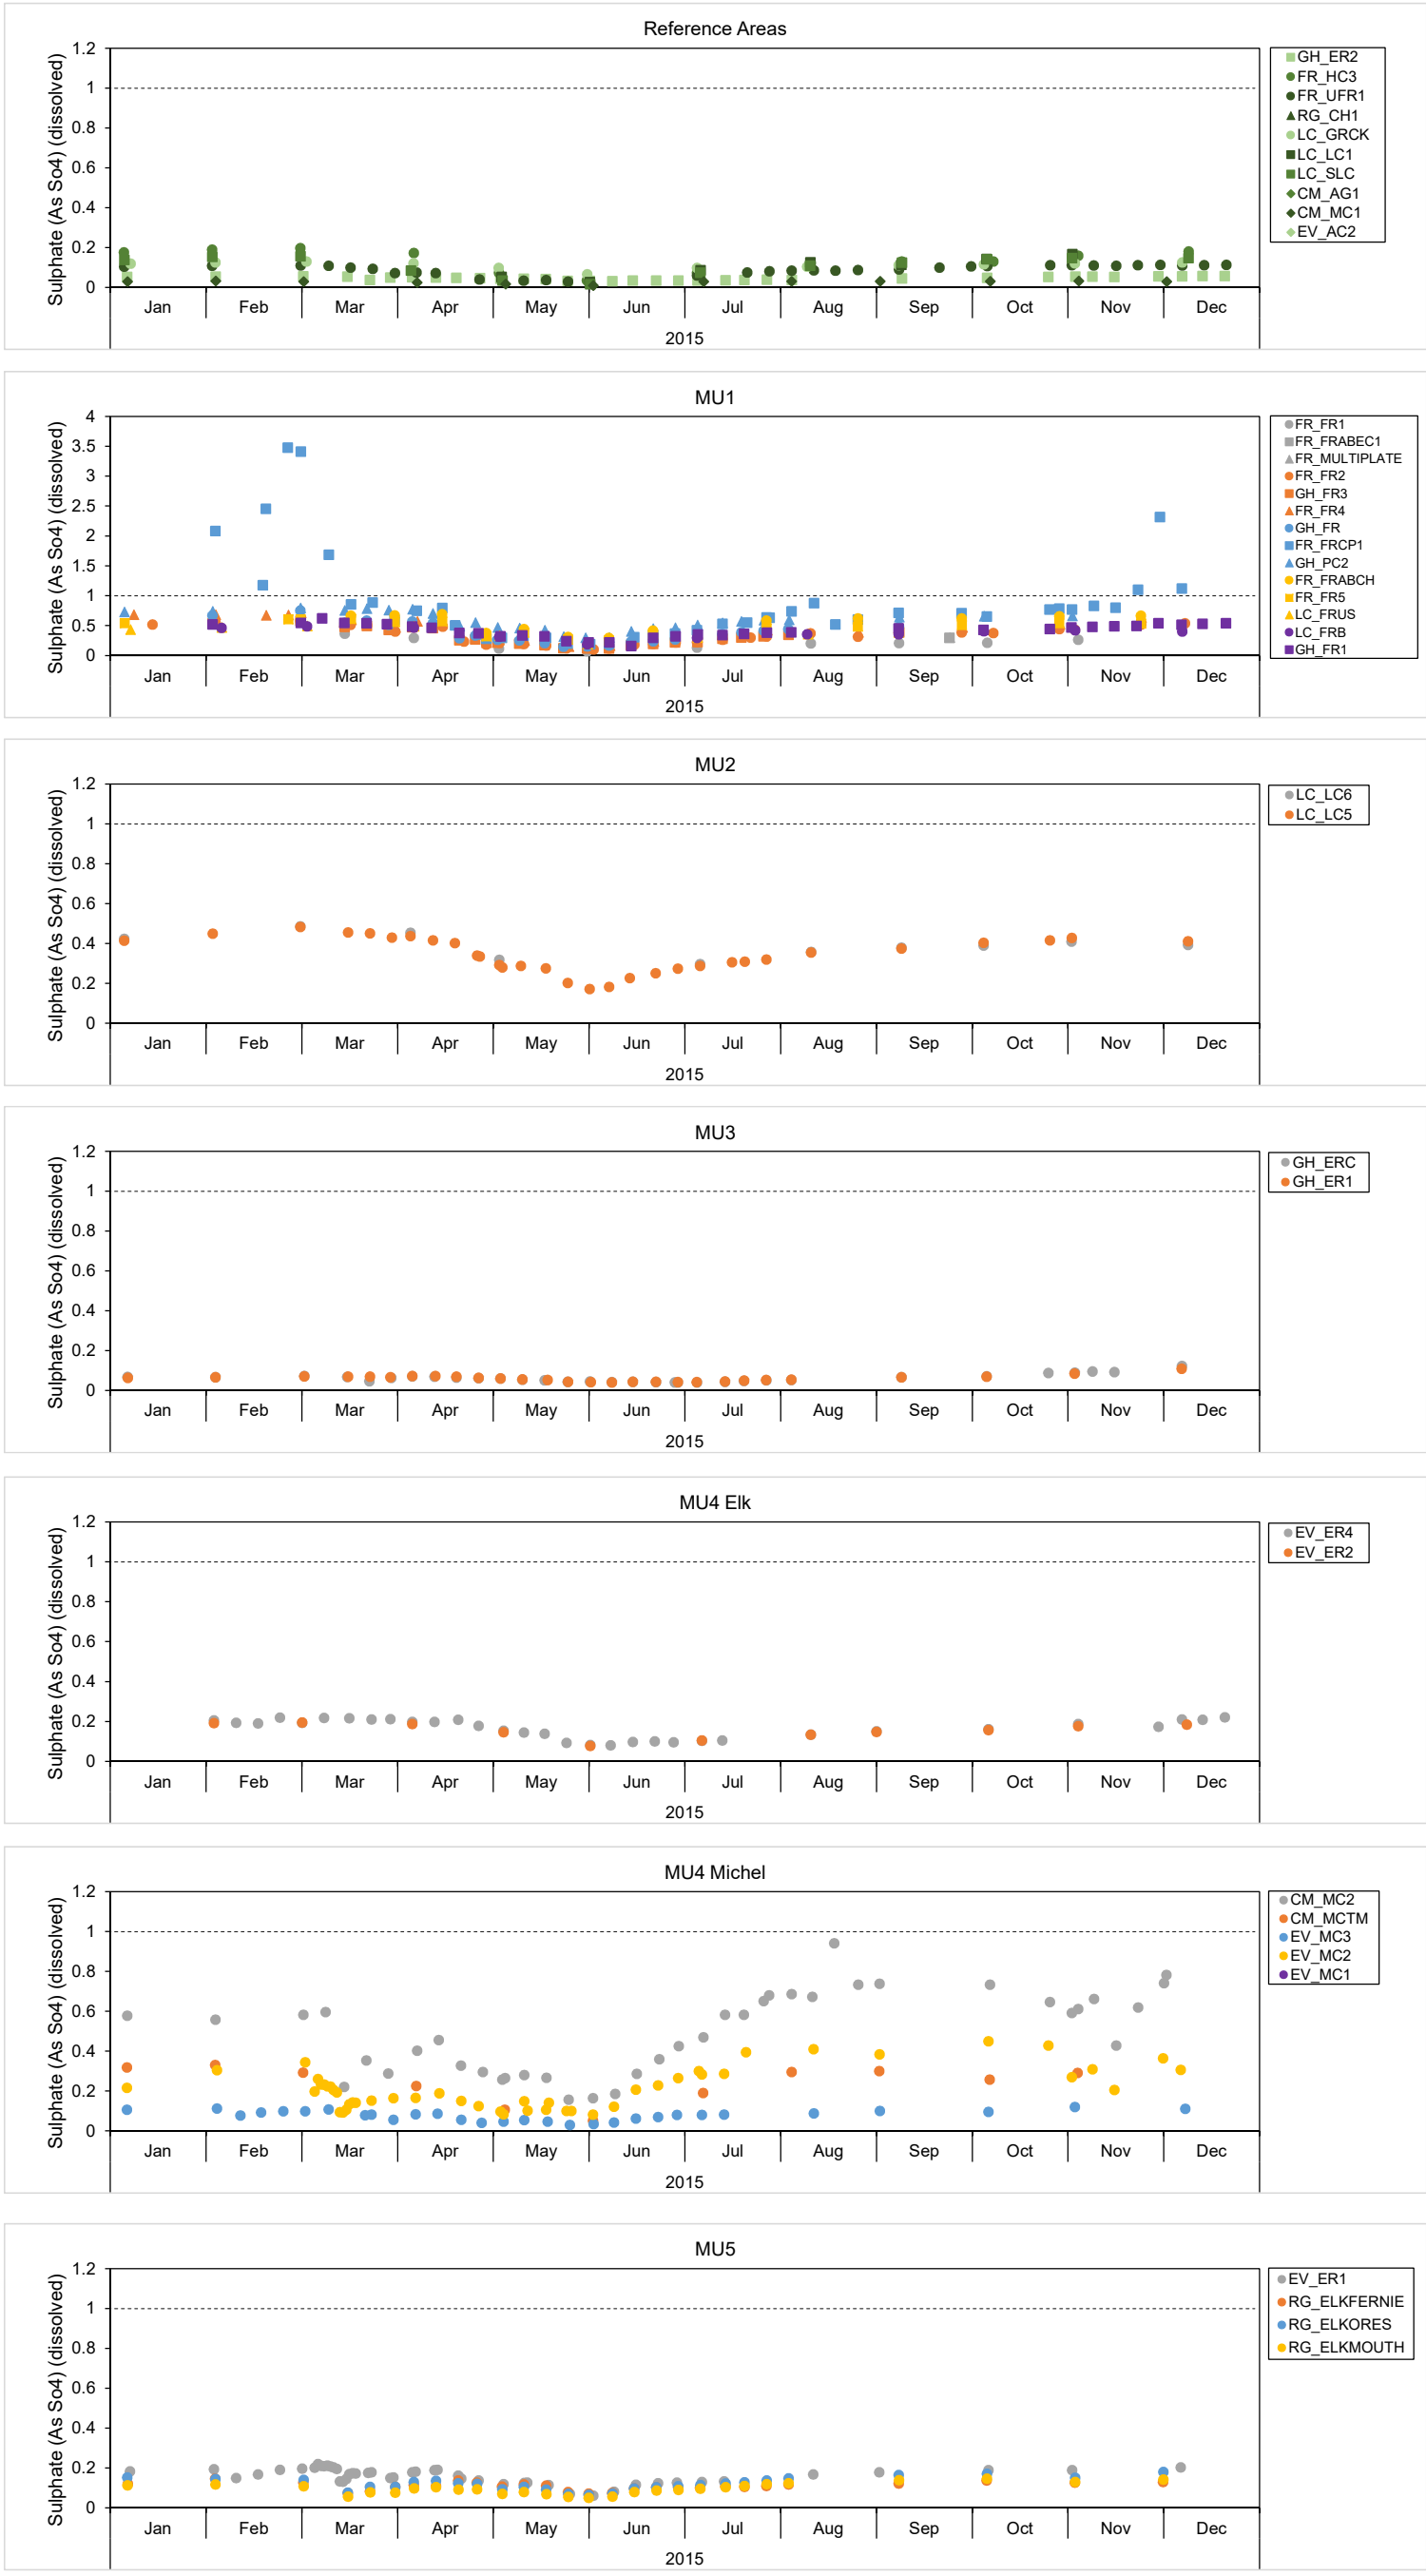

Figure C.7t: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

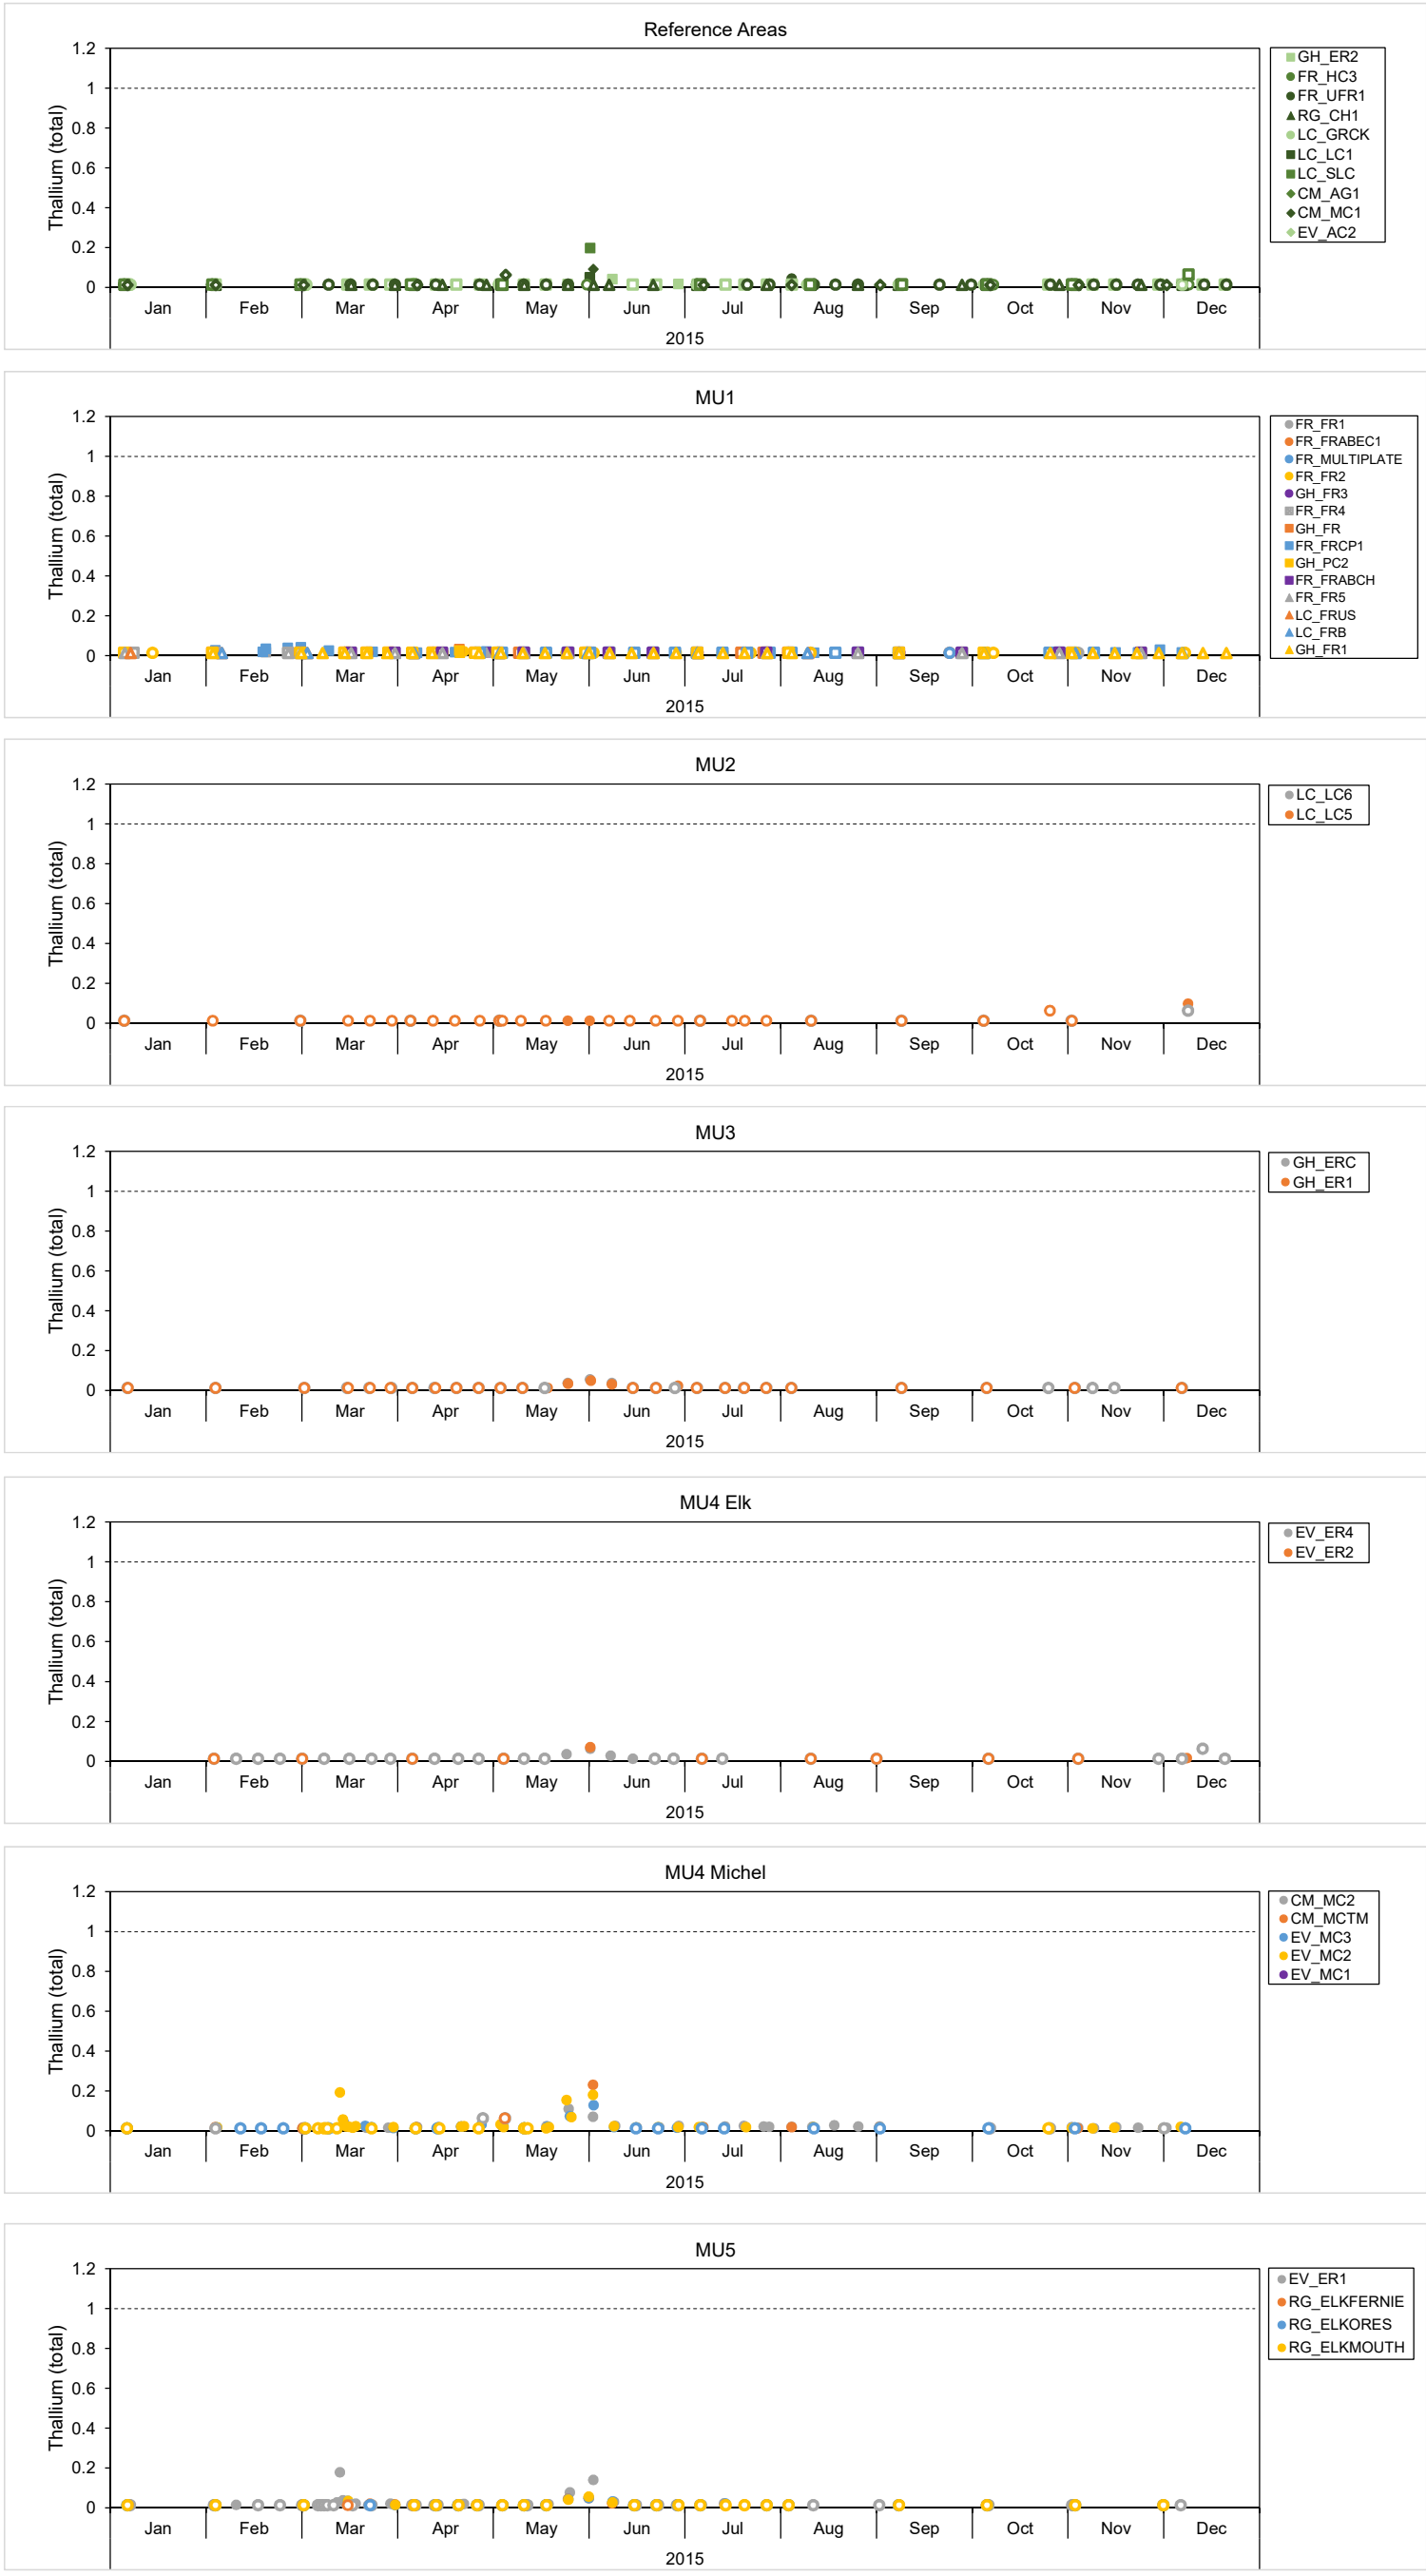

Figure C.7u: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

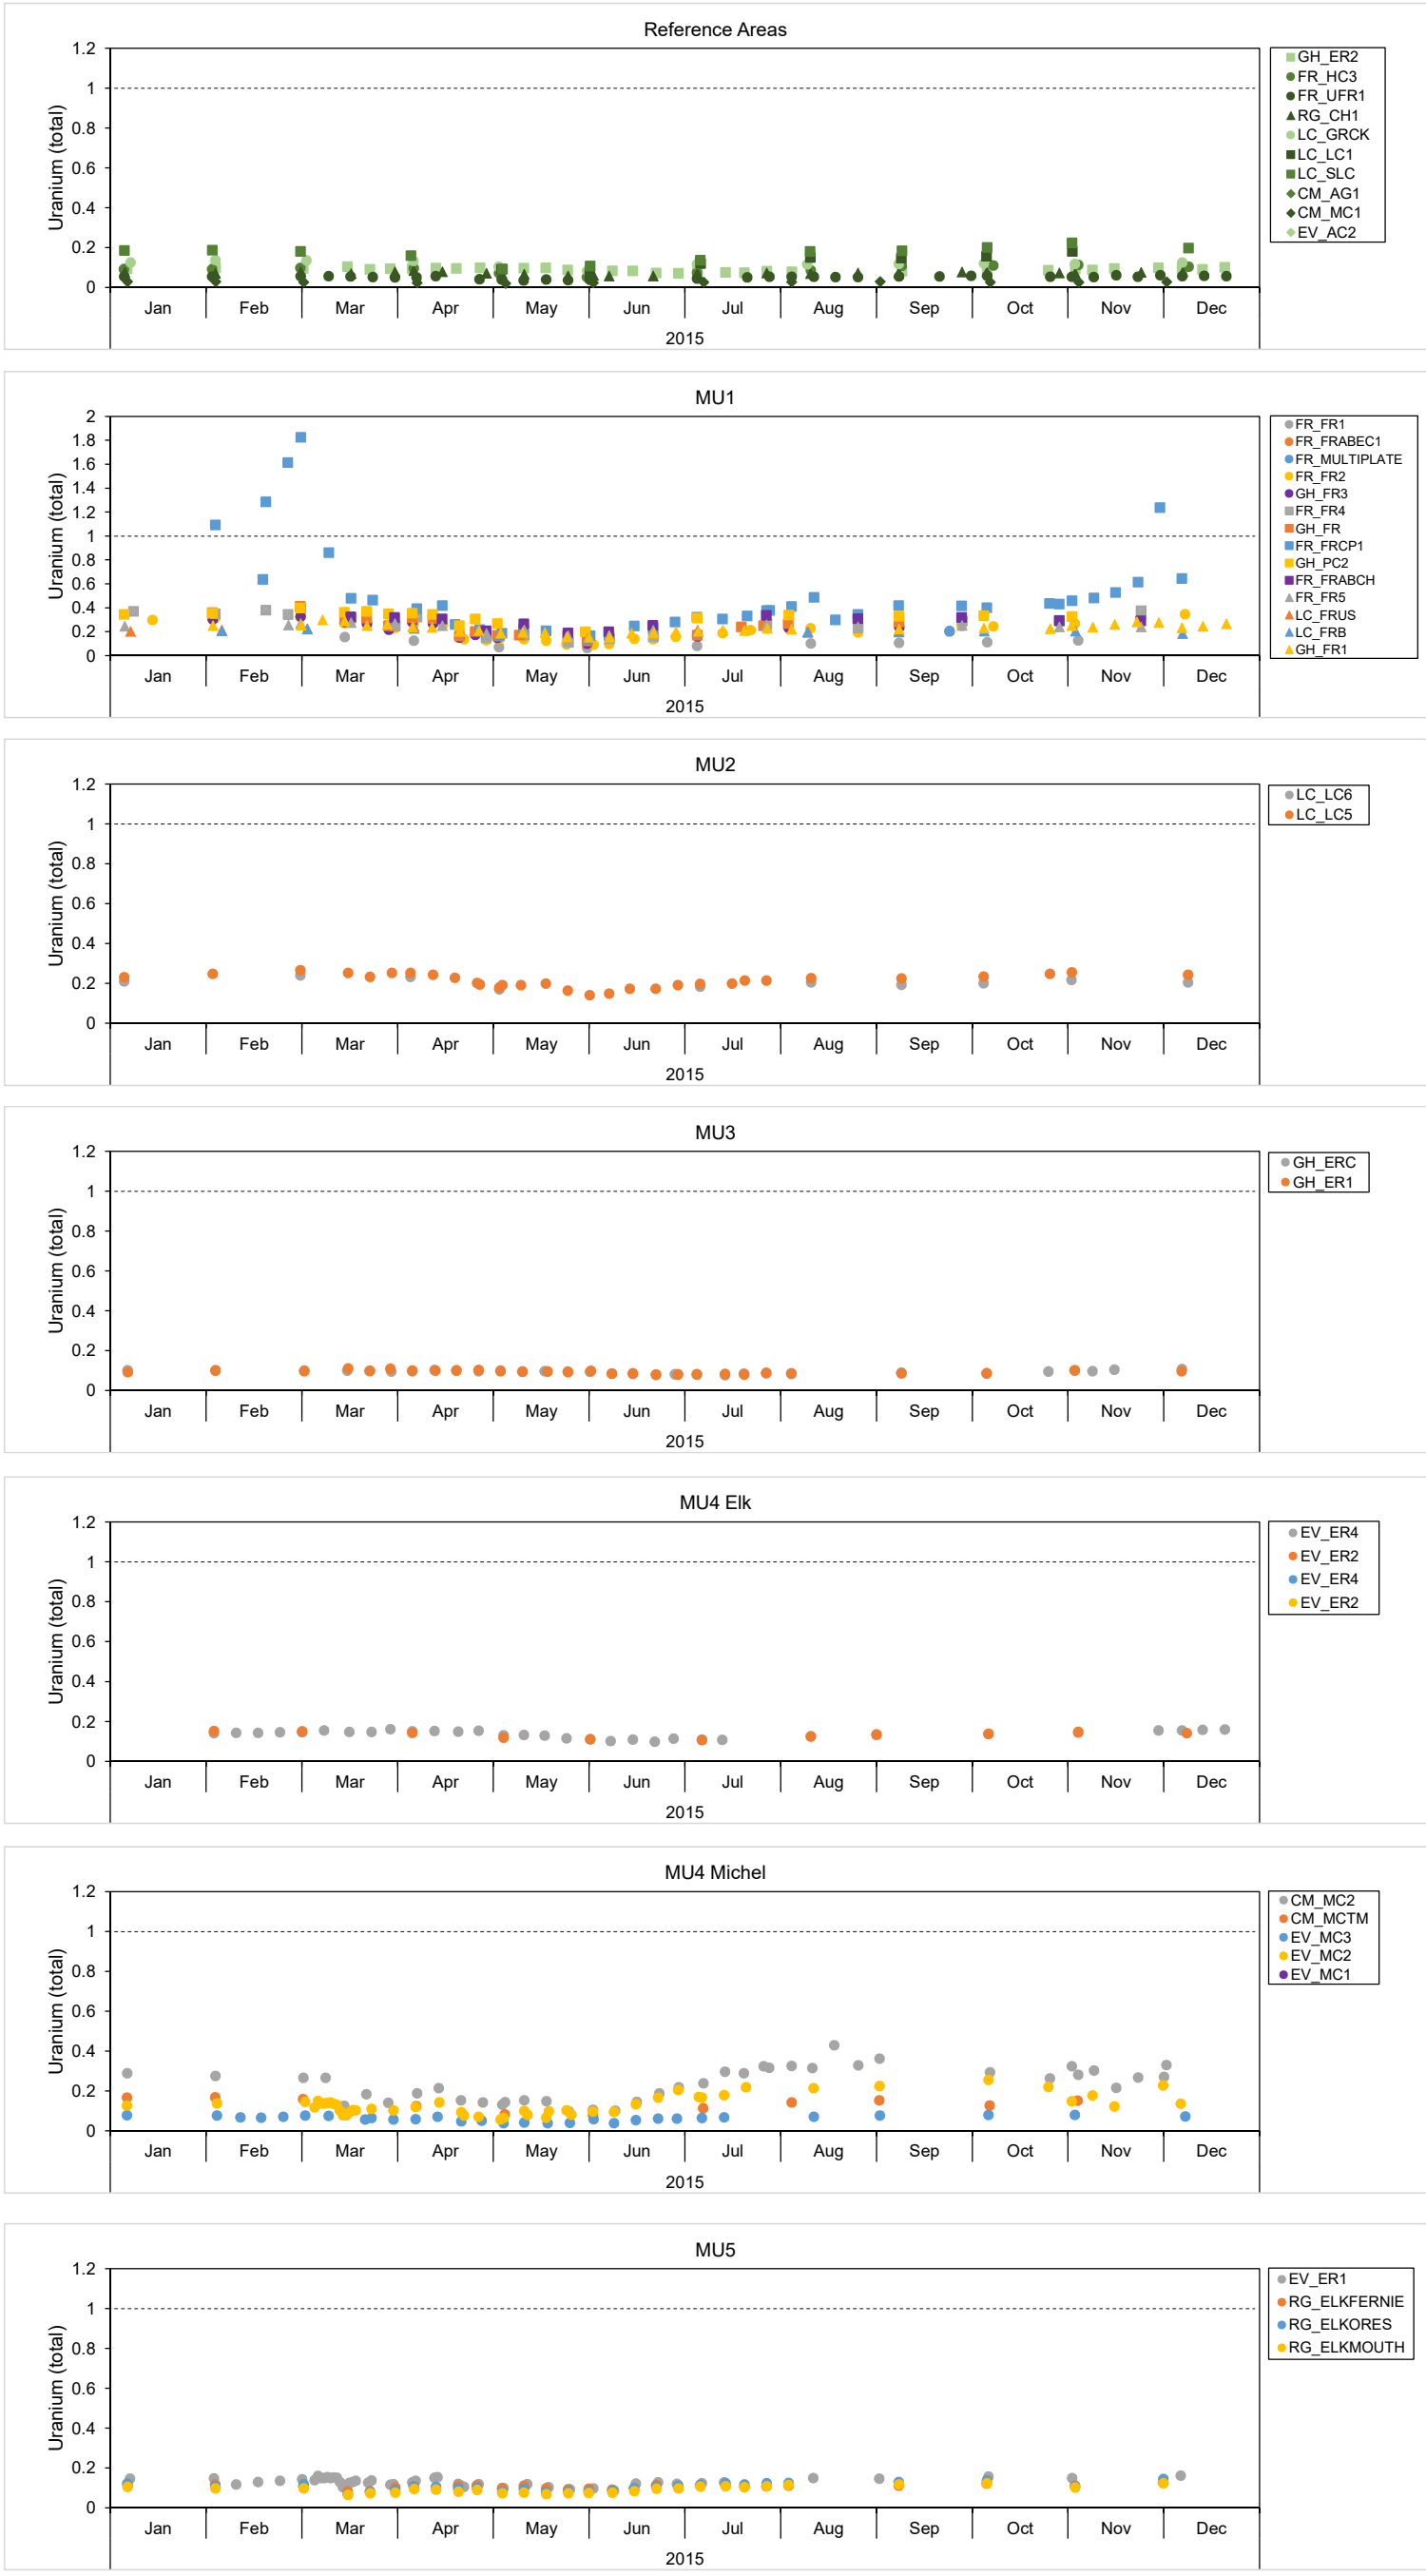

Figure C.7v: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).

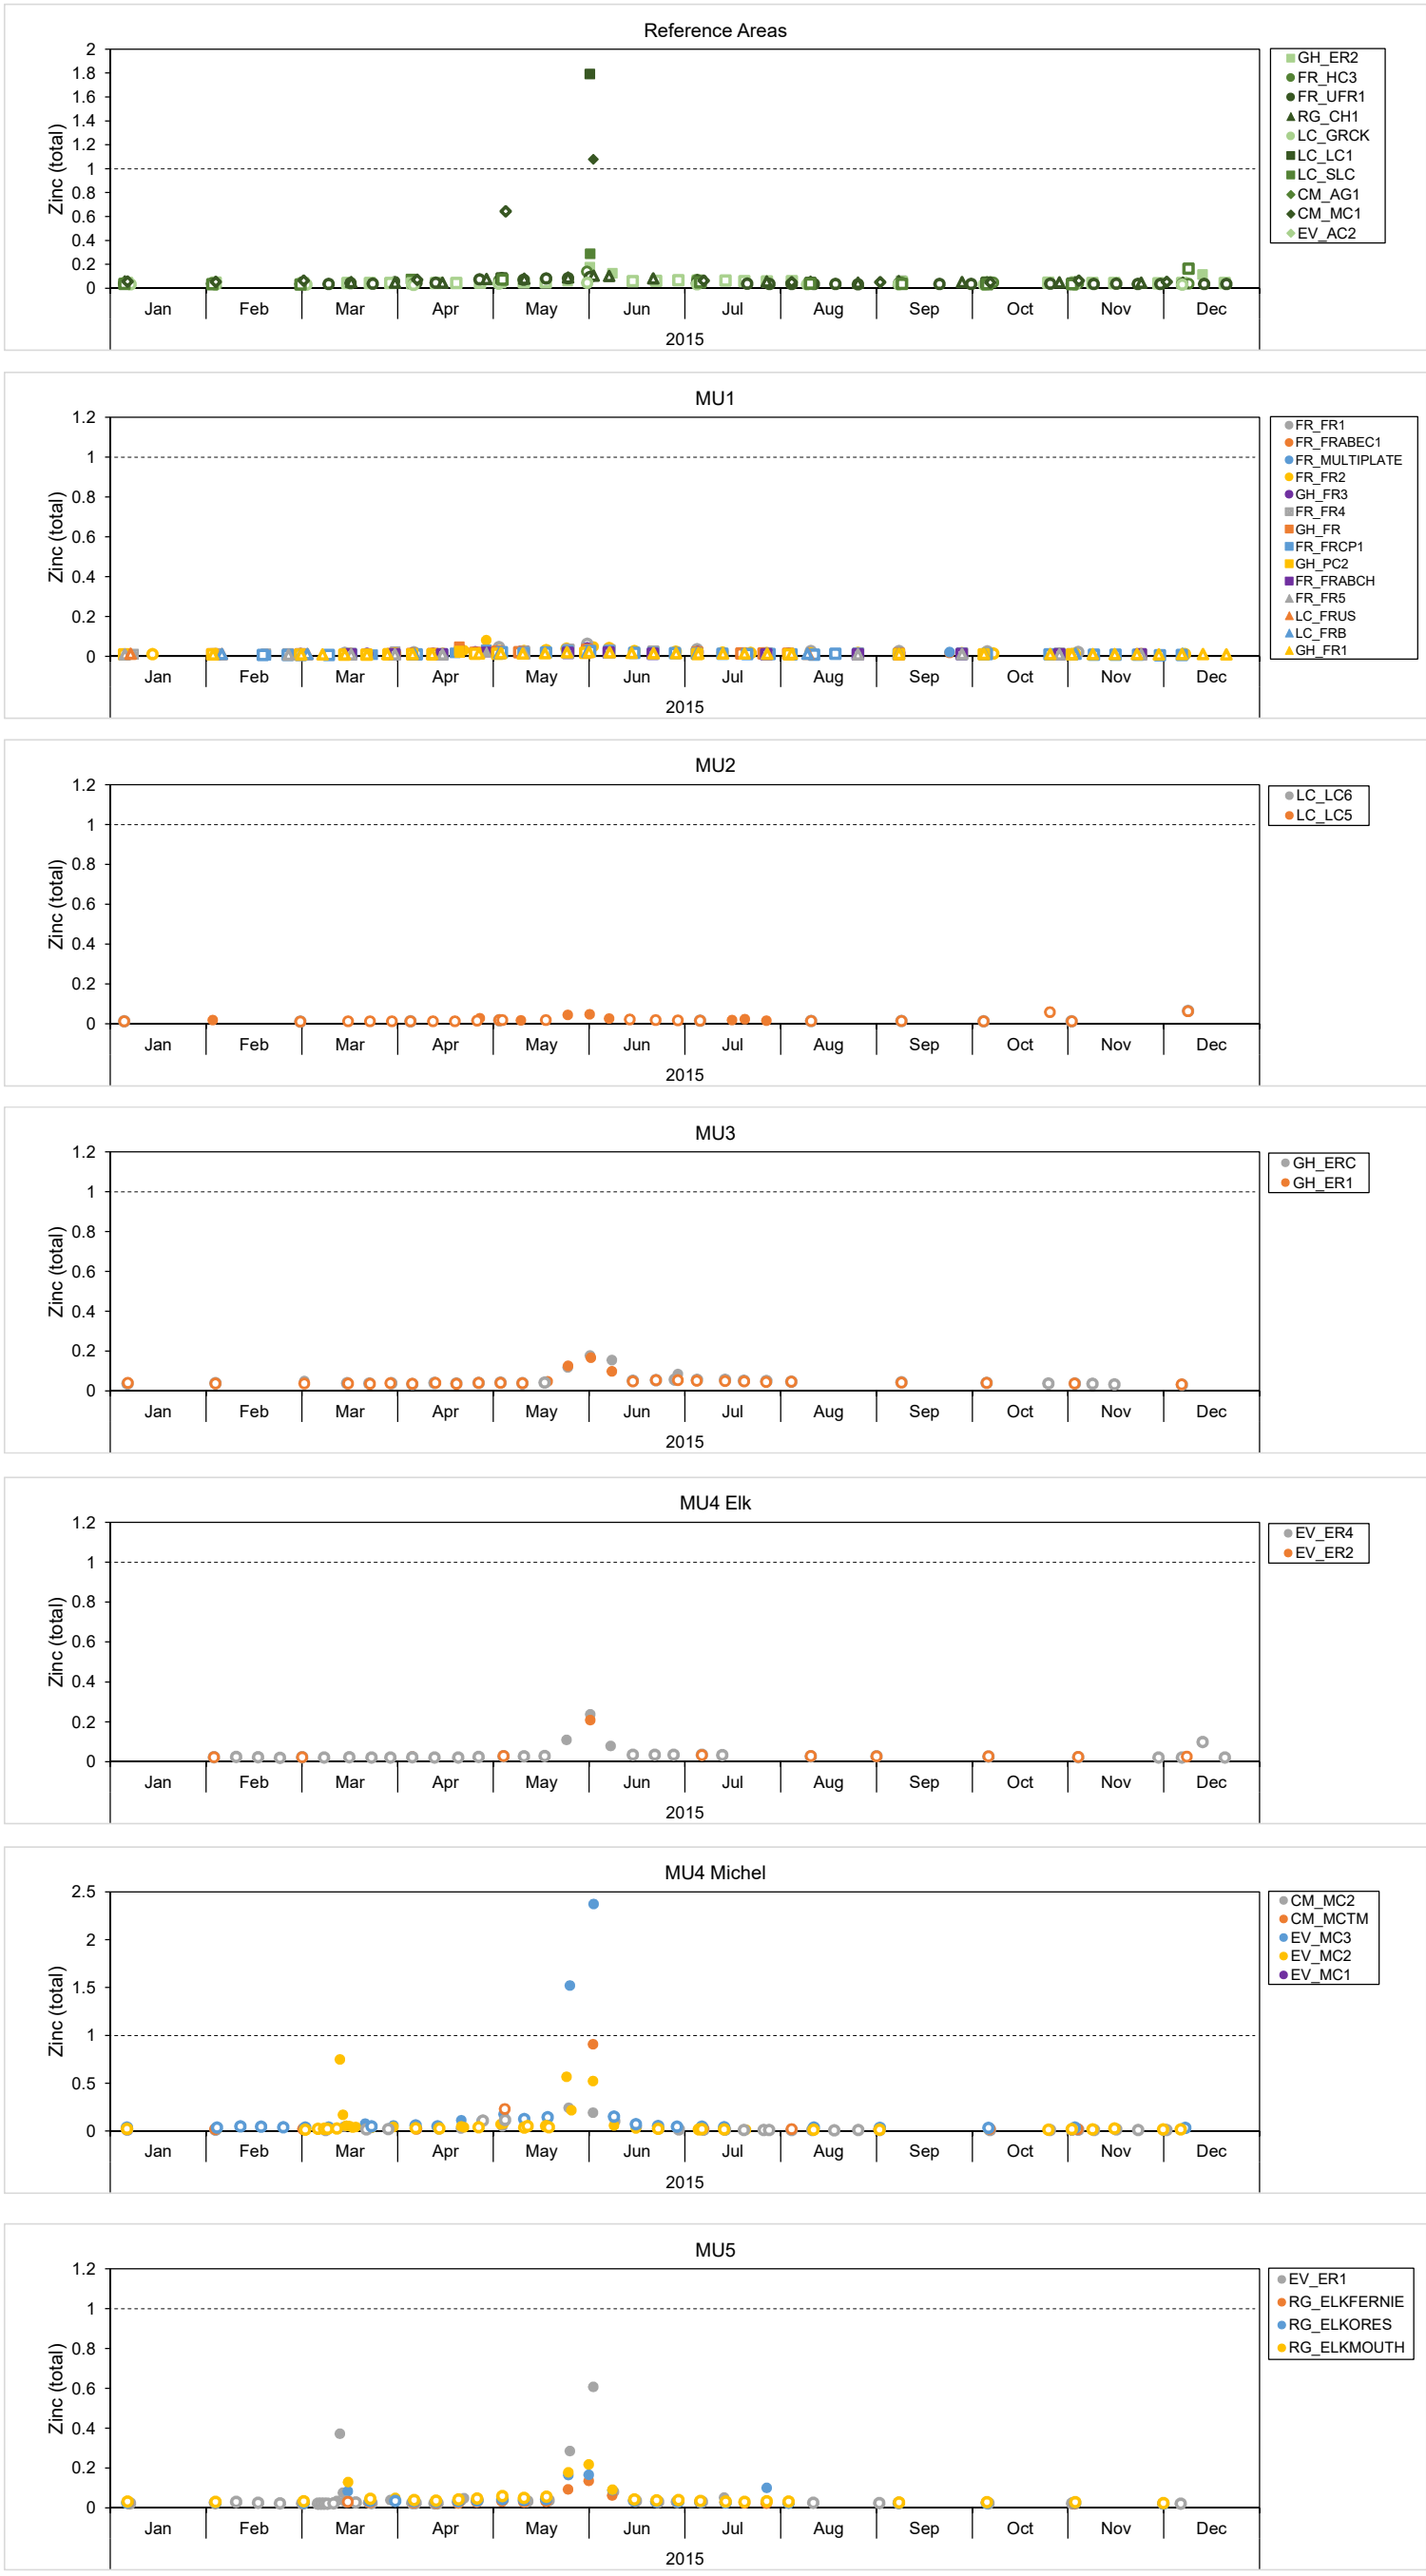

Figure C.7w: Scatterplots of Hazard Quotients for Key Water Quality Parameters for Reference and Main Stem Mine-exposed Areas, 2015, Elk Valley

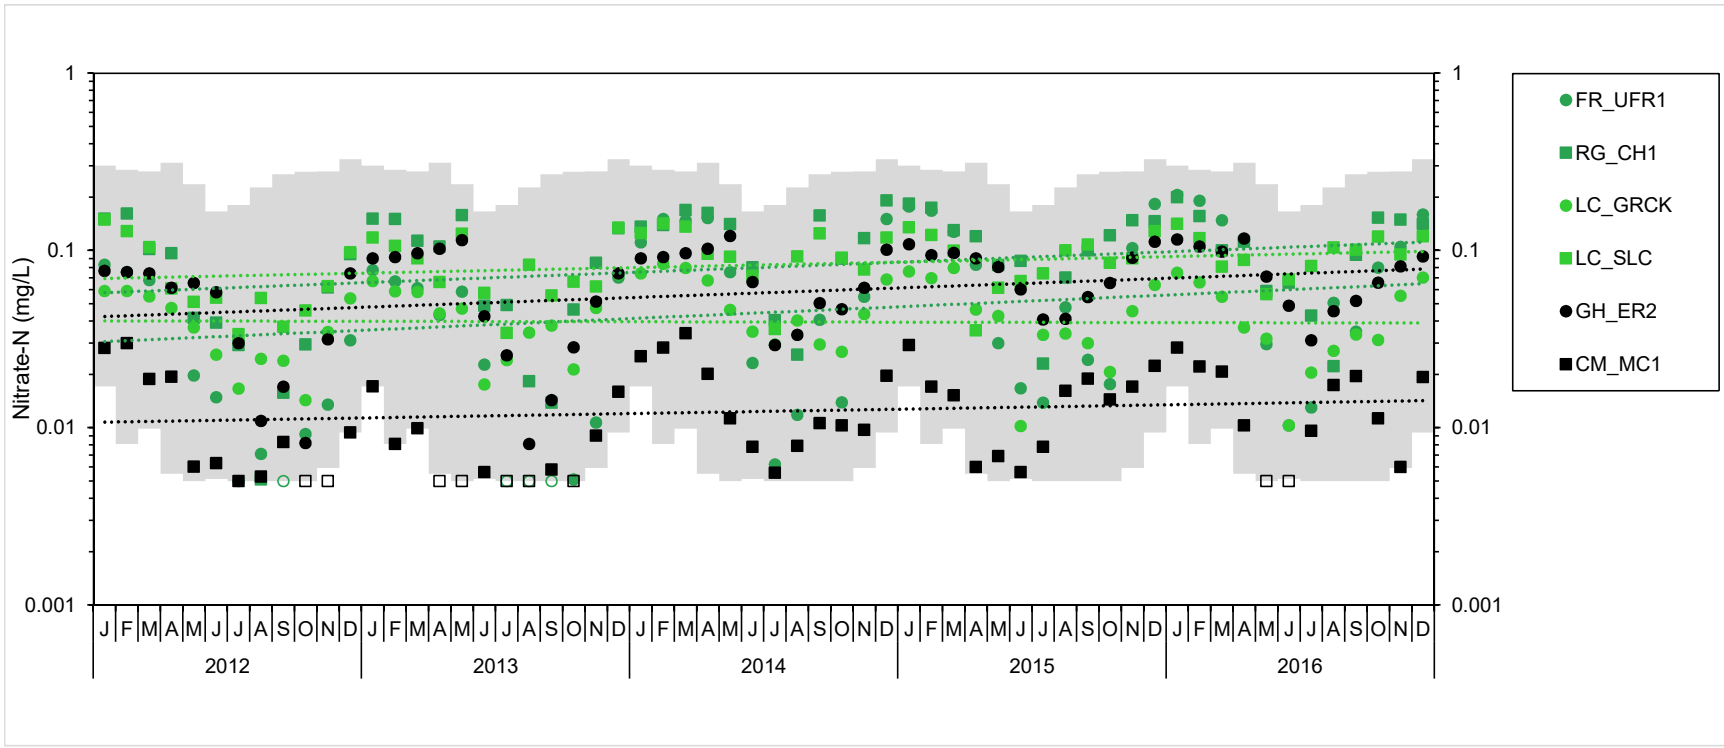
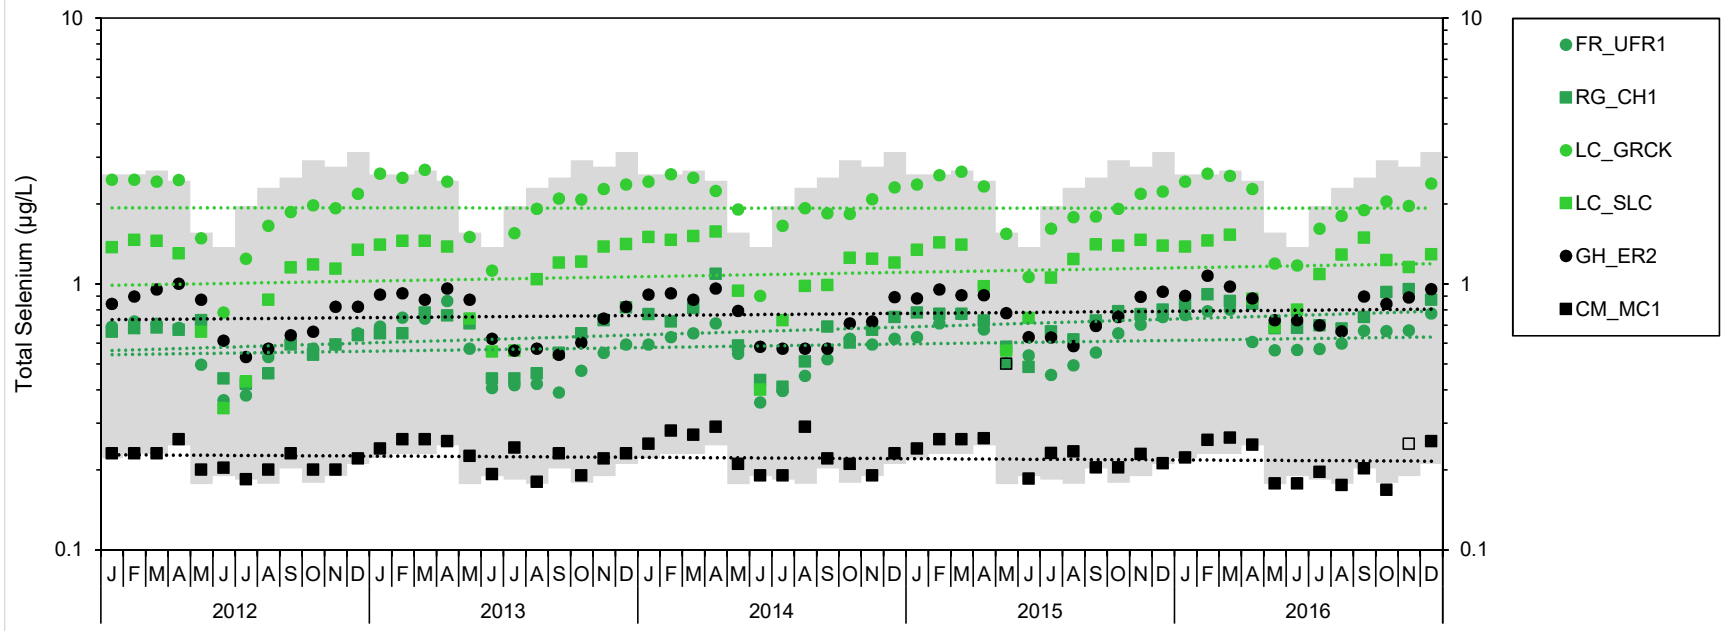
Note: Hazard quotients were calculated by dividing the individual sample concentration by the individual sample guideline. For analytes with parameter-dependent guidelines (e.g., hardness-dependent guidelines), then concurrent parameter for individual samples was used to calculate the guideline. Values above the dashed line indicate the observed concentrations was in excess of the sample-specific guideline. Open symbols indicate hazard quotients calculated using concentrations reported as below the laboratory reporting limit (LRL).





