APPENDIX D

WATER

Figure D.1: Time Series Plots for Total Antimony Concentrations from FRO LAEMP Sampling Areas, 2012 to 2022

Notes: Green data points are used for reference sites and blue data points are used for mine-exposed sites. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Constituent was plotted because it was identified as a mine-related constituent in the Adaptive Management Plan and an early warning trigger was defined (Azimuth 2018). When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

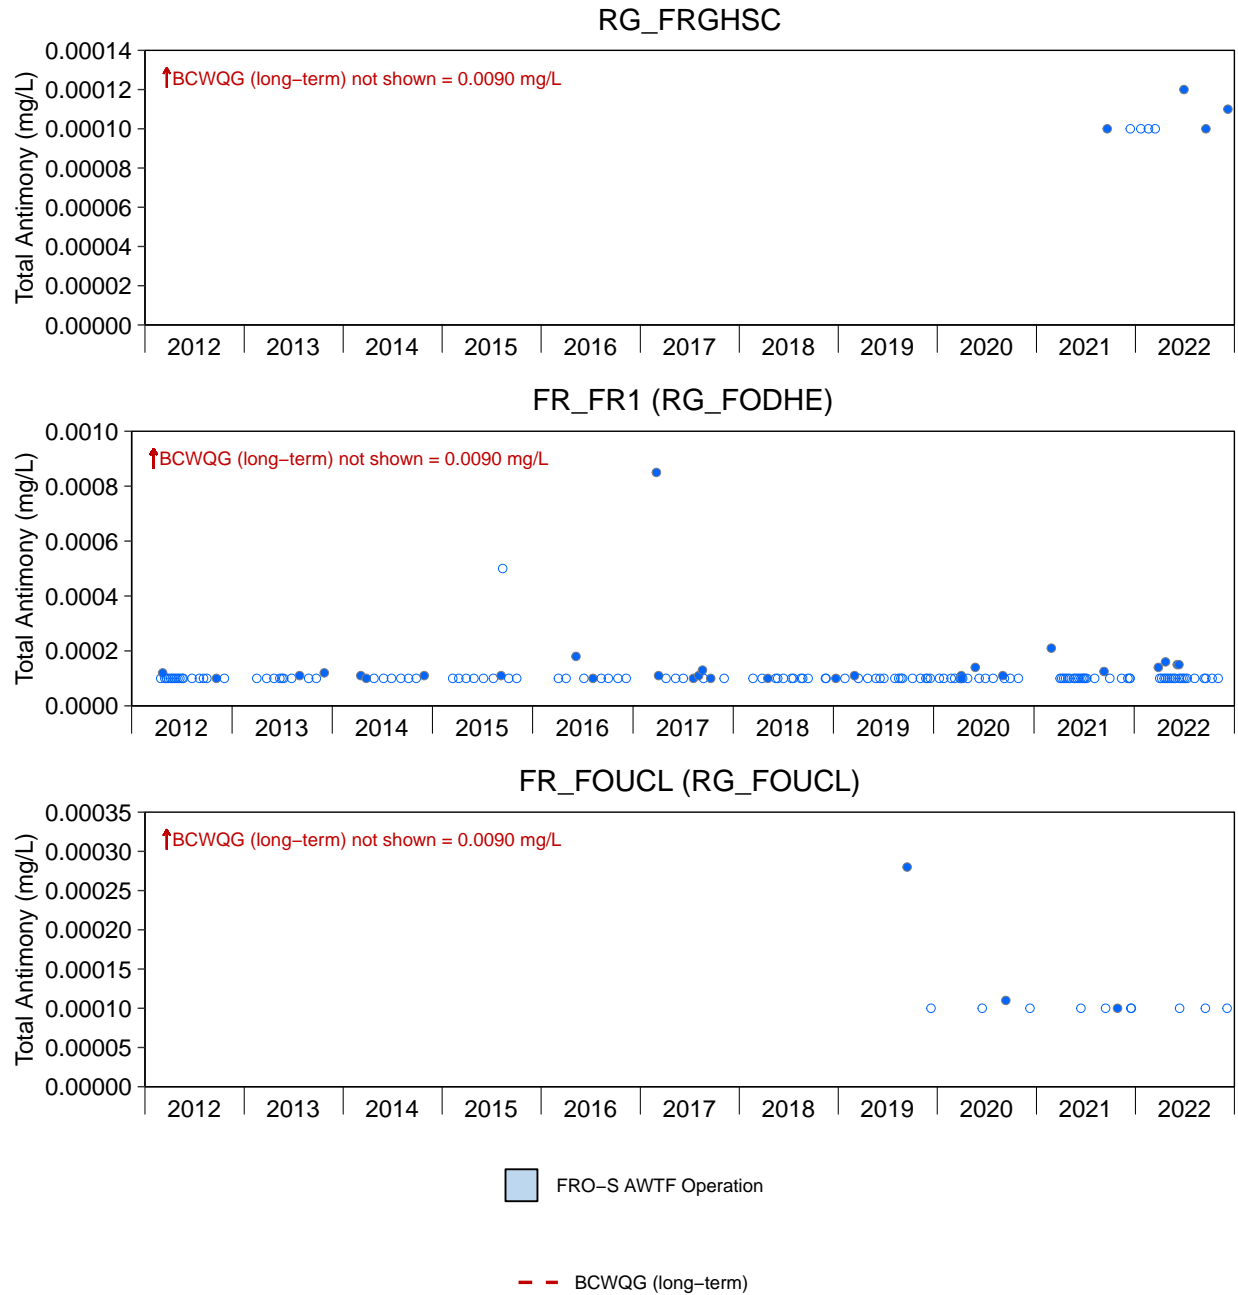

Figure D.1: Time Series Plots for Total Antimony Concentrations from FRO LAEMP Sampling Areas, 2012 to 2022

Notes: Green data points are used for reference sites and blue data points are used for mine-exposed sites. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Constituent was plotted because it was identified as a mine-related constituent in the Adaptive Management Plan and an early warning trigger was defined (Azimuth 2018). When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

Figure D.18: Time Series Plots for Total Selenium Concentrations from FRO LAEMP Sampling Stations, 2012 to 2022

Notes: Green data points are used for reference sites and blue data points are used for mine-exposed sites. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Constituent was plotted because it was identified as a mine-related constituent in the Adaptive Management Plan and an early warning trigger was defined (Azimuth 2018). When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

● RG_FOBKS (Untreated) ▲ Treated Station

Figure D.54: Differences in Monthly Mean Water Quality Analytes Before and After Treatment from FRO LAEMP Sampling Areas, 2018 to 2022

Notes: Values are plotted on the log scale to match statistical analysis. Lines connect estimated marginal means from the censored regression model. Censored values are shown as hollow symbols. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall.

Figure : Heatmap of Magnitude of Differences (MOD) from Statistical Analysis of Water Upstream and Downstream of Treatment, 2018 to 2022.

Notes: Orange boxes show significant BA (Year) x Treatment effects and red boxes show significant BA x Treatment effects. BA = Before-After term. Any MODs greater than 100 were rounded down to 100. Grey boxes indicate cases where exact p-values or MODs could not be calculated due to high censoring. Magnitude of difference was calculated as described in the table with the statistical analysis presented here.