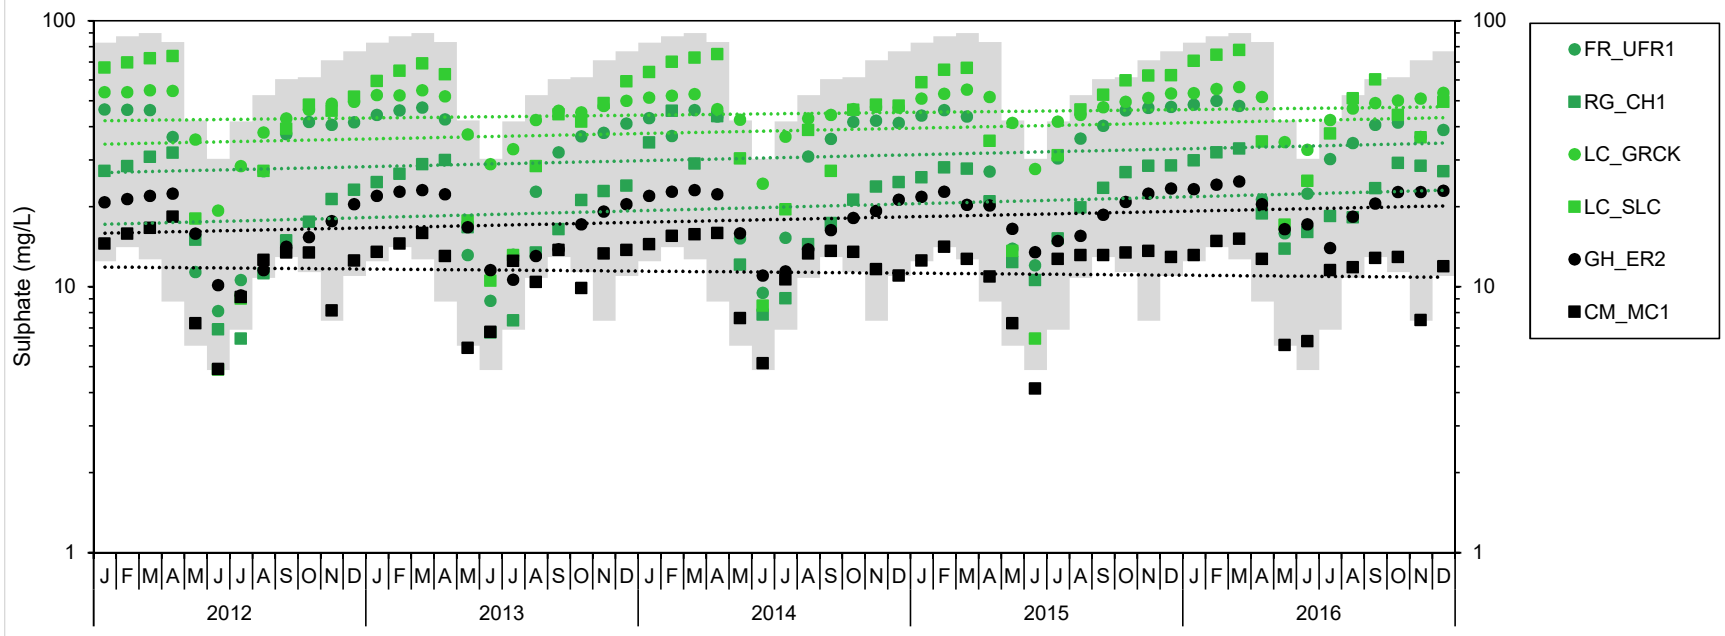


Figure C.8: Monthly Mean Water Concentrations and Linear Trendlines for Nitrate-N, Total Selenium, and Sulphate for the Six References Areas used in the Temporal Analysis, 2012 - 2016

Notes: Values below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL

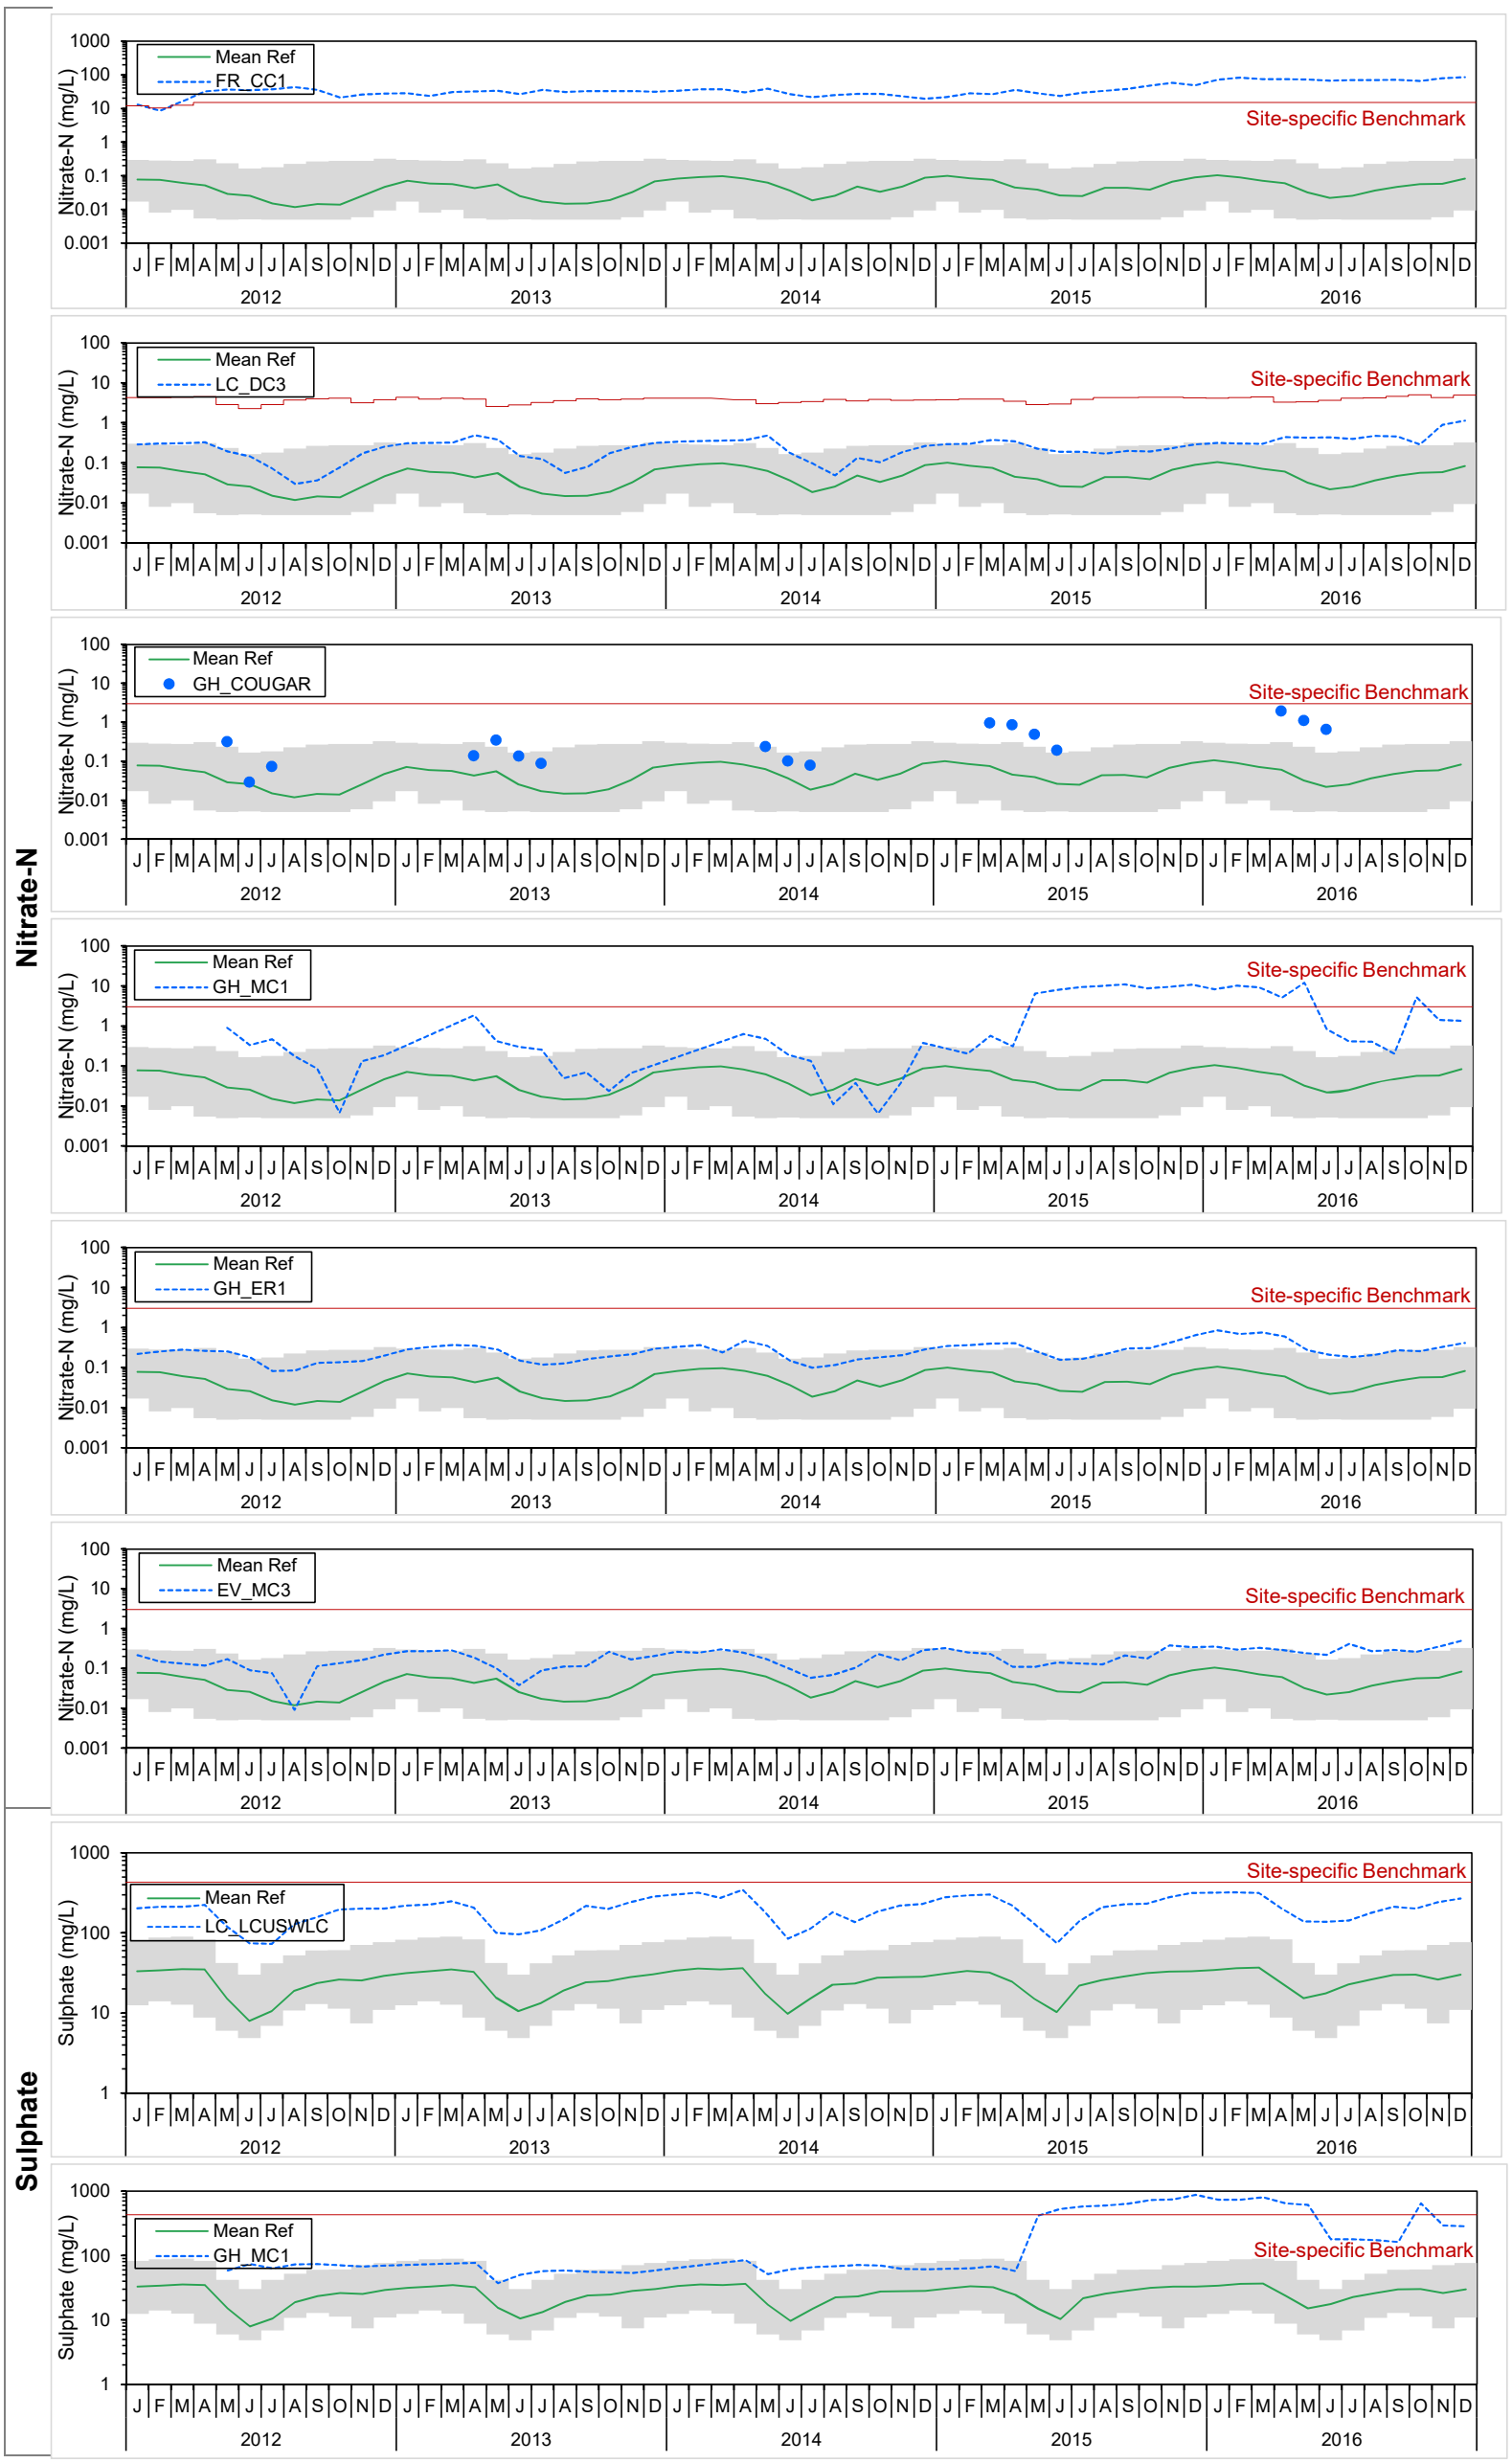

Figure C.9: Significant Increasing Temporal Changes for Nitrate, Sulphate and Selenium, Relative to Reference, 2012 - 2016

Notes: Grey shading represents the reference area normal range (2.5th and 97.5th percentiles)

Only changes greater than 50% are included for Nitrate, see Apprendix Figure C.5 for all significant trends for Nitrate.

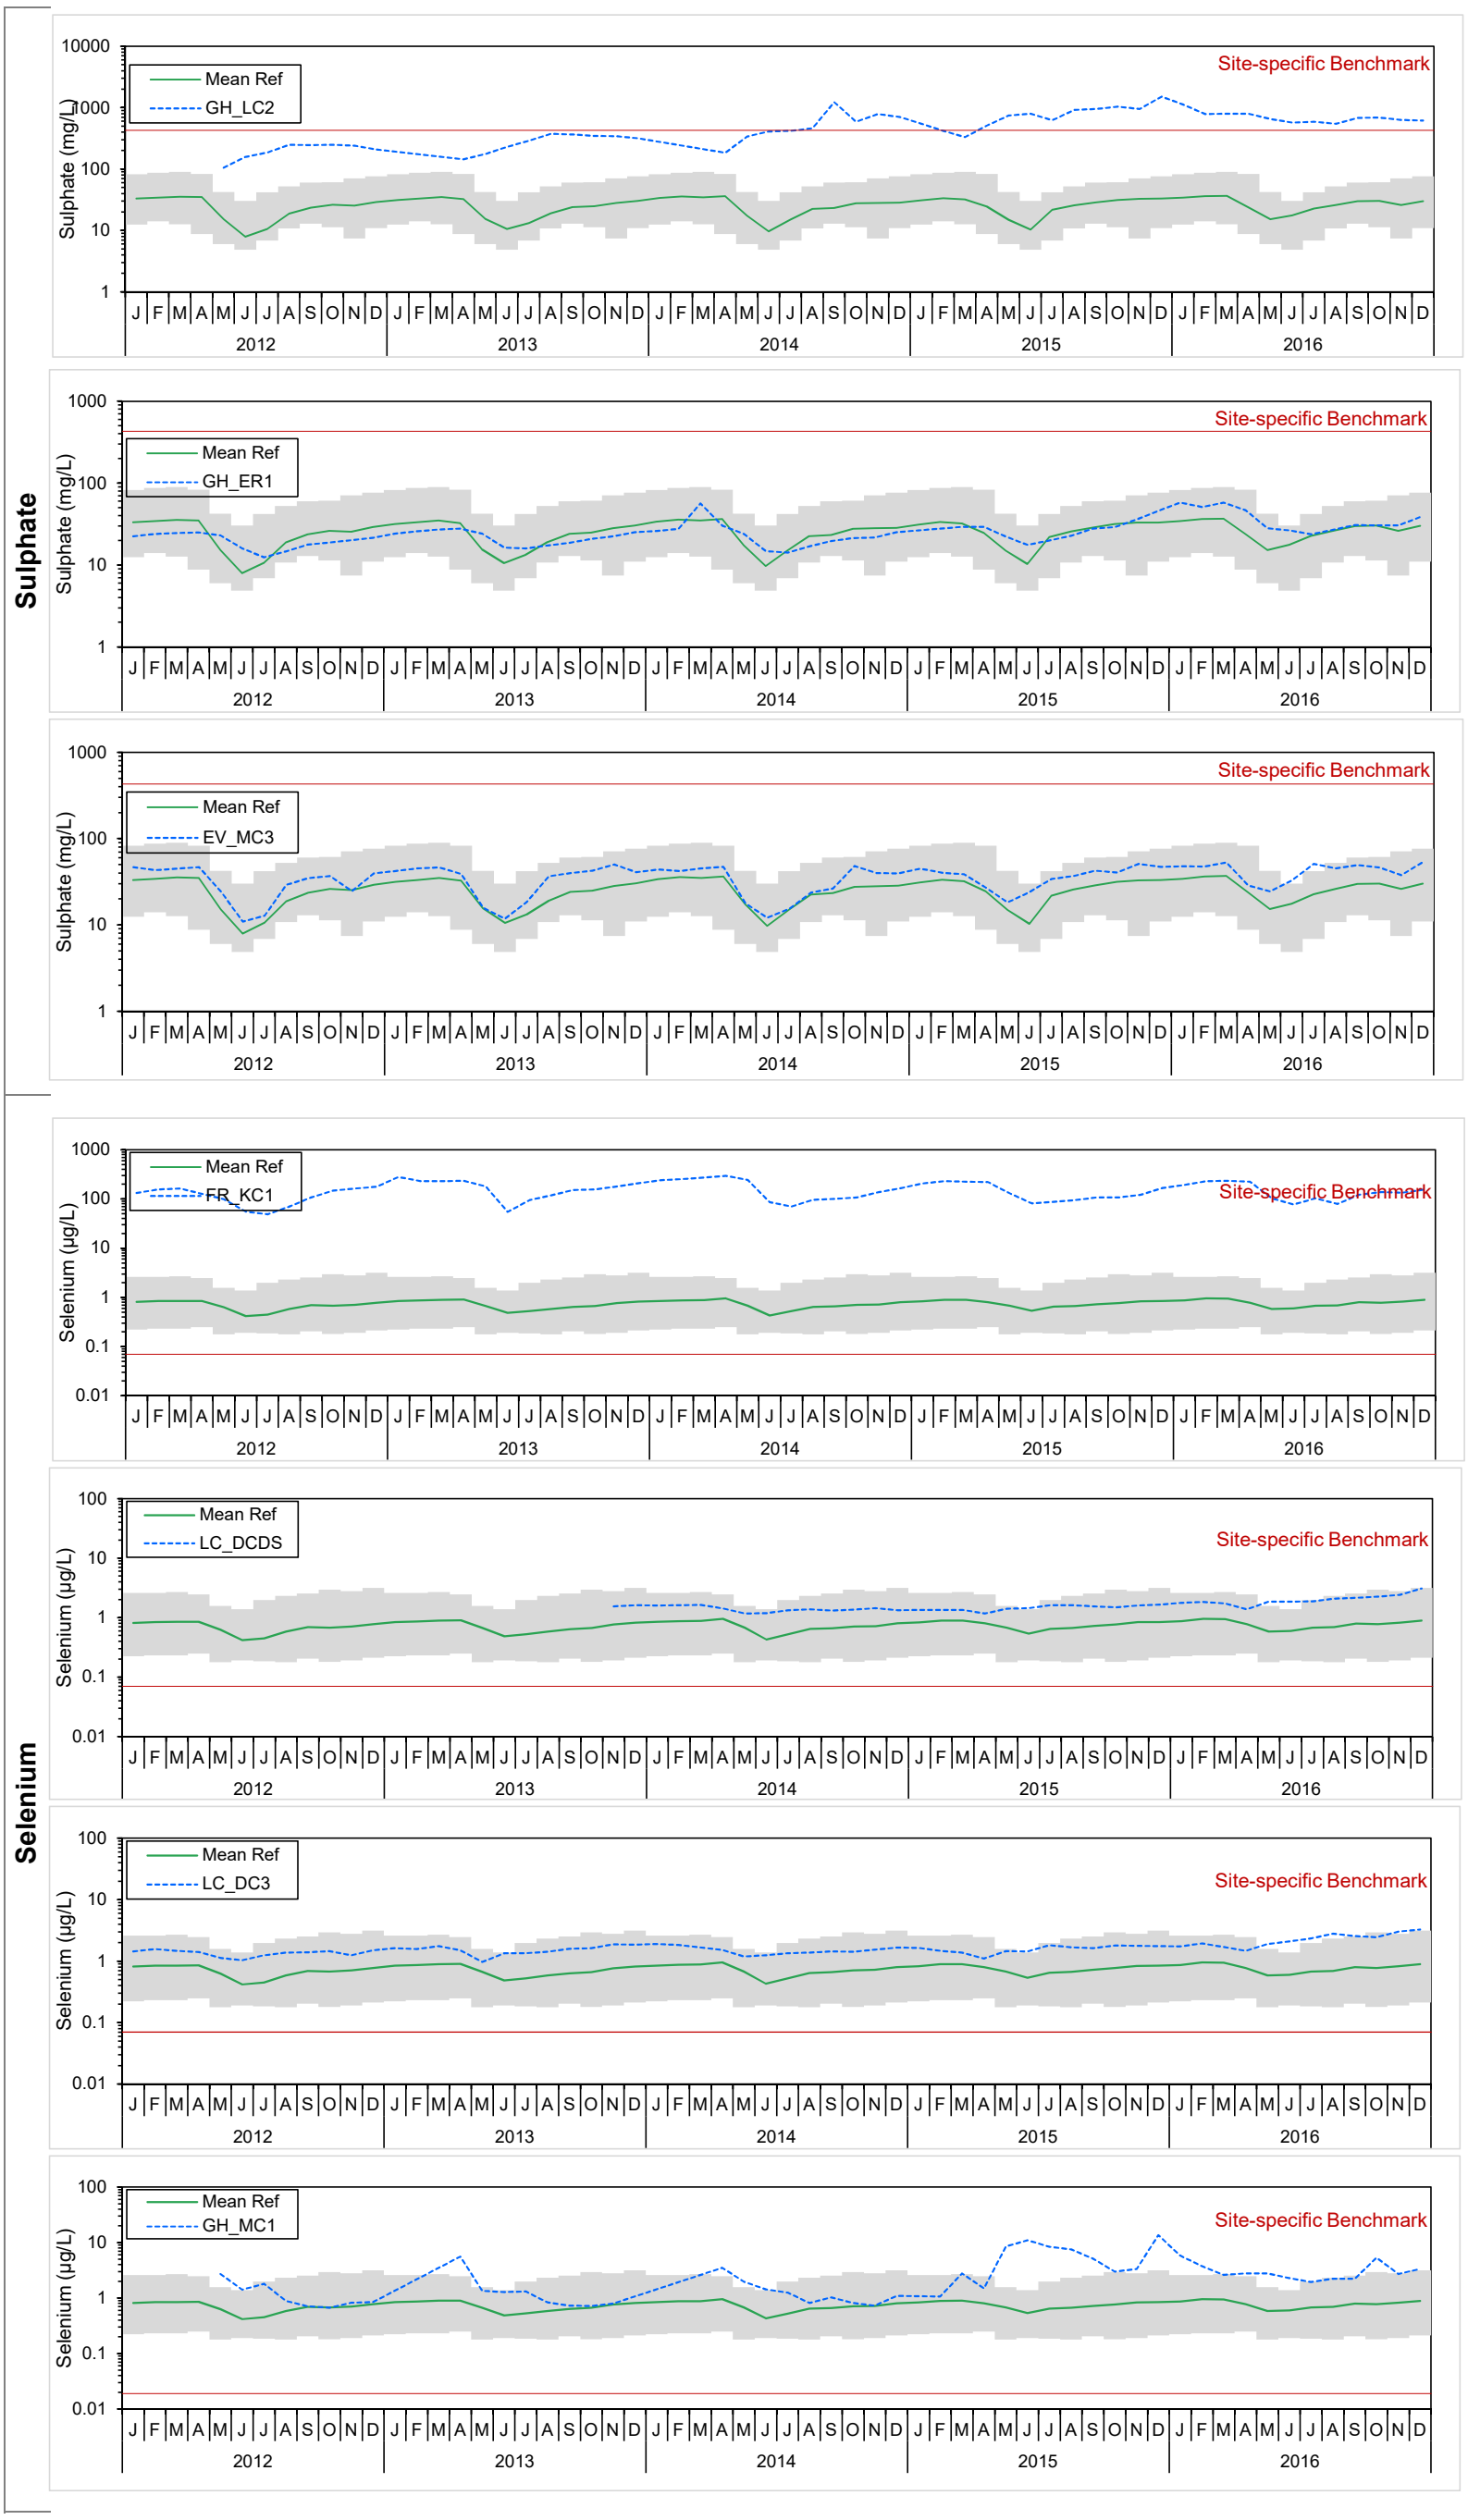

Figure C.9: Significant Increasing Temporal Changes for Nitrate, Sulphate and Selenium, Relative to Reference, 2012 - 2016

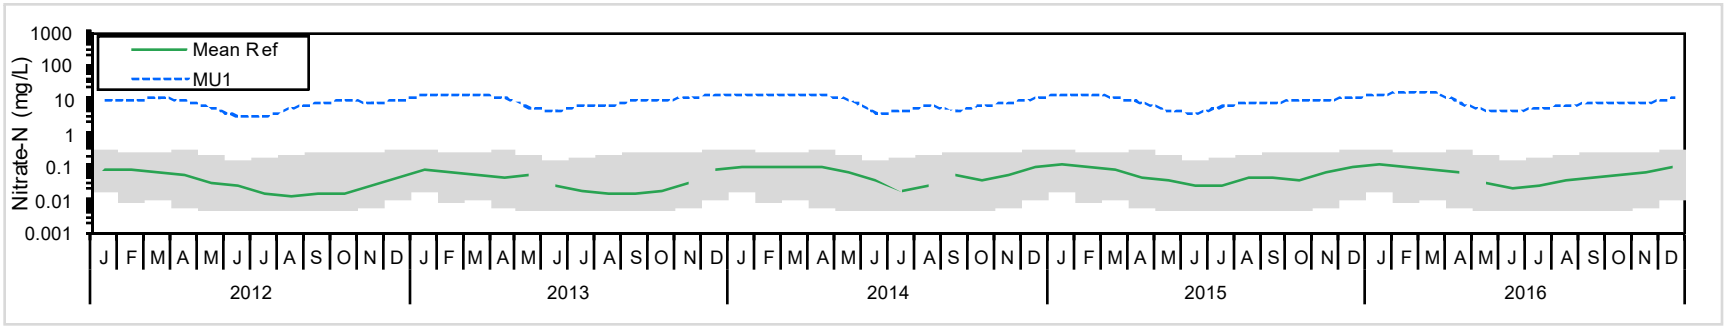
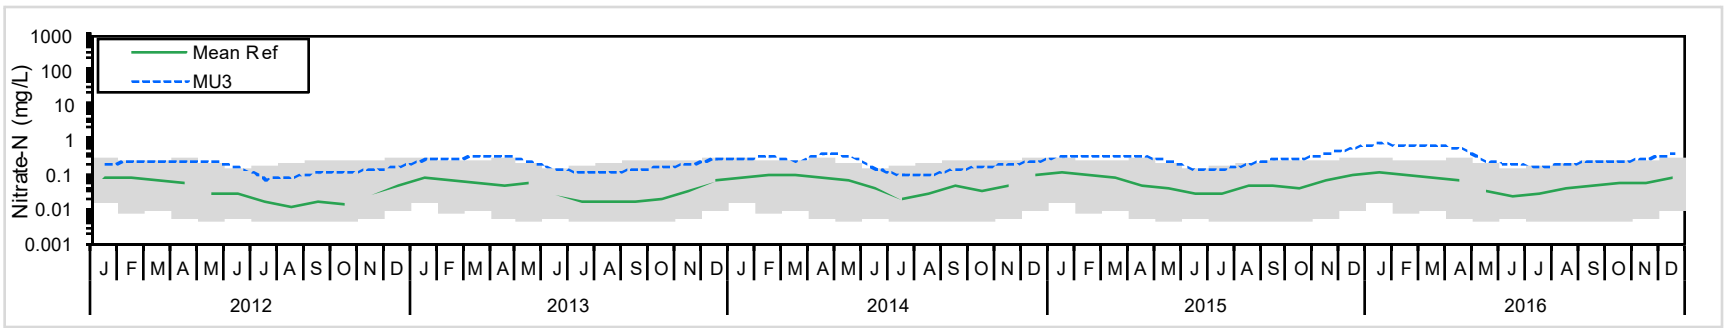
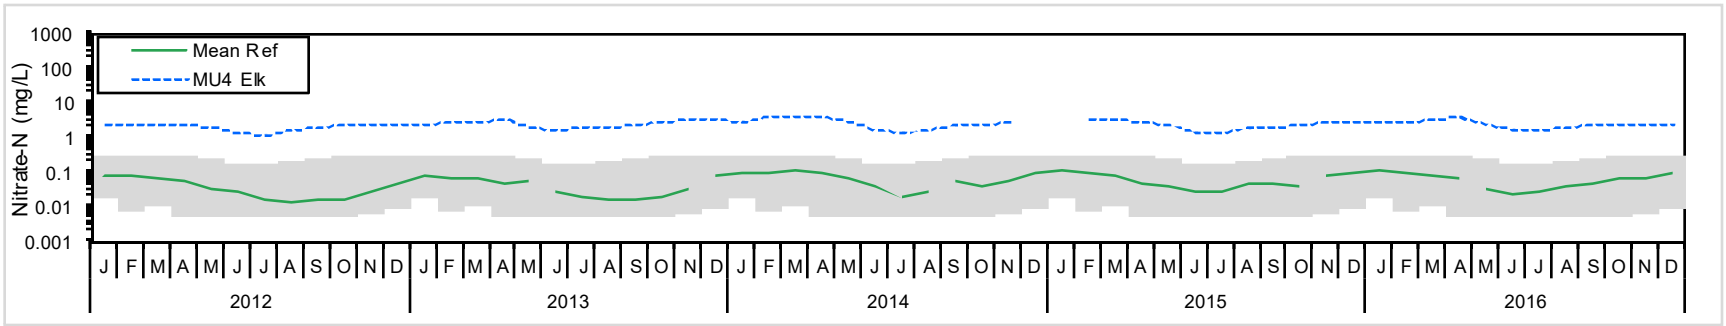
Notes: Grey shading represents the reference area normal range (2.5th and 97.5th percentiles)
Only changes greater than 50% are included for Nitrate, see Apprendix Figure C.5 for all significant trends for Nitrate.

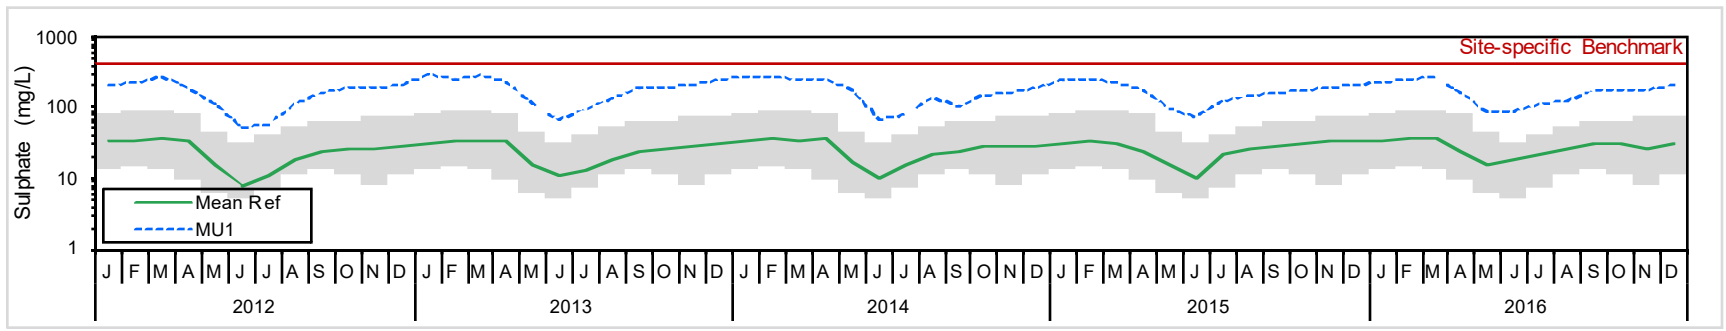
Nitrate-N

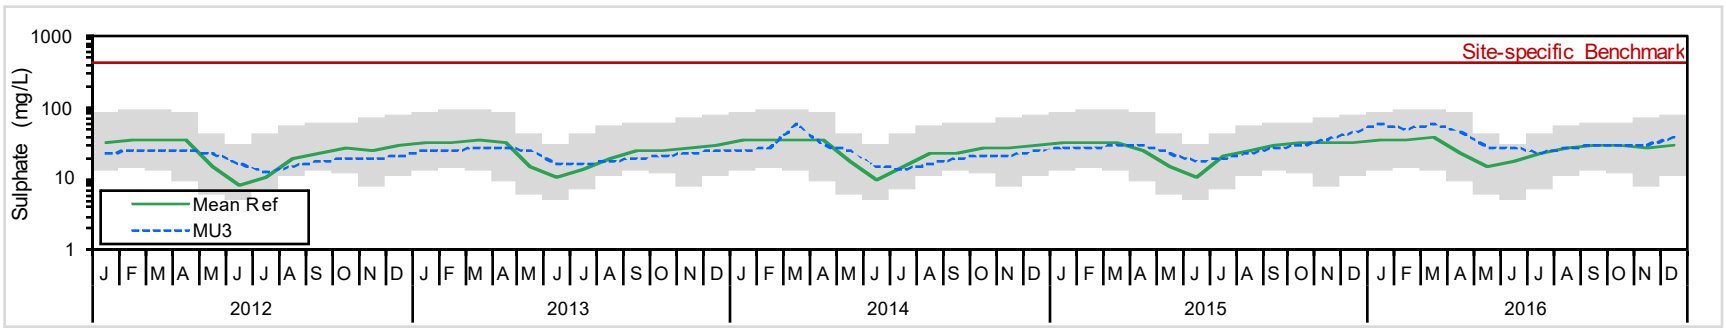




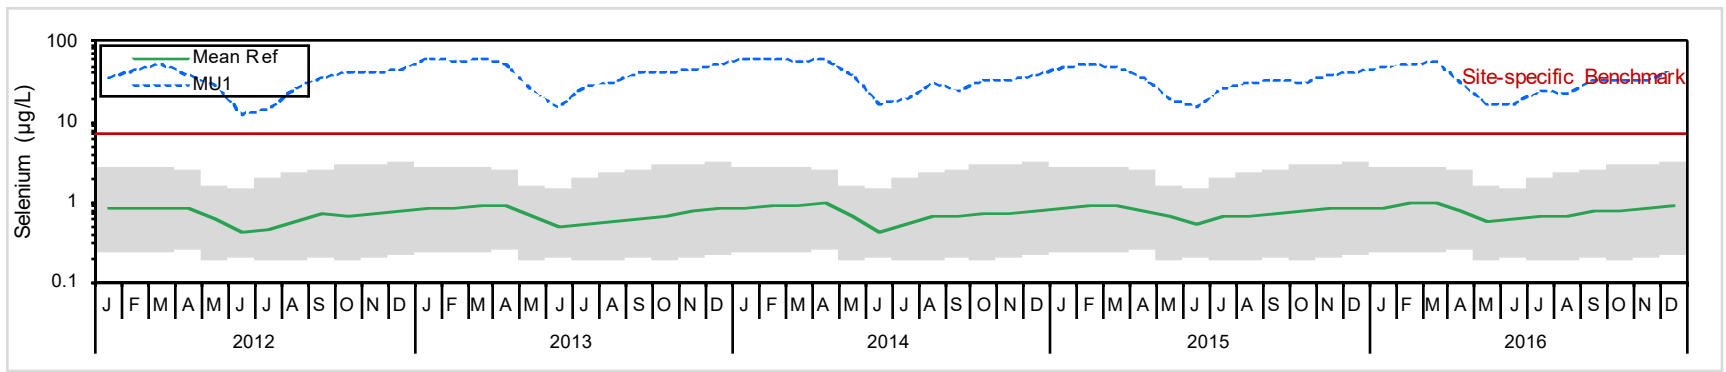


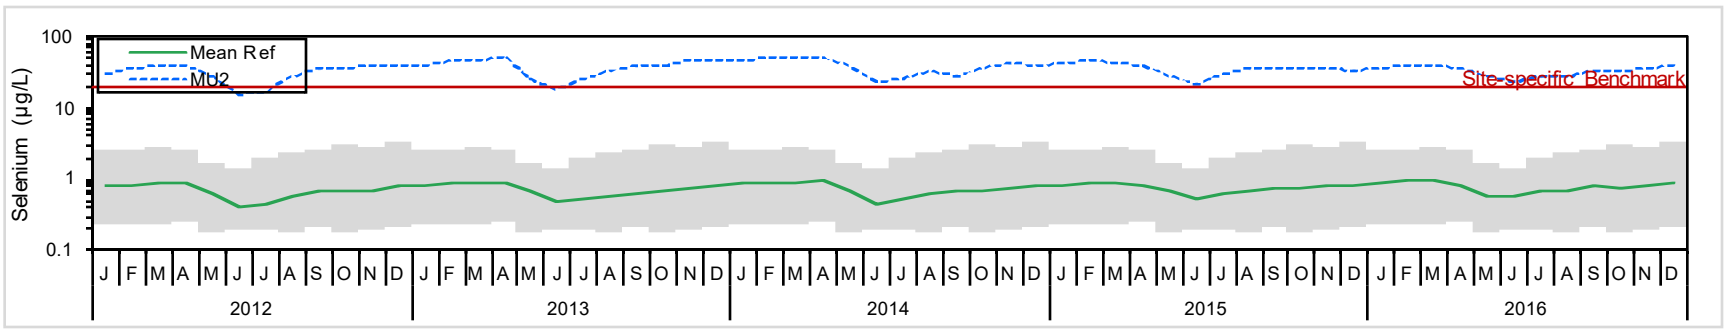
Sulphate





Selenium





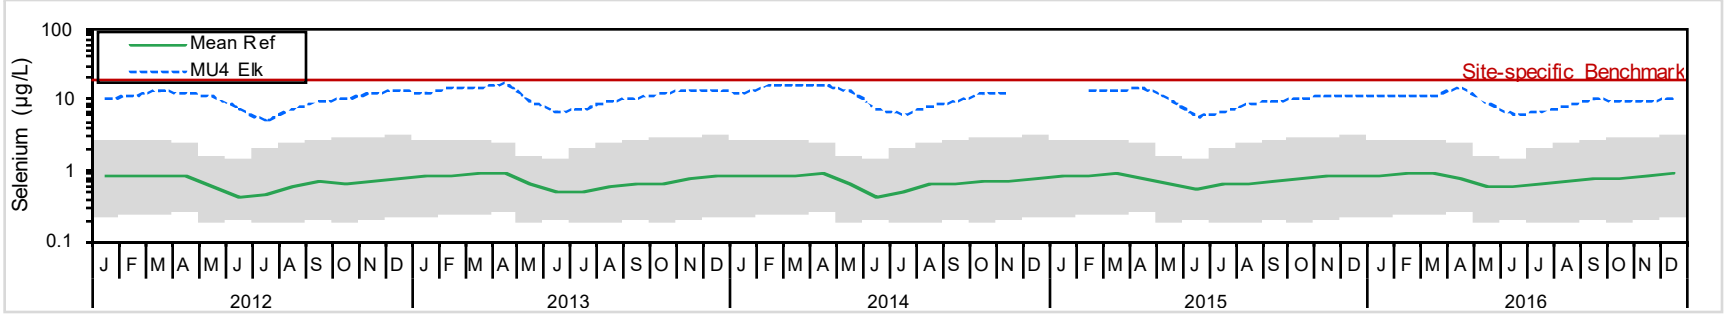


Figure C.10: MUs Where Significant Increases Were Observed Relative to the Reference Mean for Nitrate, Sulphate, or Selenium, 2012 - 2016

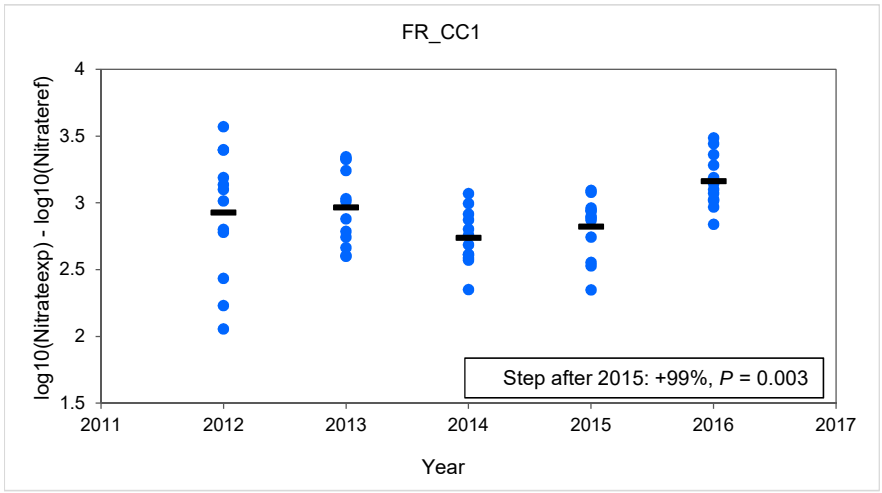
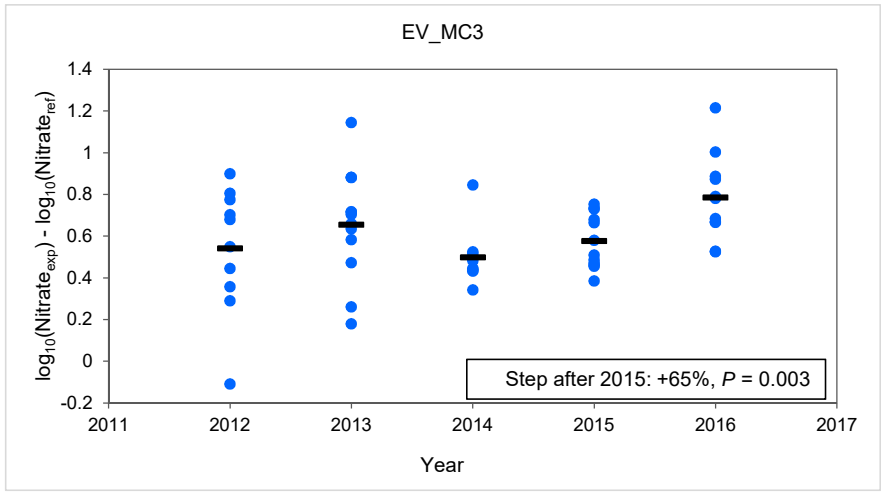
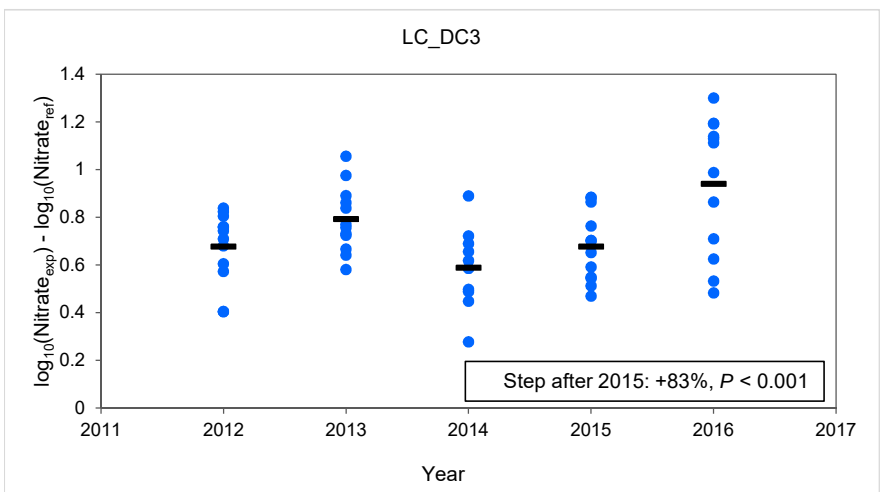
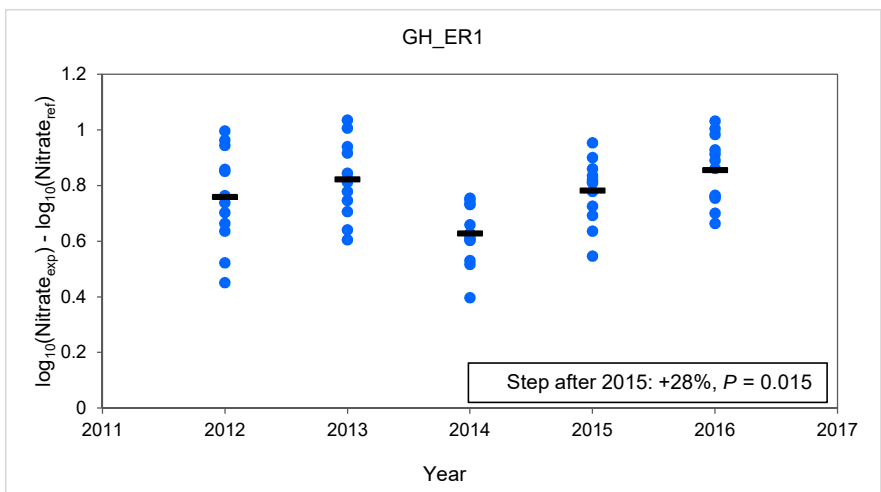
Notes: Grey shading represents the reference area normal range (2.5th and 97.5th percentiles)

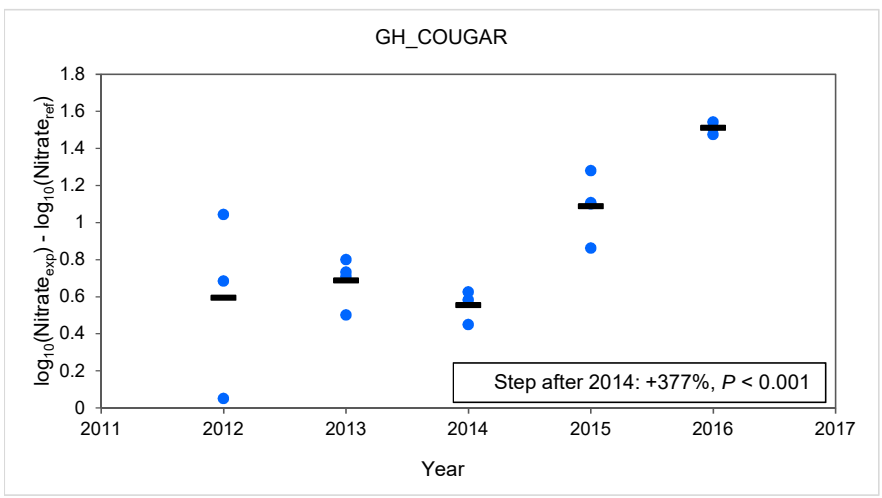
Only changes greater than 50% are included for Nitrate, see Apprendix Figure C.5 for all significant trends for Nitrate.