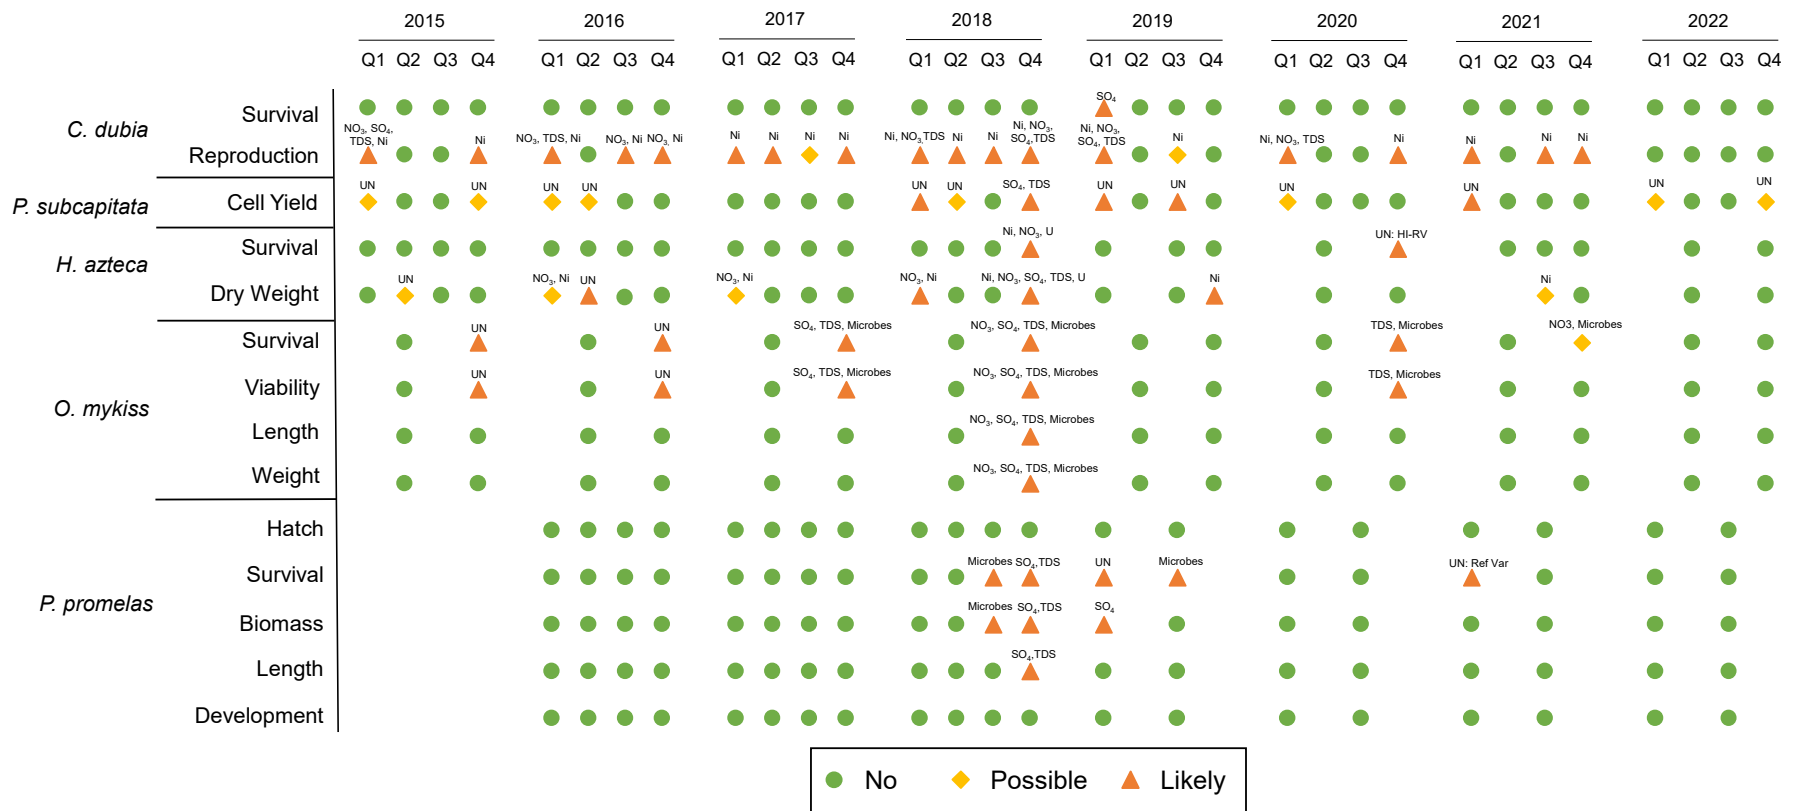

Figure D.56: Summary of Chronic Toxicity Testing Causation Assessment at FR_FRCP1, FRO LAEMP, 2022

Notes: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. Ref Var = high inter-reference variability; Ni = nickel; NO₃ = nitrate; SO₄ = sulphate; TDS = total dissolved solids; U = uranium; UN = unknown: no water quality constituent was identified. Figure adapted from WSP Golder (2023).

Figure D.56: Summary of Chronic Toxicity Testing Causation Assessment at FR_FRABCH, FRO LAEMP, 2022

Notes: Results were categorized using local and regional normal ranges calculated in this report, see Section 3.2.3. Possible and likely symbols are annotated with constituent(s) identified as potentially contributing to observed response. Ref Var = high inter-reference variability; HI-RV = high inter-replicate variability; NO₃ = nitrate; UN = unknown: no water quality constituent was identified. Figure adapted from WSP Golder (2023).