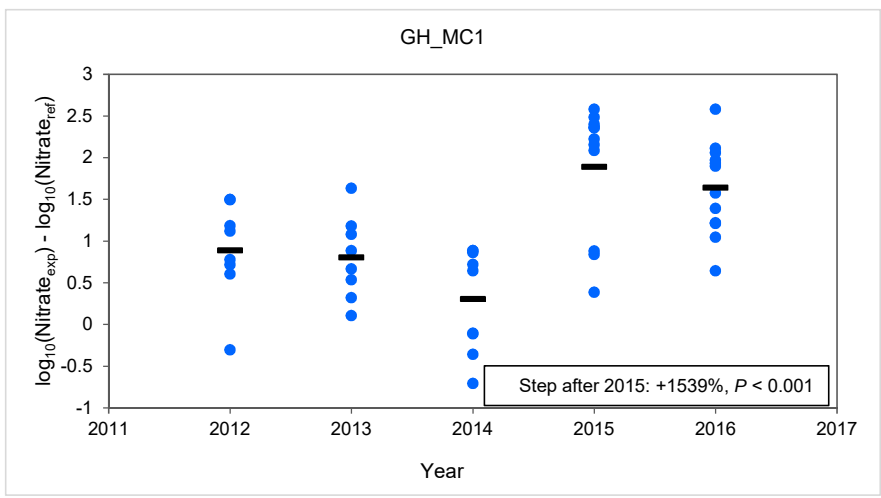


Figure C.11: Scatteplots of the Differences in Nitrate Concentrations (Log_{10}-transformed) Between Mine-exposed Monthly Means and the Mean of Reference Monthly Means by Year for Mine-exposed Areas With a Significant Increase Over Time

Notes: Blue circle = difference in monthly means (exp - ref) and black dash = average of the monthly means for a year

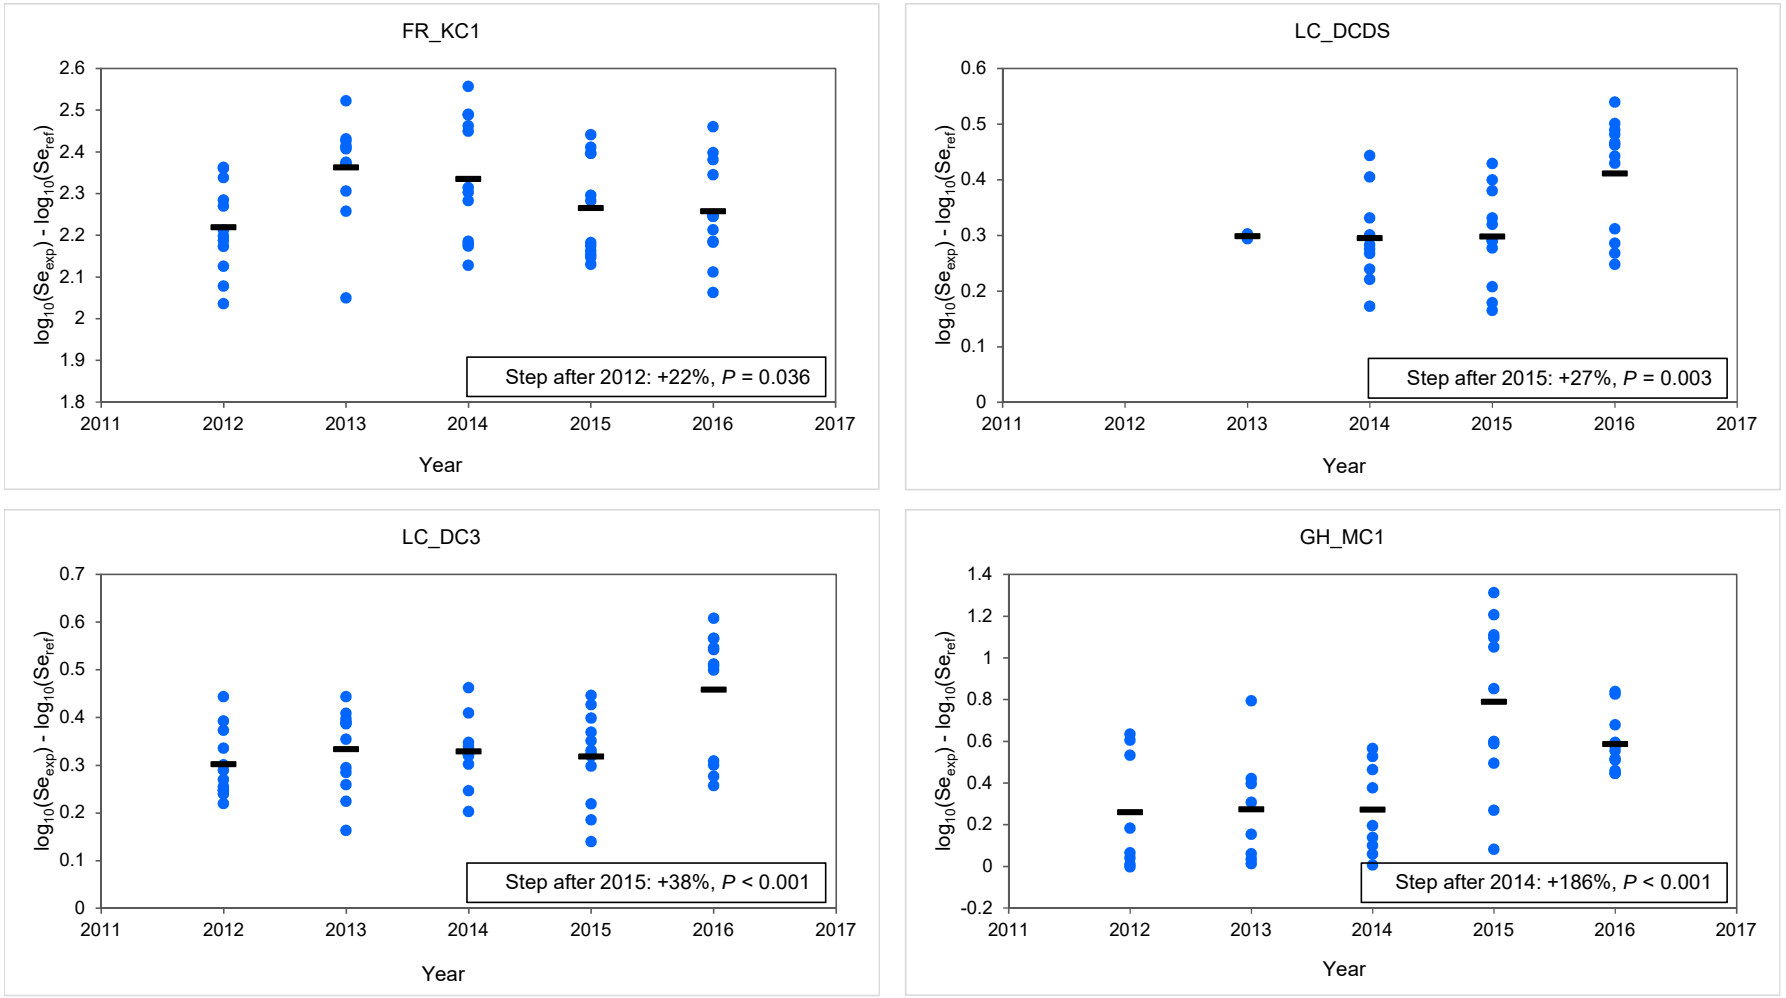

Figure C.12: Scatteplots of the Differences in Total Selenium Concentrations (Log_{10}-transformed) Between Mine-exposed Monthly Means and the Mean of Reference Monthly Means by Year for Mine-exposed Areas With a Significant Increase Over Time

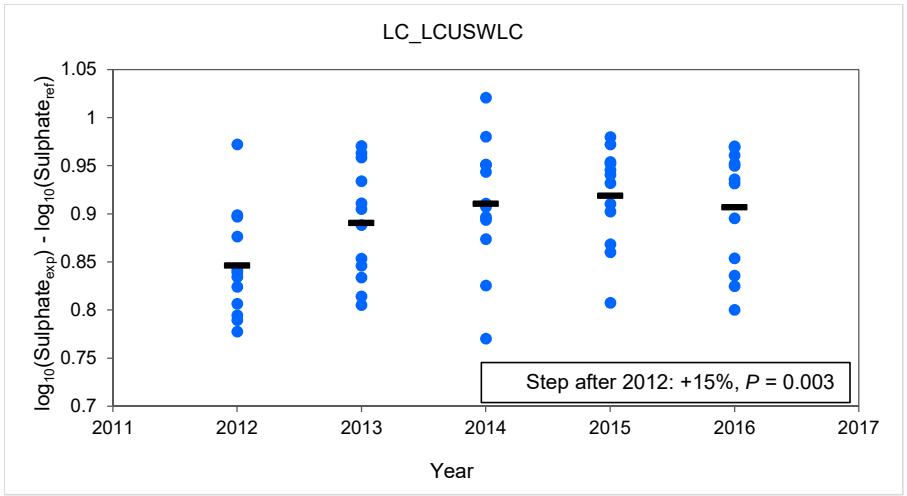
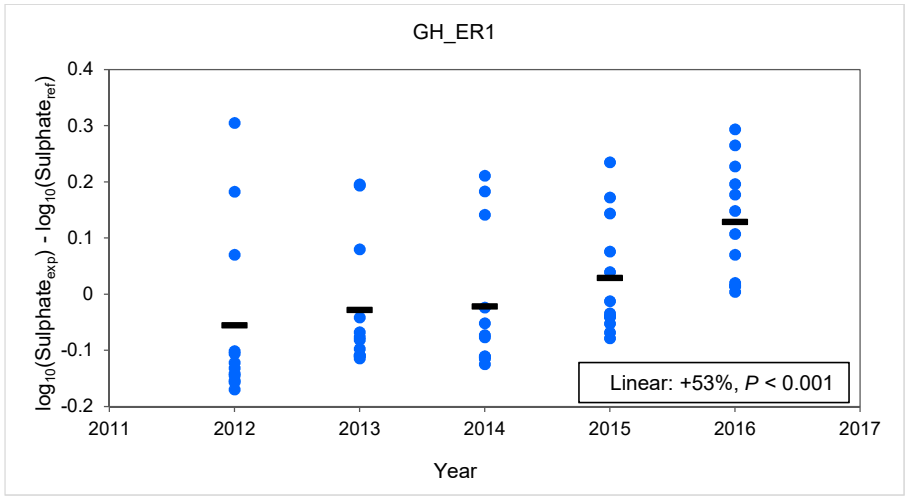
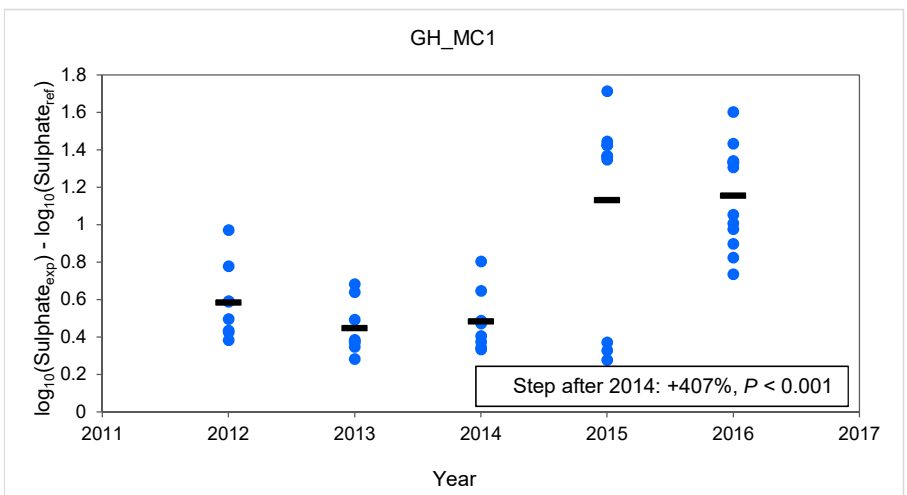
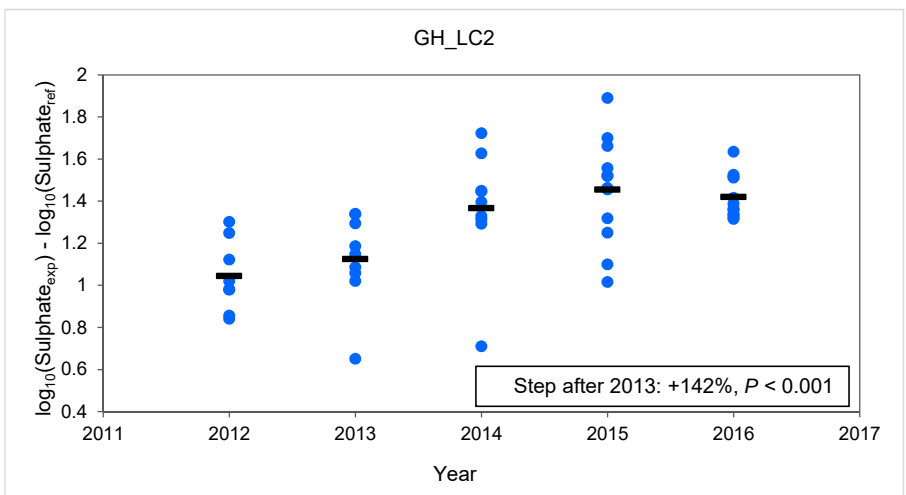
Notes: Blue circle = difference in monthly means (exp - ref) and black dash = average of the monthly means for a year









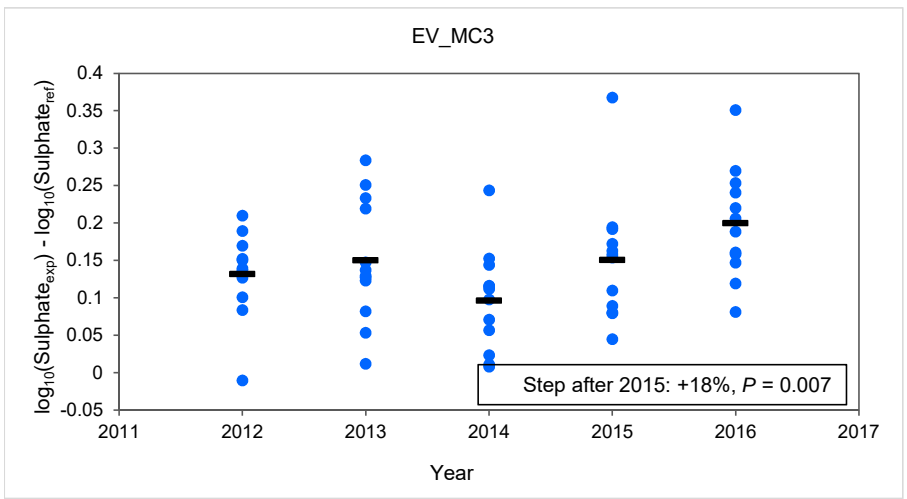


Figure C.13: Scatteplots of the Differences in Sulphate Concentrations (Log_{10}-transformed) Between Mine-exposed Monthly Means and the Mean of Reference Monthly Means by Year for Mine-exposed Areas With a Significant Increase Over Time

Notes: Blue circle = difference in monthly means (exp - ref) and black dash = average of the monthly means for a year

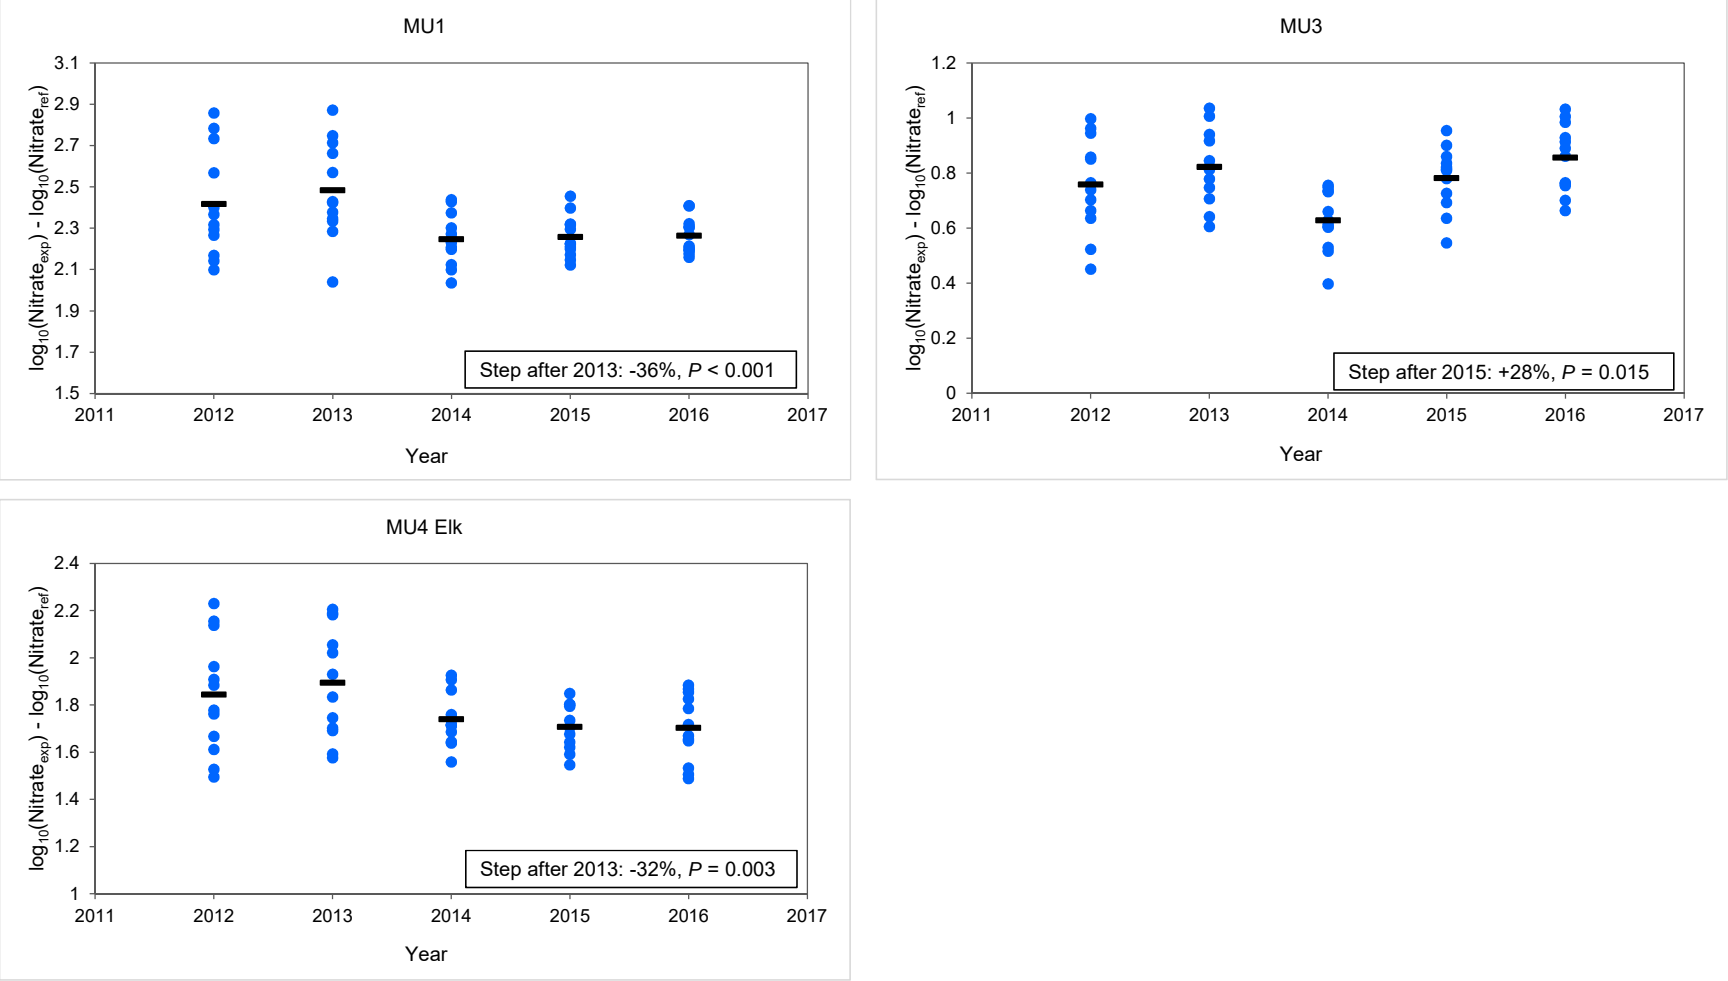

Figure C.14: Monthly Mean Nitrate Concentrations (Log_{10}-transformed) Main Stem Areas within each Management Unit Compared to Reference Monthly Means if a Significant Relative Increase was Observed Over Time

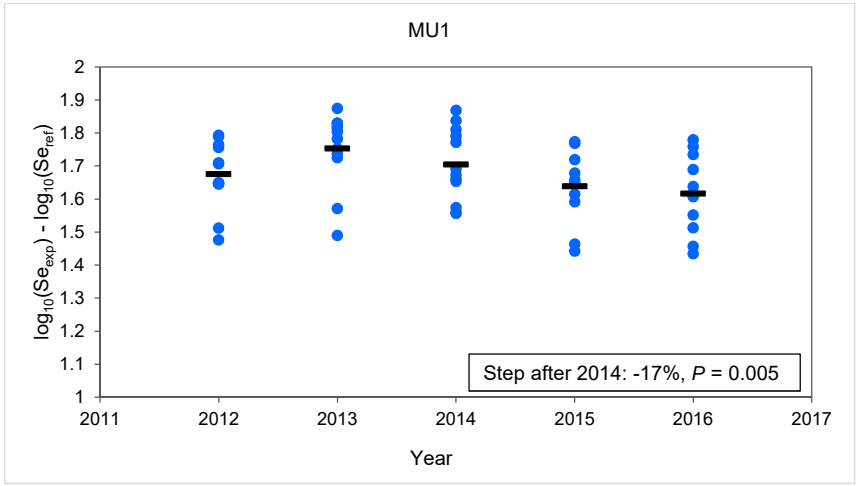
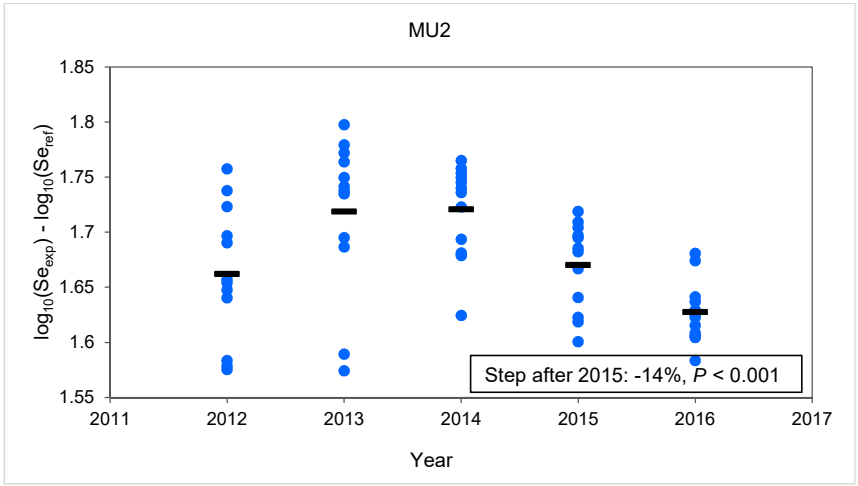
Notes: Blue circle = difference in monthly means (exp - ref) and black dash = average of the monthly means for a year





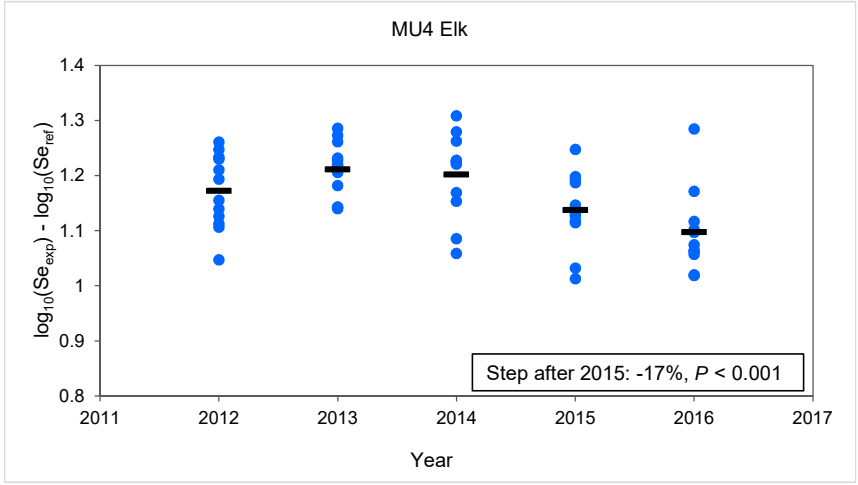


Figure C.14: Monthly Mean Total Selenium Concentrations (Log_{10}-transformed) Main Stem Areas within each Management Unit Compared to Reference Monthly Means if a Significant Relative Increase was Observed Over Time

Notes: Blue circle = difference in monthly means (exp - ref) and black dash = average of the monthly means for a year

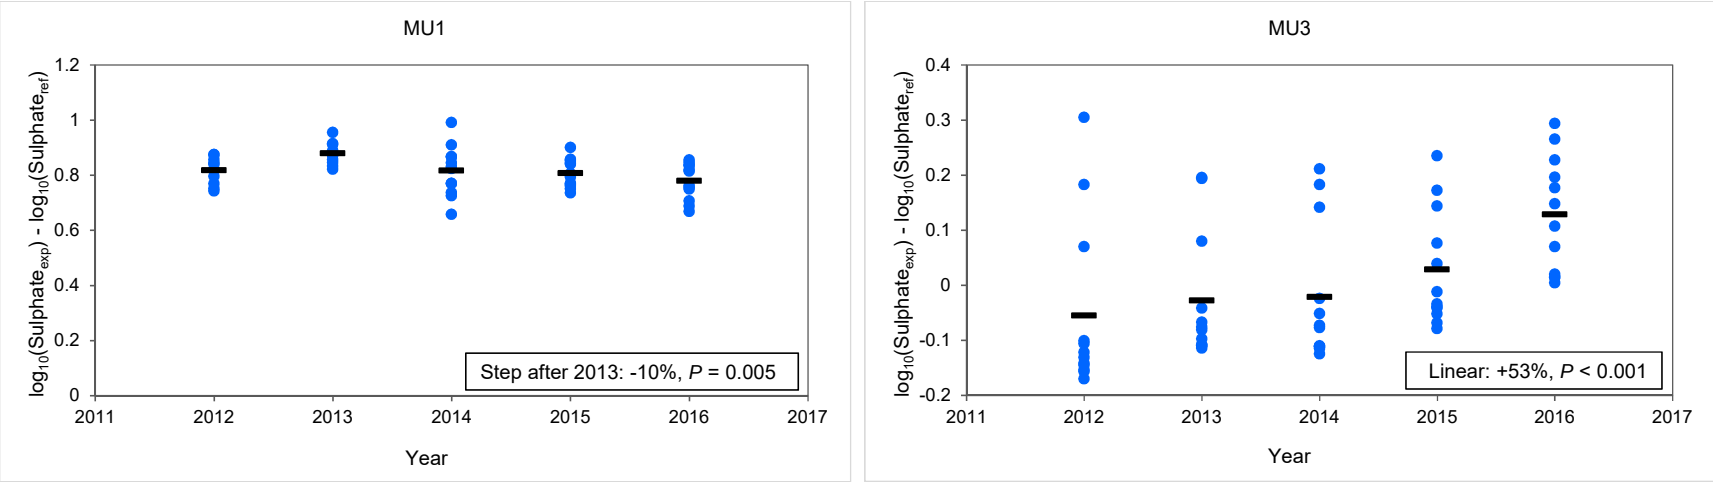

Figure C.14: Monthly Mean Sulphate Concentrations (Log10-transformed) Main Stem Areas within each Management Unit Compared to Reference Monthly Means if a Significant Relative Increase was Observed Over Time

Notes: Blue circle = difference in monthly means (exp - ref) and black dash = average of the monthly means for a year

Table C.1: Lotic Areas Where Water Samples were Collected Concurrently with Benthic Invertebrate Samples in September 2015

Exposure Type	Management Unit	Main Watershed	Stream Type (M-Main Stem; T-Tributary)	Water Station Code	ENV EMS Number	Area Description	UTM (NAD83, 11U)

	Total Manganese	0.288	-0.559
	Total Mercury	-	-
	Total Molybdenum	0.832	0.105
	Total Nickel	0.824	-0.039
	Total Phosphorus	-0.042	-0.828
	Total Potassium	0.941	0.002
	Total Selenium	0.812	0.442
	Total Silver	-	-
	Total Sodium	0.607	-0.287
	Total Strontium	0.611	-0.109
	Total Thallium	0.590	-0.301
	Total Tin	-	-
	Total Titanium	-	-
	Total Uranium	0.865	0.428
	Total Vanadium	-	-
	Total Zinc	0.571	-0.169

r > 0.6 or r < -0.6

Notes: "-" = not included in PCA becase more than 50% of samples were less than laboratory reported limit. P-value not reported because with a large sample size (1,395), the critical is 0.052 at α=0.05

Table C.4: Spearman Rank Correlation Coefficients for Order Constituents vs. all Other Water Quality Constituents in Samples (n = 2,121) Collected at Mine-exposed Areas in Routine Monitoring in 2015

P-value < 0.05.

[a] HQ - hazard quotient. Observed concentration divided by Level 1 effect benchmark defined in the Elk Valley Water Quality Plan (selenium, sulphate, nitrate, cadmium), the upper normal range limit defined by Minnow (2016; calcite index), or BC water quality guidelines (the other water quality variables), as applicable.

[b] Selenium, sulphate, nitrate-N.

Note: All samples collected in September 2015 (one per area). PCA conducted on correlation matrix for concentration and covariance matrix for HQ.

Table C.7: Pearson Correlation of Log_{10}-transformed Water Quality Variables for n = 60 Samples from Reference (n = 5) and Mine-exposed (n = 55) Lentic Areas where Other Types of Samples were Collected in May, August, and September 2015 vs. the First Two Principal Components (PC-1 and PC-2) from a PCA of all Water Quality Variables

Shading indicates absolute r values greater than 0.6

Shading indicates P-values less than 0.05

Note: NA indicates to few concurrent data pairs to perform correlation.

Note: 97.5th percentiles in parentheses were manually lowered due to the presence of censored data at a higher laboratory reporting limit (LRL)

[1] Chronic guidelines were applied when available, otherwise acute guidelines were applied. For guidelines and site-specific benchmarks (SSBM) that are parameter-dependant (e.g., hardness), concurrent monthly means of parameters were used for determining the guideline or SSBM.

Table C.10: Summary Statistics for the Reference Area Monthly Means used to Define Reference Normal Ranges for Water Quality Constituents in Samples Collected between 2012 and 2016

Note: 97.5th percentiles in parentheses were manually lowered due to the presence of censored data at a higher laboratory reporting limit

[1] Chronic guidelines were applied when available, otherwise acute guidelines were applied. For guidelines and site-specific benchmarks (SSBM) that are parameter-dependant (e.g., hardness), concurrent monthly means of parameters were used for determining the guideline or SSBM.

Table C.10: Summary Statistics for the Reference Area Monthly Means used to Define Reference Normal Ranges for Water Quality Constituents in Samples Collected between 2012 and 2016

Note: 97.5th percentiles in parentheses were manually lowered due to the presence of censored data at a higher laboratory reporting limit

[1] Chronic guidelines were applied when available, otherwise acute guidelines were applied. For guidelines and site-specific benchmarks (SSBM) that are parameter-dependant (e.g., hardness), concurrent monthly means of parameters were used for determining the guideline or SSBM.

Note: 97.5th percentiles in parentheses were manually lowered due to the presence of censored data at a higher laboratory reporting limit

[1] Chronic guidelines were applied when available, otherwise acute guidelines were applied. For guidelines and site-specific benchmarks (SSBM) that are parameter-dependant (e.g., hardness), concurrent monthly means of parameters were used for determining the guideline or SSBM.

Table C.11: Summary Statistics for the Reference Area Data used to Define Overall (Annual) Reference Normal Ranges for Key Water Quality Parameters, 2012 - 2016

Parameter	Units	Sample size and Laboratory Reporting Limit (LRL)			Statistics Estimated using the Kaplan-Meier Method								
		Sample size	% of values < LRL	Maximum LRL	Minimum	2.5th Percentile	25th Percentile	Median	75th Percentile	97.5th Percentile	Maximum	Mean	Standard Deviation
Dissolved Cadmium	µg/L	443	66	0.01	<0.005	<0.005	0.0069	0.0058	0.0085	0.012	0.018	0.0069	0.0028

Total Selenium	µg/L	452	0.44	0.5	0.168	0.19	0.56	0.77	1.2	2.6	3.1	0.96	0.63
Sulphate	mg/L	455	0	-	4.1	6.7	15	27	47	78	90	32	20

Estimates of the reference area normal range, all months combined.

Table C.12: Regression Statistics used to Define Covariate-adjusted (Total Suspended Solids and Turbidity) Reference Area Normal Ranges for Total Aluminum, Iron, Manganese, and Phosphorus, based on Values Above the Laboratory Reporting Limit at Reference Areas from 2012 - 2016

Parameter	Covariate	n (After Outliers Removed)	n Outliers Removed[a]	Slope	Intercept	r^2	$P_{97.5}$ of Residuals
$\log_{10}$(Aluminum)	$\log_{10}$(TSS)	218	2	0.893564	-1.80486	0.5969	0.6031576
	$\log_{10}$(Turbidity)	598	12	1.026581	-1.43008	0.8741	0.4240145
$\log_{10}$(Iron)	$\log_{10}$(TSS)	197	4	0.932715	-1.73366	0.8489	0.4508072
	$\log_{10}$(Turbidity)	341	11	0.857862	-1.30424	0.8203	0.4601021
$\log_{10}$(Manganese)	$\log_{10}$(TSS)	212	8	0.953787	-3.07948	0.7608	1.0650375
	$\log_{10}$(Turbidity)	616	7	0.914816	-2.67962	0.5848	0.8536949
$\log_{10}$(Phosphorus)	$\log_{10}$(TSS)	198	6	0.715018	-2.48996	0.7587	0.3524754
	$\log_{10}$(Turbidity)	-[b]	-	-	-	-	-

Note: only detected concentrations were used in the regression models.

[a] Outliers were considered to be observations with with Studentized residuals with magnitude > 4. Then assessed again as residuals that exceeded Q3 + 1.5(Q3 - Q1) to be consistent with outlier evaluations for defining normal ranges in this report.

[b] Regression not conducted due to non-linearity and higher variability than the regression with TSS

Table C.13: Frequency (%) of Individual Samples with Total Metal Concentrations Exceeding the Normal Range at Lotic Water Monitoring Stations, 2015

Note: if data were reported as below the laboratory reporting limit (LRL), then they were not included in the normal range screening. Normal ranges that were reported as below the LRL were screened as 1×LRL. Only stations with data for at least 8 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months.

[1] Analytes for which monthly NR's were adjusted for either concurrent total suspended solids or turbidity; see methods text for details.

Shading indicates frequencies above 2.5%

Note: if data were reported as below the laboratory reporting limit (LRL), then they were not included in the normal range screening. Normal ranges that were reported as below the LRL were screened as 1×LRL. Only stations with data for at least 8 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months.

[1] Analytes for which monthly NR's were adjusted for either concurrent total suspended solids or turbidity; see methods text for details.

Shading indicates frequencies above 2.5%

Note: if data were reported as below the laboratory reporting limit, then they were not included in the normal range screening. Only stations with data for at least 8 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months.

Shading indicates frequencies above 2.5%

[1] Dissovled oxygen NRQ was calculated as P2.5 / concentration since the concern is with lower oxygen, not higher

[2] Analytes for which monthly NR's were adjusted for either concurrent total suspended solids or turbidity; see methods text for details.

Note: if data were reported as below the laboratory reporting limit, then they were not included in the normal range screening. Only stations with data for at least 8 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months.

Shading indicates frequencies above 2.5%

Table C.16: Total Individual Sample Counts at Each Lotic Water Monitoring Station, 2015

Note: if data were reported as below the laboratory reporting limit, then they were not included in the normal range screening. Only stations with data for at least 8 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months.

[1] Only stations with data for at least 7 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months. Values less than the laboratory reporting limit (LRL) were excluded from evaluation if the LRL was greater than the SSBM / guideline. Only constituents that had at least one SSBM/ guideline exceedance are reported.

[2] For total iron, normal ranges were adjusted for total suspended solids for each month. Refer to methods for details.

[3] For total mercury, the most conservative guideline was applied (0.00000125 mg/L).

Shading indicates frequency exceeded 0%.

[1] Only stations with data for at least 7 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months. Values less than the laboratory reporting limit (LRL) were excluded from evaluation if the LRL was greater than the SSBM / guideline. Only constituents that had at least one SSBM/ guideline exceedance are reported.

[2] For total mercury, the most conservative guideline was applied (0.00000125 mg/L).

Shading indicates HQ > 1. If the concentration was < the laboratory reporting limit (LRL) and the LRL exceeded the guideline, the HQ was not shaded.

[1] Only stations with data for at least 7 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months. Values less than the laboratory reporting limit (LRL) were excluded from evaluation if the LRL was greater than the SSBM / guideline. Only constituents that had at least one SSBM/ guideline exceedance are reported.

[2] For total mercury, the most conservative guideline was applied (0.00000125 mg/L).

Shading indicates HQ > 1. If the concentration was < the laboratory reporting limit (LRL) and the LRL exceeded the guideline, the HQ was not shaded.

[1] Only stations with data for at least 7 months were included to ensure sufficient annual coverage. One exception, LC_LC1, had data for 7 months. Values less than the laboratory reporting limit (LRL) were excluded from evaluation if the LRL was greater than the SSBM / guideline. Only constituents that had at least one SSBM/ guideline exceedance are reported.

[2] For total mercury, the most conservative guideline was applied (0.00000125 mg/L).

Shading indicates frequency exceeded 0%.

[1] Only stations with data for at least 8 months were included. One exception, LC_LC1, had data for 7 months. Values less than the laboratory reporting limit (LRL) were excluded from evaluation if the LRL was greater than the SSBM/ guideline. Only parameters that had at least one guideline exceedance are reported.

[2] For mercury, the most conservative guideline was applied (0.00000125 mg/L).

Table C.28: Hazard Quotients for Monthly Mean Dissolved Cadmium Concentrations at Each Water Station in 2015 and the Samples Collected Concurrently with Biological Samples in September, 2015

Decrease

Notes: "ND" = not determined (insufficient data to test this contrast)

[a] Percent change = (observed - expected)/expected × 100%; For linear change: observed = value observed in the most recent year and expected = predicted value if the mine-exposed area did not change relative to reference in the first year of the comparison; For step change: observed = mean value observed after the step change and expected = predicted mean value after the step change if the mine-exposed area did not change relative to reference prior to the step change

Table C.33: Temporal Analysis of the Differences between Mine-exposed and Mean Reference Area Concentrations of Total Selenium, 2012 - 2016

Notes: "ND" = not determined (insufficient data to test this contrast)

[a] Percent change = (observed - expected)/expected × 100%; For linear change: observed = value observed in the most recent year and expected = predicted value if the mine-exposed area did not change relative to reference in the first year of the comparison; For step change: observed = mean value observed after the step change and expected = predicted mean value after the step change if the mine-exposed area did not change relative to reference prior to the step change

P-value < 0.05
Reference area included in temporal analysis relative to reference mean
Increase
Decrease

Notes: "ND" = not determined (insufficient data to test this contrast). Analysis is based on absolute change(s) in each area not relative to reference mean.

[a] For linear change: percent change in the most recent year relative to the first year of the comparison; For step change: percent chance after the step change relative to before the step change.

Table C.37: Results of Temporal Analysis of Monthly Mean Total Selenium Concentrations in Reference and Mine-exposed Areas, 2012 - 2016 (not relative to reference means)

P-value < 0.05
Reference area included in temporal analysis relative to reference mean
Increase
Decrease

Notes: "ND" = not determined (insufficient data to test this contrast). Analysis is based on absolute change(s) in each area not relative to reference mean.

[a] For linear change: percent change in the most recent year relative to the first year of the comparison; For step change: percent chance after the step change relative to before the step change.

Table C.39: Results of Temporal Analysis on the Mean Concentrations of Nitrate, Sulphate, and Selenium for Mine-exposed Main Stem Areas, 2012 - 2016 (not relative to reference means)

Parameter	Management Unit	Number of Stations	Teck Water Station Codes	ANOVA P-value	Linear		Step after 2012		Step after 2013		Step after 2014		Step after 2015

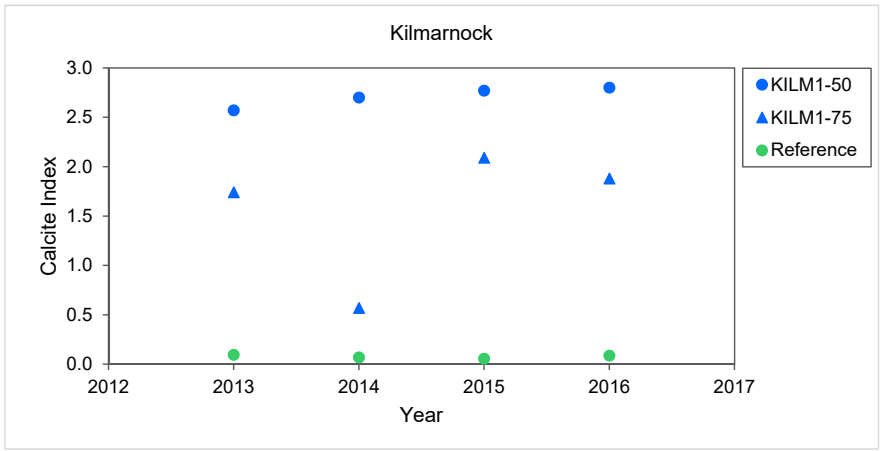
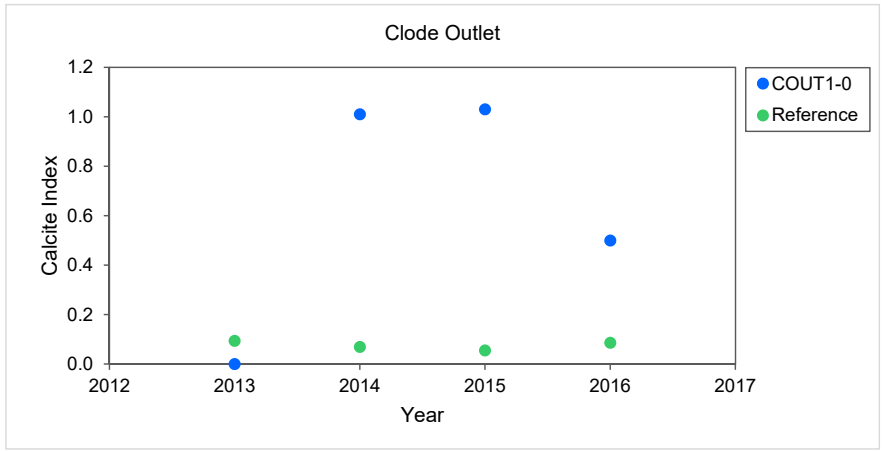
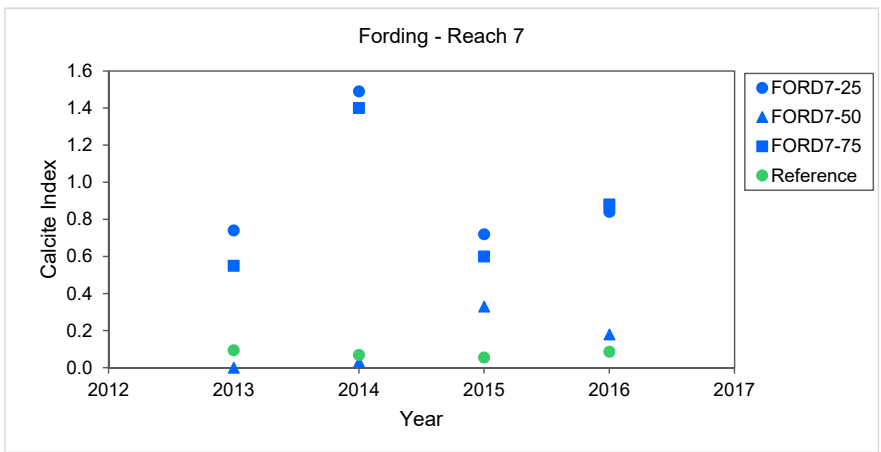
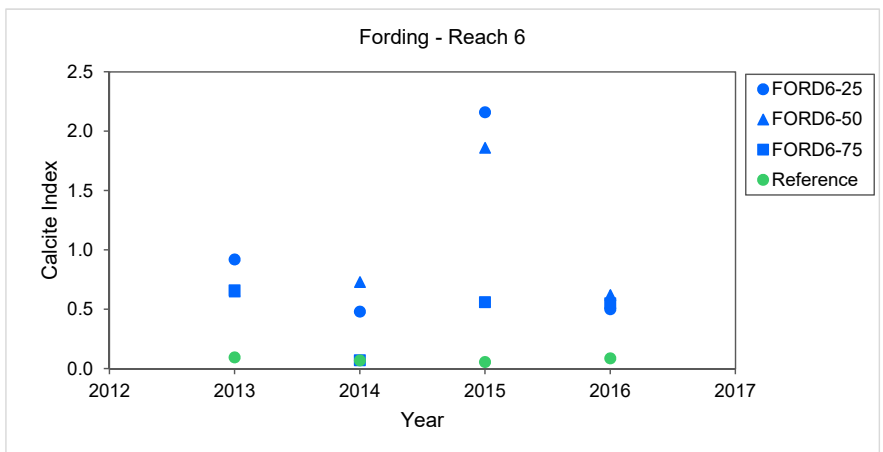
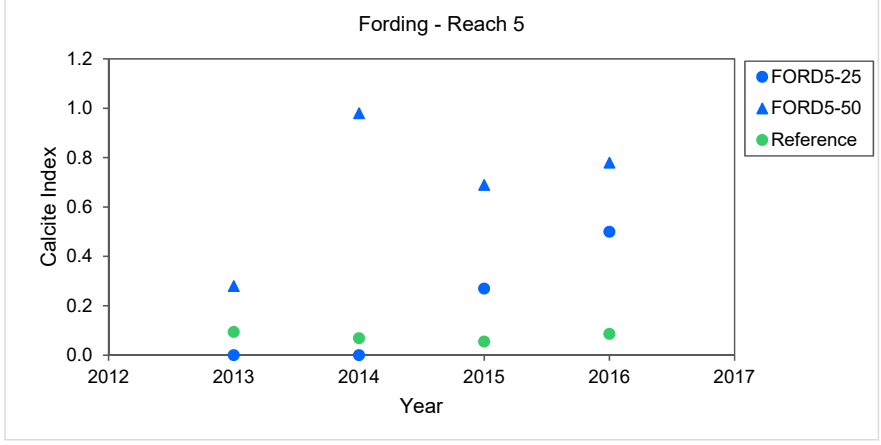
APPENDIX D
CALCITE

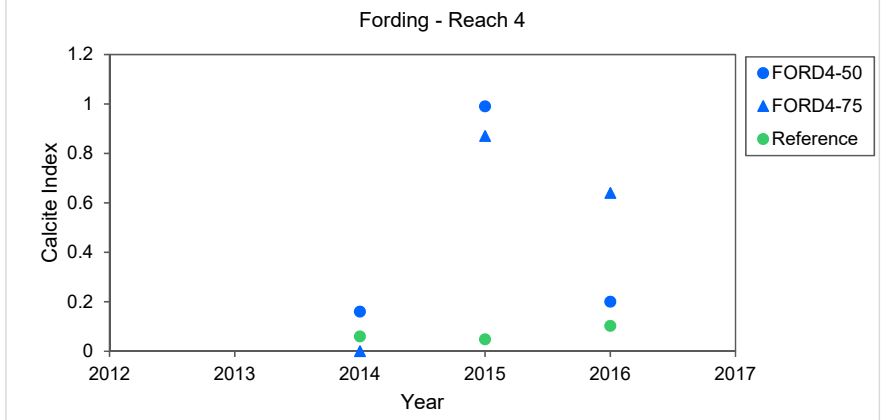


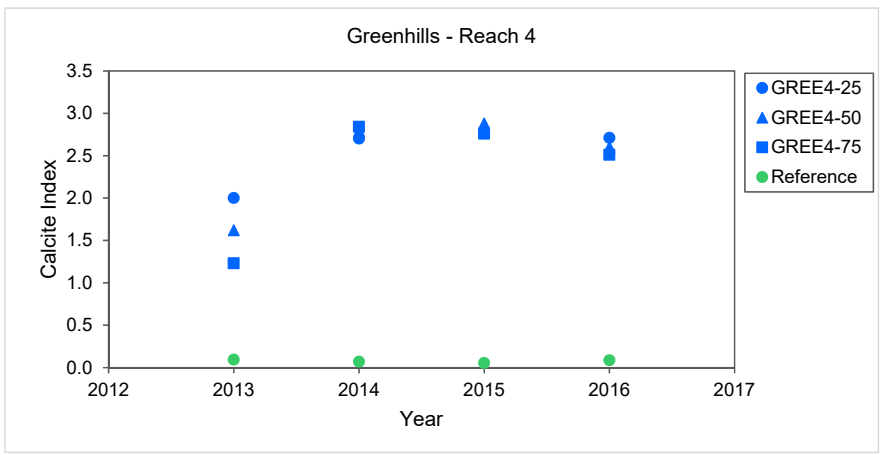


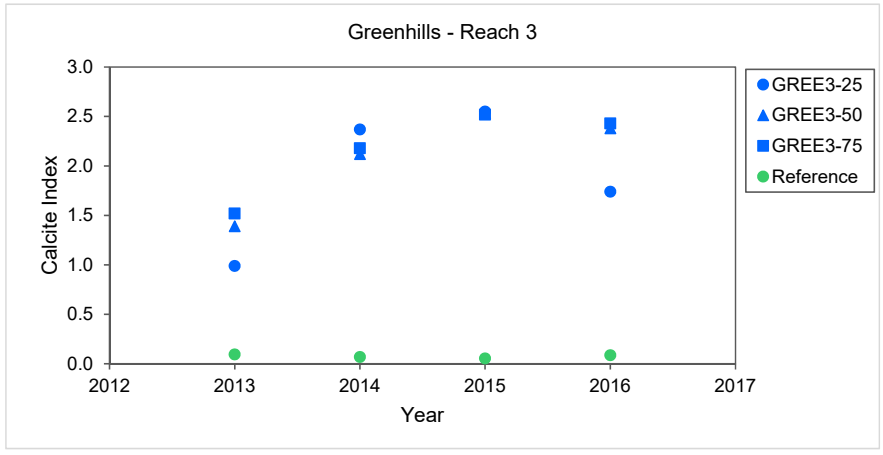


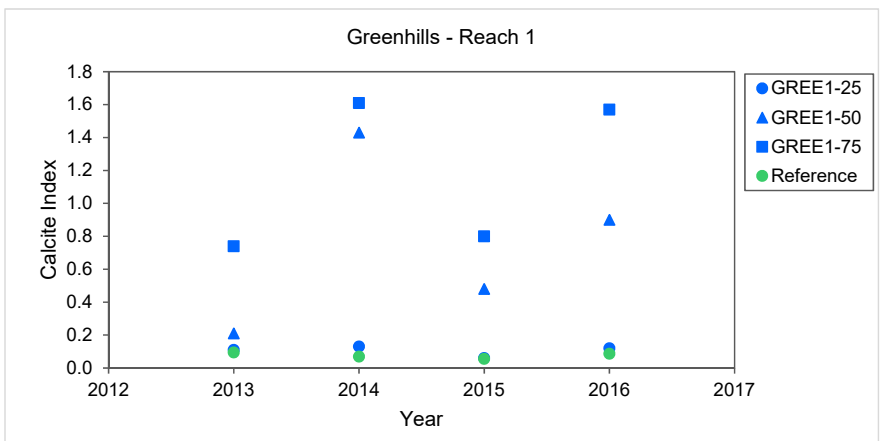


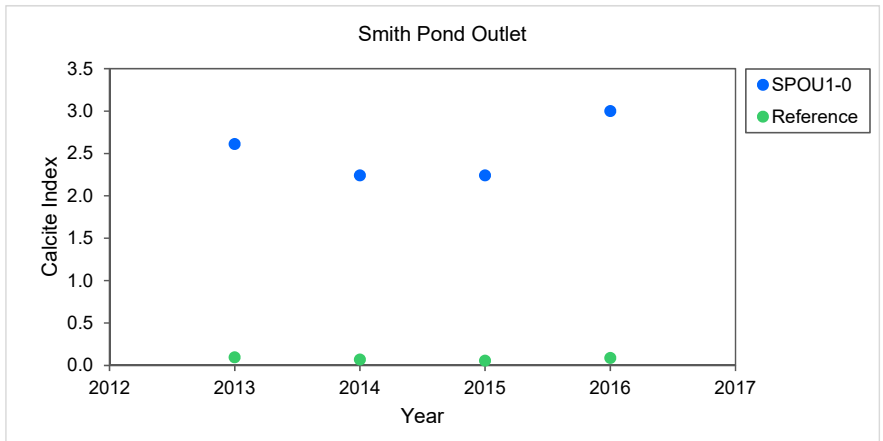


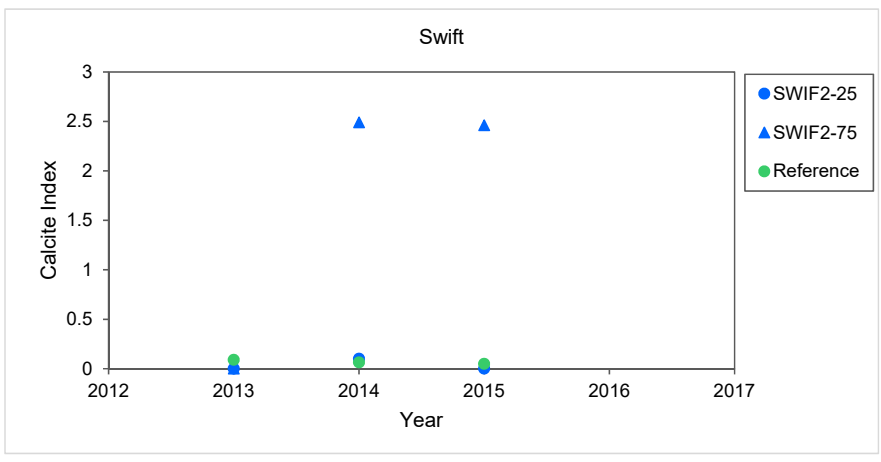












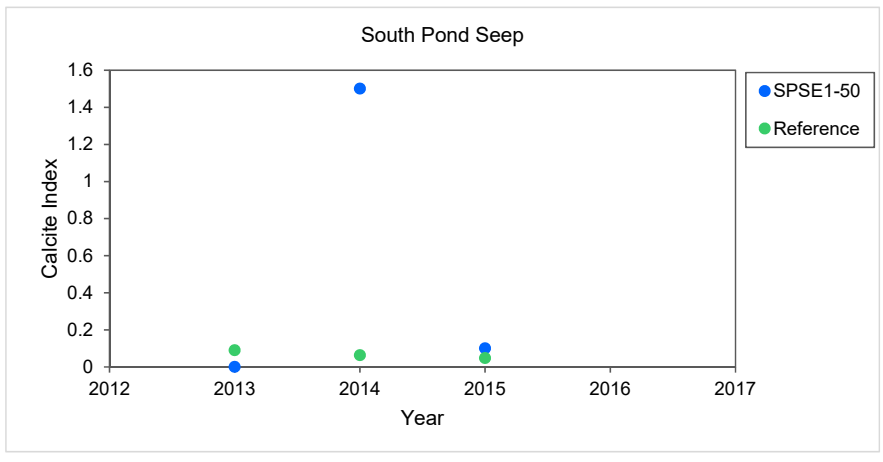


Figure D.1: Scatterplots of Calcite Index versus Year for the Mean Reference and Mine-exposed Stations within Reaches that had at Least One Significant Contrast with an Increase Relative to Reference

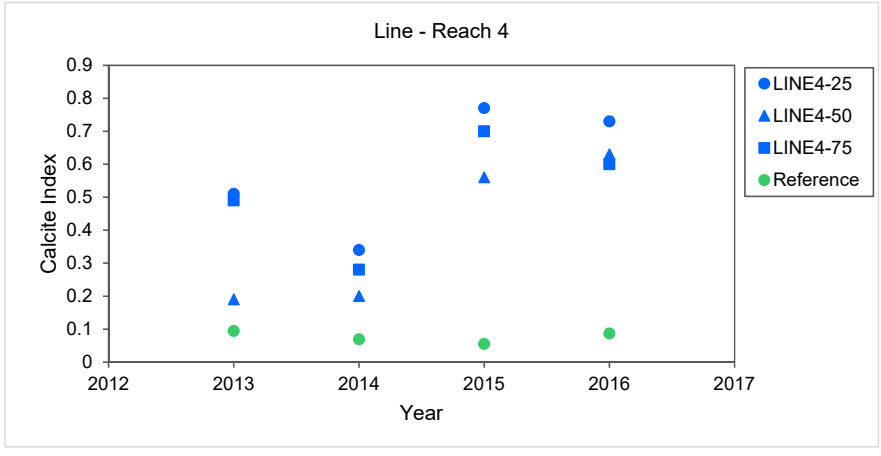
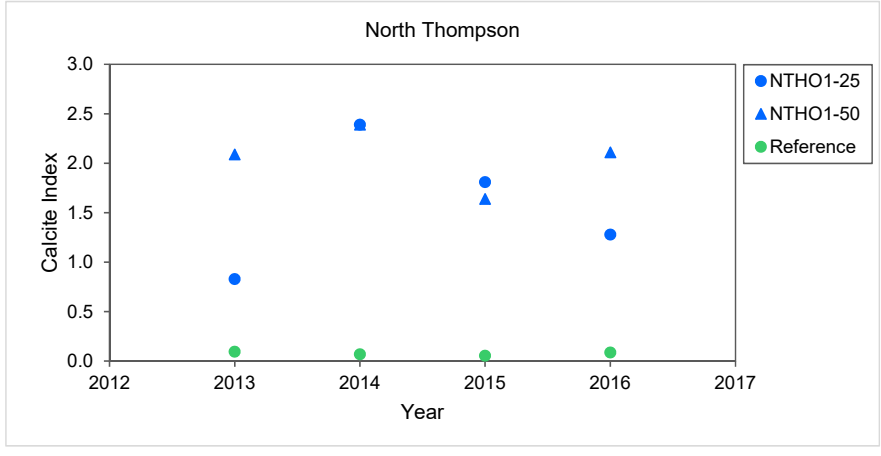
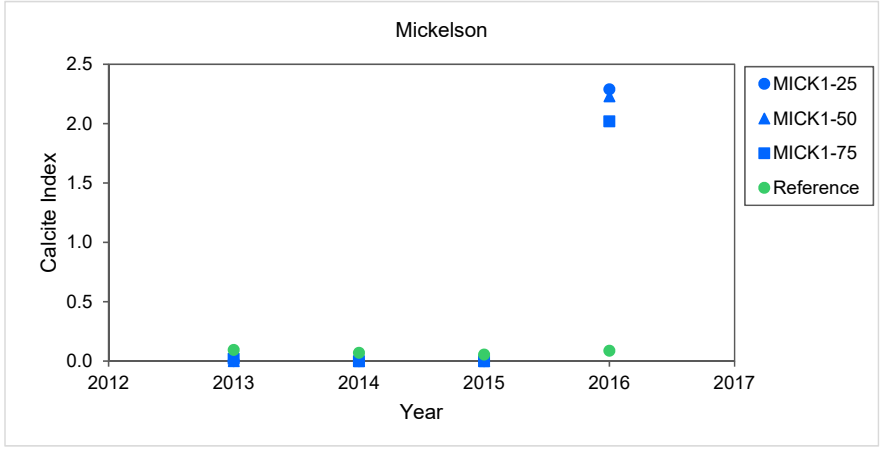
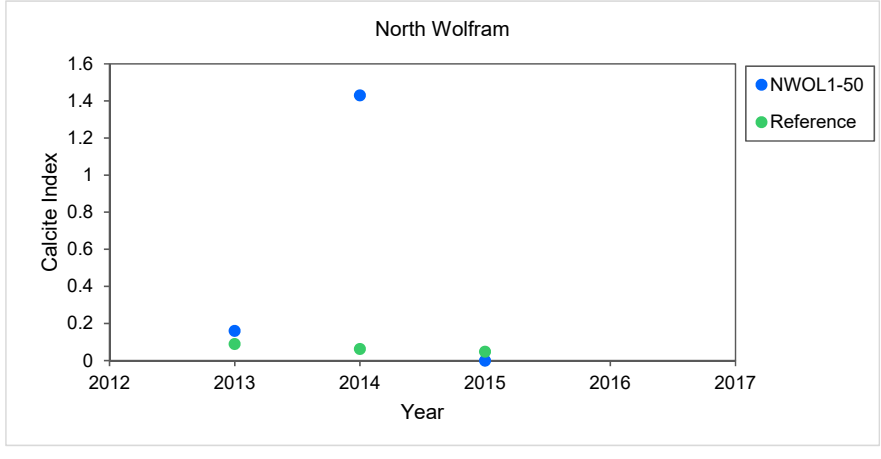
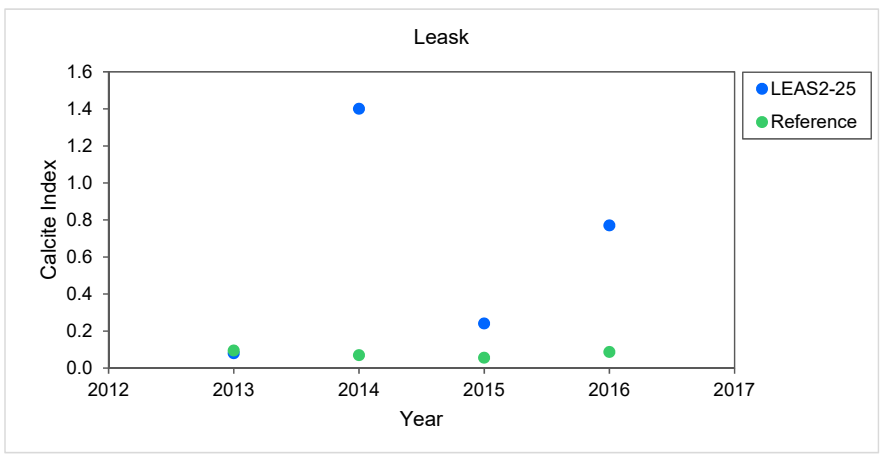
Note: Reference means in each plot represent the means of the reference area data used in that specific contrast

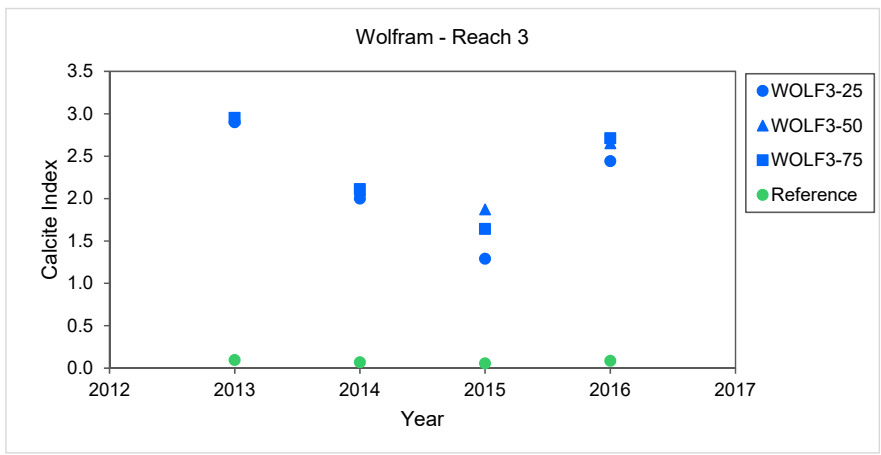


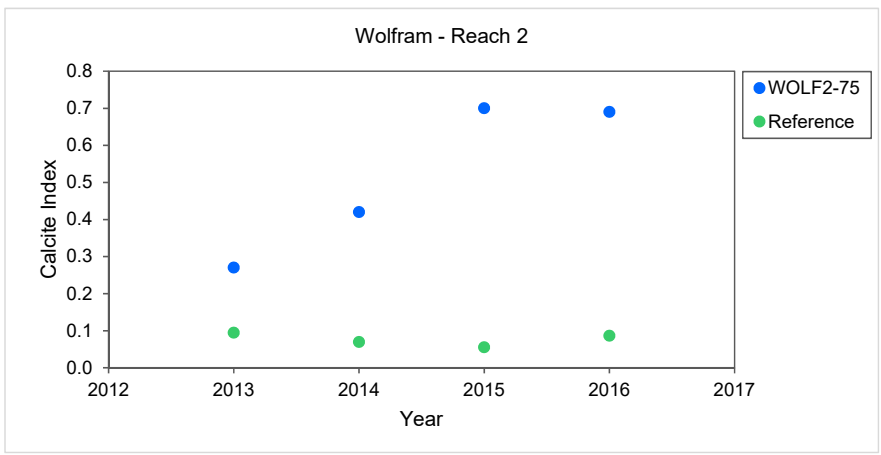


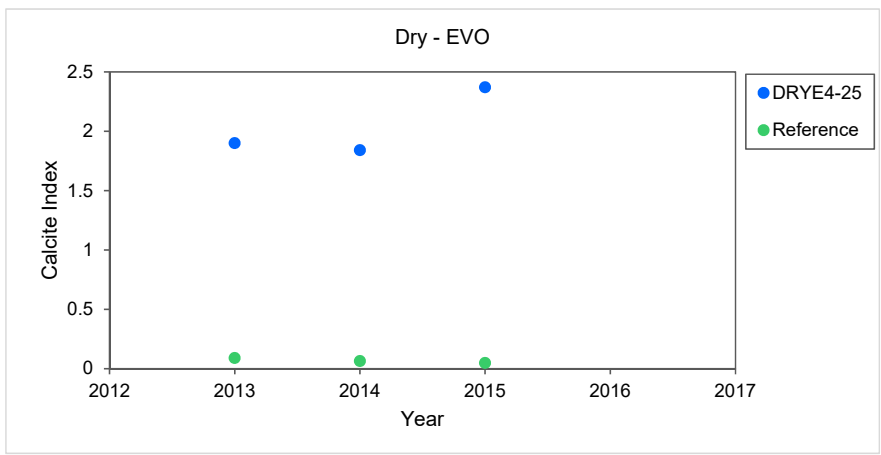


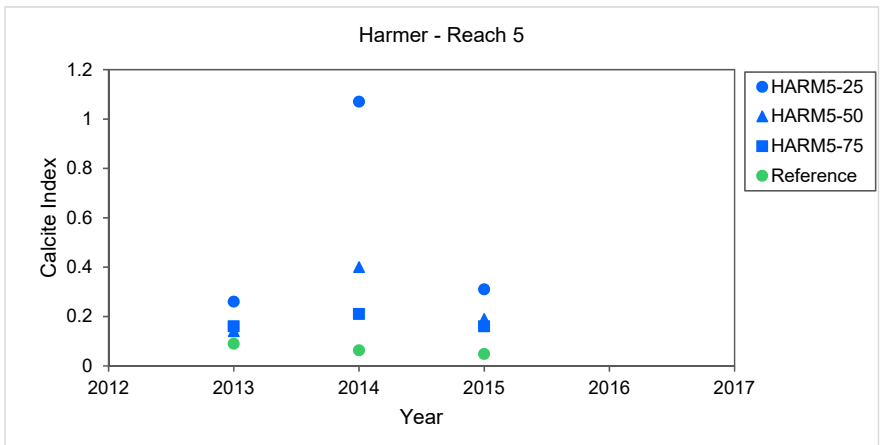


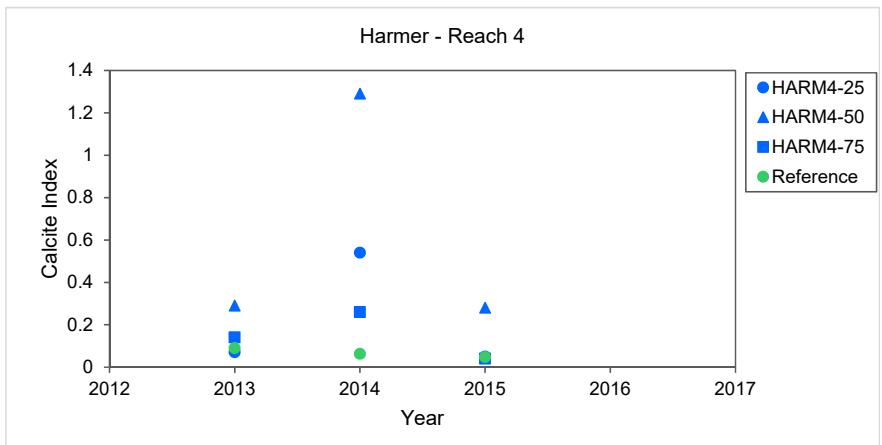


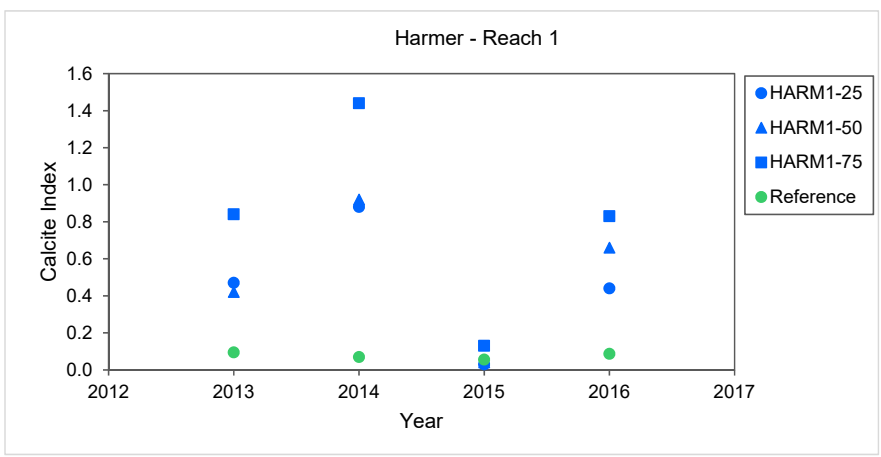












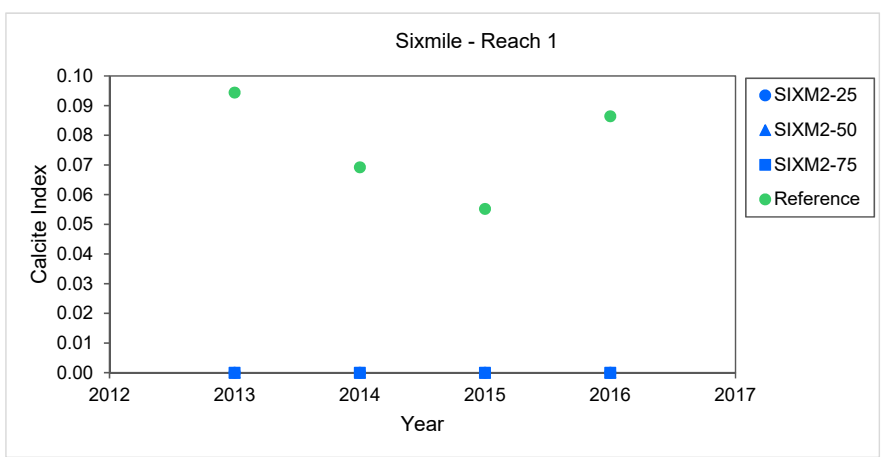


Figure D.1: Scatterplots of Calcite Index versus Year for the Mean Reference and Mine-exposed Stations within Reaches that had at Least One Significant Contrast with an Increase Relative to Reference

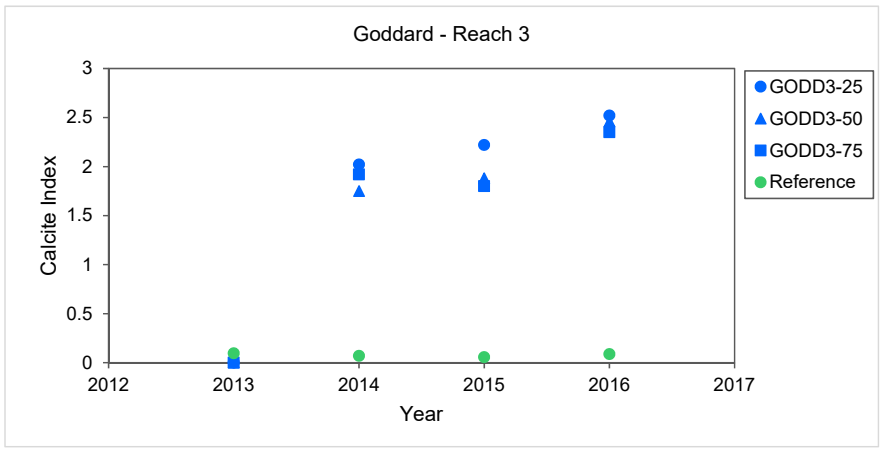
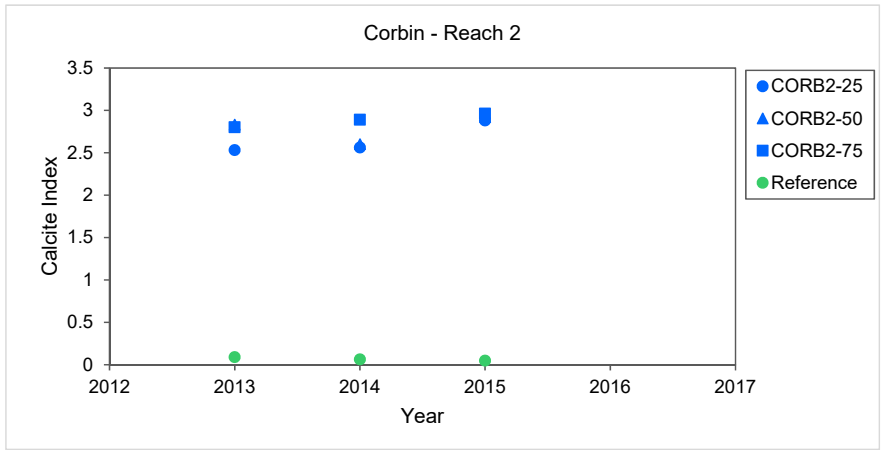
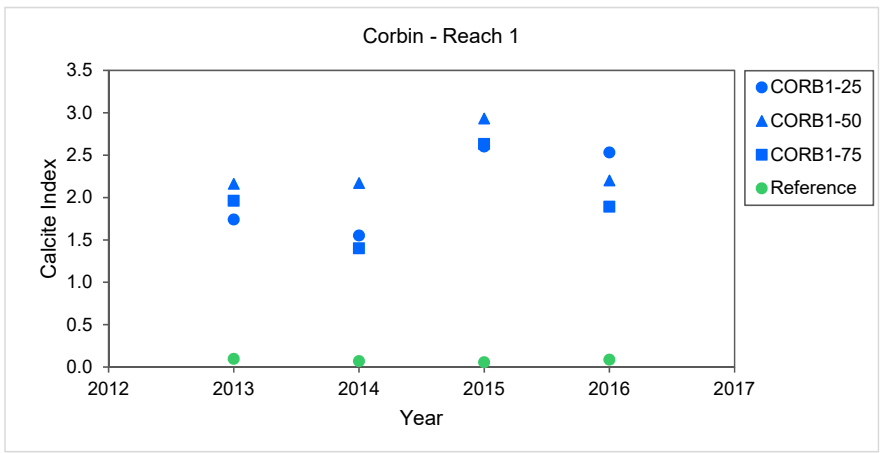
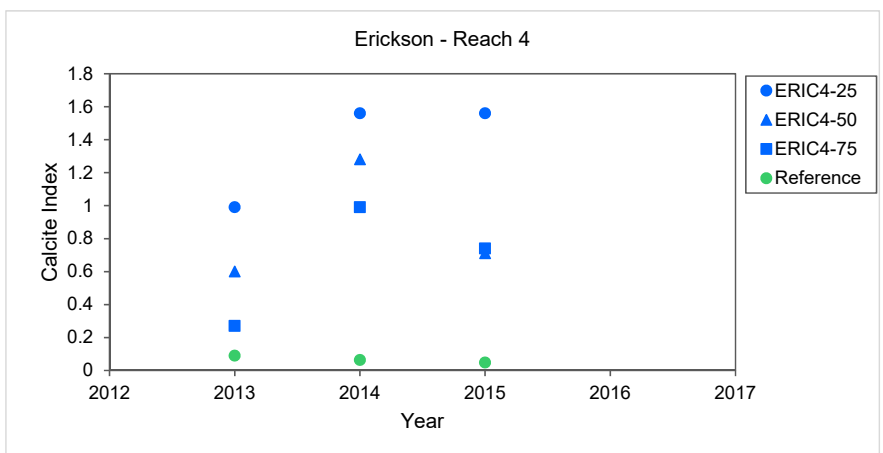
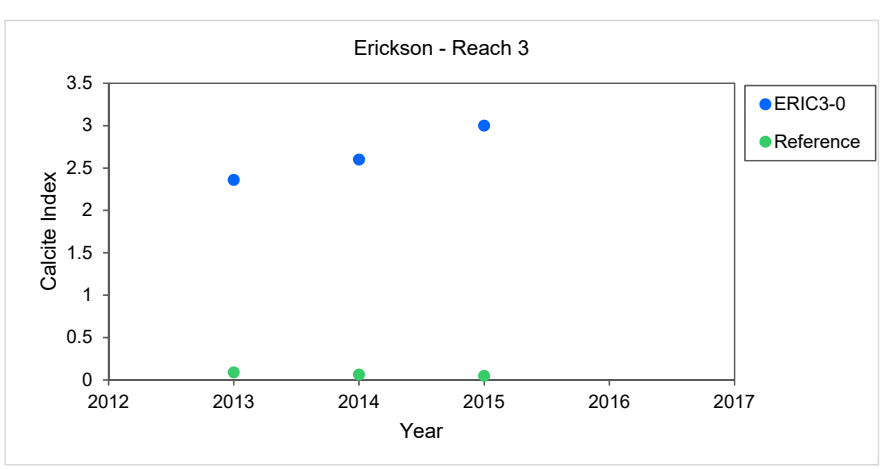
Note: Reference means in each plot represent the means of the reference area data used in that specific contrast

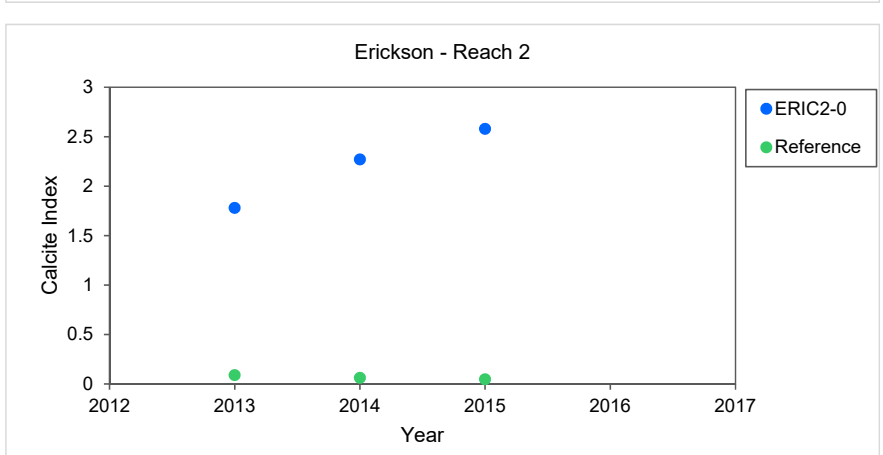


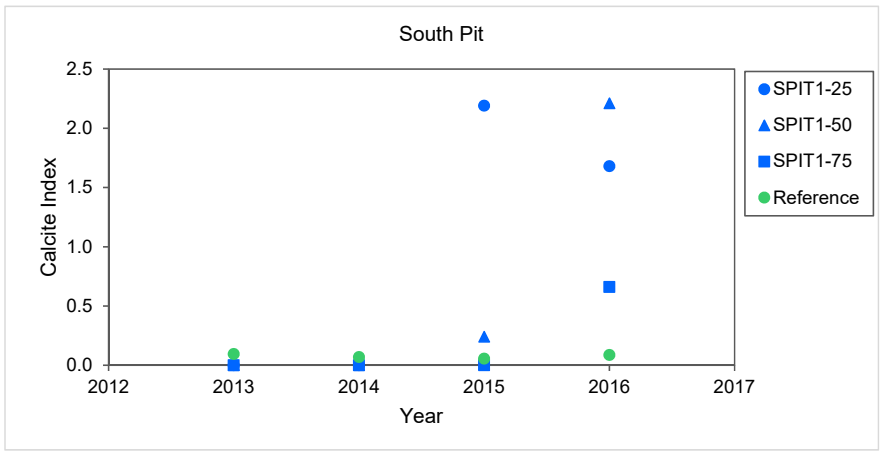


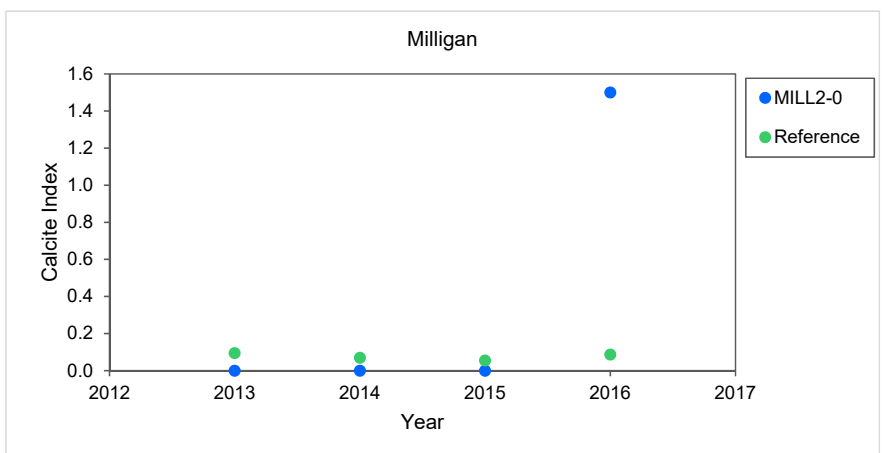


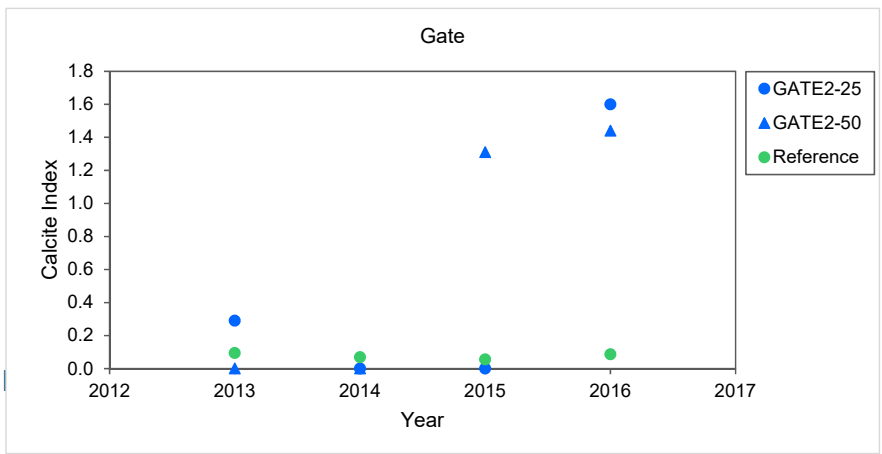


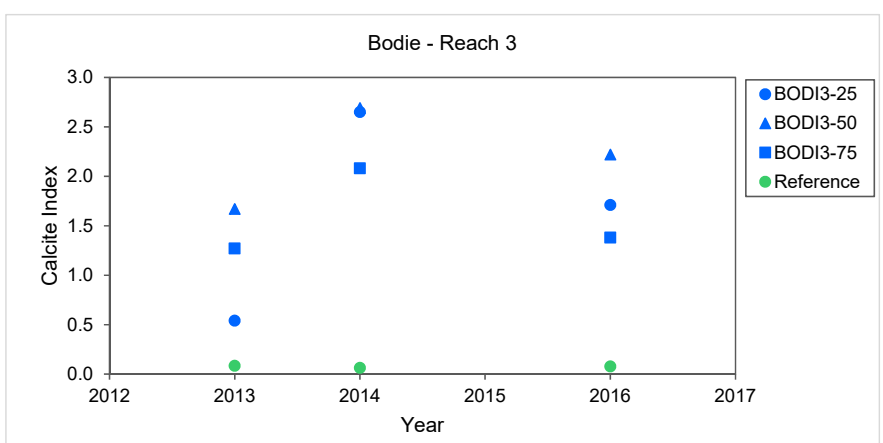












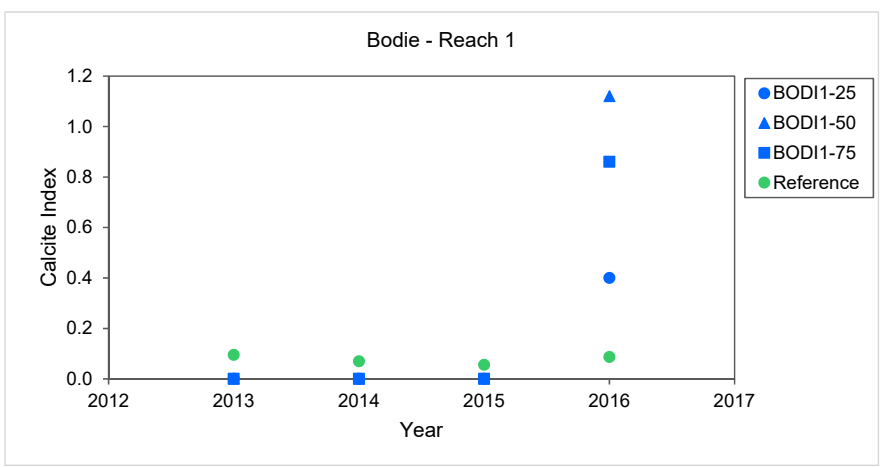


Figure D.1: Scatterplots of Calcite Index versus Year for the Mean Reference and Mine-exposed Stations within Reaches that had at Least One Significant Contrast with an Increase Relative to Reference

Note: Reference means in each plot represent the means of the reference area data used in that specific contrast

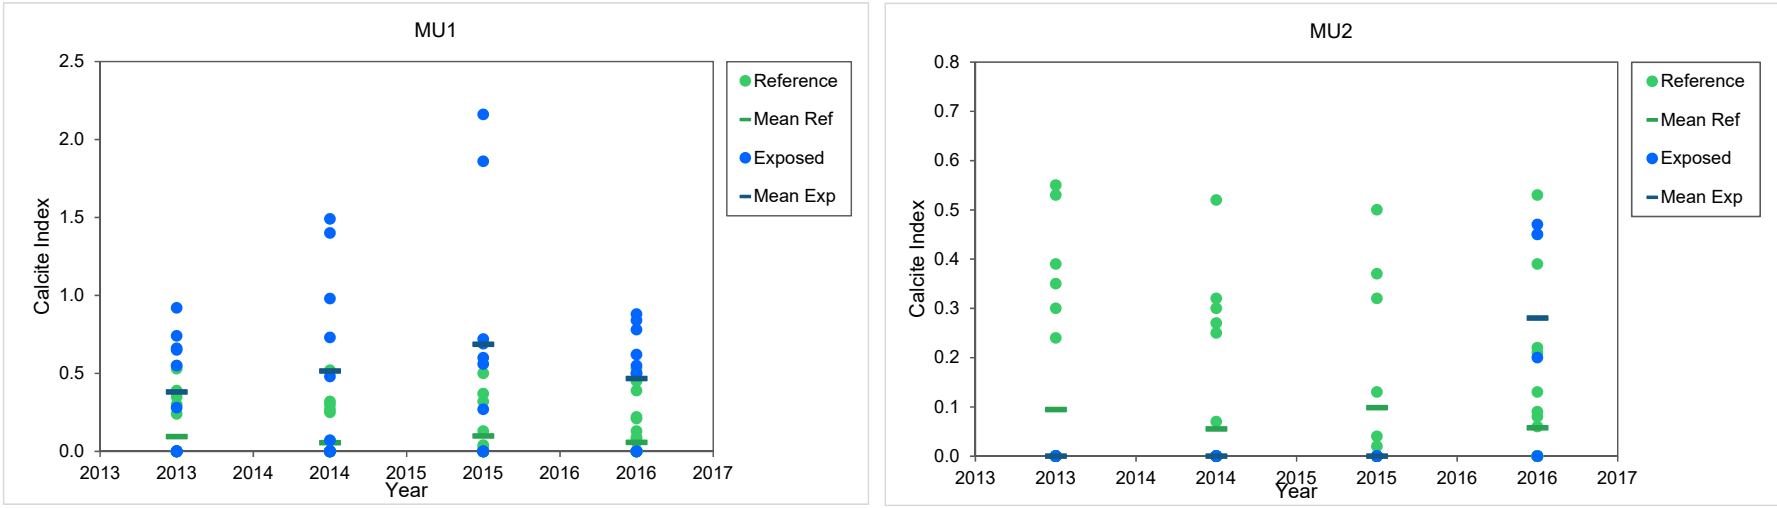

Figure D.2: Scatterplots of Calcite Index versus Year for the Mean Reference and Main Stem Mine-exposed Stations by Management Unit for Comparisons that had at Least One Significant Contrast with an Increase Relative to Reference

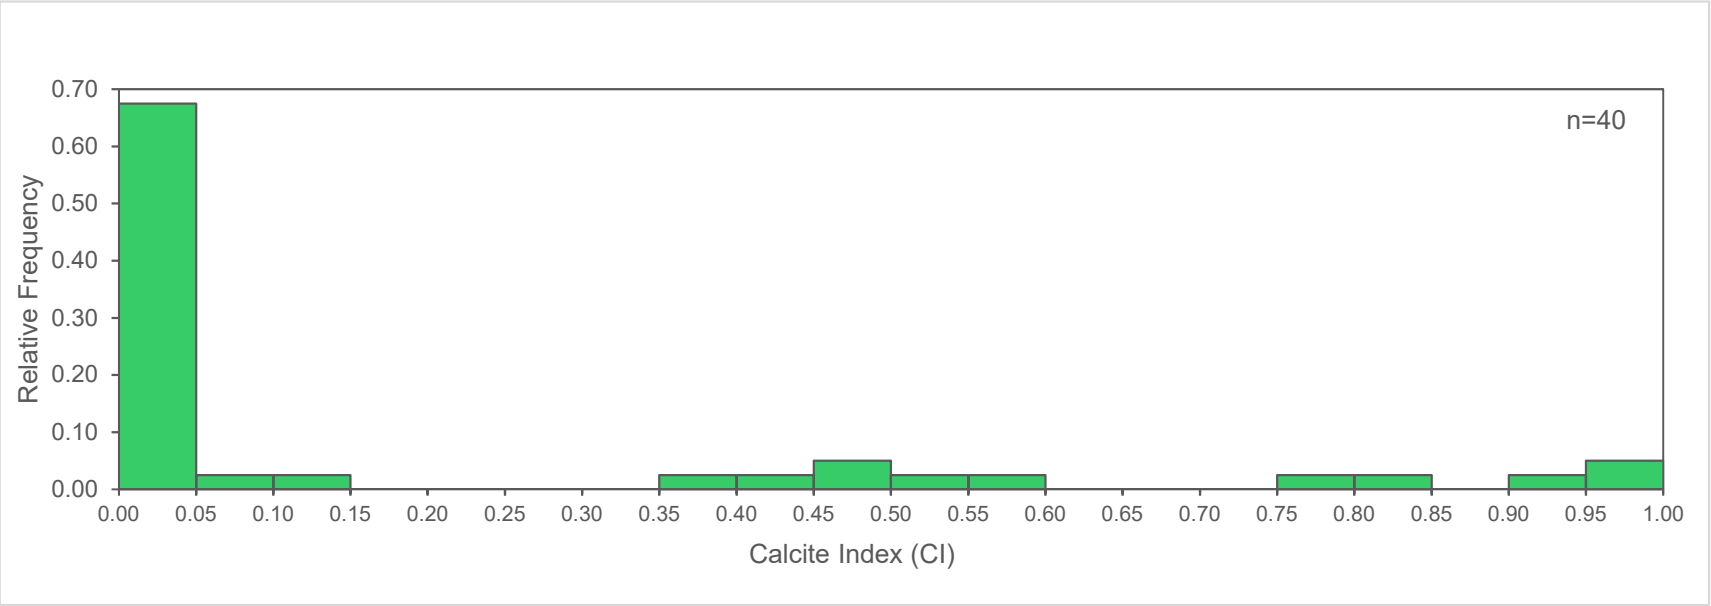

Figure D.3: Distribution of Reference Area Calcite Index Values, September 2015

Notes: 2.5th and 97.5th percentiles are 0 and 0.97, respectively. The upper limit of the normal range (i.e., the 97.5th percentile) was rounded to 1.