Table D.1: Seasonal Kendall Trend Analysis For Water Quality Constituents Collected at Routine Monitoring Stations, Fording River LAEMP, 2012 to 2022

Constituent	Units	Reference		Mine-exposed											
		FR_HC3 (RG_HENUP)	FR_UFR1 (RG_UFR1)	FR_FR1 (RG_FODHE)	FR_MULTIPLATE (RG_MP1)	FR_FRNTP (RG_FOUSH)	FR_FR2 (RG_FOUKI)	FR_FR3 (RG_FOBKS)	FR_SCOUTDS (RG_SCOUTDS)	FR_FR4 (RG_FOBSC)	FR_FRCP1 (RG_FOBCP)	FR_FRRD (RG_FRUPO)	GH_PC2 (RG_FODPO)	FR_FRABCH (RG_FO22)	FR_FR5
Nitrate (as N)	mg/L	NS	3.5	-4.5	6.3	9.3	7.4	7.0	17	6.0	4.4	2.8	NS	1.8	1.2

P-value < 0.05.
 Significant decreasing temporal trend (Seasonal Kendall test for monotonic trend at $\alpha = 0.05$). Value reported is the Sen's slope reported as a percentage of the median concentration or value.
 Significant increasing temporal trend (Seasonal Kendall test for monotonic trend at $\alpha = 0.05$). Value reported is the Sen's slope reported as a percentage of the median concentration or value.
 Notes: "NS" = no significant temporal trend (Seasonal Kendall test for monotonic trend at $\alpha = 0.05$). "-" = no data or insufficient data ($n < 5$) to test for trend. LRL = No trend test because percent of values at the LRL ≥ 75 .

Table D.2. Temporal Changes in Water Chemistry Constituents at Routine Monitoring Stations, FRO LAEMP, 2012 to 2022

Constituents	Status	Station	Annual Variation ^a		Q1. Is there a positive or negative change in concentrations since the base year (b) of monitoring?											Q2. Is the 2022 annual mean greater or less than all annual historical means (2012 to 2021) and the previous year (2021)? ^c																
			DF	P-Value	Magnitude of Difference (MOD) ^b and Significance (bolded) from Base Year (b) ^c																											
					2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022	2022 vs. 2012-2021	2022 vs. 2021

- P-value < 0.05 (annual variation).
- > 20% Decrease in concentration.
- > 33% Decrease in concentration.
- > 43% Decrease in concentration.
- > 50% Decrease in concentration.
- > 25% Increase in concentration.
- > 50% Increase in concentration.
- > 75% Increase in concentration.
- > 100% Increase in concentration.

***Bold** Significant increase or decrease from base year.

Notes: Temporal trends were only conducted for areas that have a complete routine water quality monitoring dataset. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and analyzed together with the biological monitoring area depicted in parenthesis. Only constituents considered mine-related under the Adaptive Management Plan (AMP) and that have early warning triggers, and orthophosphate and total phosphorus were analyzed for temporal trends.

^a The presence of annual variation was determined by a significant Year term (α = 0.05) using an ANOVA with factors Year and Month.

^b Magnitude of Difference (MOD) was calculated as the concentrations in each year minus the concentration in the first year divided by the concentration in the first year × 100.

^c Significance between each year determined using all pairwise comparisons with Tukey correction.

^d "-" insufficient data for comparison, where insufficient data is less than 6 months of recorded data or > 75% LRL data in a given year. "nc" = post-hoc test not conducted because of non-significant year term.

> 5% of samples exceed the guideline or benchmark.
 > 50% of samples exceed the guideline or benchmark.
 > 95% of samples exceed the guideline or benchmark.

Notes: "UEC" = Updated Effects Concentration. "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline. UEC's are shown for Nitrate and Sulphate, Proposed Benchmark for Dissolved Nickel, Level 1 Screening Value for Total Dissolved Solids, and EVWQP benchmarks are shown for all other relevant parameters. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and tabulated together with the biological monitoring area depicted in parenthesis. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

^a Long-term average BCQWG for the Protection of Aquatic Life.
^b Short-term maximum BCQWG for the Protection of Aquatic Life.

> 5% of samples exceed the guideline or benchmark.
 > 50% of samples exceed the guideline or benchmark.
 > 95% of samples exceed the guideline or benchmark.

Notes: "UEC" = Updated Effects Concentration. "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline. UEC's are shown for Nitrate and Sulphate, Proposed Benchmark for Dissolved Nickel, Level 1 Screening Value for Total Dissolved Solids, and EVWQP benchmarks are shown for all other relevant parameters. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and tabulated together with the biological monitoring area depicted in parenthesis. RG_FR2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

^a Long-term average BCWQG for the Protection of Aquatic Life.
^b Short-term maximum BCWQG for the Protection of Aquatic Life.