Measured concurrently with invertebrate samples

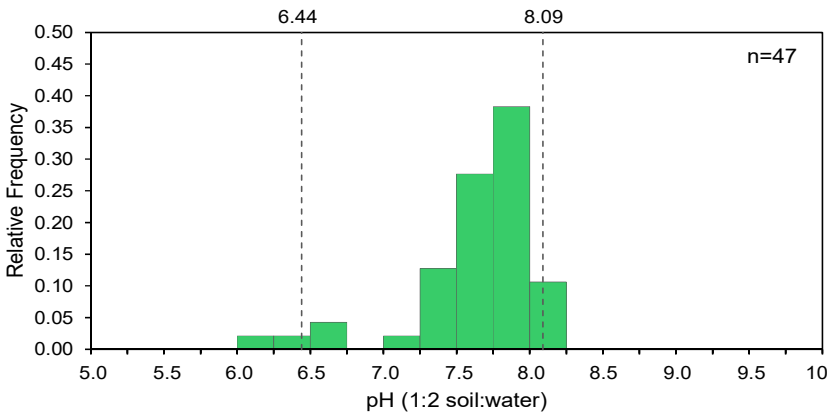
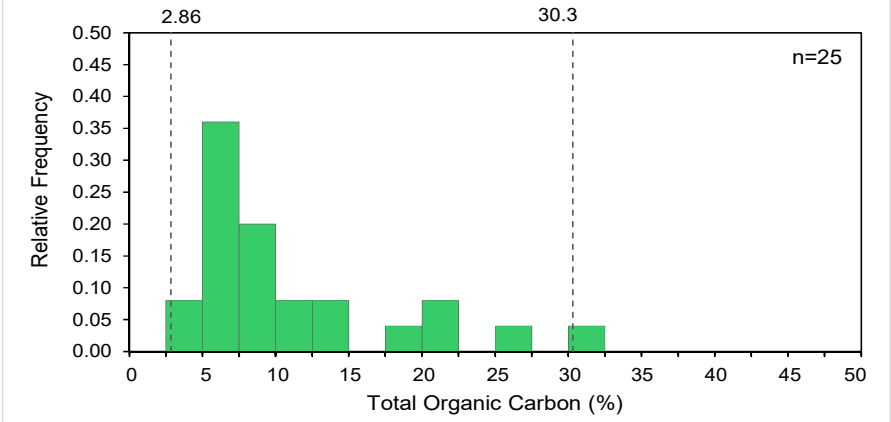
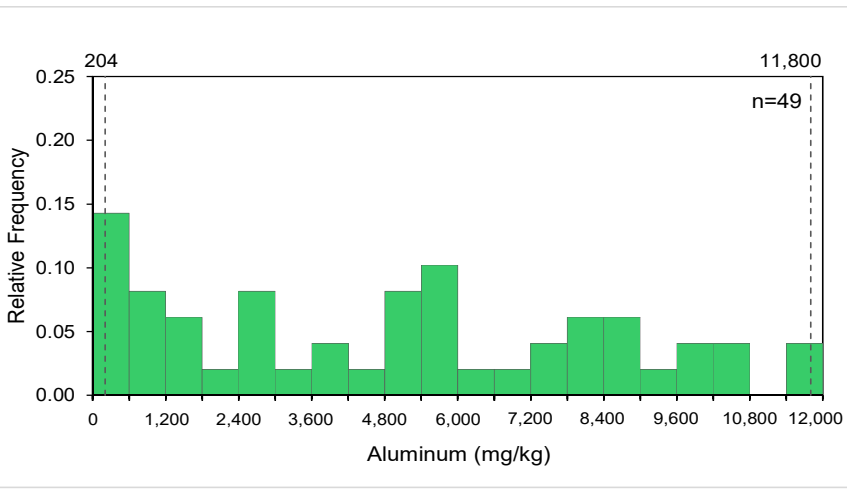
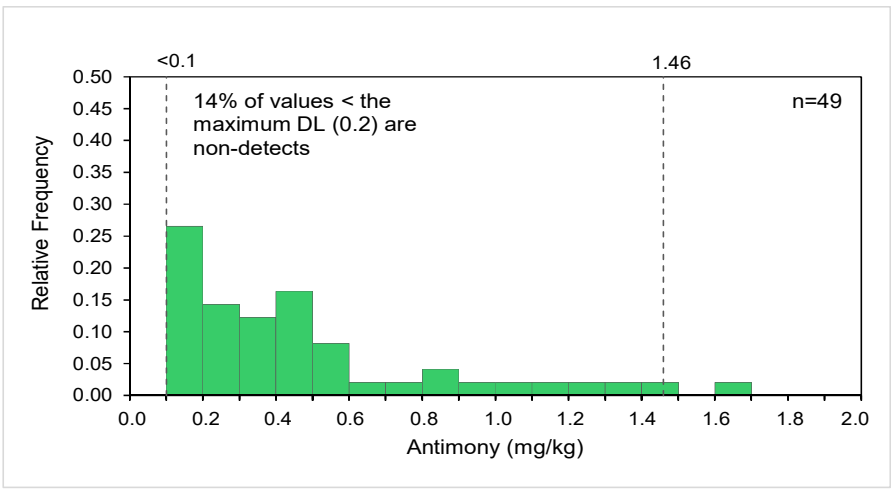
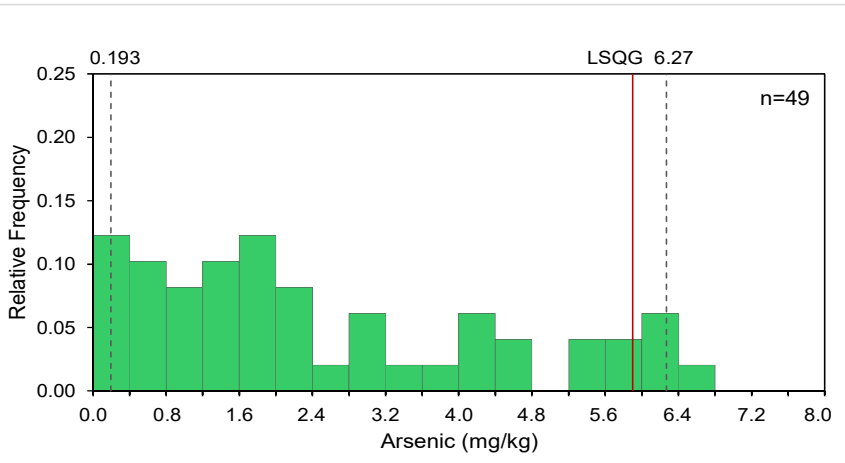
APPENDIX E
SEDIMENT QUALITY

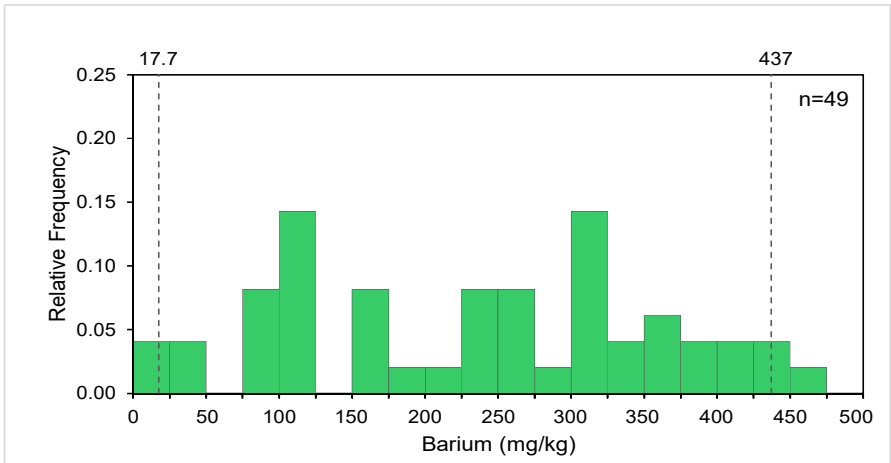


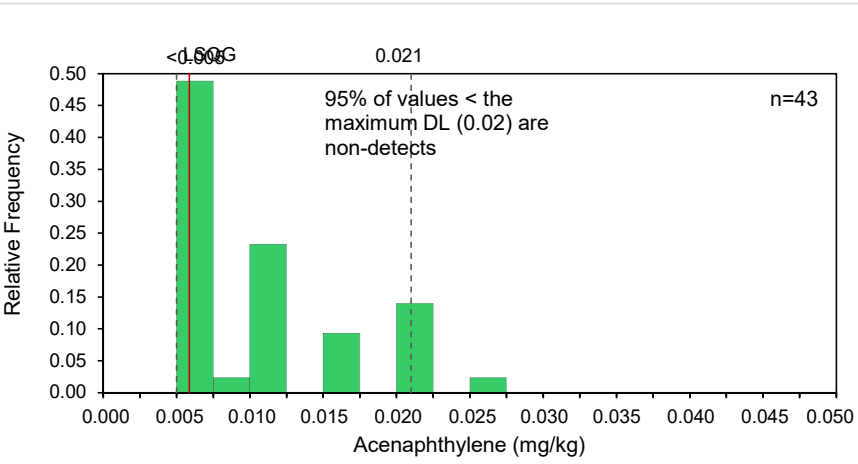


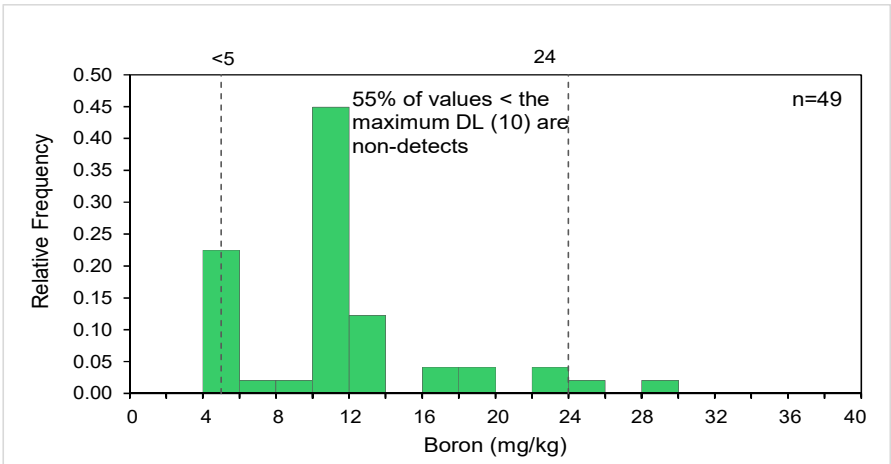


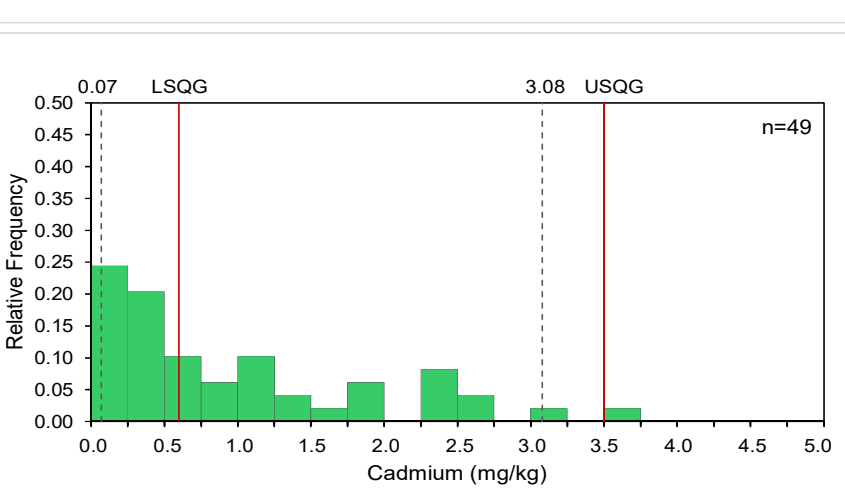












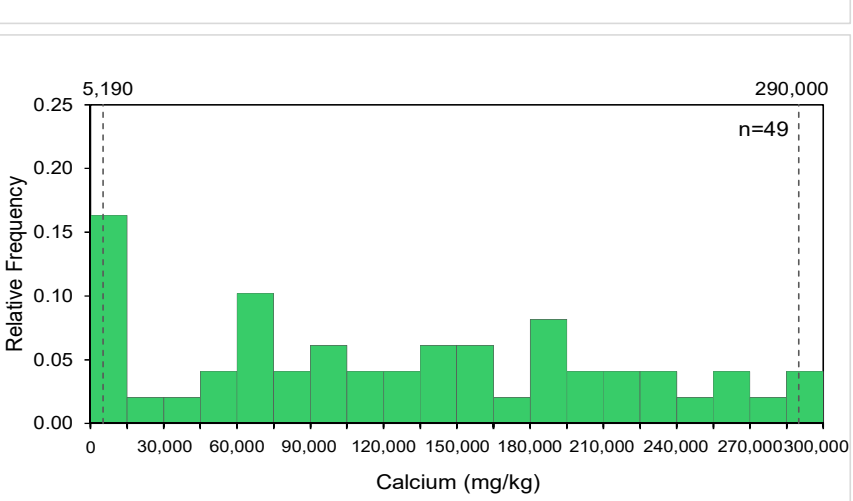


Figure E.1: Distribution of Reference Area Data (after Removal of Outliers and Poor Detection Limits) used to Define Reference Normal Ranges ($P_{2.5}$ and $P_{97.5}$) for Parameters Measured in Sediment, 2013 and 2015

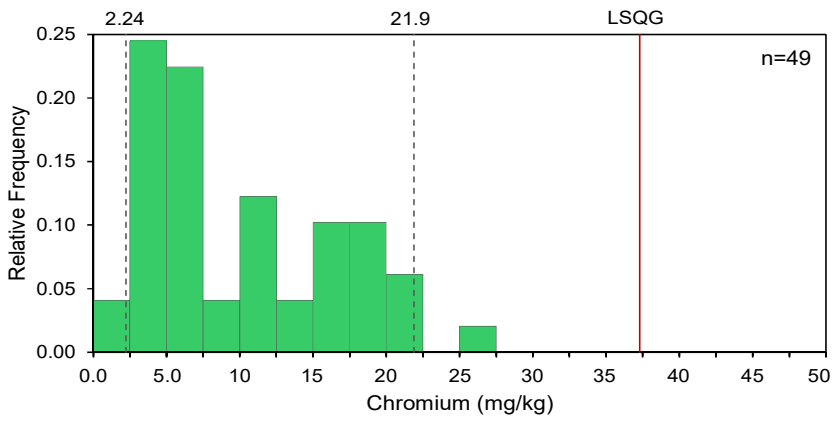
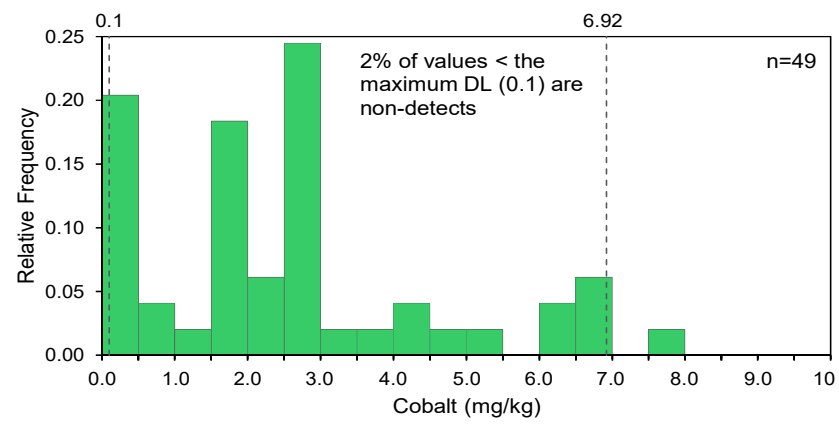
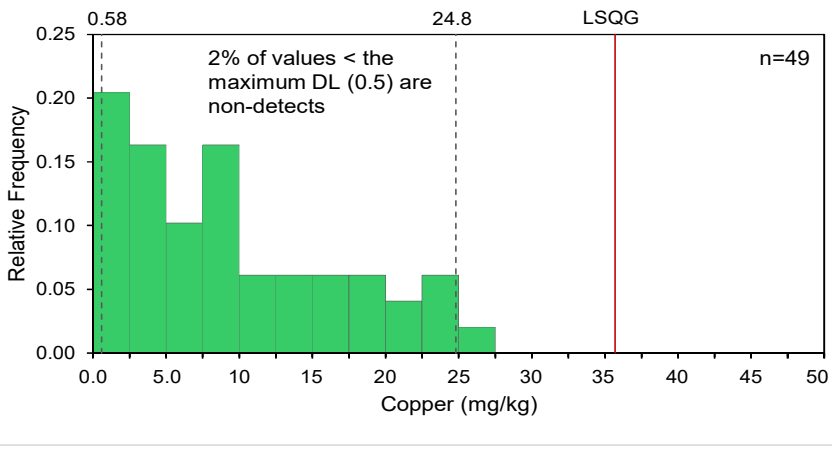
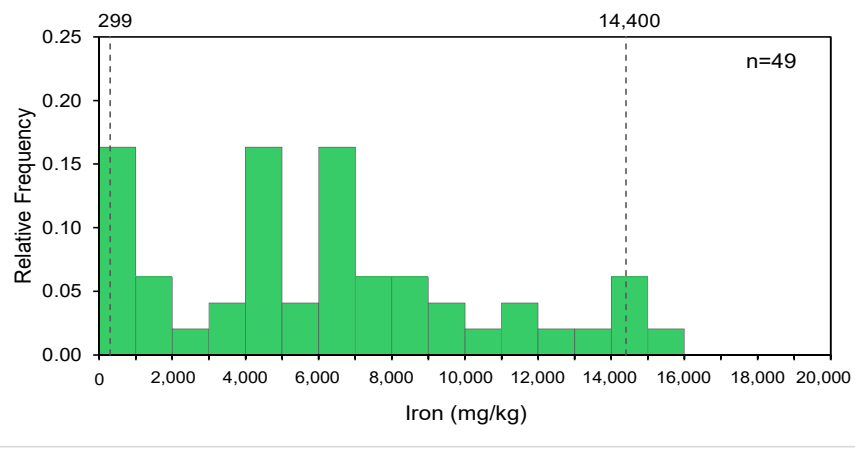
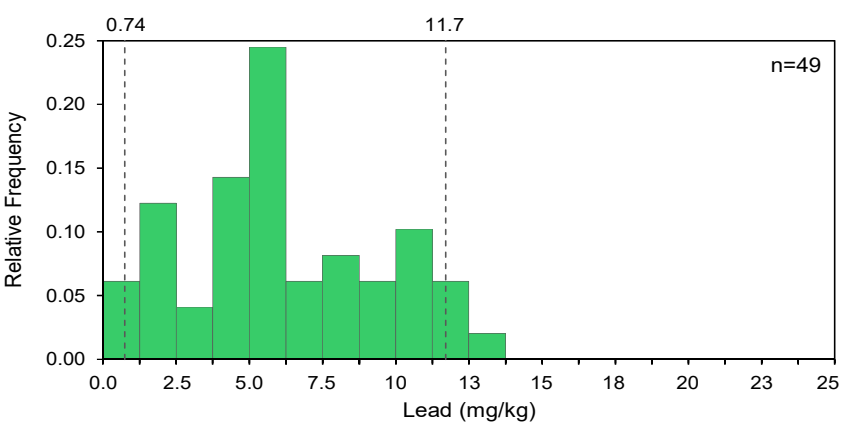
Notes: Dashed vertical lines = 2.5th and 97.5th percentiles
LSQG = Lower Working Sediment Quality Guideline
USQG = Upper Working Sediment Quality Guideline

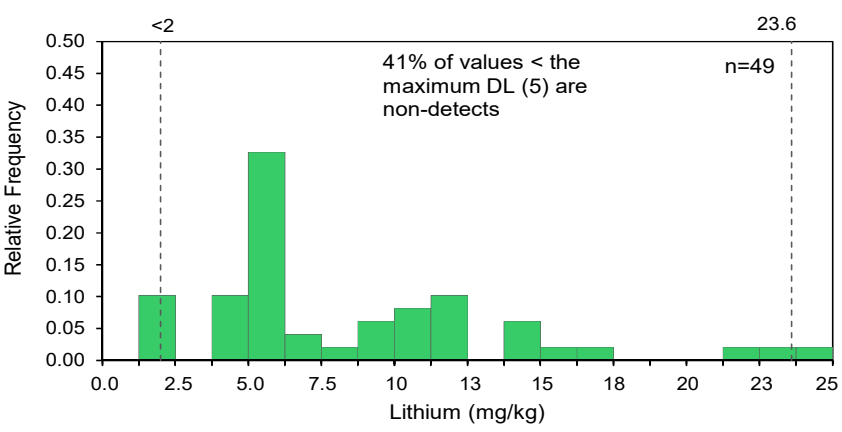


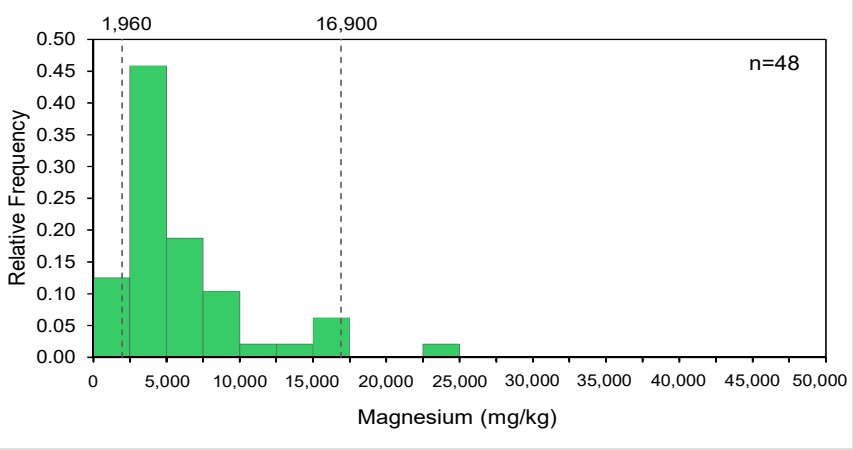


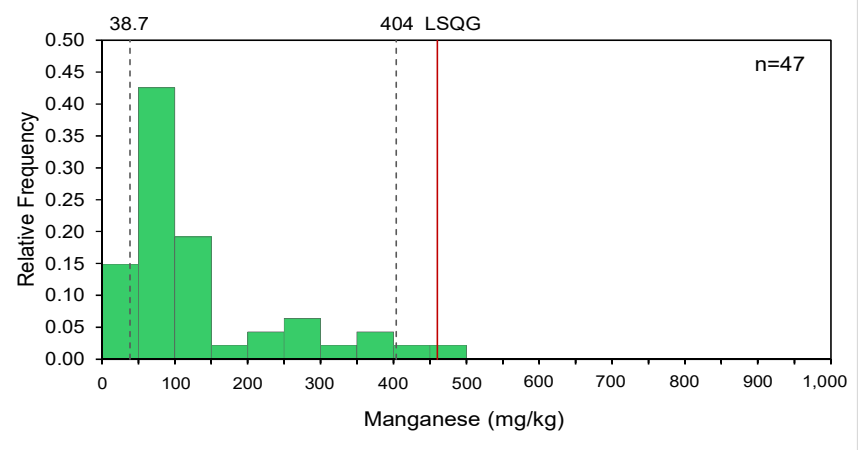


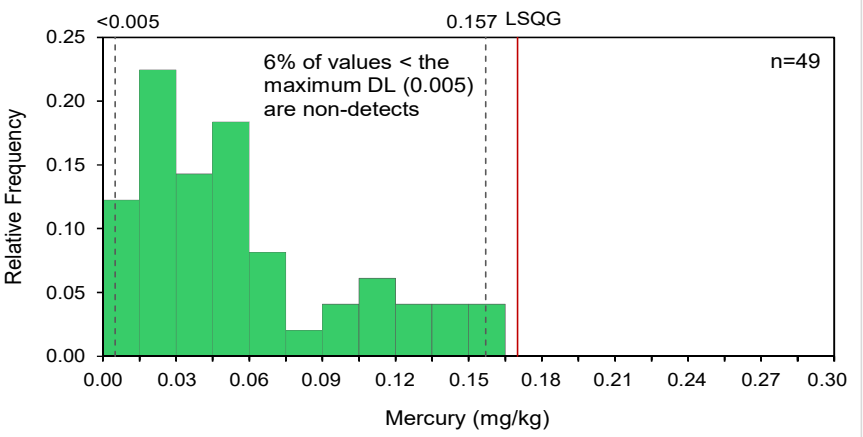












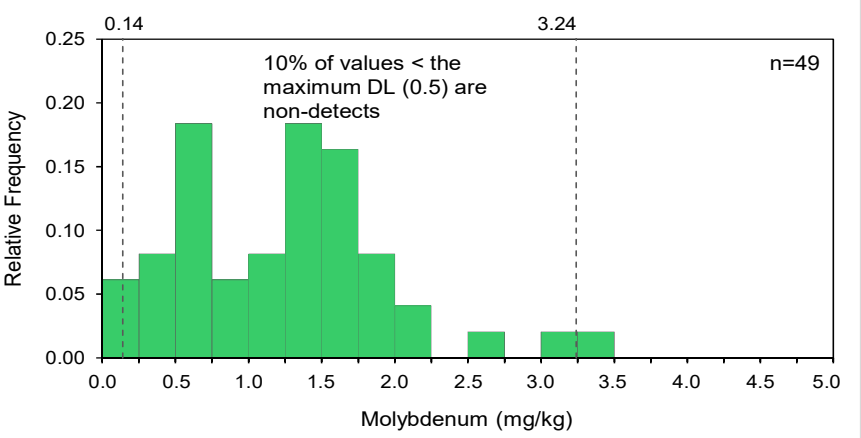


Figure E.1: Distribution of Reference Area Data (after Removal of Outliers and Poor Detection Limits) used to Define Reference Normal Ranges ($P_{2.5}$ and $P_{97.5}$) for Parameters Measured in Sediment, 2013 and 2015

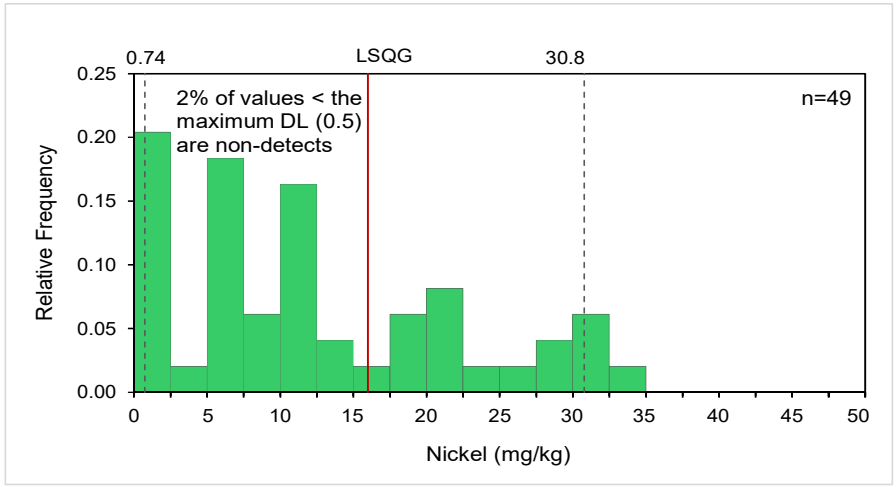
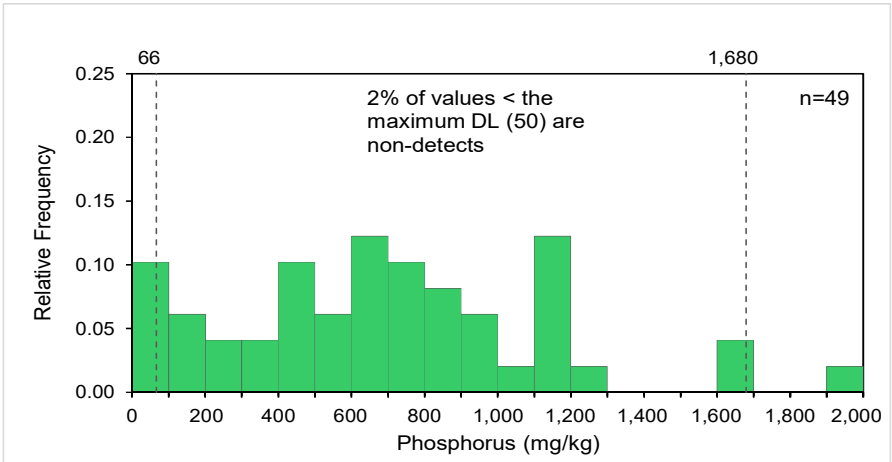
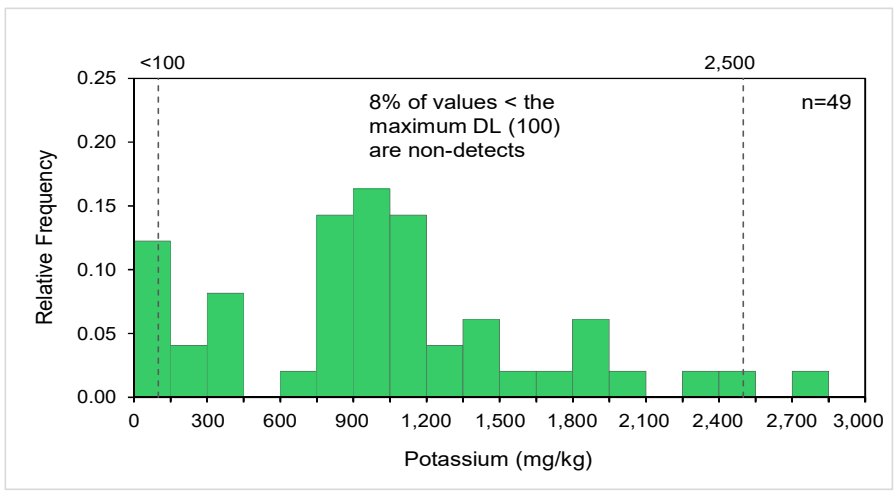
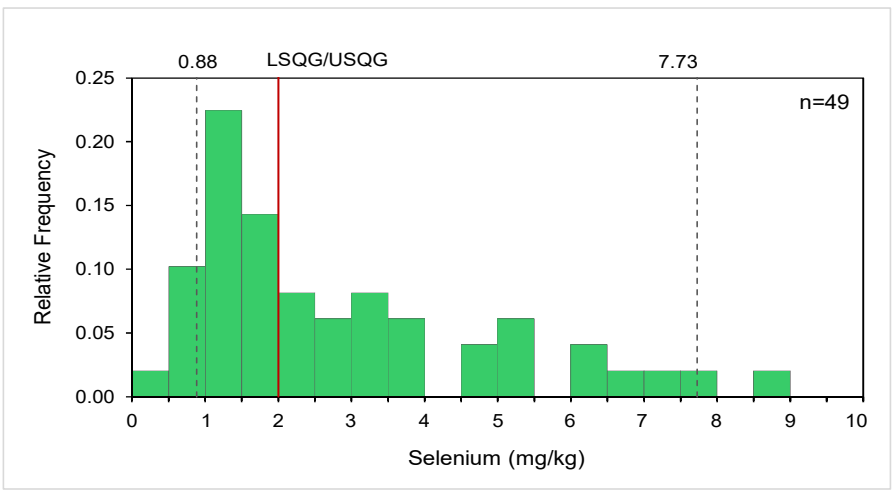
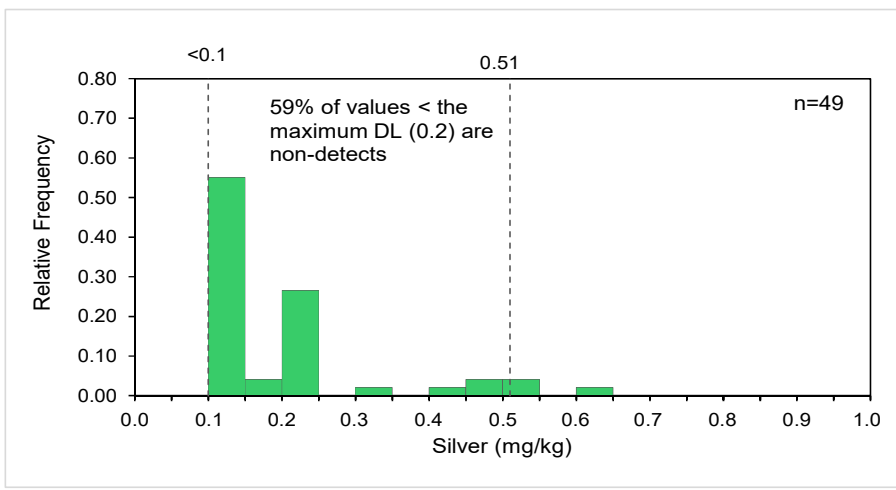
Notes: Dashed vertical lines = 2.5th and 97.5th percentiles
LSQG = Lower Working Sediment Quality Guideline
USQG = Upper Working Sediment Quality Guideline

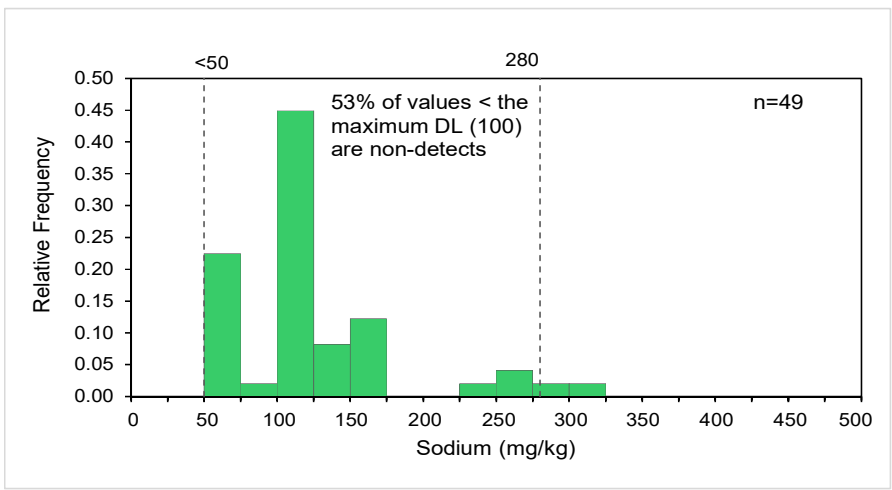


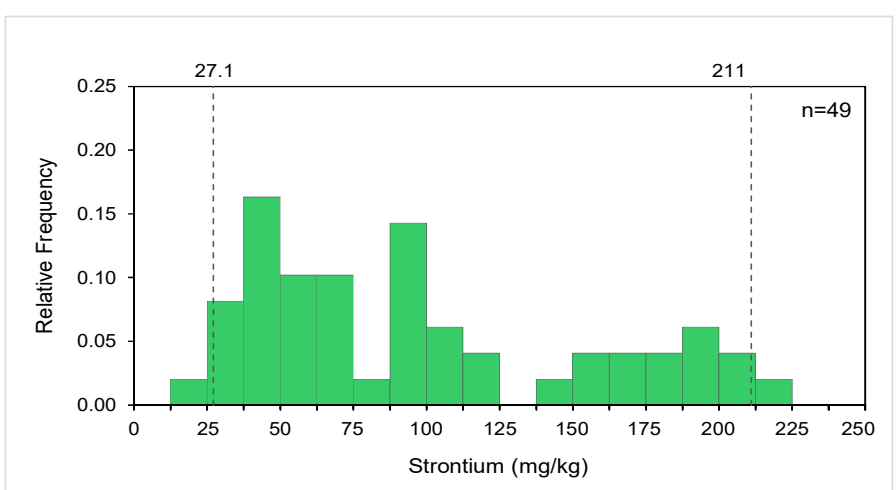


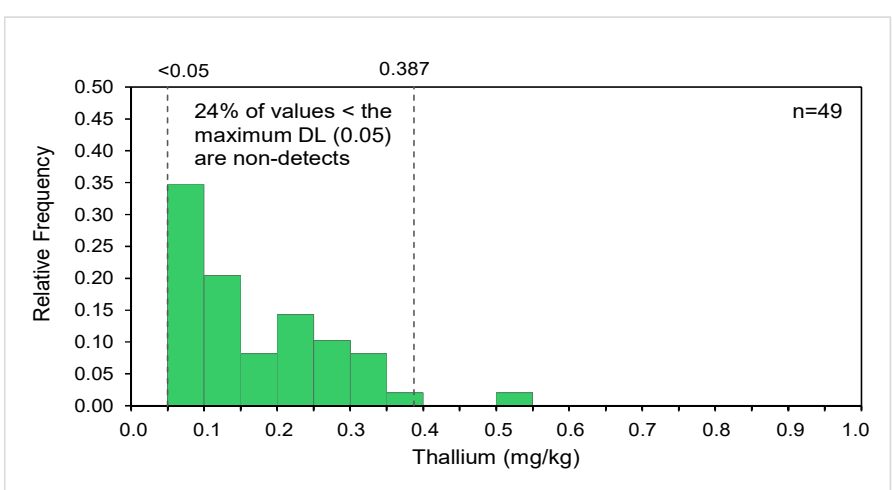


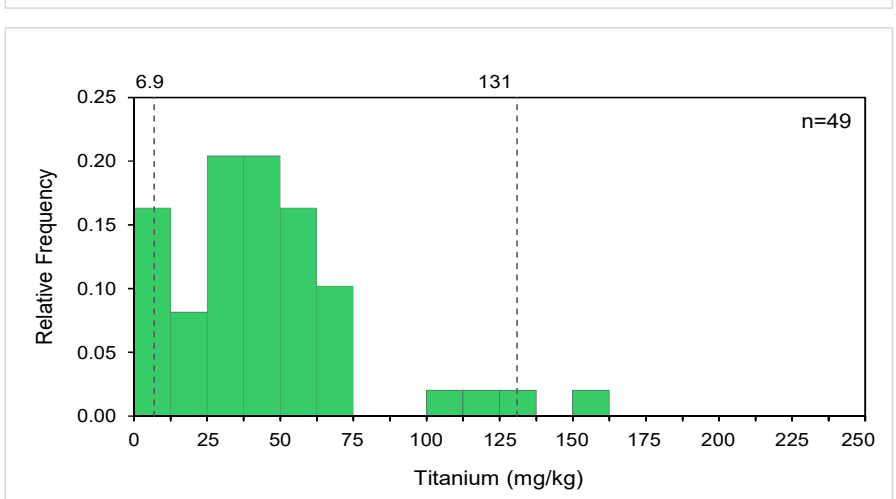












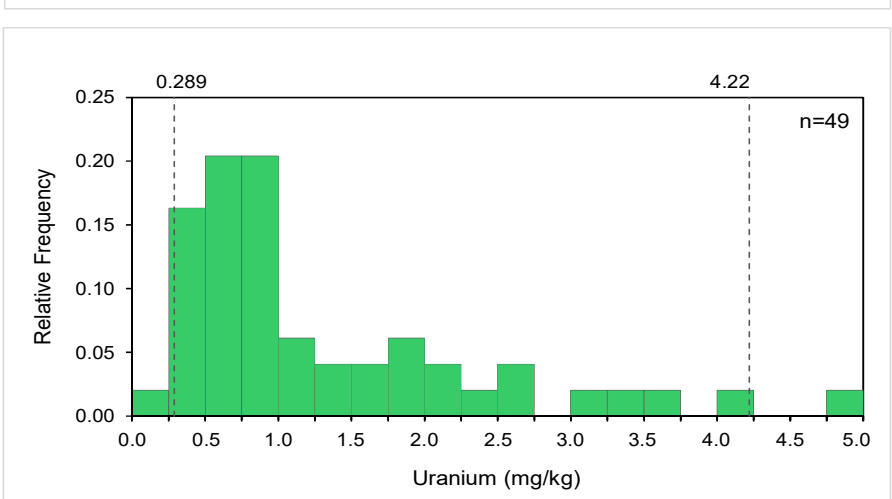


Figure E.1: Distribution of Reference Area Data (after Removal of Outliers and Poor Detection Limits) used to Define Reference Normal Ranges ($P_{2.5}$ and $P_{97.5}$) for Parameters Measured in Sediment, 2013 and 2015

Notes: Dashed vertical lines = 2.5th and 97.5th percentiles
LSQG = Lower Working Sediment Quality Guideline
USQG = Upper Working Sediment Quality Guideline

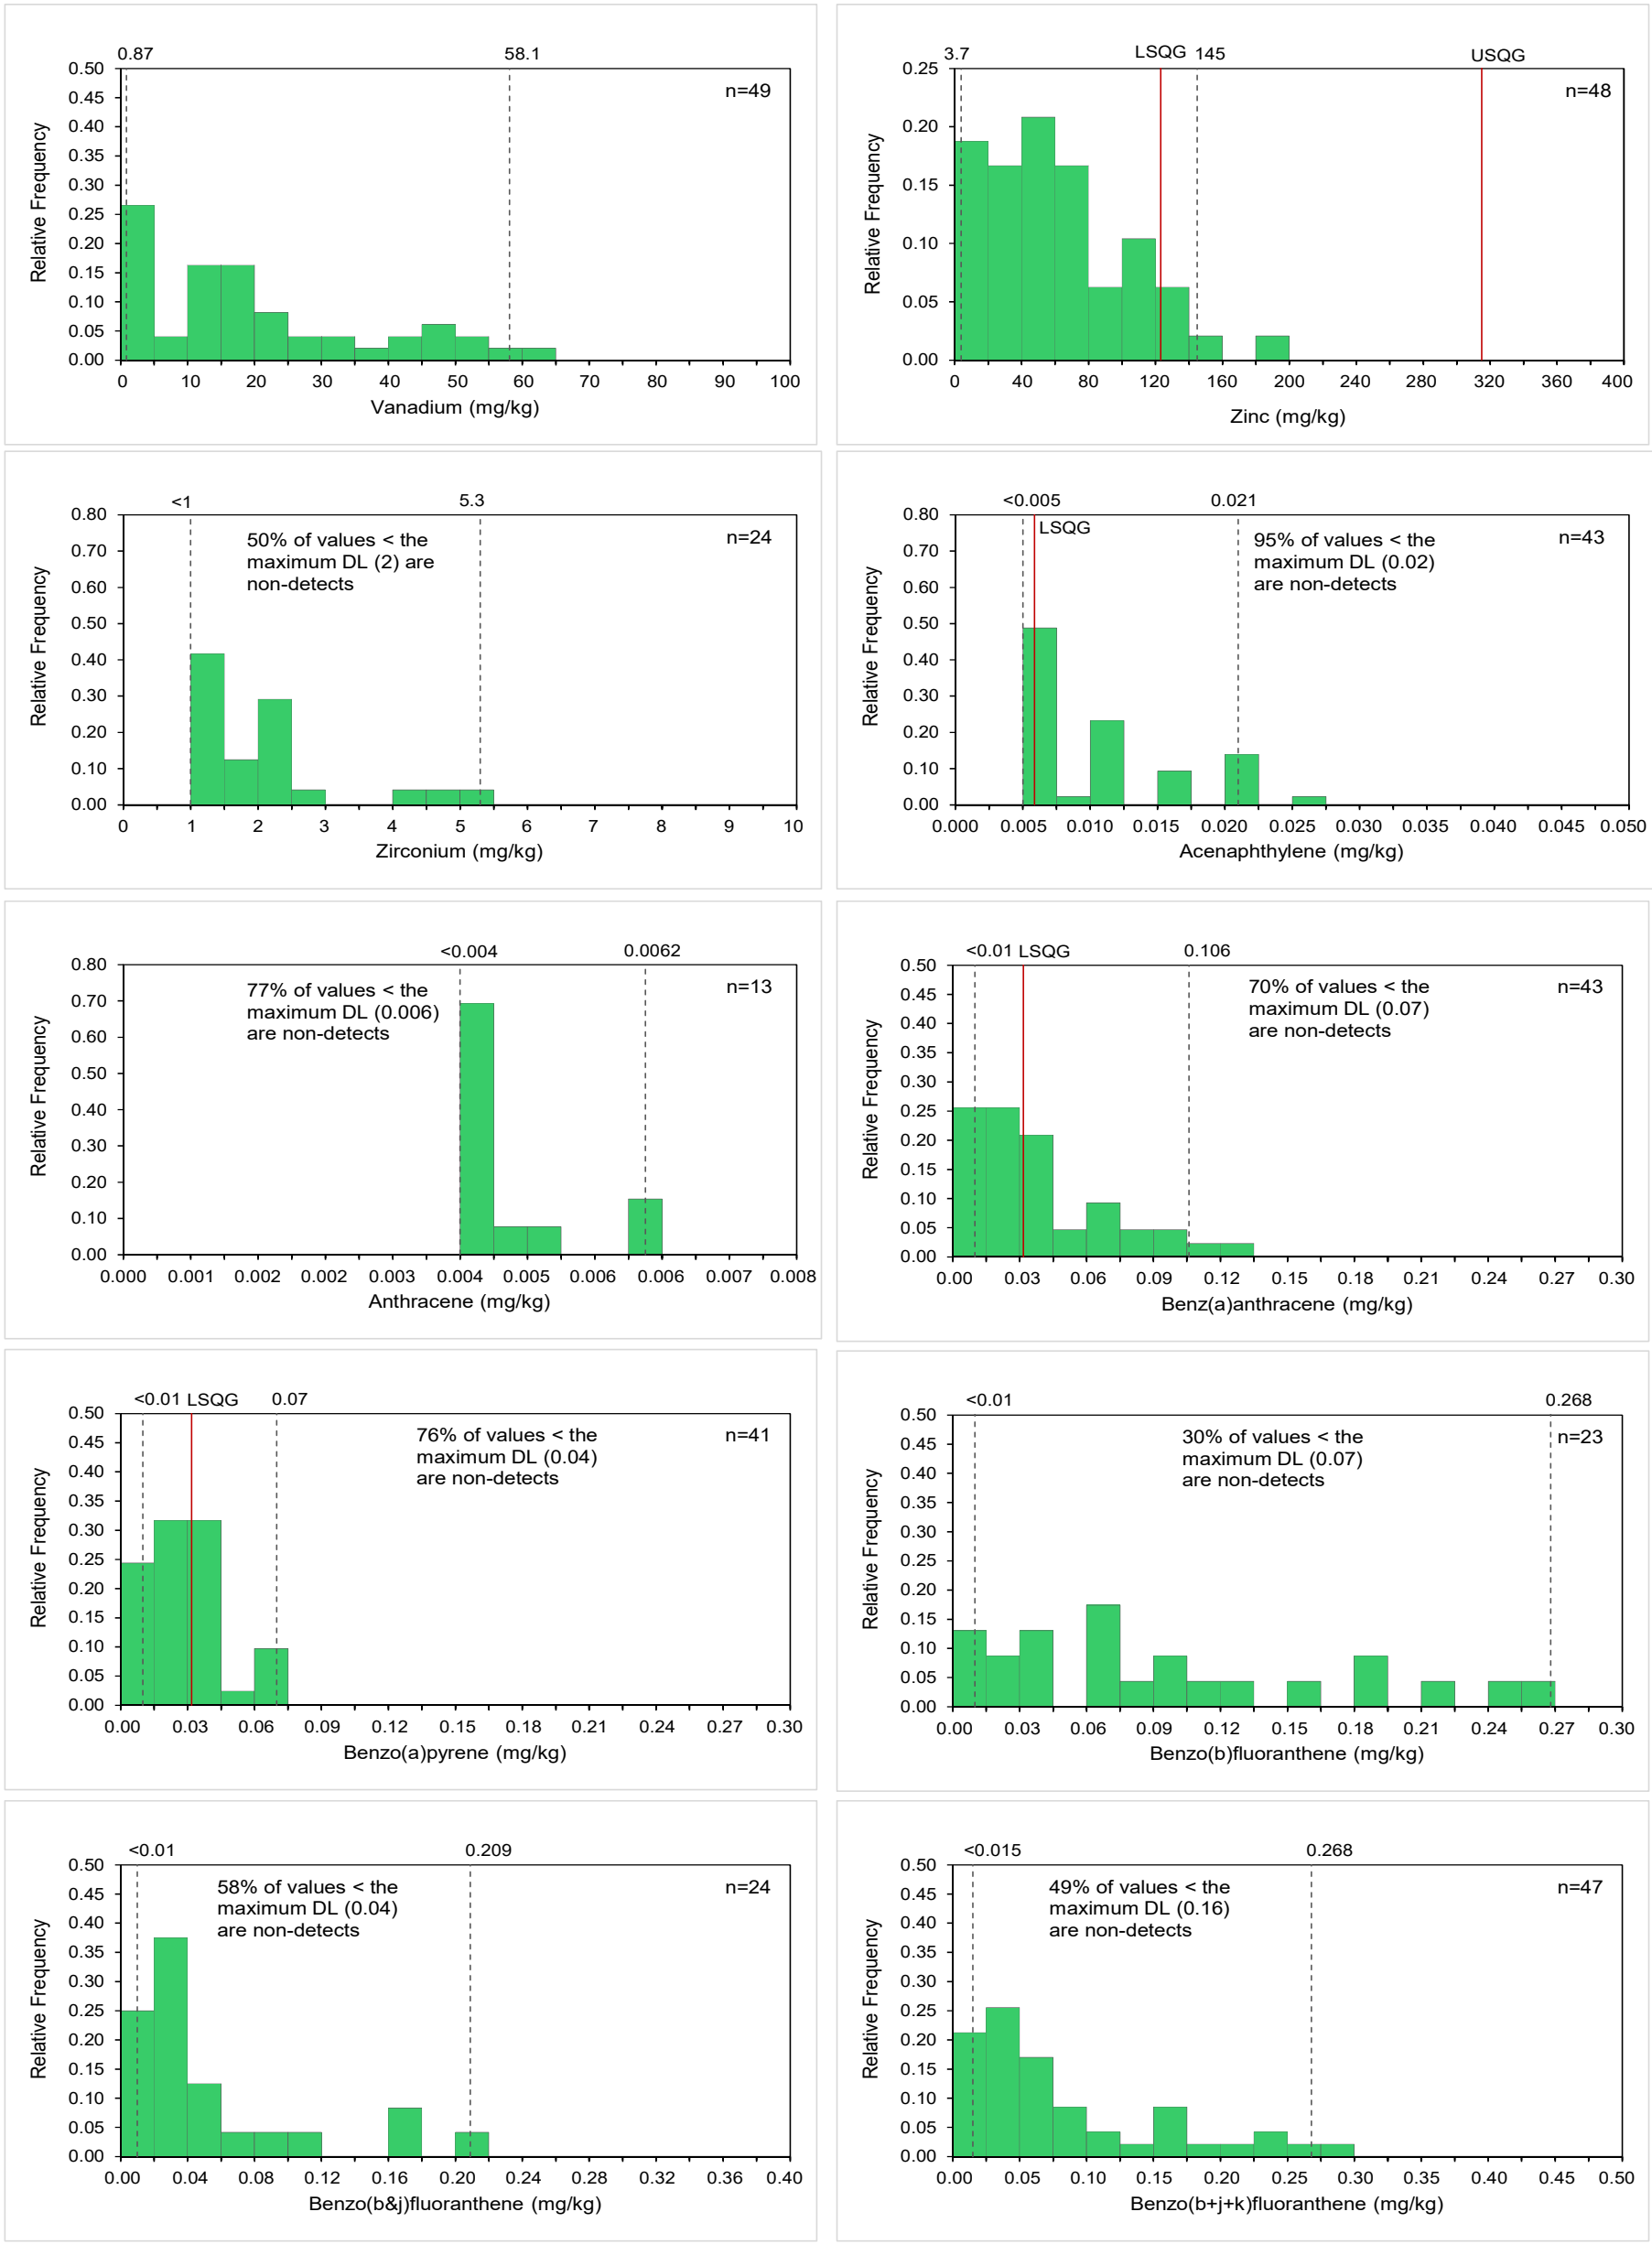

Figure E.1: Distribution of Reference Area Data (after Removal of Outliers and Poor Detection Limits) used to Define Reference Normal Ranges ($P_{2.5}$ and $P_{97.5}$) for Parameters Measured in Sediment, 2013 and 2015

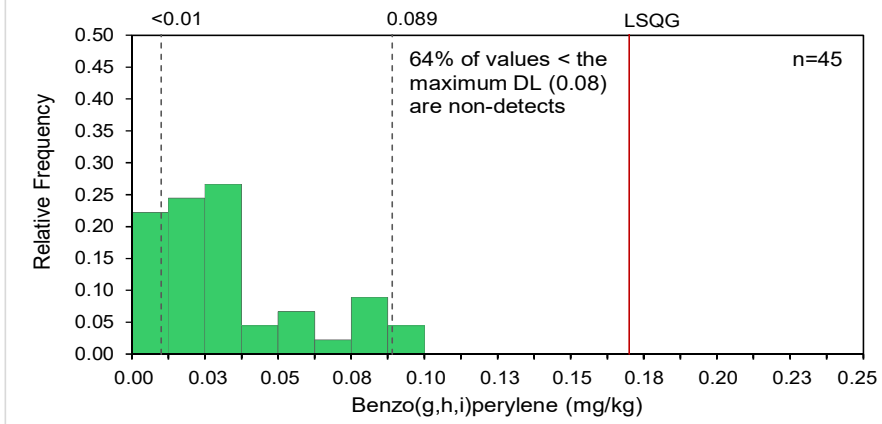
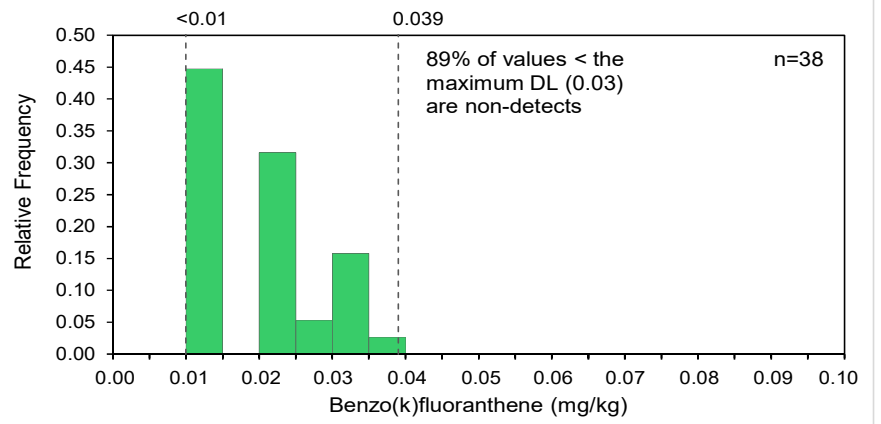
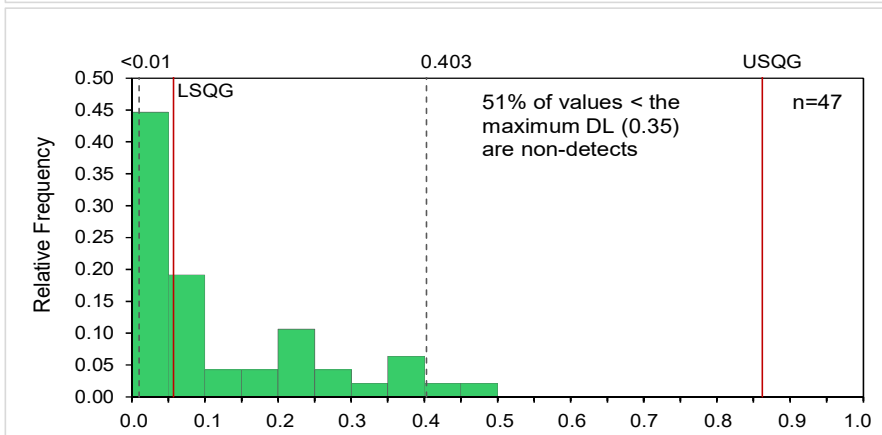
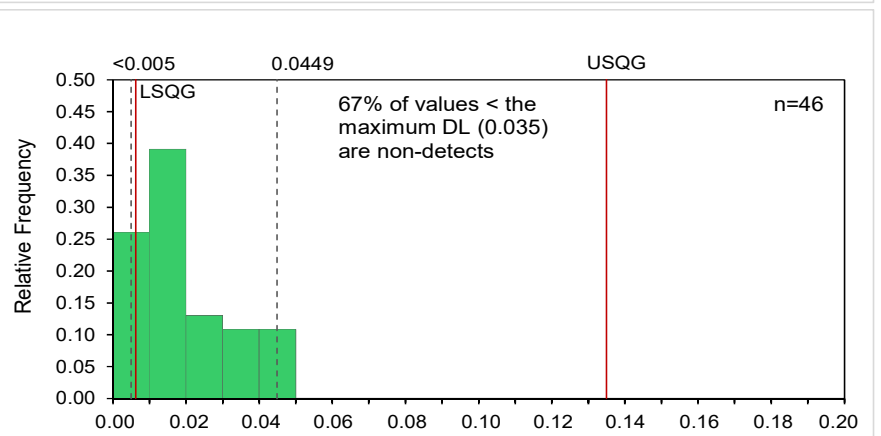
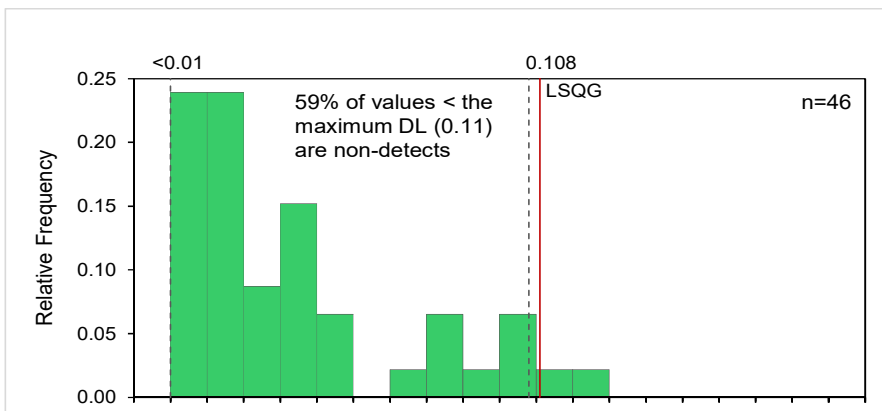
Notes: Dashed vertical lines = 2.5th and 97.5th percentiles
LSQG = Lower Working Sediment Quality Guideline
USQG = Upper Working Sediment Quality Guideline

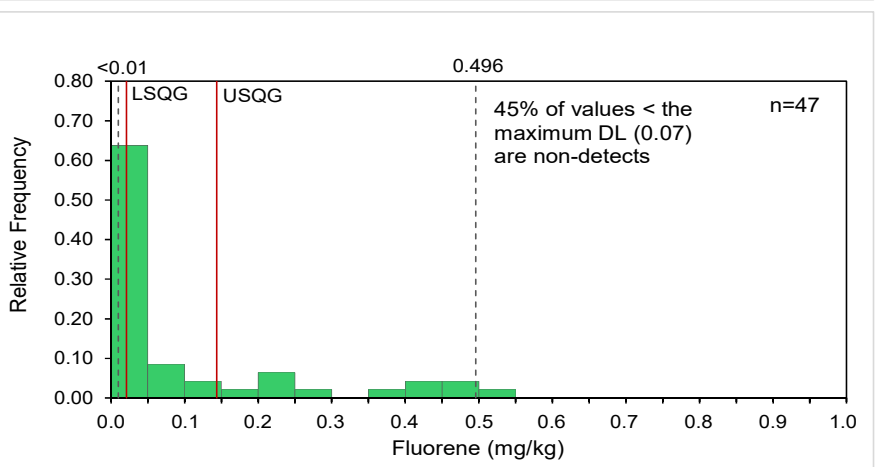


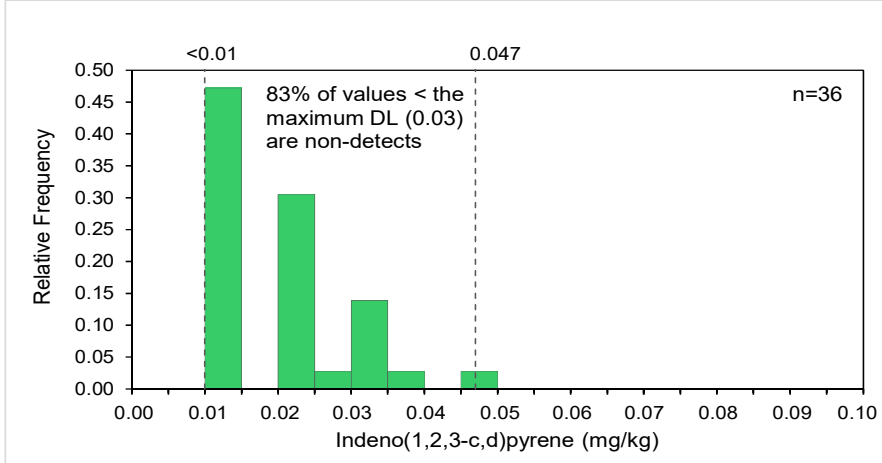


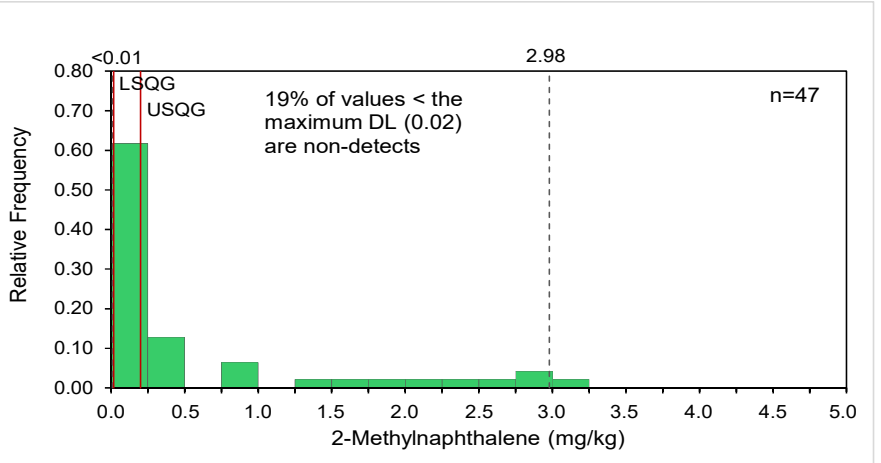


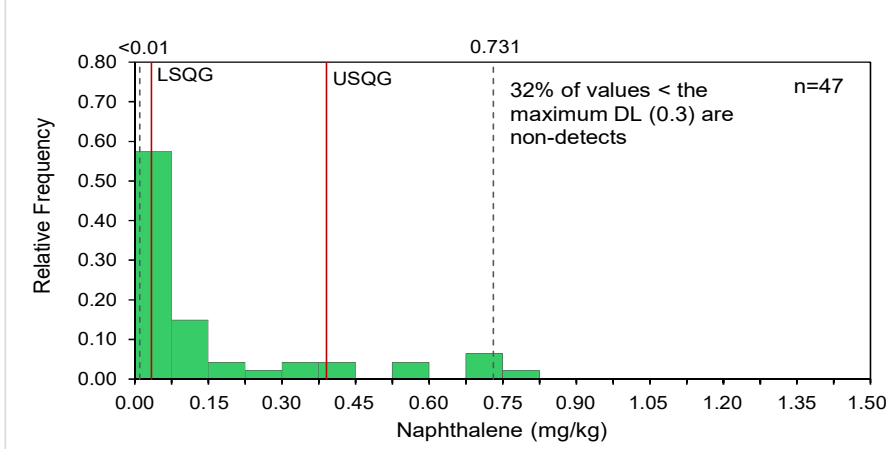












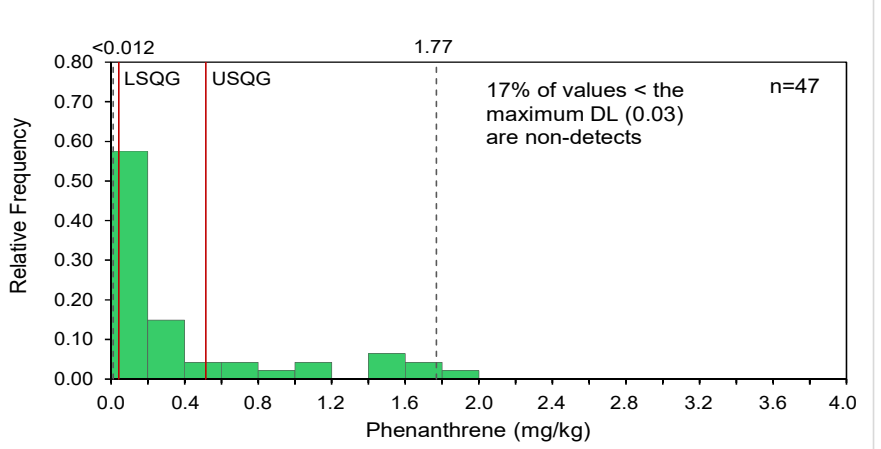


Figure E.1: Distribution of Reference Area Data (after Removal of Outliers and Poor Detection Limits) used to Define Reference Normal Ranges ($P_{2.5}$ and $P_{97.5}$) for Parameters Measured in Sediment, 2013 and 2015

Notes: Dashed vertical lines = 2.5th and 97.5th percentiles
LSQG = Lower Working Sediment Quality Guideline
USQG = Upper Working Sediment Quality Guideline

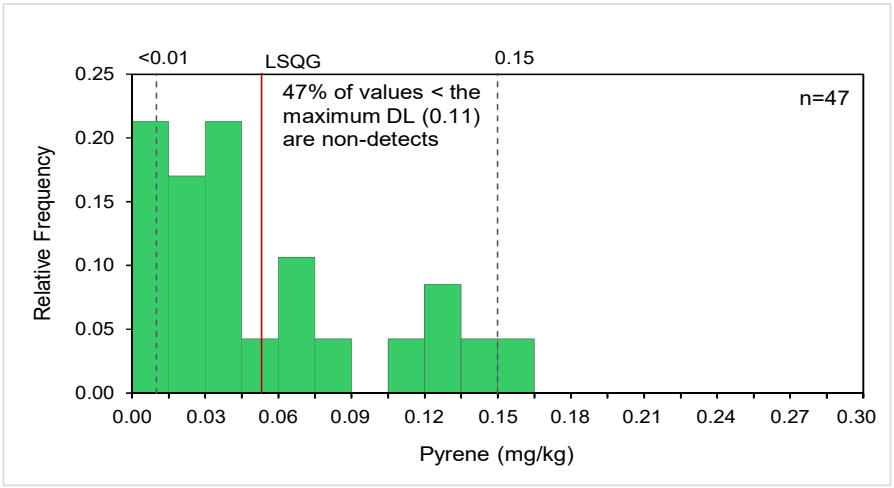

Figure E.1: Distribution of Reference Area Data (after Removal of Outliers and Poor Detection Limits) used to Define Reference Normal Ranges ($P_{2.5}$ and $P_{97.5}$) for Parameters Measured in Sediment, 2013 and 2015

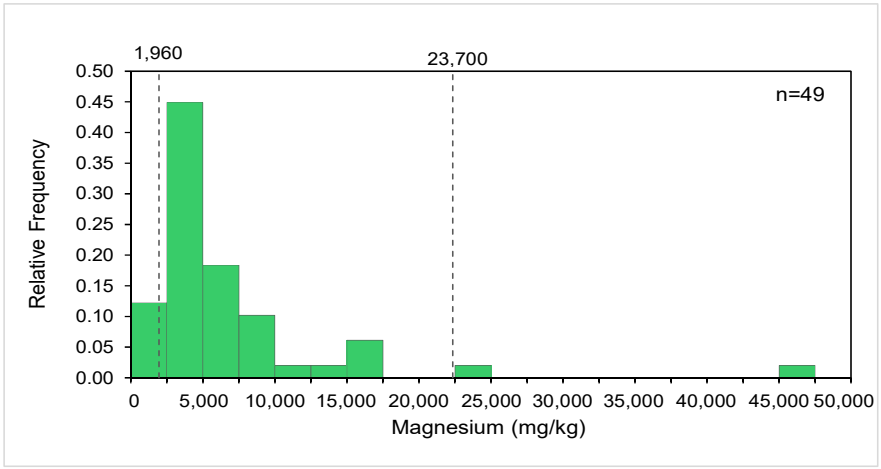
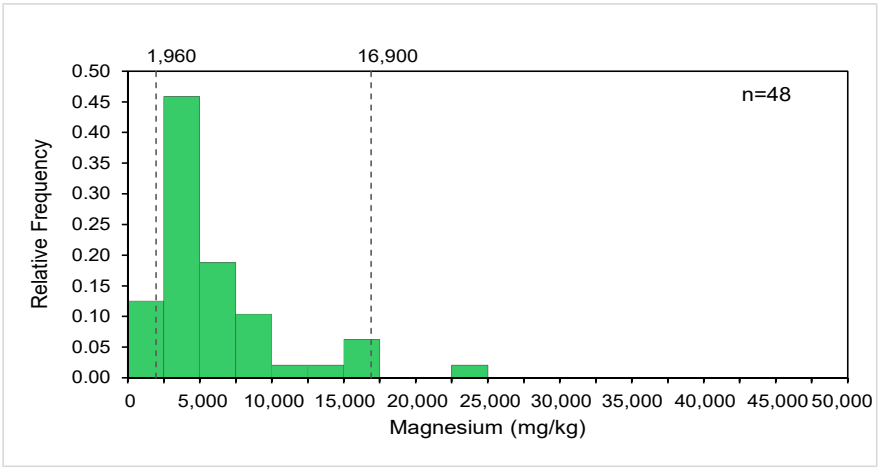
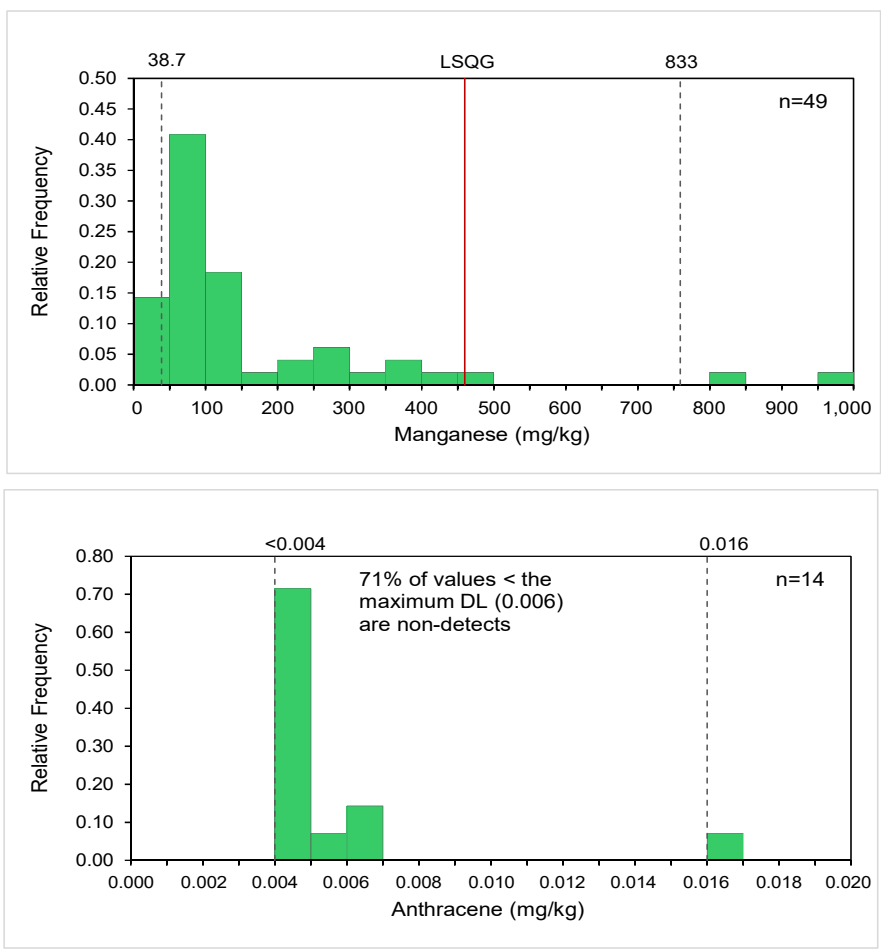
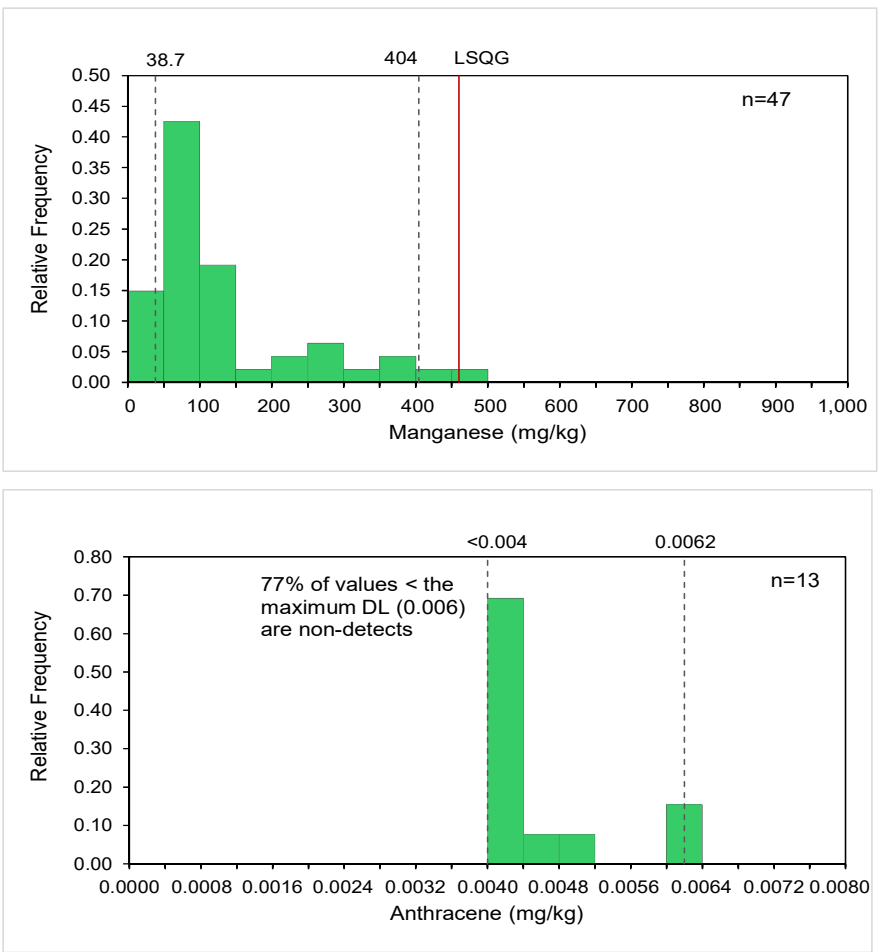
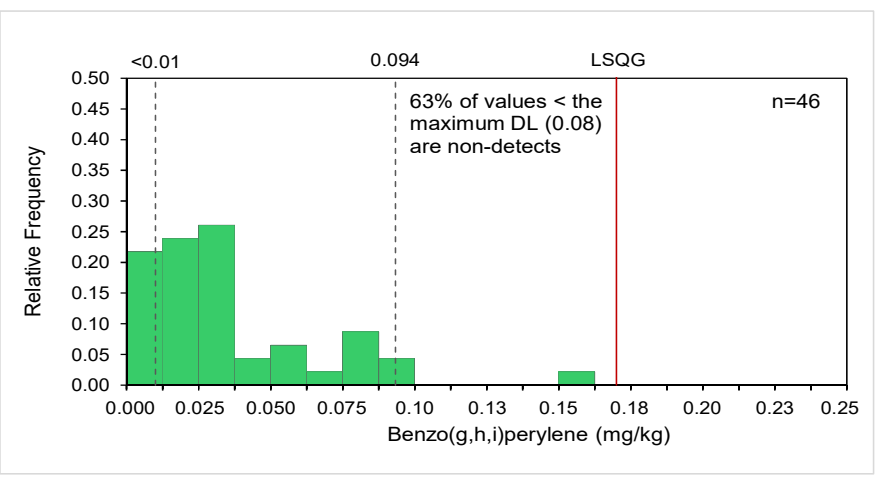
Notes: Dashed vertical lines = 2.5th and 97.5th percentiles
LSQG = Lower Sediment Quality Guideline
USQG = Upper Sediment Quality Guideline











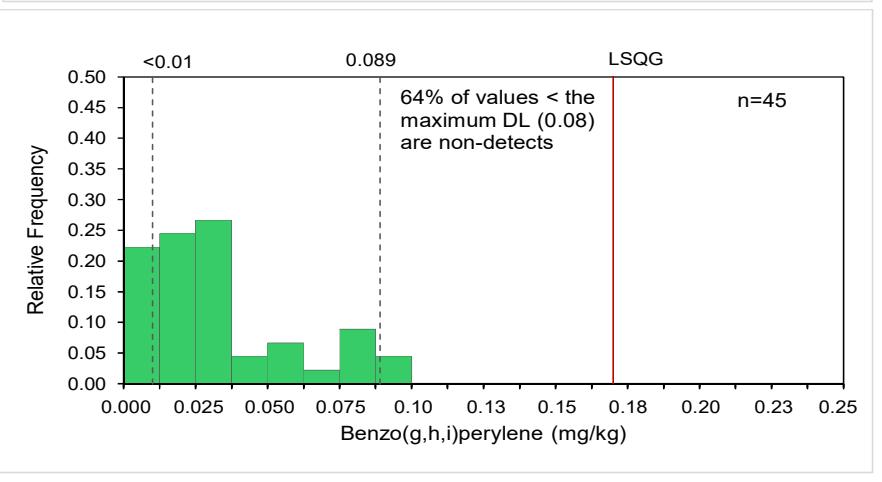


Figure E.2: Distribution of Reference Area Sediment Data (2013 and 2015) for Parameters with Outliers (all data on left and data after removal of outliers on right)

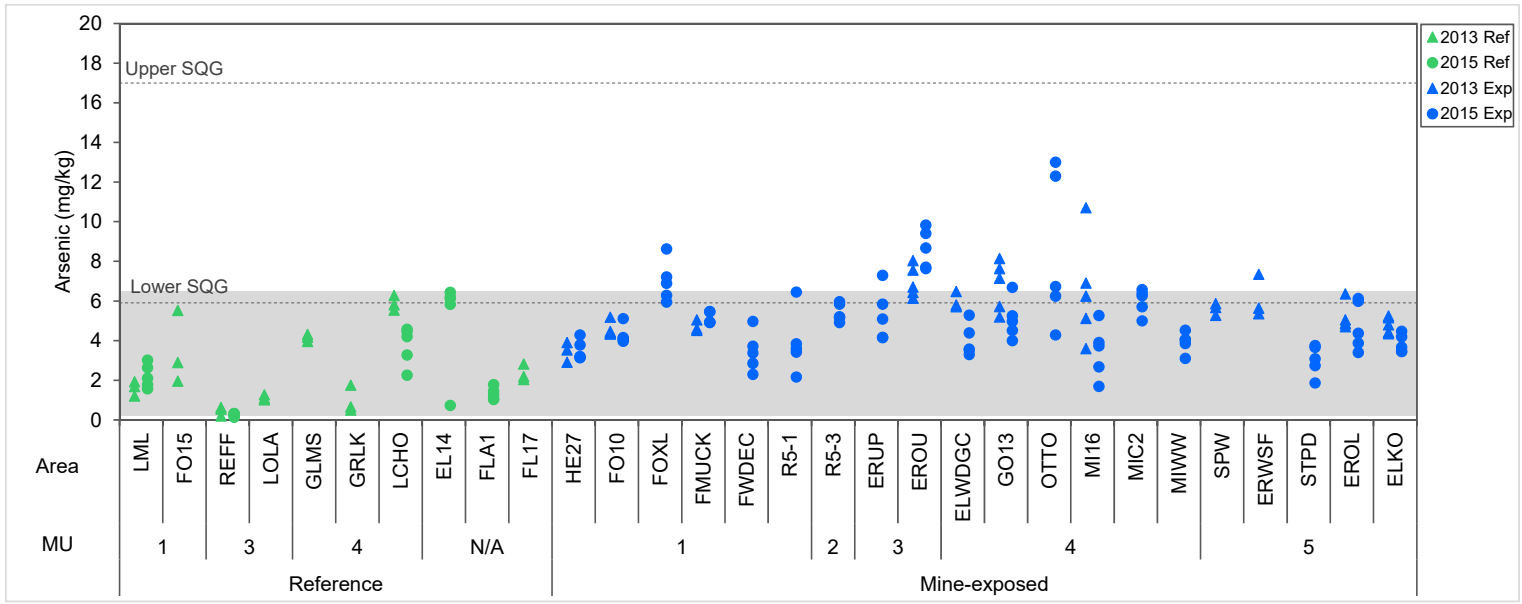
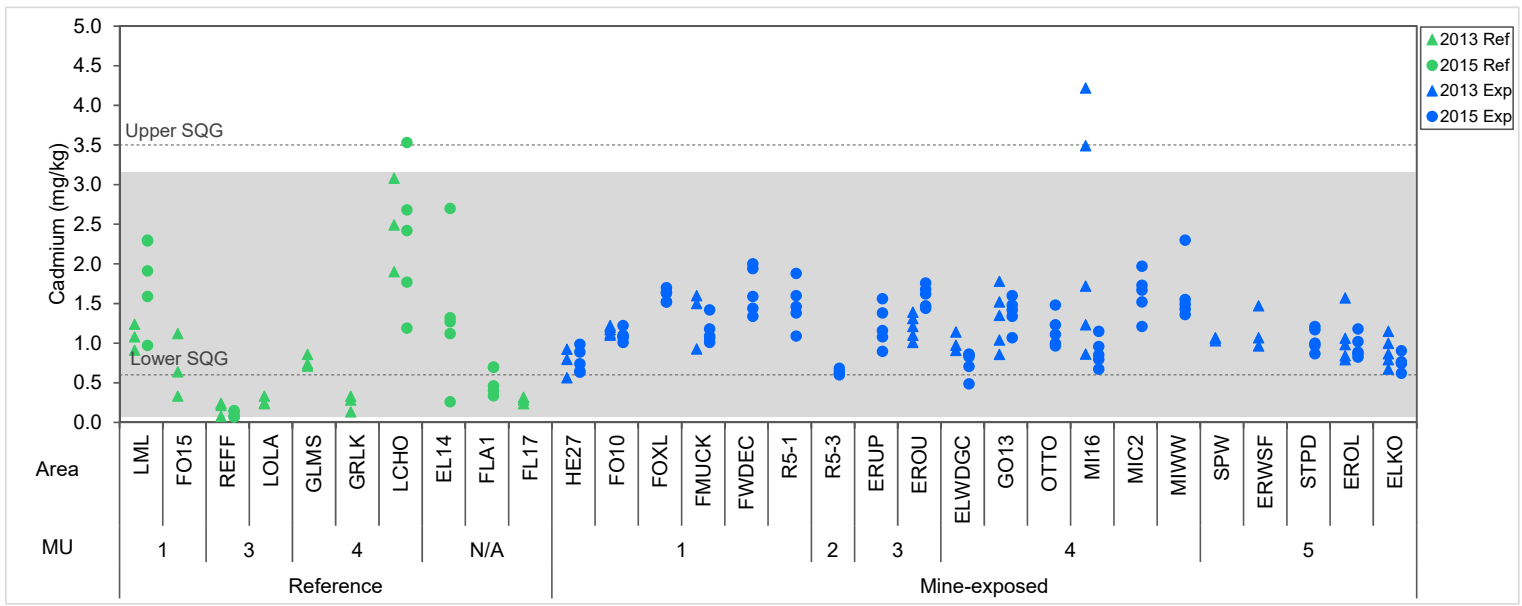
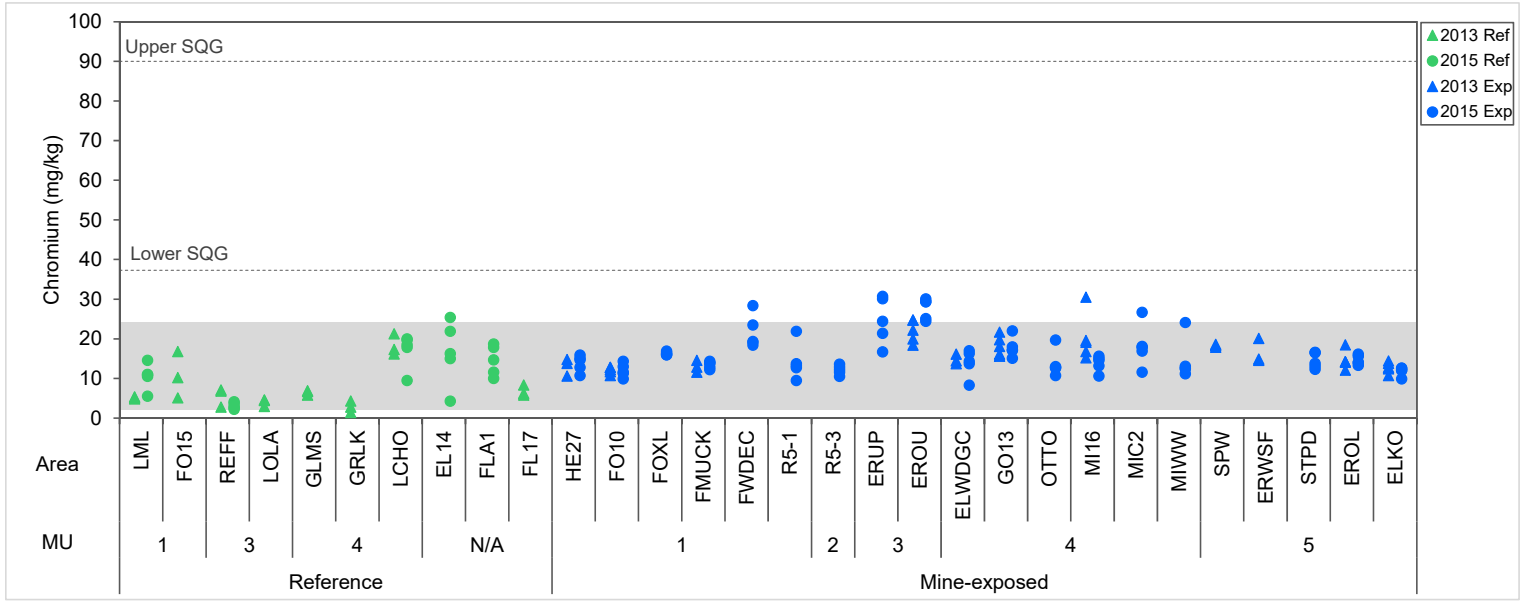
Notes: Dashed vertical lines = 2.5th and 97.5th percentiles
LSQG = Lower Sediment Quality Guideline
USQG = Upper Sediment Quality Guideline







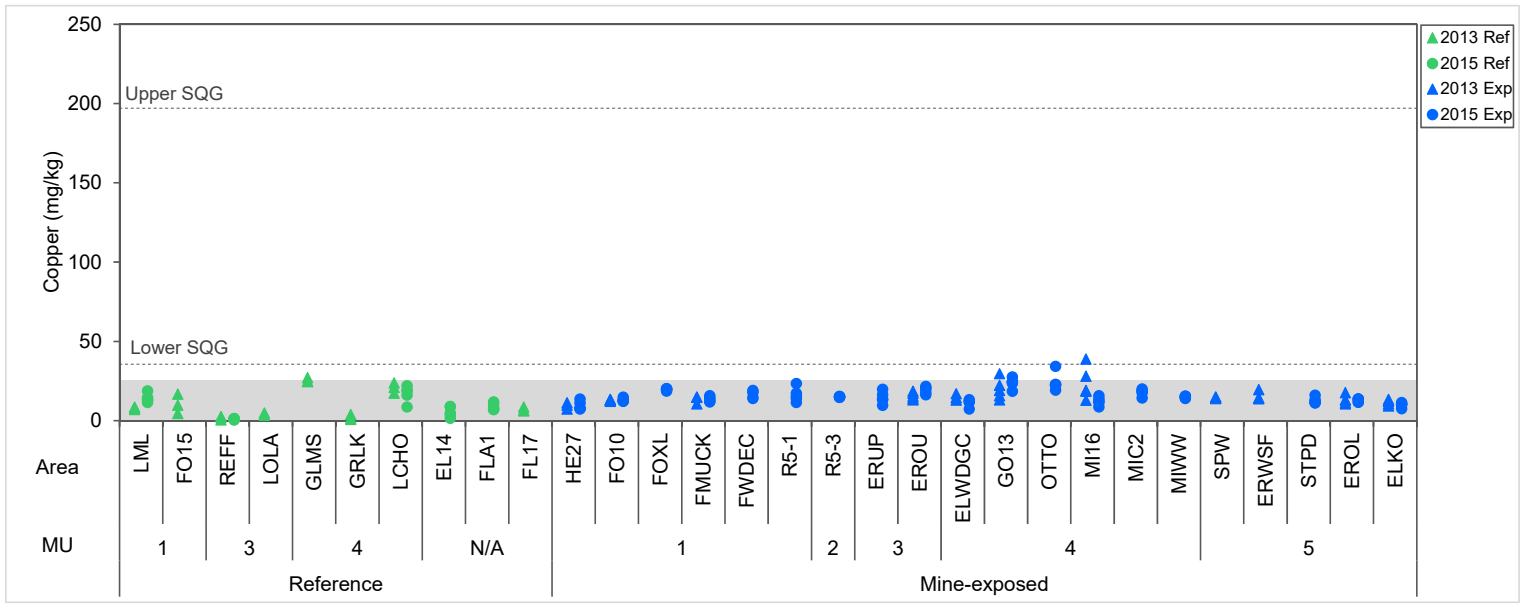


Figure E.3: Sediment Metal Concentrations Relative to BC Sediment Quality Guidelines, August 2013 and 2015

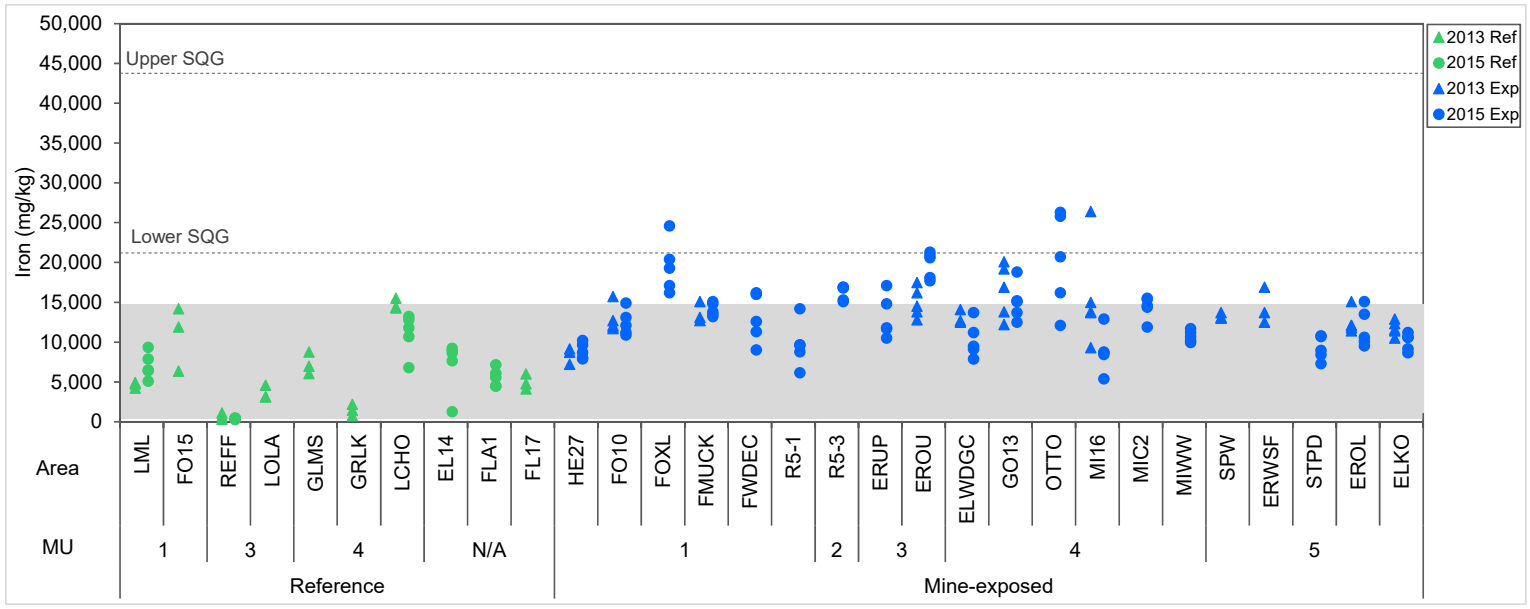
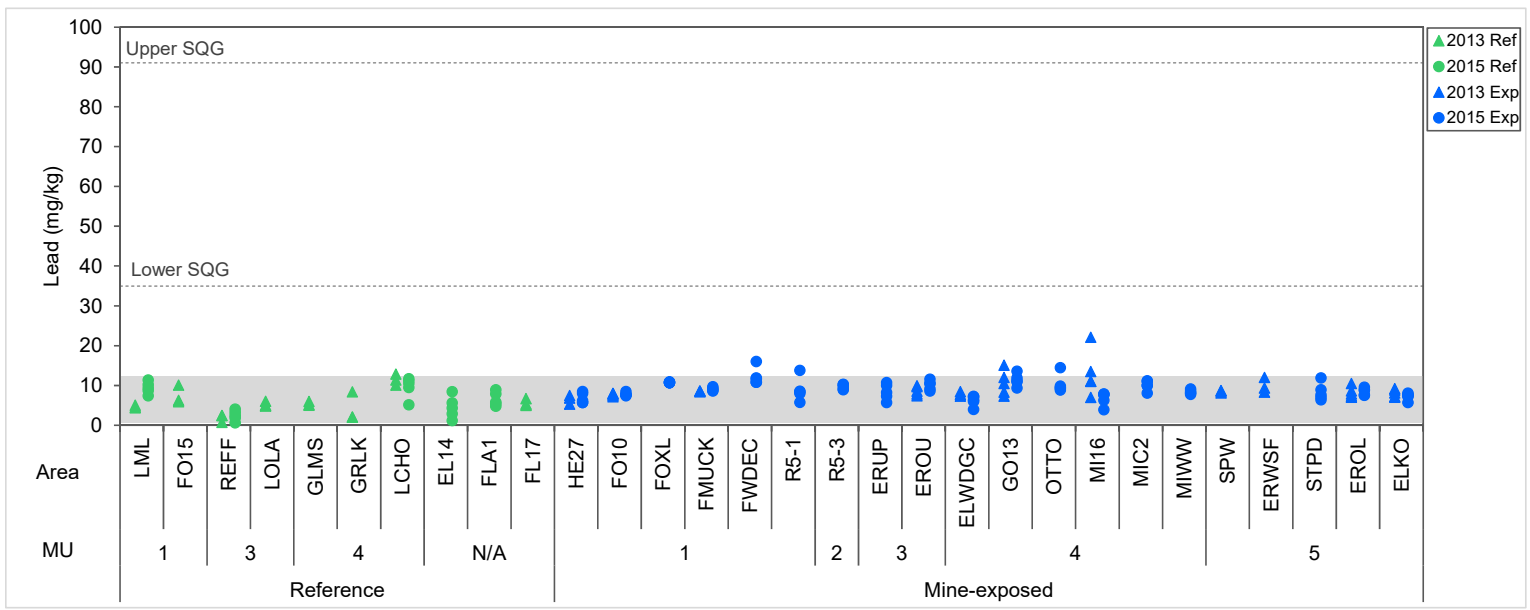
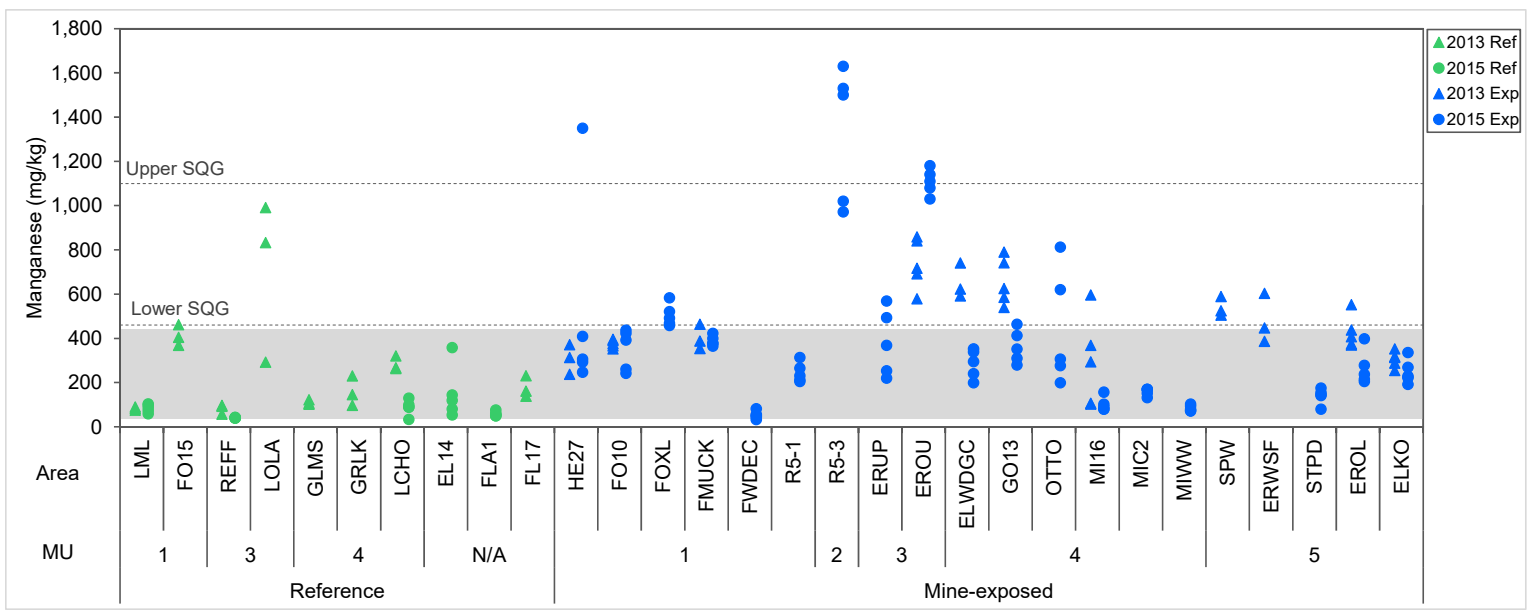
Notes: Samples areas are shown in Figure 6.1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).