- > 95% of samples exceed the guideline or benchmark.

Notes: "UEC" = Updated Effects Concentration. "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline. UEC's are shown for Nitrate and Sulphate, Proposed Benchmark for Dissolved Nickel, Level 1 Screening Value for Total Dissolved Solids, and EVWQP benchmarks are shown for all other relevant parameters. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and tabulated together with the biological monitoring area depicted in parenthesis. RG_FR5 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

^a Long-term average BCQWG for the Protection of Aquatic Life.

^b Short-term maximum BCQWG for the Protection of Aquatic Life.

- P-Value < 0.1.
- MOD > 25 %.
- MOD < -25%.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = $(MCT_{Treated, after} - MCT_{Predicted, after}) / MCT_{Predicted, after} * 100\%$, where $MCT_{Predicted, After} = MCT_{Untreated, after} + (MCT_{Treated, Before} - MCT_{Untreated Before})$ and MCT = Measure of Central Tendency. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (ie., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

APPENDIX E
HYDROLOGY

Figure E.1: Continuous Water Temperature Logging in the Fording River, 2022

Notes: Black line represents average daily water temperature. Blue line represents maximum and minimum daily water temperature. Gaps in data are due to logger corruption, loss of logger due to environmental conditions and/or values below 0°C. Areas with a constant temperature of ~0°C during the winter represent periods where the loggers were entombed in ice. Data loggers were installed at FR_UFR1, FR_FR1, FR_FRDSCC1, and FR_SCOUTDS in summer of 2020 and the data logger at FR_FOUCL was installed in the spring of 2021.

Figure E.1: Continuous Water Temperature Logging in the Fording River, 2022

Figure .1 : Percent Effluent of Total Fording River Discharge at the Fording River Outfall, FRO LAEMP, 2022

Table E.1: Seasonal Kendall Trend Analysis For Water Temperature in the Fording River, 2017 to 2022

Constituent	Units	Reference	Mine-exposed											
		RG_UFR1 (FR_UFR1)	RG_FODHE (FR_FR1)	RG_FOUCL (FR_FOUCL)	FR_FRDSCC1 (FR_FRDSCC1)	RG_FOUKI (FR_FR2)	RG_FOBKS (FR_FR3)	RG_SCOUTDS (FR_SCOUTDS)	RG_FOBSC (FR_FR4)	RG_FOBPCP (FR_FRCP1)	RG_FRCP1SW (FR_FRCP1SW)	RG_FRUPO (FR_FRRD)	RG_FODPO (GH_PC2)	RG_FO22 (FR_FRABCH)
Temperature	°C	NS	NS	-	NS	2.8	5.6	NS	4.3	NS	NS	NS	NS	NS

P-value < 0.05.

Significant decreasing temporal trend (Seasonal Kendall test for monotonic trend at $\alpha = 0.05$). Value reported is the Sen's slope reported as a percentage of the median concentration or value.

Significant increasing temporal trend (Seasonal Kendall test for monotonic trend at $\alpha = 0.05$). Value reported is the Sen's slope reported as a percentage of the median concentration or value.

Notes: "NS" = no significant temporal trend (Seasonal Kendall test for monotonic trend at $\alpha = 0.05$). "-" = no data or insufficient data ($n < 5$) to test for trend. RG_FOUCL had insufficient data for analysis, RG_UFR1, RG_FODHE, FR_FRDSCC1, and RG_SCOUTDS had a maximum of three years of data for a given month, and the remaining stations had a maximum of five years of data for a given month. Logger stations associated with biological monitoring areas are outlined in brackets.

Table E.2: Predicted Water Temperature Differences Upstream and Downstream of the FRO-S AWTF Outfall, Fording River 2022 Relative to Pre-Commissioning (2020 and 2021)

Month	Predicted Mean Difference (RG_SCOUTDS - RG_FOBKS)			2022 _{Difference} - Pre-Commissioning Year _{Difference}	
	2020	2021	2022	2022 versus 2020 ^a	2022 versus 2021 ^a
Mar	-	-0.410	0.324	-	0.733
Apr	-	-0.390	0.235	-	0.624
May	-	-0.350	0.156	-	0.506
Jun	-	-0.270	0.0843	-	0.355
Jul	-	-0.171	0.0203	-	0.191
Aug	-0.183	-0.0991	-0.0442	0.139	0.0549
Sep	-0.333	-0.0881	-0.102	0.231	-0.0140
Oct	-0.479	-0.108	-0.152	0.326	-0.0444

Bold Non-overlapping 95 % Confidence Limits in Estimates of Mean differences.