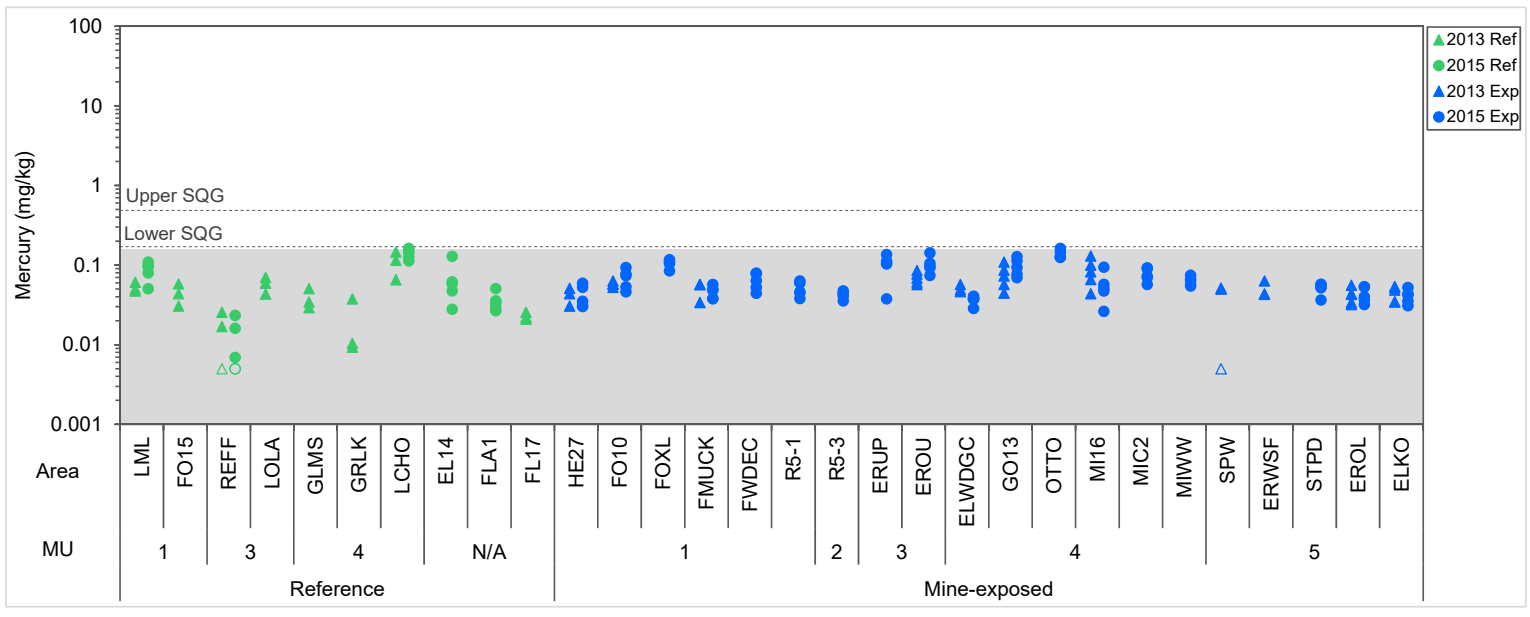


Figure E.3: Sediment Metal Concentrations Relative to BC Sediment Quality Guidelines, August 2013 and 2015

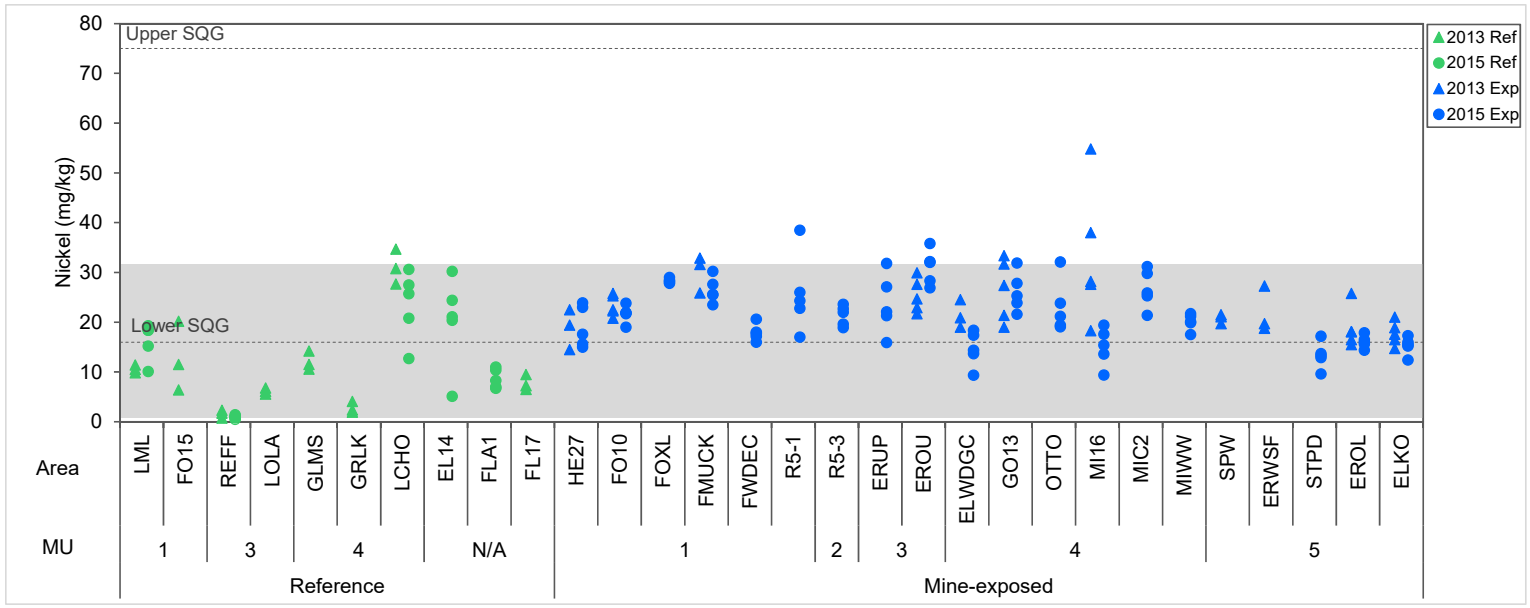
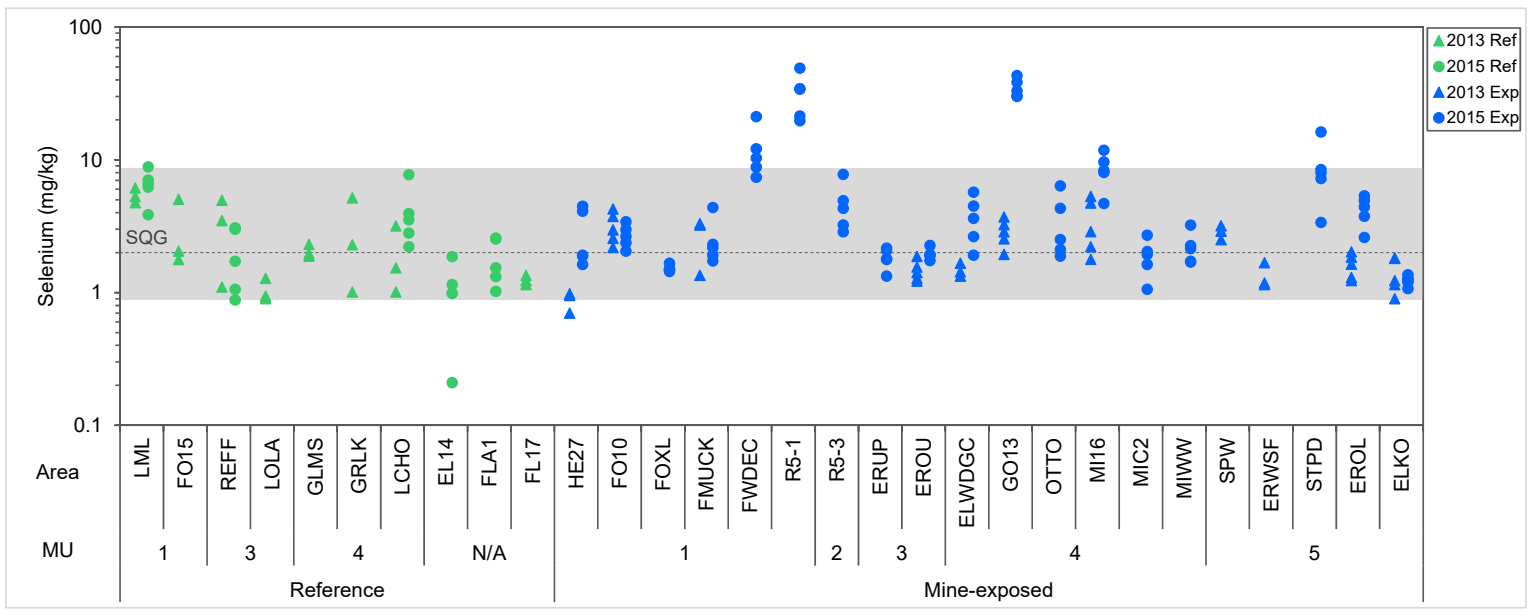
Notes: Samples areas are shown in Figure 6.1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).





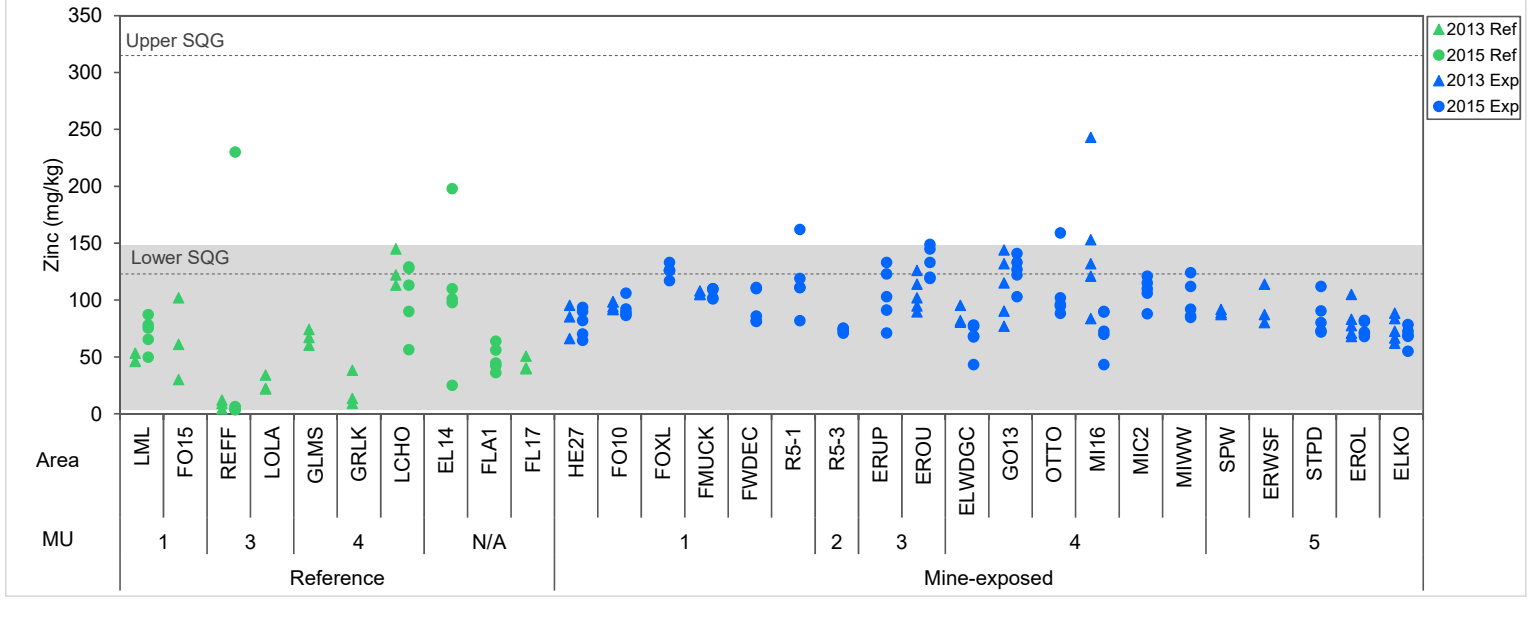


Figure E.3: Sediment Metal Concentrations Relative to BC Sediment Quality Guidelines, August 2013 and 2015

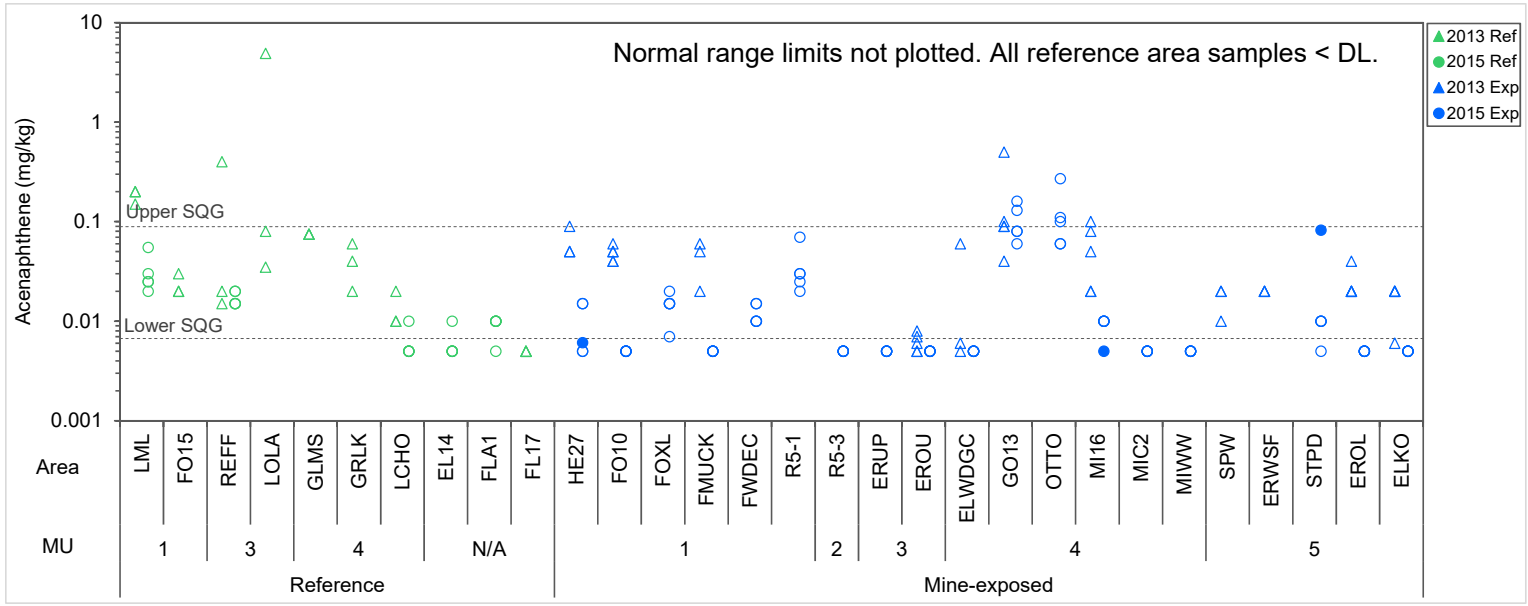
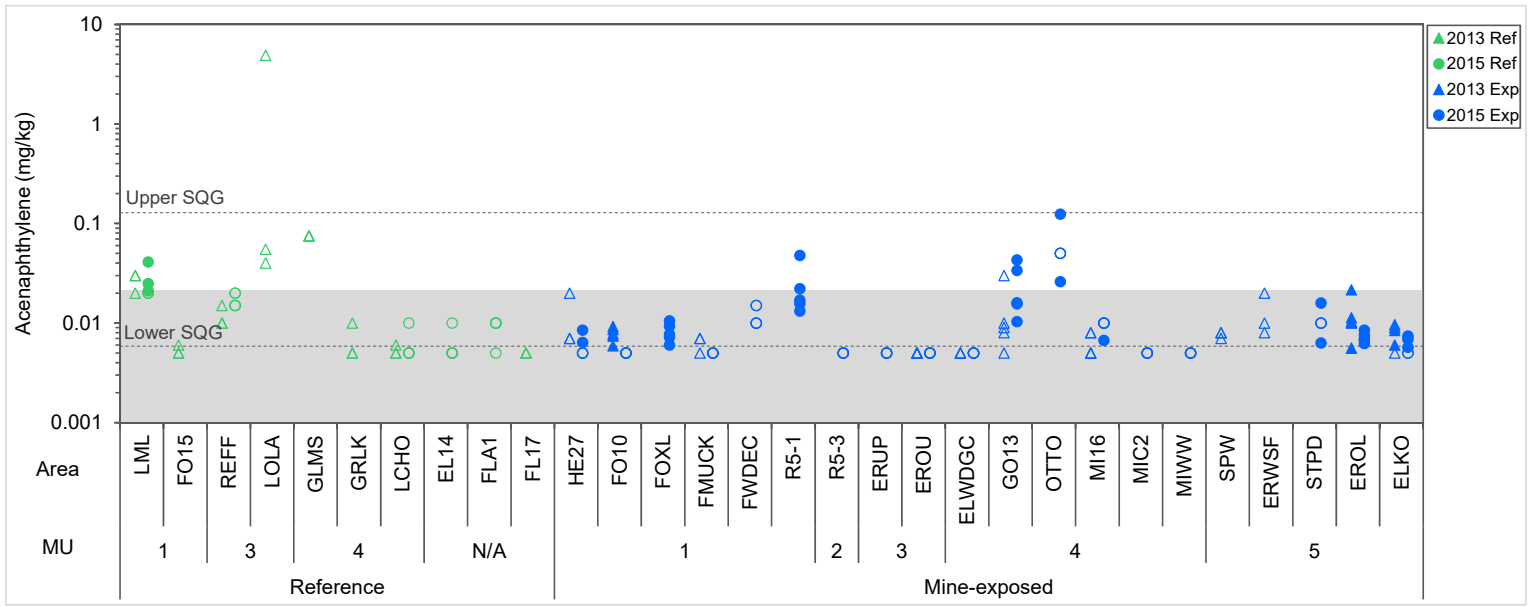
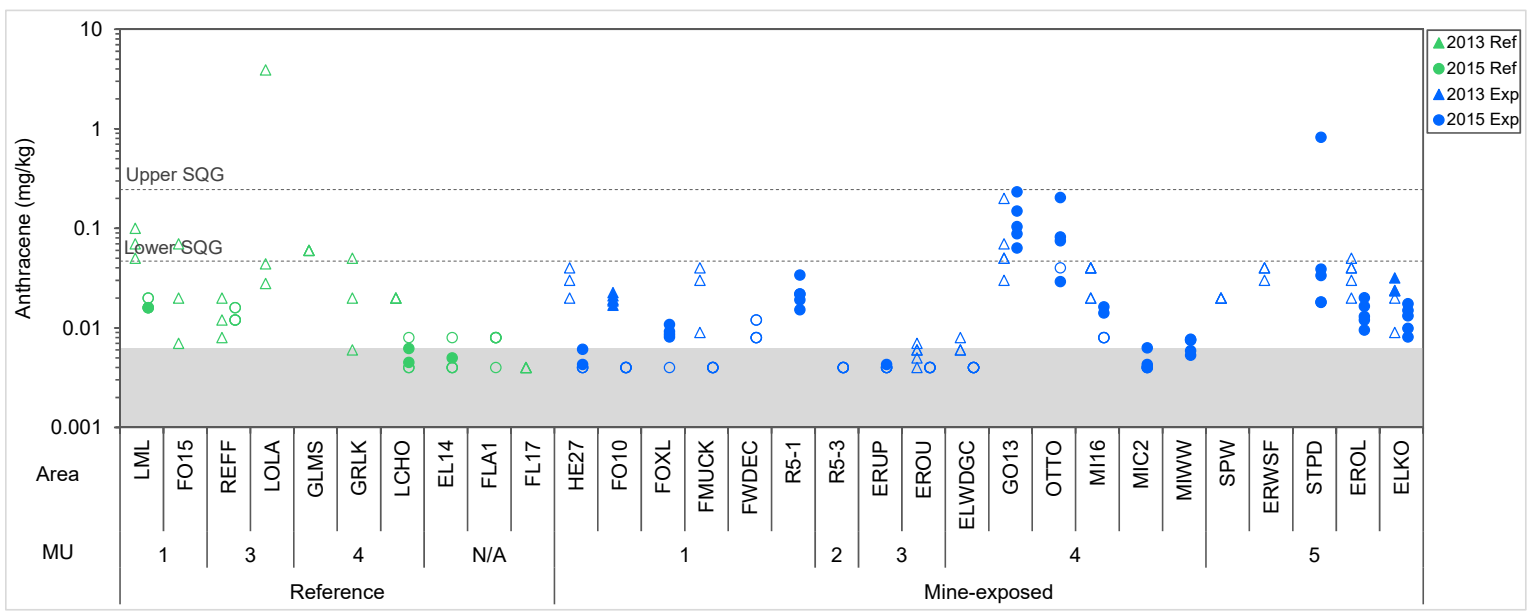
Notes: Samples areas are shown in Figure 6.1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).







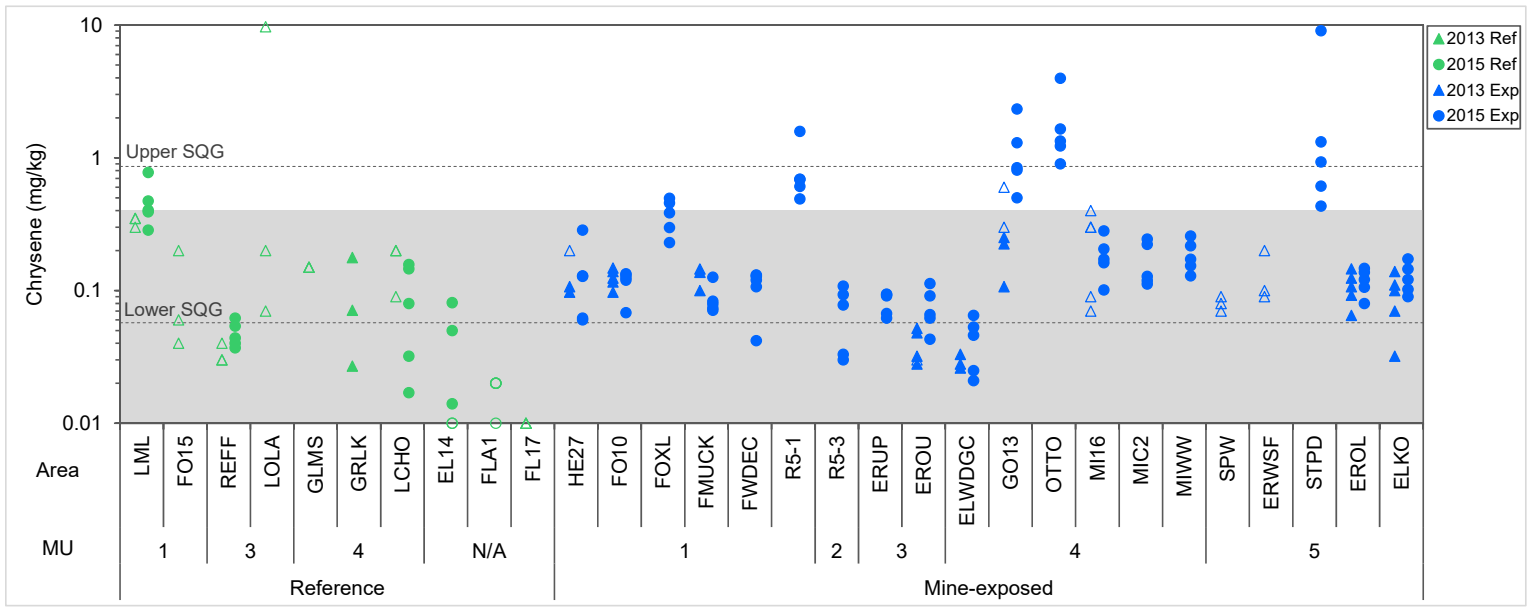


Figure E.4: Sediment Polycyclic Aromatic Hydrocarbon (PAH) Concentrations Relative to BC Sediment Quality Guidelines, August 2013 and 2015

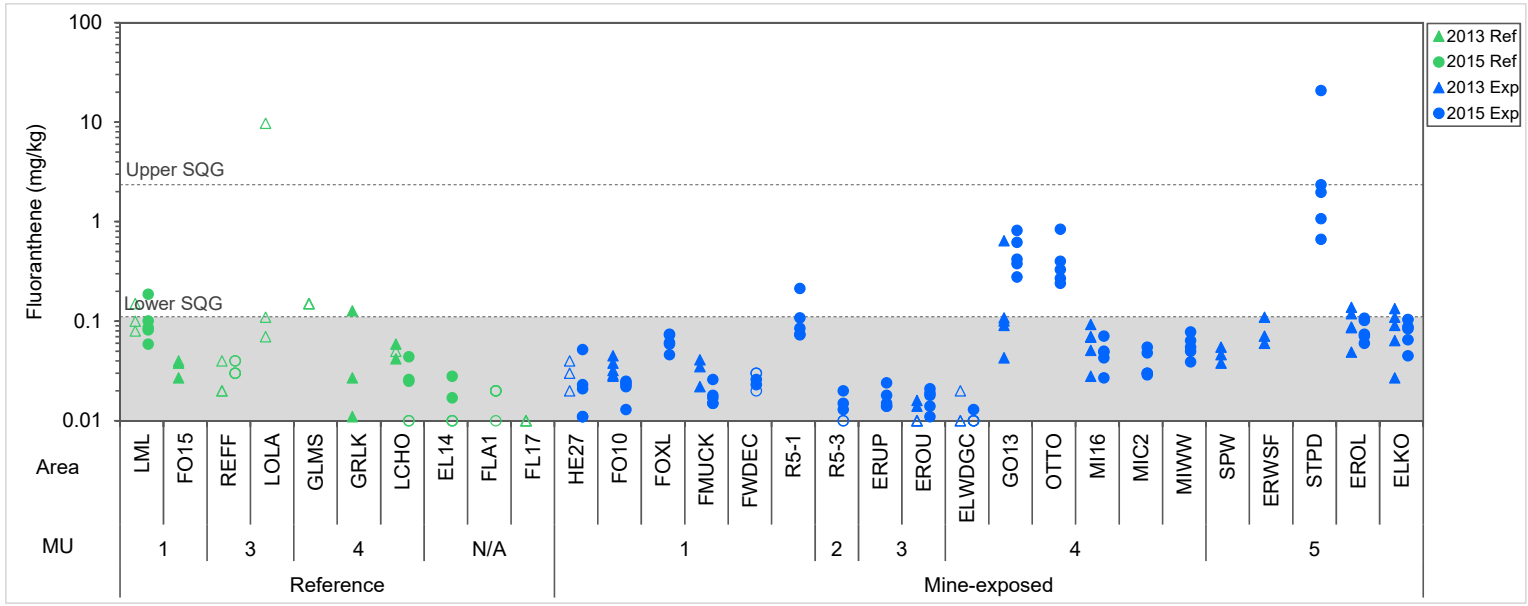
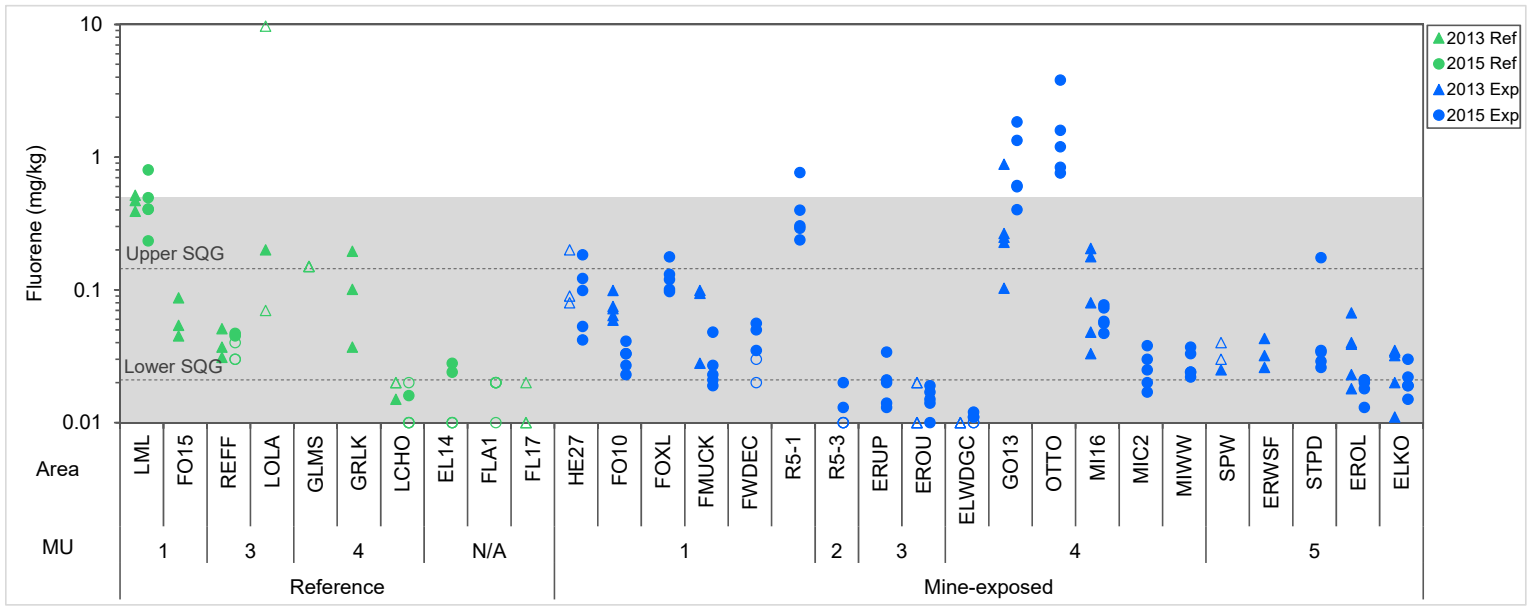
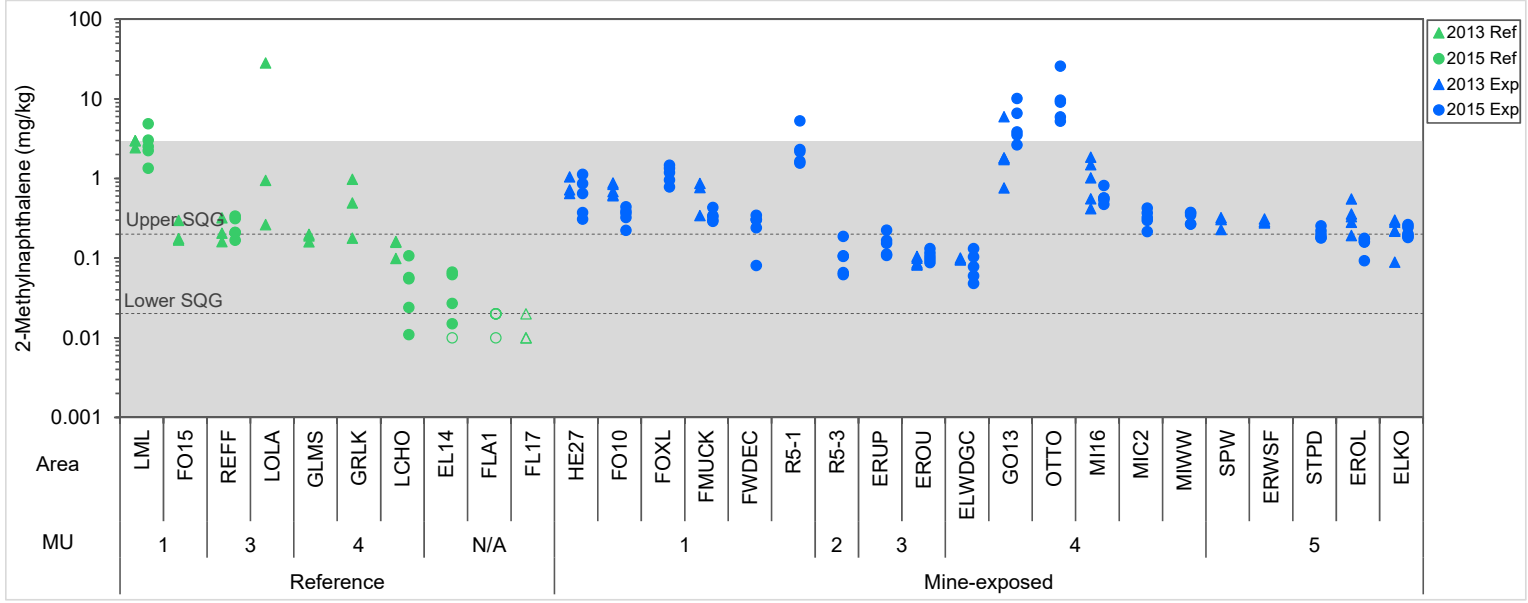
Notes: Sampling areas are shown in Figure 6.1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).







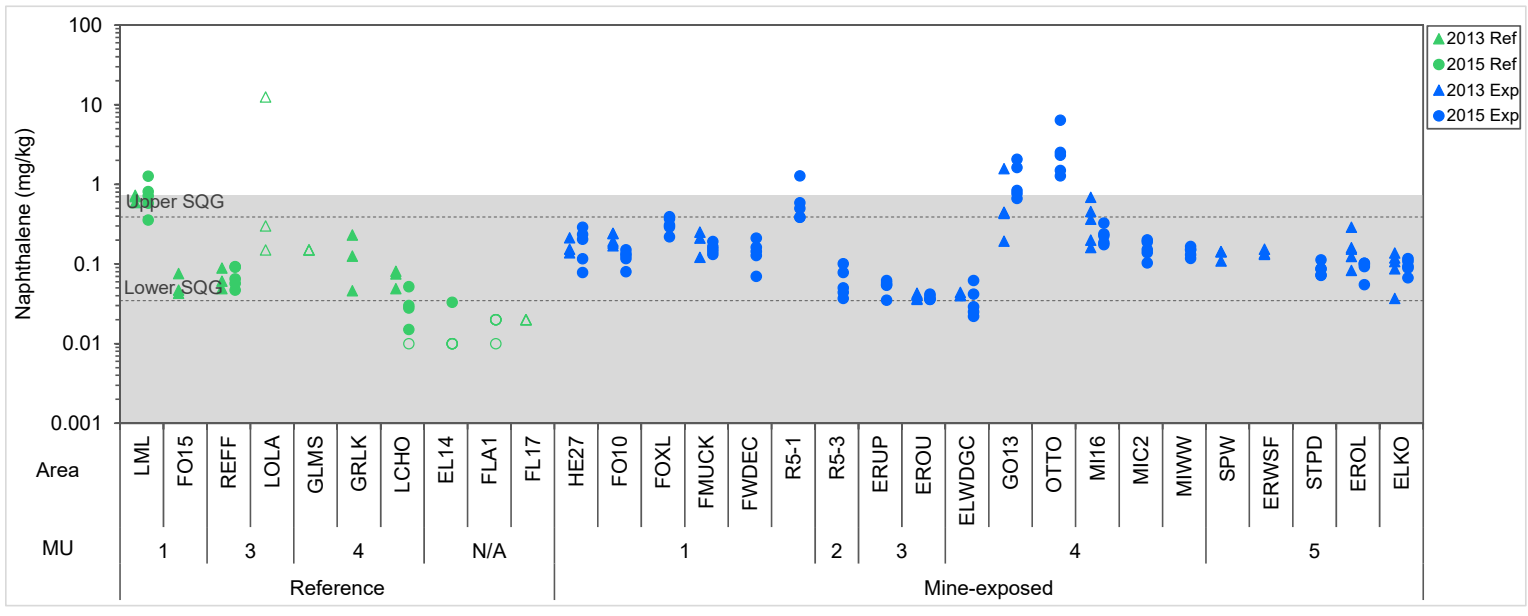


Figure E.4: Sediment Polycyclic Aromatic Hydrocarbon (PAH) Concentrations Relative to BC Sediment Quality Guidelines, August 2013 and 2015

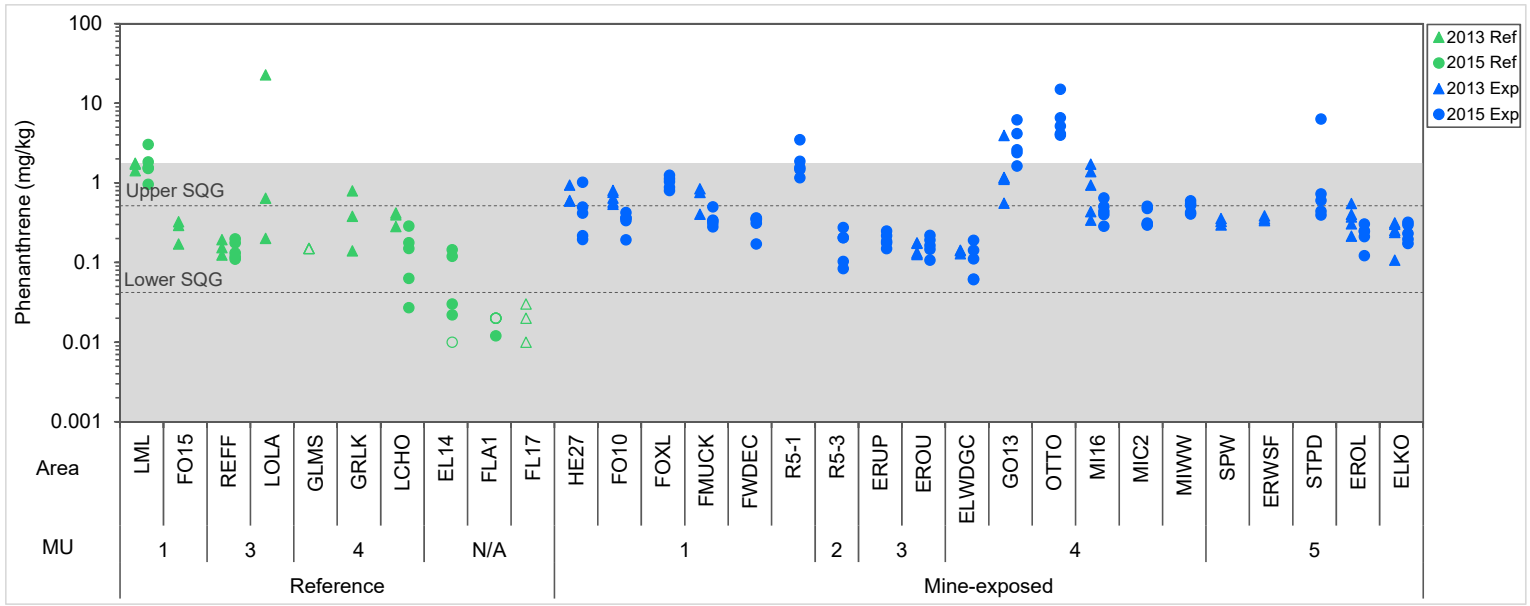
Notes: Sampling areas are shown in Figure 6.1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).



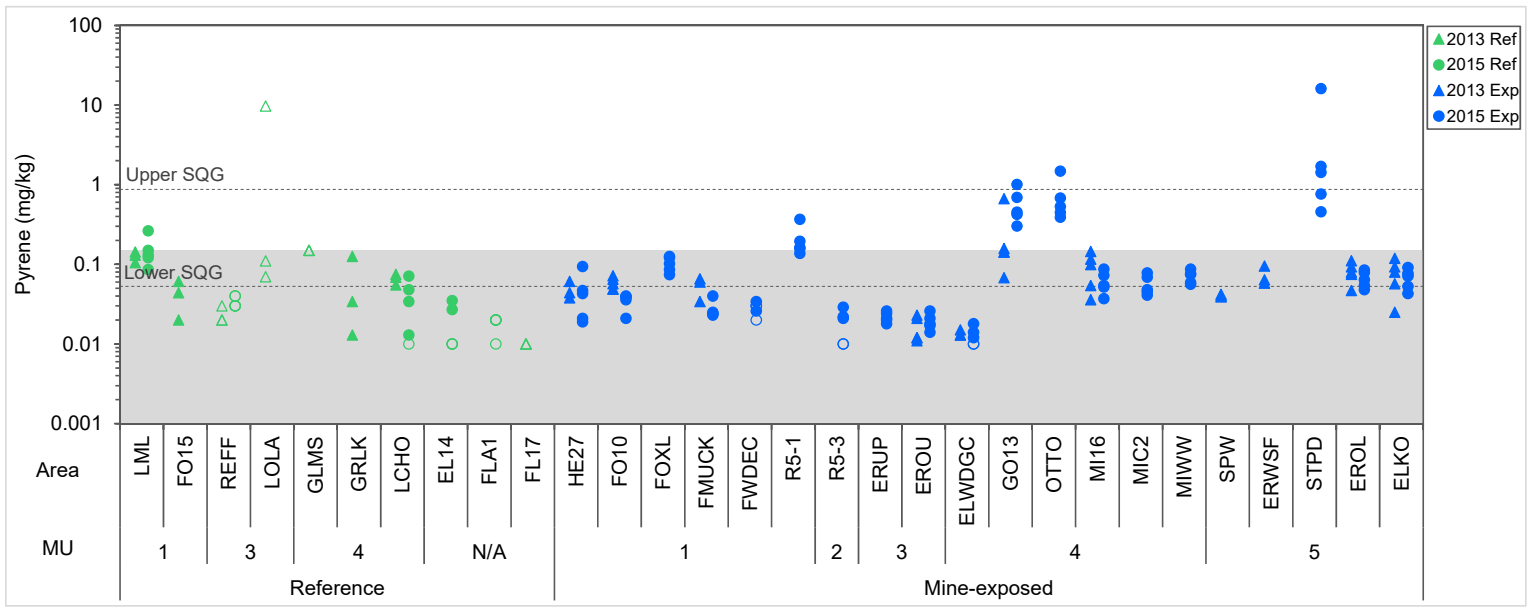


Figure E.4: Sediment Polycyclic Aromatic Hydrocarbon (PAH) Concentrations Relative to BC Sediment Quality Guidelines, August 2013 and 2015

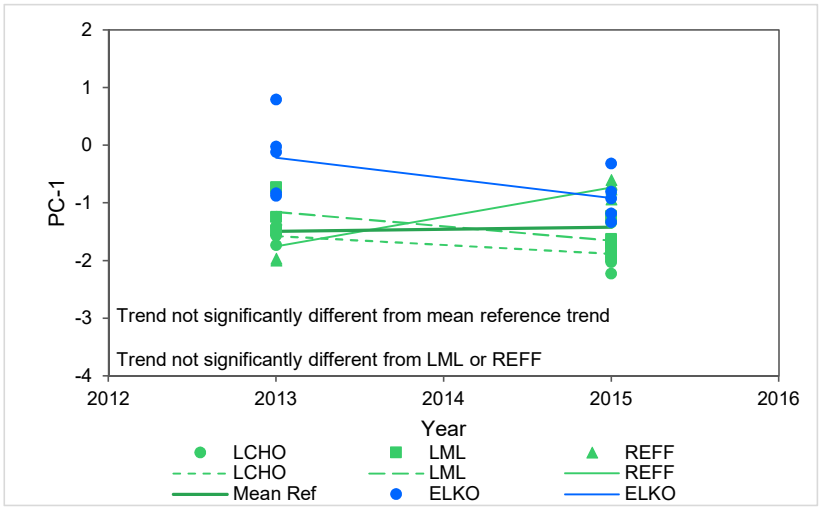
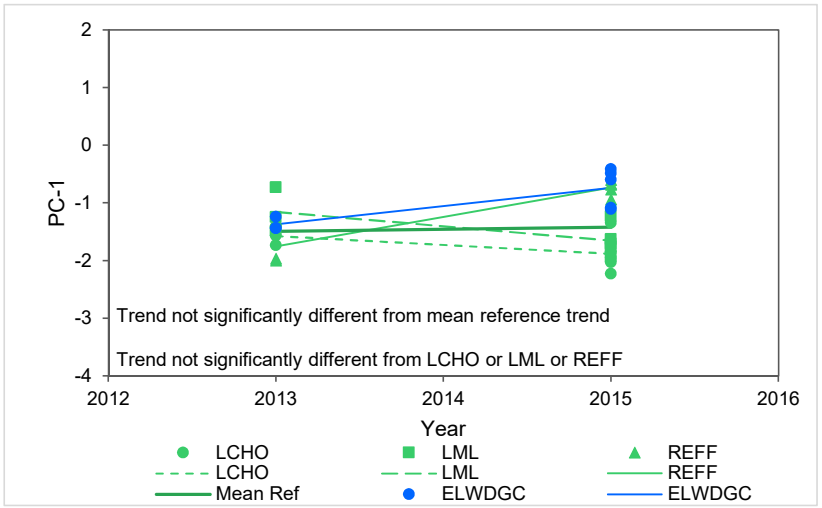
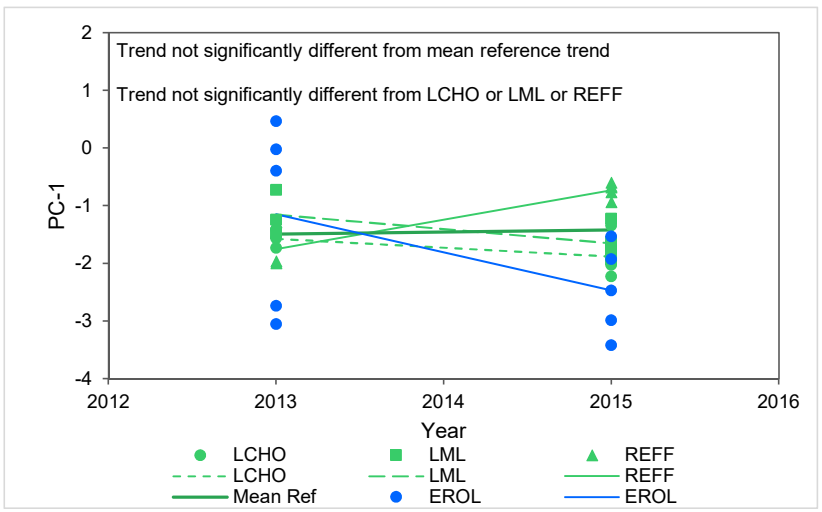
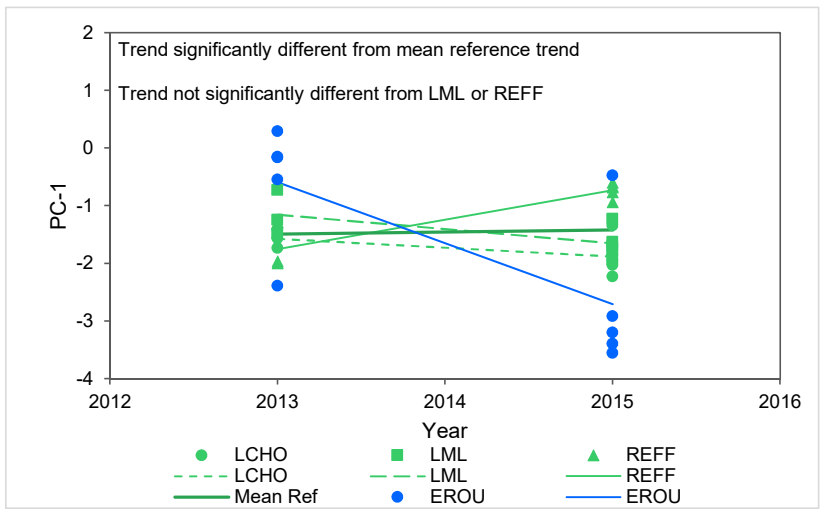
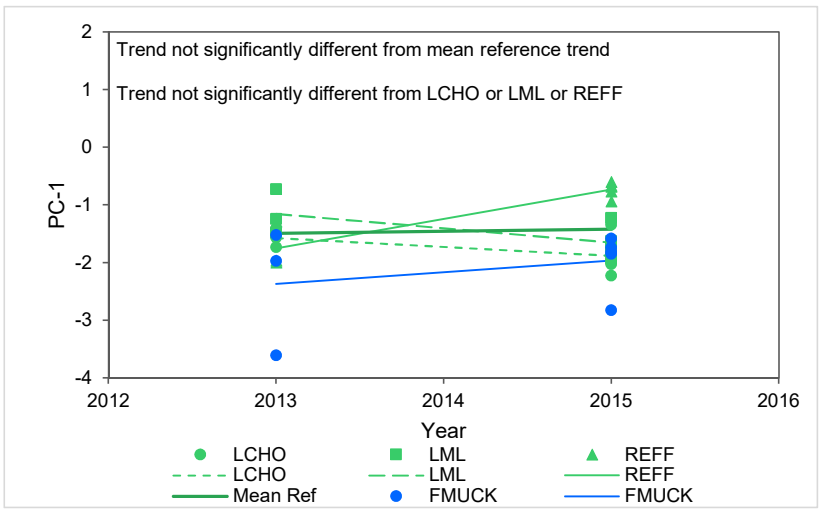
Notes: Sampling areas are shown in Figure 6.1. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Shading represents the normal range (2.5th and 97.5th percentiles of the pooled 2013 and 2015 reference area distribution after removal of outliers).

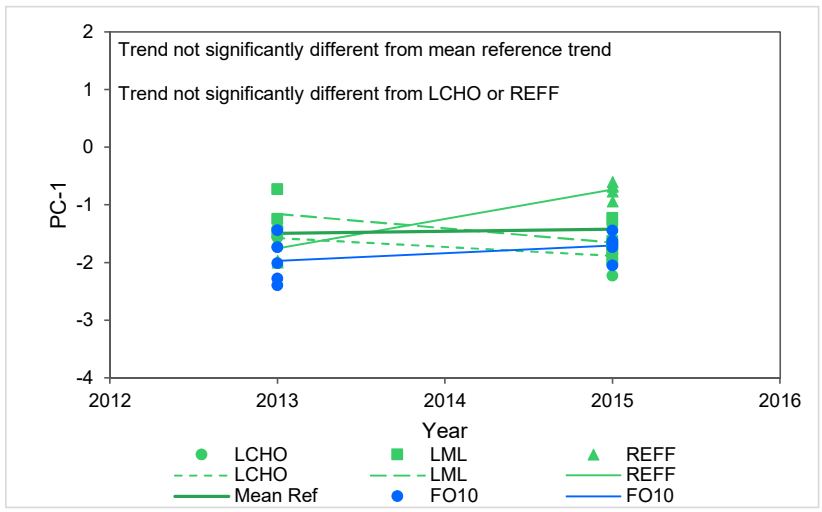


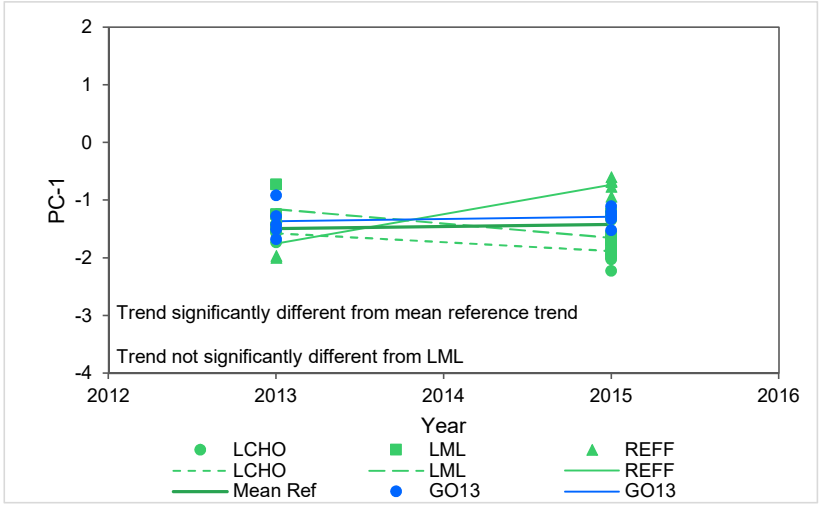


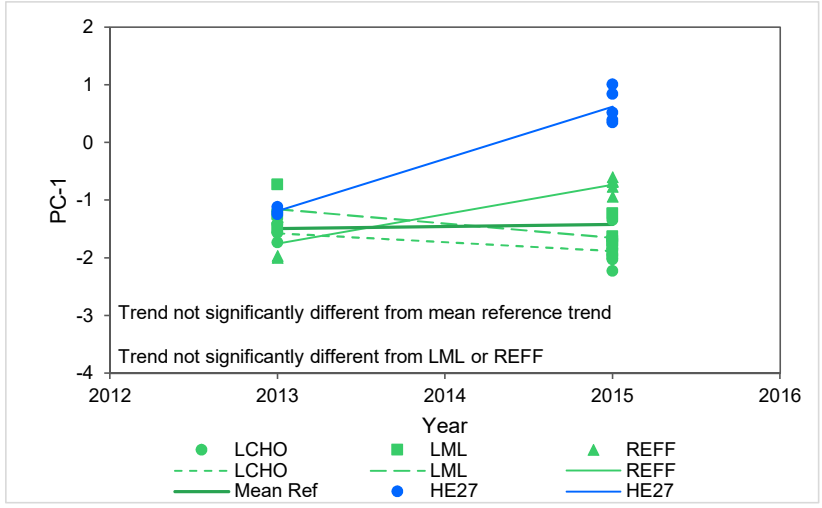












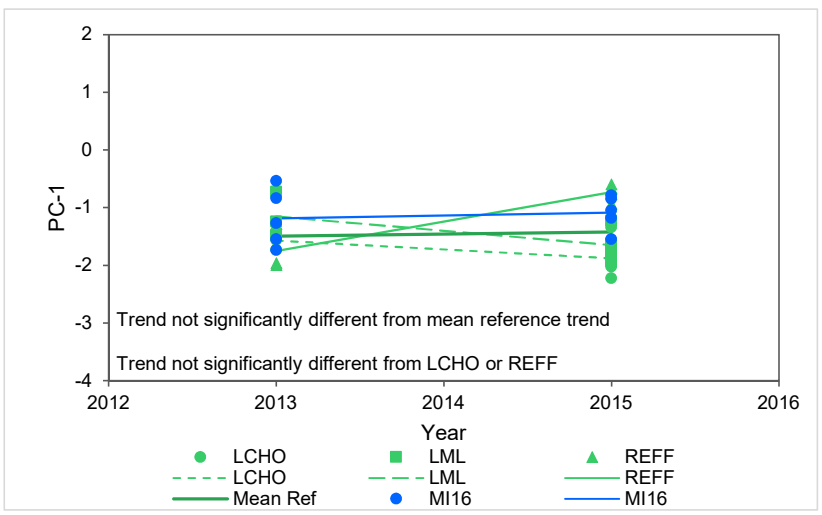


Figure E.5: Scatterplot of Principle Component 1 (PC-1) from a PCA of Metals and PAH Concentrations in Sediment for Reference Areas (LCHO, LML, and REFF) and Each Mine-exposed Area in 2013 and 2015

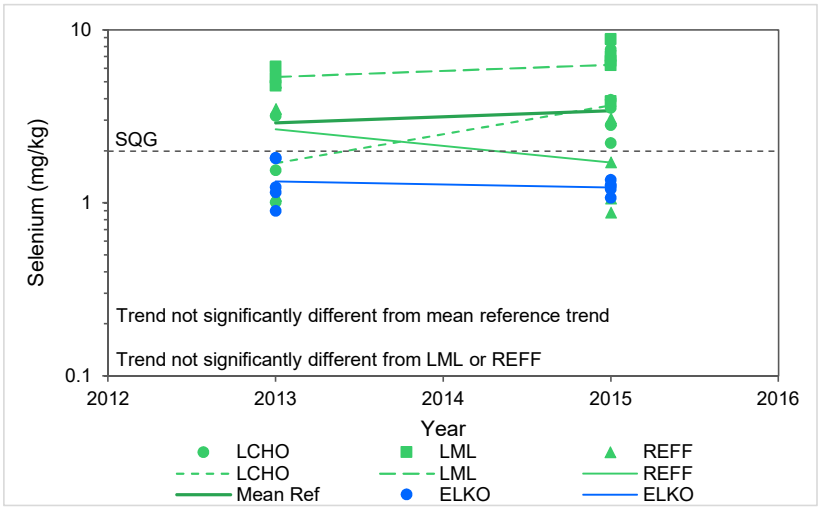

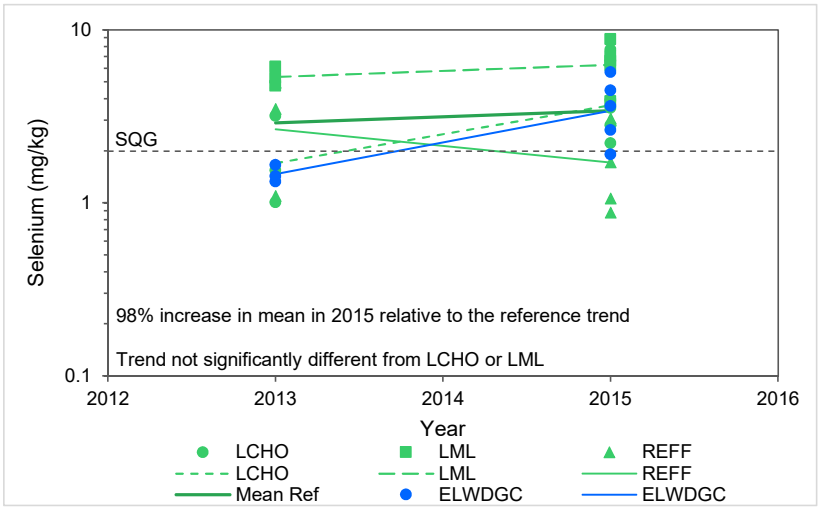

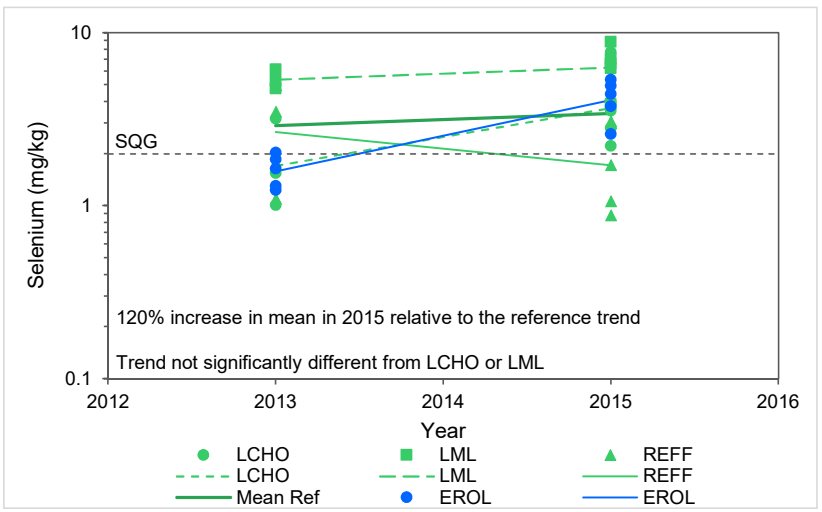

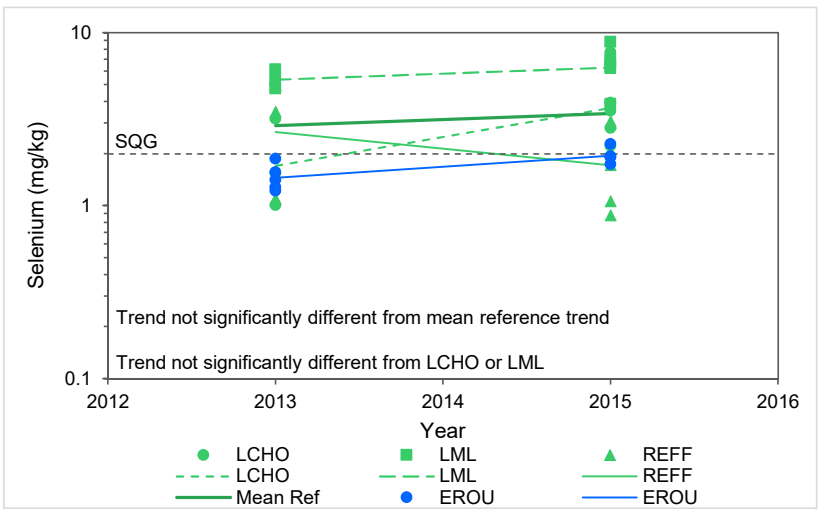

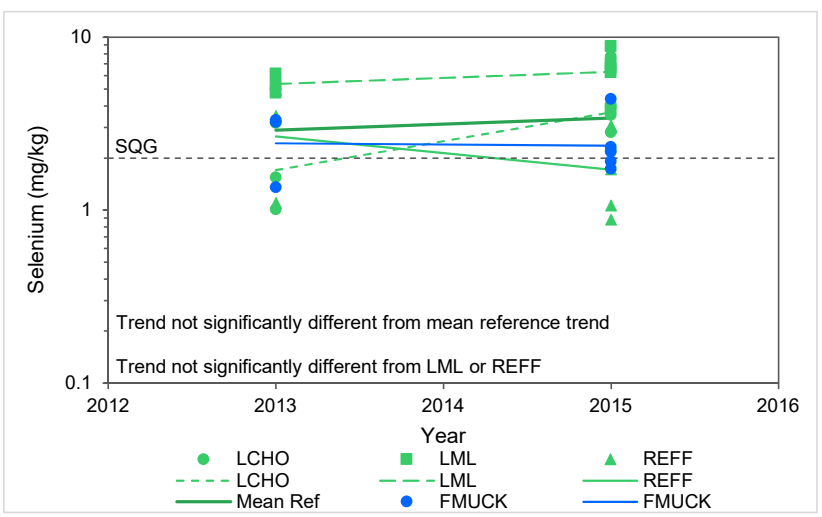

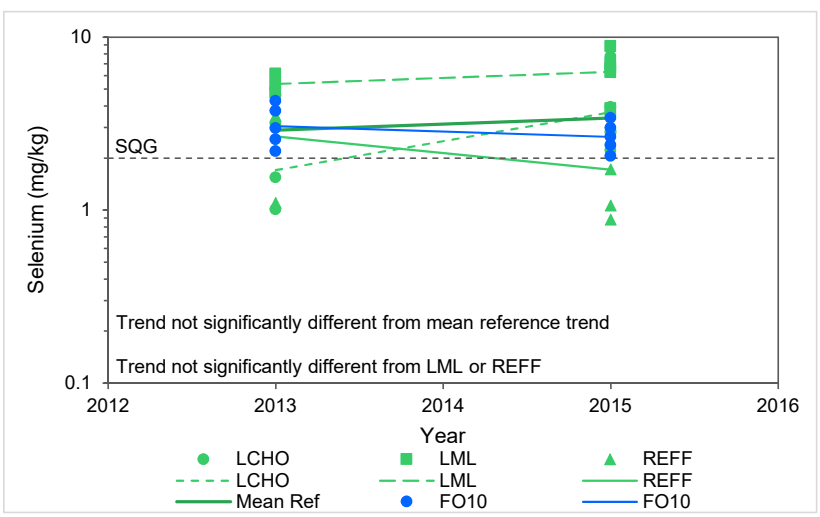

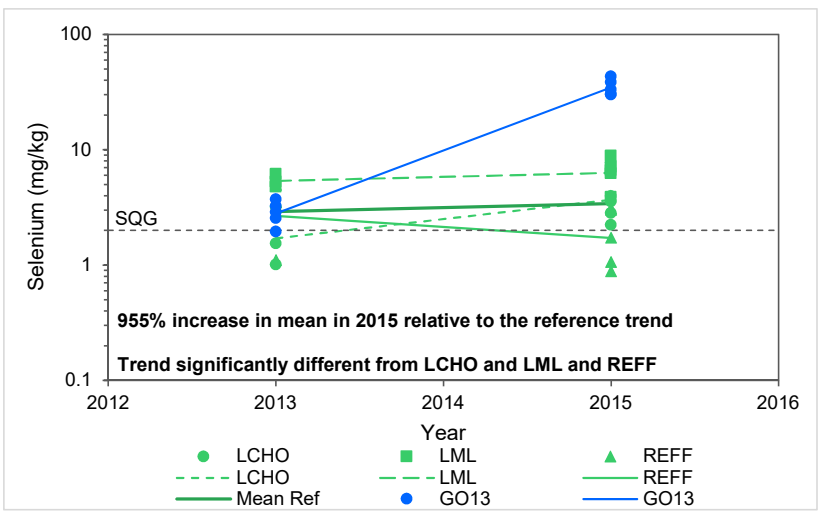

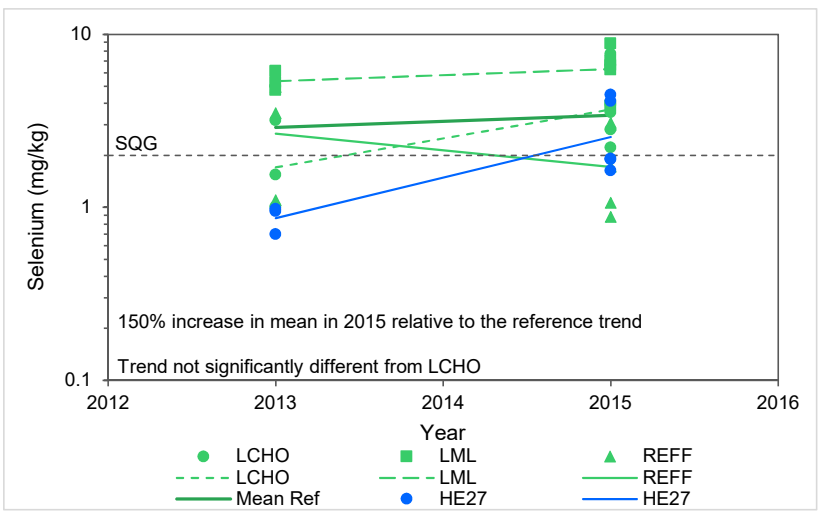

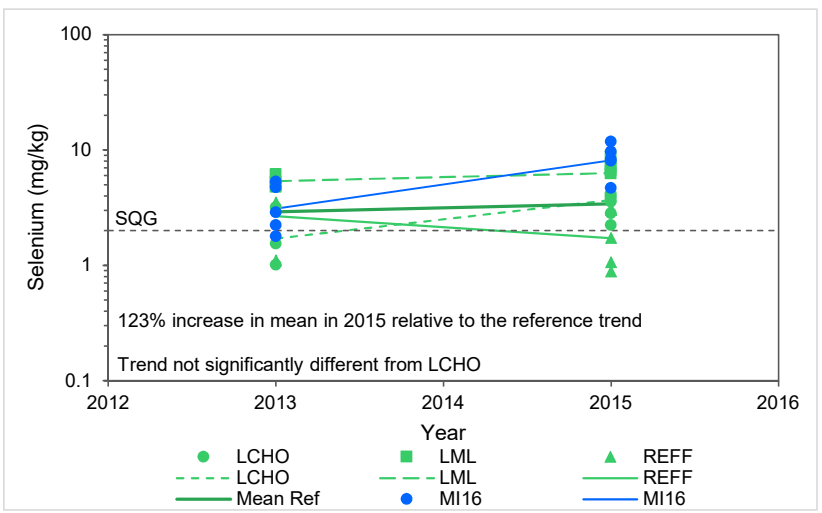

Figure E.6: Scatterplot of Concentrations of Selenium in Sediment for Reference Areas (LCHO, LML, and REFF) and Each Mine-exposed Area in 2013 and 2015

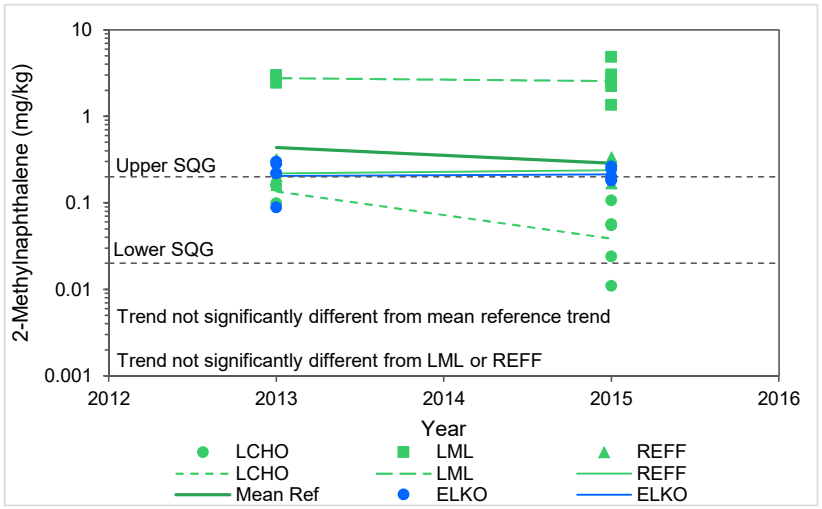

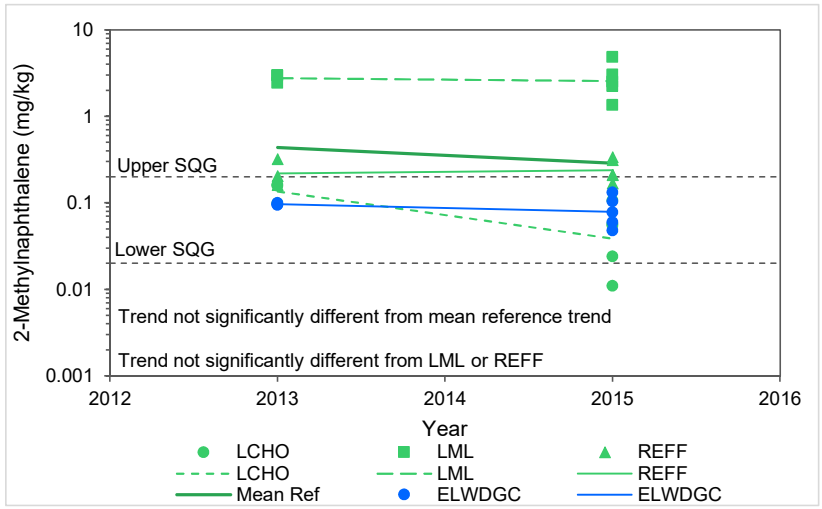

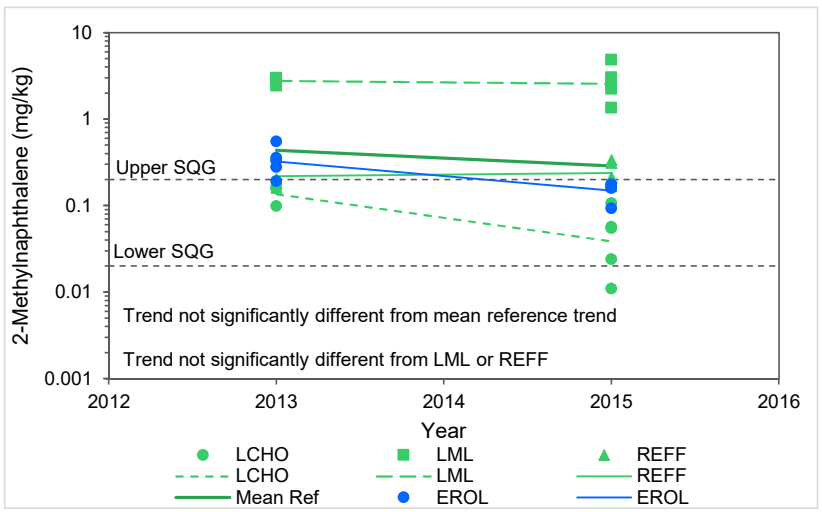

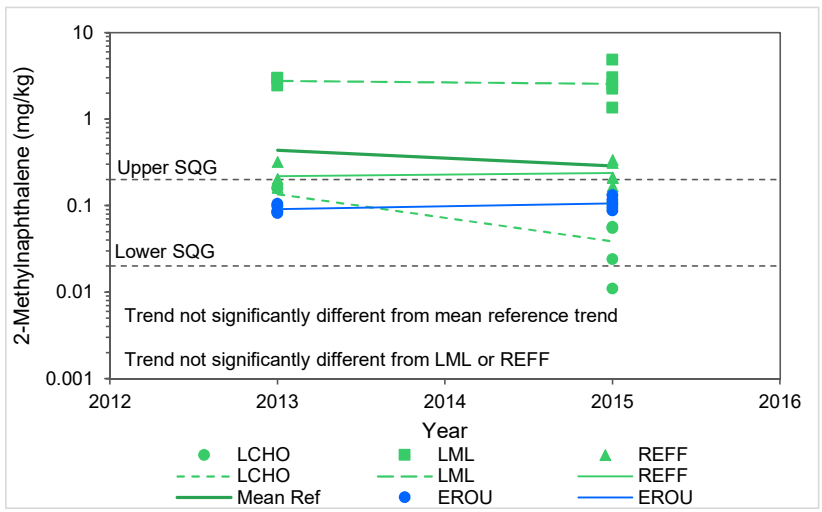

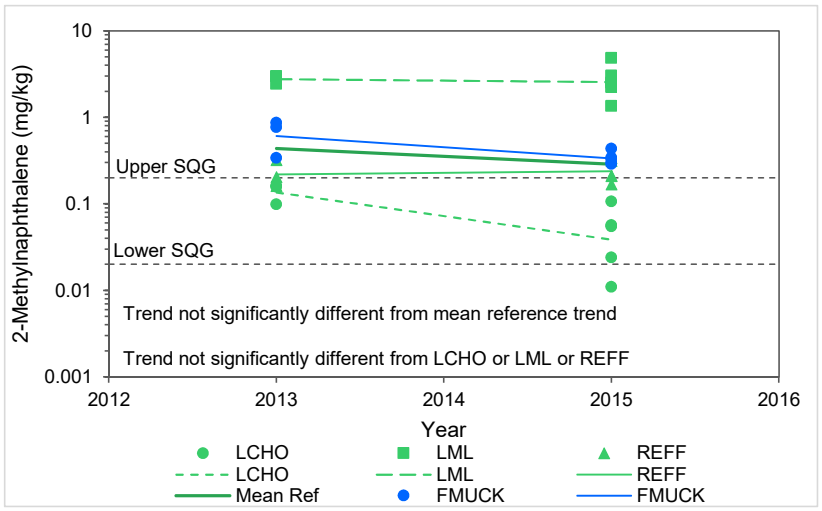

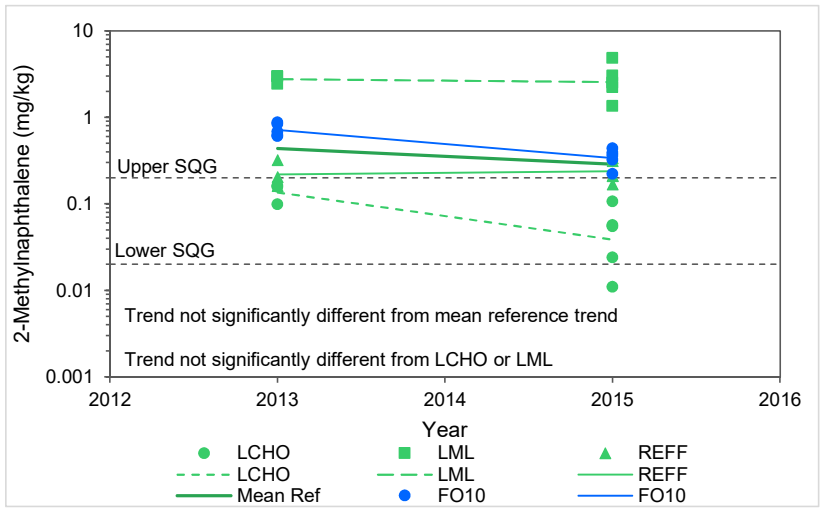

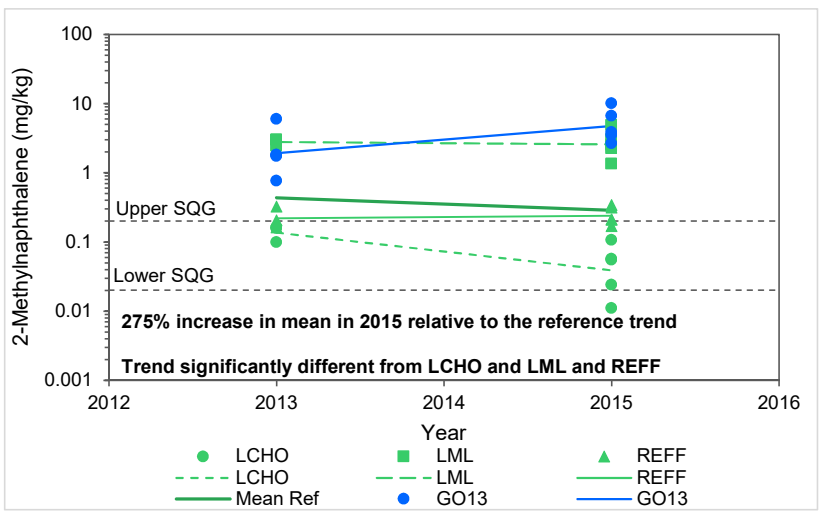

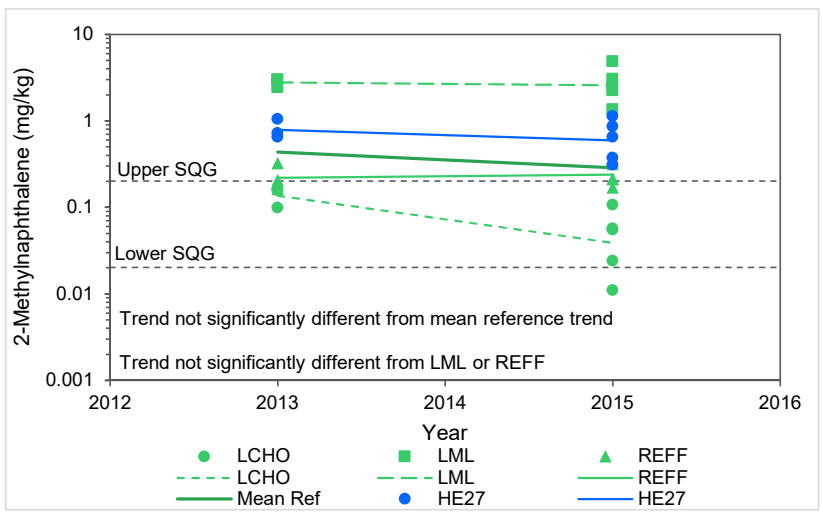

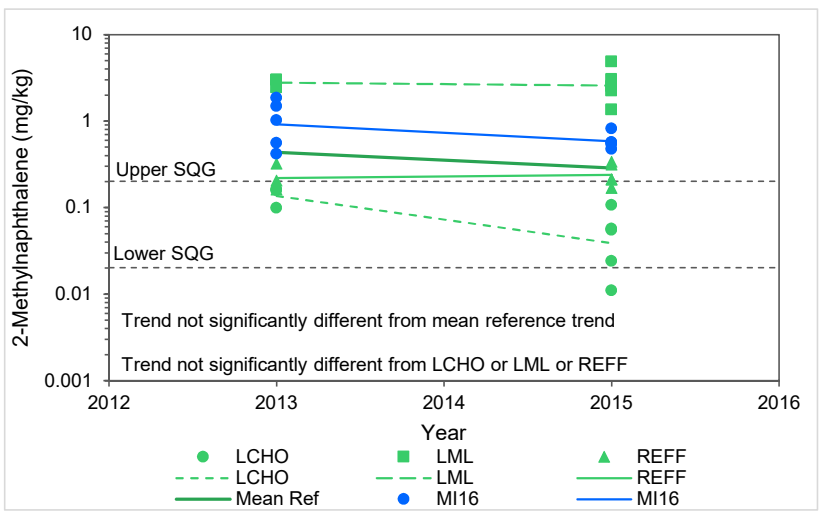

Figure E.7: Scatterplot of Concentrations of 2-Methylnaphthalene in Sediment for Reference Areas (LCHO, LML, and REFF) and Each Mine-exposed Area in 2013 and 2015

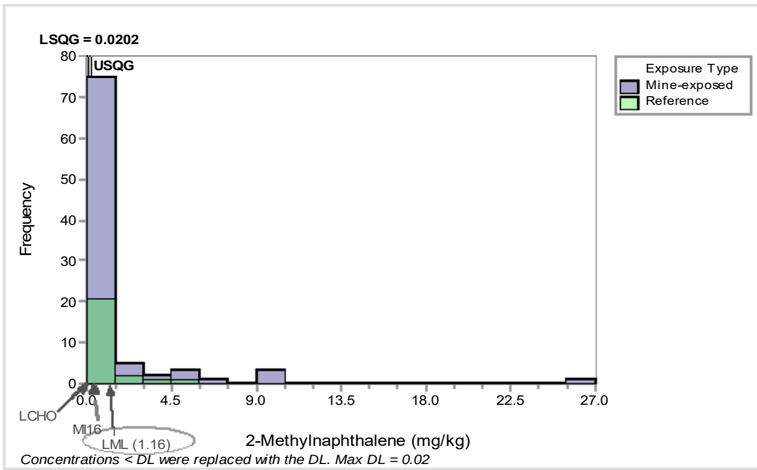

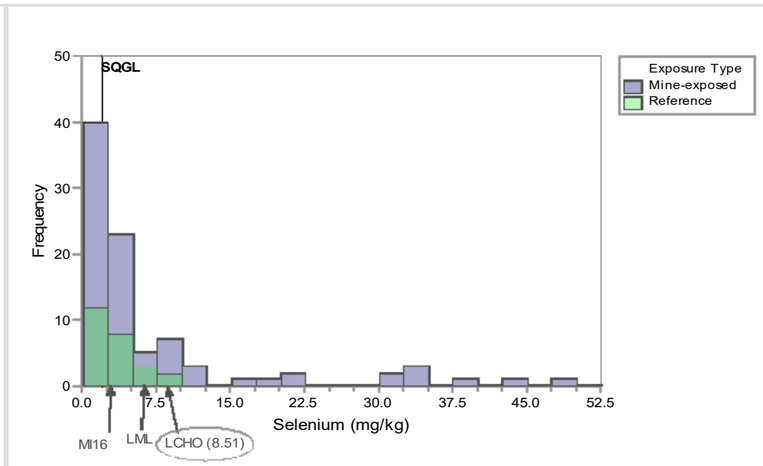

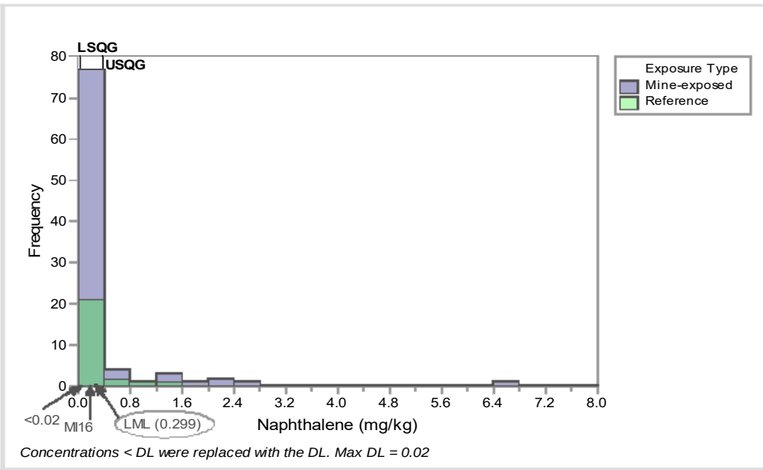

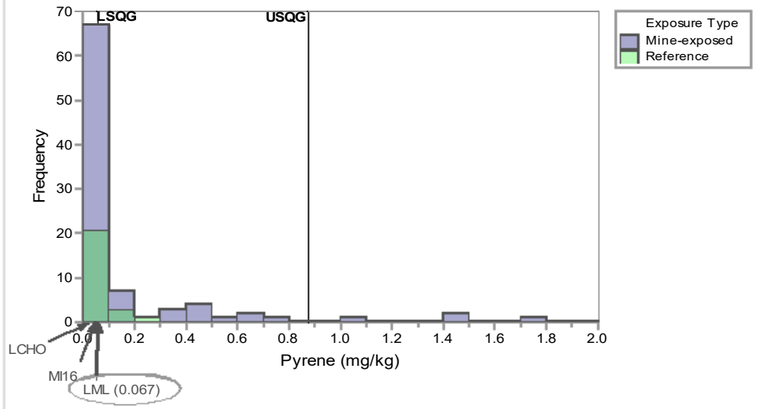

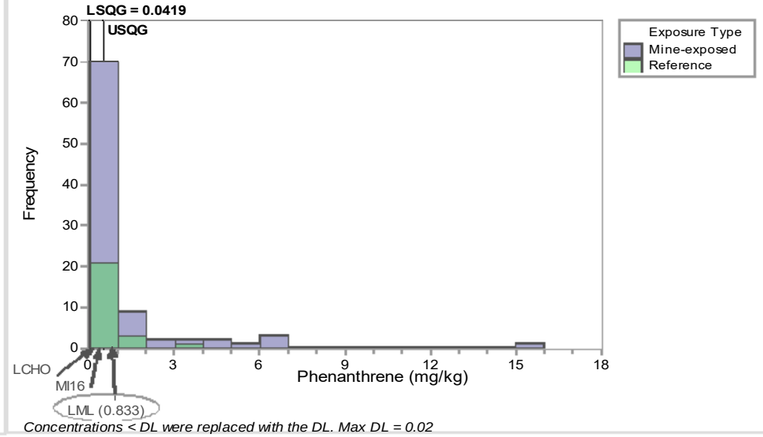

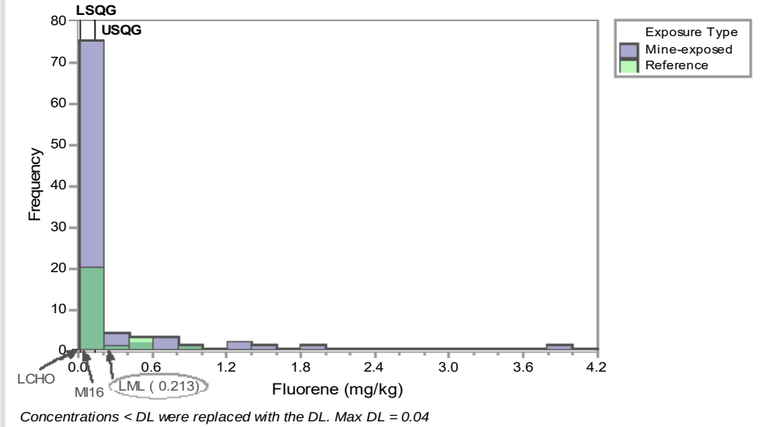

Figure E.8: Histograms of Concentrations of Selenium and 5 PAHs in Sediment Samples Collected from Reference and Mine-exposed Areas for the REAMP, August 2015

Notes: Grey labels depict areas that showed no toxicity in the sediment toxicity testing conducted in September 2015. Grey circles depict the highest non-toxic concentration (See Appendix Table E.17).
LCHO and LML are reference areas and MI16, R5-1, GO13, OTTO, and STPD are mine-exposed areas.

Table E.1: Areas Sampled for Sediment Chemistry in August 2013 and/or August 2015

Exposure Type	Manage-ment Unit	Monitoring Area Code	Stream Name	UTM (NAD 83, 11U)		Sampling Method	Rationale for 2015 Sampling
				Easting	Northing		
Reference	1	LML	Lake Mountain Lake	650106	5565031	Corer	Previously sampled for sediment in 2013 with high PAH concentrations.
		FO15	Fording River Wetland	654807	5542584	Ponar	Sampled in 2013 only.
	3	REFF	Unnamed Wetland near Elk River north of Elkford	645869	5556297	Corer	Proposed reference area for LSU. Area used by amphibians. Previously sampled for sediment in 2013.
		LOLA	Lost Lake	650934	5542536	Corer	Sampled in 2013 only.
	4	GLMS	Grave Lake Marsh	654720	5525553	Corer	Sampled in 2013 only.
		GRLK	Grave Lake	655563	5525690	Corer	Sampled in 2013 only.
		LCHO	Leach Creek Oxbow	658746	5489172	Ponar	Previously sampled for sediment in 2013. Some elevated metal concentrations observed.
	Not Applicable	EL14	Elk Lakes	635321	5601878	Corer	Commonly used reference area for WCT that was inaccessible in 2013 due to flood/washed out road.
		FLA1	Flathead Side Channel	681815	5443615	Corer	Proposed reference area for LSU. Not previously sampled for sediment.
		FL17	Flathead Pond	681226	5440716	Corer	Sampled in 2013 only.
Mine-exposed	1	HE27	Henretta Lake	652573	5566275	Corer	Area used by WCT for overwintering. Previously sampled for sediment in 2013.
		FO10	Fording River Oxbow	654209	5555290	Corer	Area used by WCT and SPSA. Previously sampled for sediment in 2013.
		FOXL	Lower Fording River Oxbow	654878	5554437	Corer	Oxbow previously isolated from Fording River (very low Se in water and BI in 2012). May have changed after flood. Not previously sampled for sediment.
		FMUCK	Meadow area u/s Chauncey Creek	654771	5553328	Corer	Overwintering area for WCT. Previously sampled for sediment in 2013.
		FWDEC	Fording River wetland d/s Ewin Creek	656896	5547095	Corer	Extensive lentic area not previously sampled for sediment or biota
		R5-1	Off channel area of Fording d/s Greenhills	653010	5545714	Corer	Larger area with elevated selenium concentrations in invertebrates. Not previously sampled for sediment.
	2	R5-3	Lentic area off Fording River d/s Josephine Falls	652358	5539932	Corer	Larger area with elevated selenium concentrations in water and invertebrates. Not previously sampled for sediment.
	3	ERUP	Elk River Upper Ponds	651742	5530538	Ponar	Area used by fish. Proposed LSU sampling area downstream of FRO and GHO. Not previously sampled for sediment.
		EROU	Upper Elk River Oxbow	652364	5529872	Corer	Area used by fish. Alternative to ERUP for LSU sampling. Previously sampled for sediment in 2013.
	4	ELWDGC	Elk River Wetland Downstream of Grave Creek	653175	5521300	Corer	Area used by amphibians. Proposed LSU sampling area downstream of FRO, GHO and EVO (if LSU present). Previously sampled for sediment in 2013.
		GO13	Goddard Marsh	652955	5514065	Corer	Area used by fish,amphibians and RWBL. Proposed LSU sampling area downstream of EVO. Previously sampled for sediment in 2013 with potential toxicity to *Chironomus riparius* noted.
		OTTO	Otto Creek	652537	5512801	Corer	Area used by fish, amphibians and RWBL. Proposed LSU sampling area downstream of EVO. Not previously sampled for sediment.
		MI16	Michel Creek Wetland	665083	5489403	Corer	Area used by RWBL and amphibians. Previously sampled for sediment in 2013, with Cd concentrations exceeding PEL.
		MIC2	Michel Oxbow #2	659533	5496626	Ponar	Alternate LSU sampling area (for MIWW) downstream of CMO. Not previously sampled for sediment.
		MIWW	Lower Michel Wetland	659707	5498474	Spoon	Area used by RWBL and amphibians. Proposed LSU sampling area downstream of CMO (if present). Previously sampled for sediment in 2013.
	5	SPW	Sparwood Wetland	651182	5511239	Corer	Sampled in 2013 only.
		ERWSF	Elk River	639138	5484622	Corer	Sampled in 2013 only.
		STPD	Stanford Pond	639864	5483139	Spoon	Area used by fish. Proposed LSU sampling area downstream of all mines. Not previously sampled for sediment.
		EROL	Elk River Lower Oxbow	640877	5477999	Corer	Area used by fish. Alternative to STPD for LSU sampling. Previously sampled for sediment in 2013.
		ELKO	Elko Reservoir	637800	5461540	Corer	Area used by fish. Lentic area furthest downstream of all mines. Previously sampled for sediment in 2013.

Table E.2: Sediment Quality in Mine-exposed Areas and Associated Summary statistics, 2015

Analyte		Units	Fording River Watershed