 Temperature difference in 2022 is higher than the temperature difference before AWTF operation.

 Temperature difference in 2022 is lower than the temperature difference before AWTF operation.

^aAbsolute difference between years calculated as 2022_{Difference} - Pre-Commissioning Year_{Difference} - Predicted difference values were calculated using a generalized additive model (GAM) with temperature difference (RG_SCOUTDS - RG_FOBKS) as the response variable, year as a factor, and Julian day as a smoothing factor with a cubic regression spline. An autocorrelation correction with a lag of one was also included in the model.

APPENDIX F

**SUBSTRATE
QUALITY**

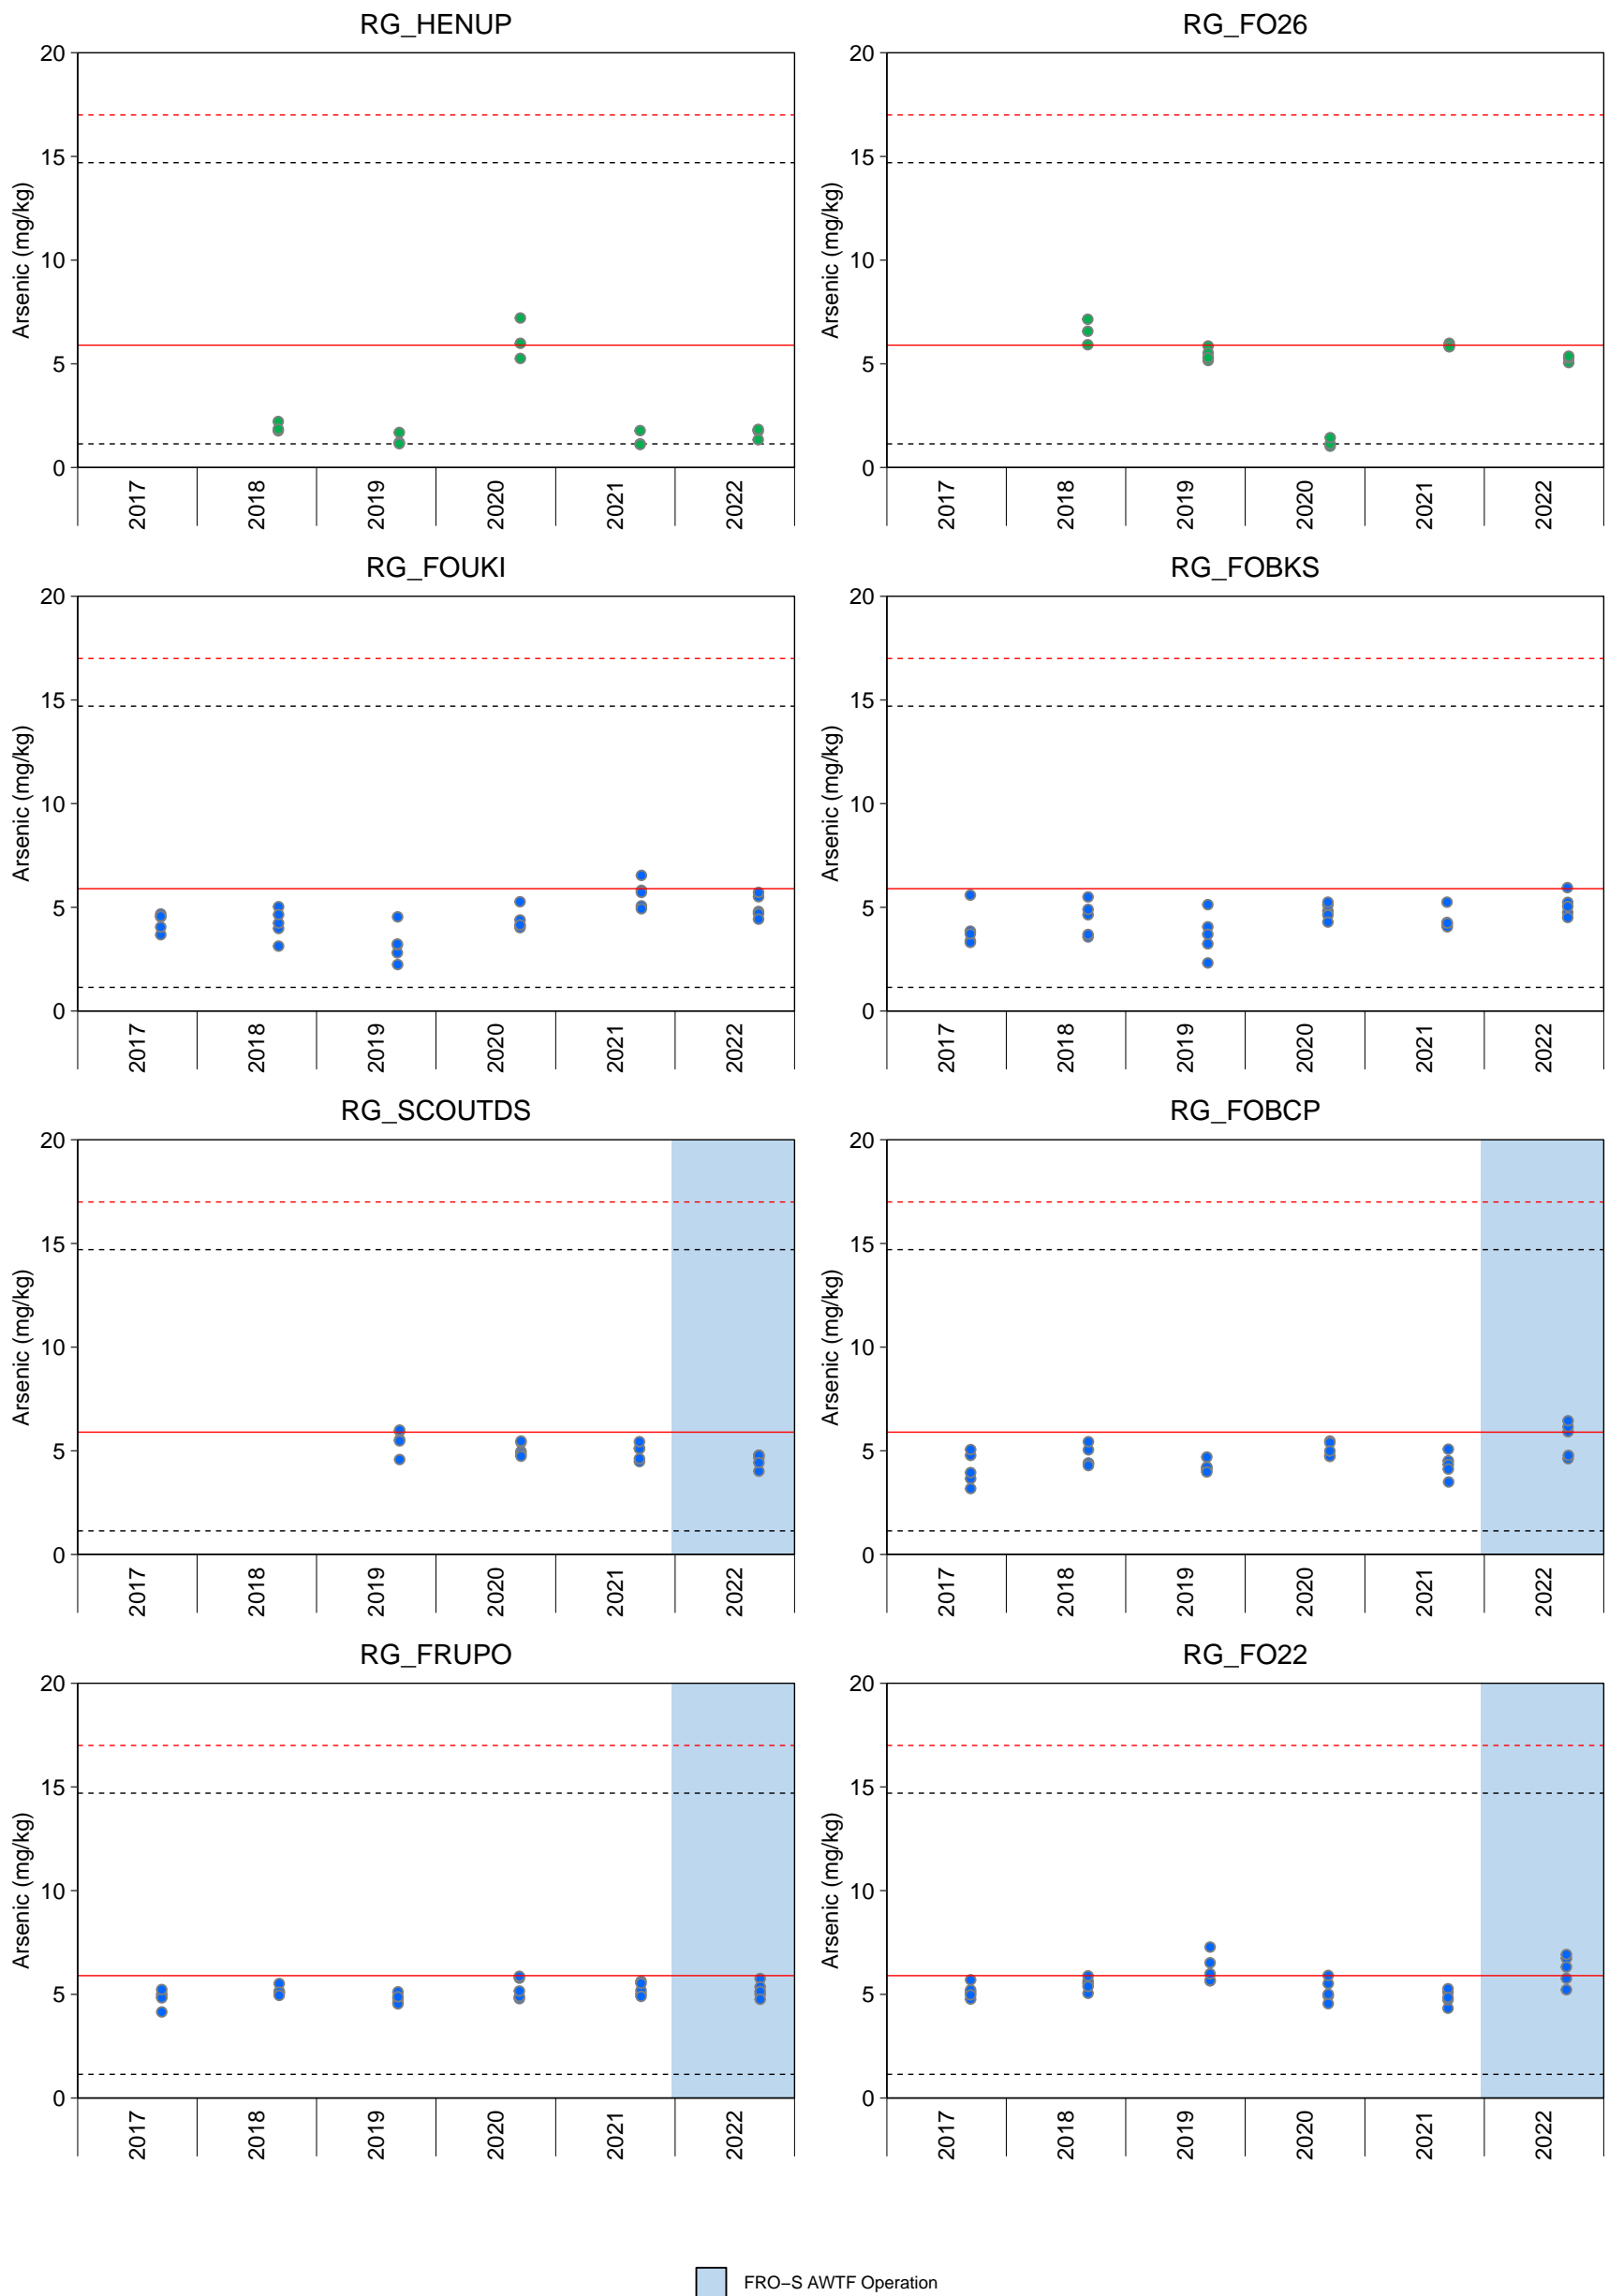

Figure .1: Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2022

Notes: Green represents reference stations and blue represents mine-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium; BCMOECs 2021). Hashed black lines represent the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

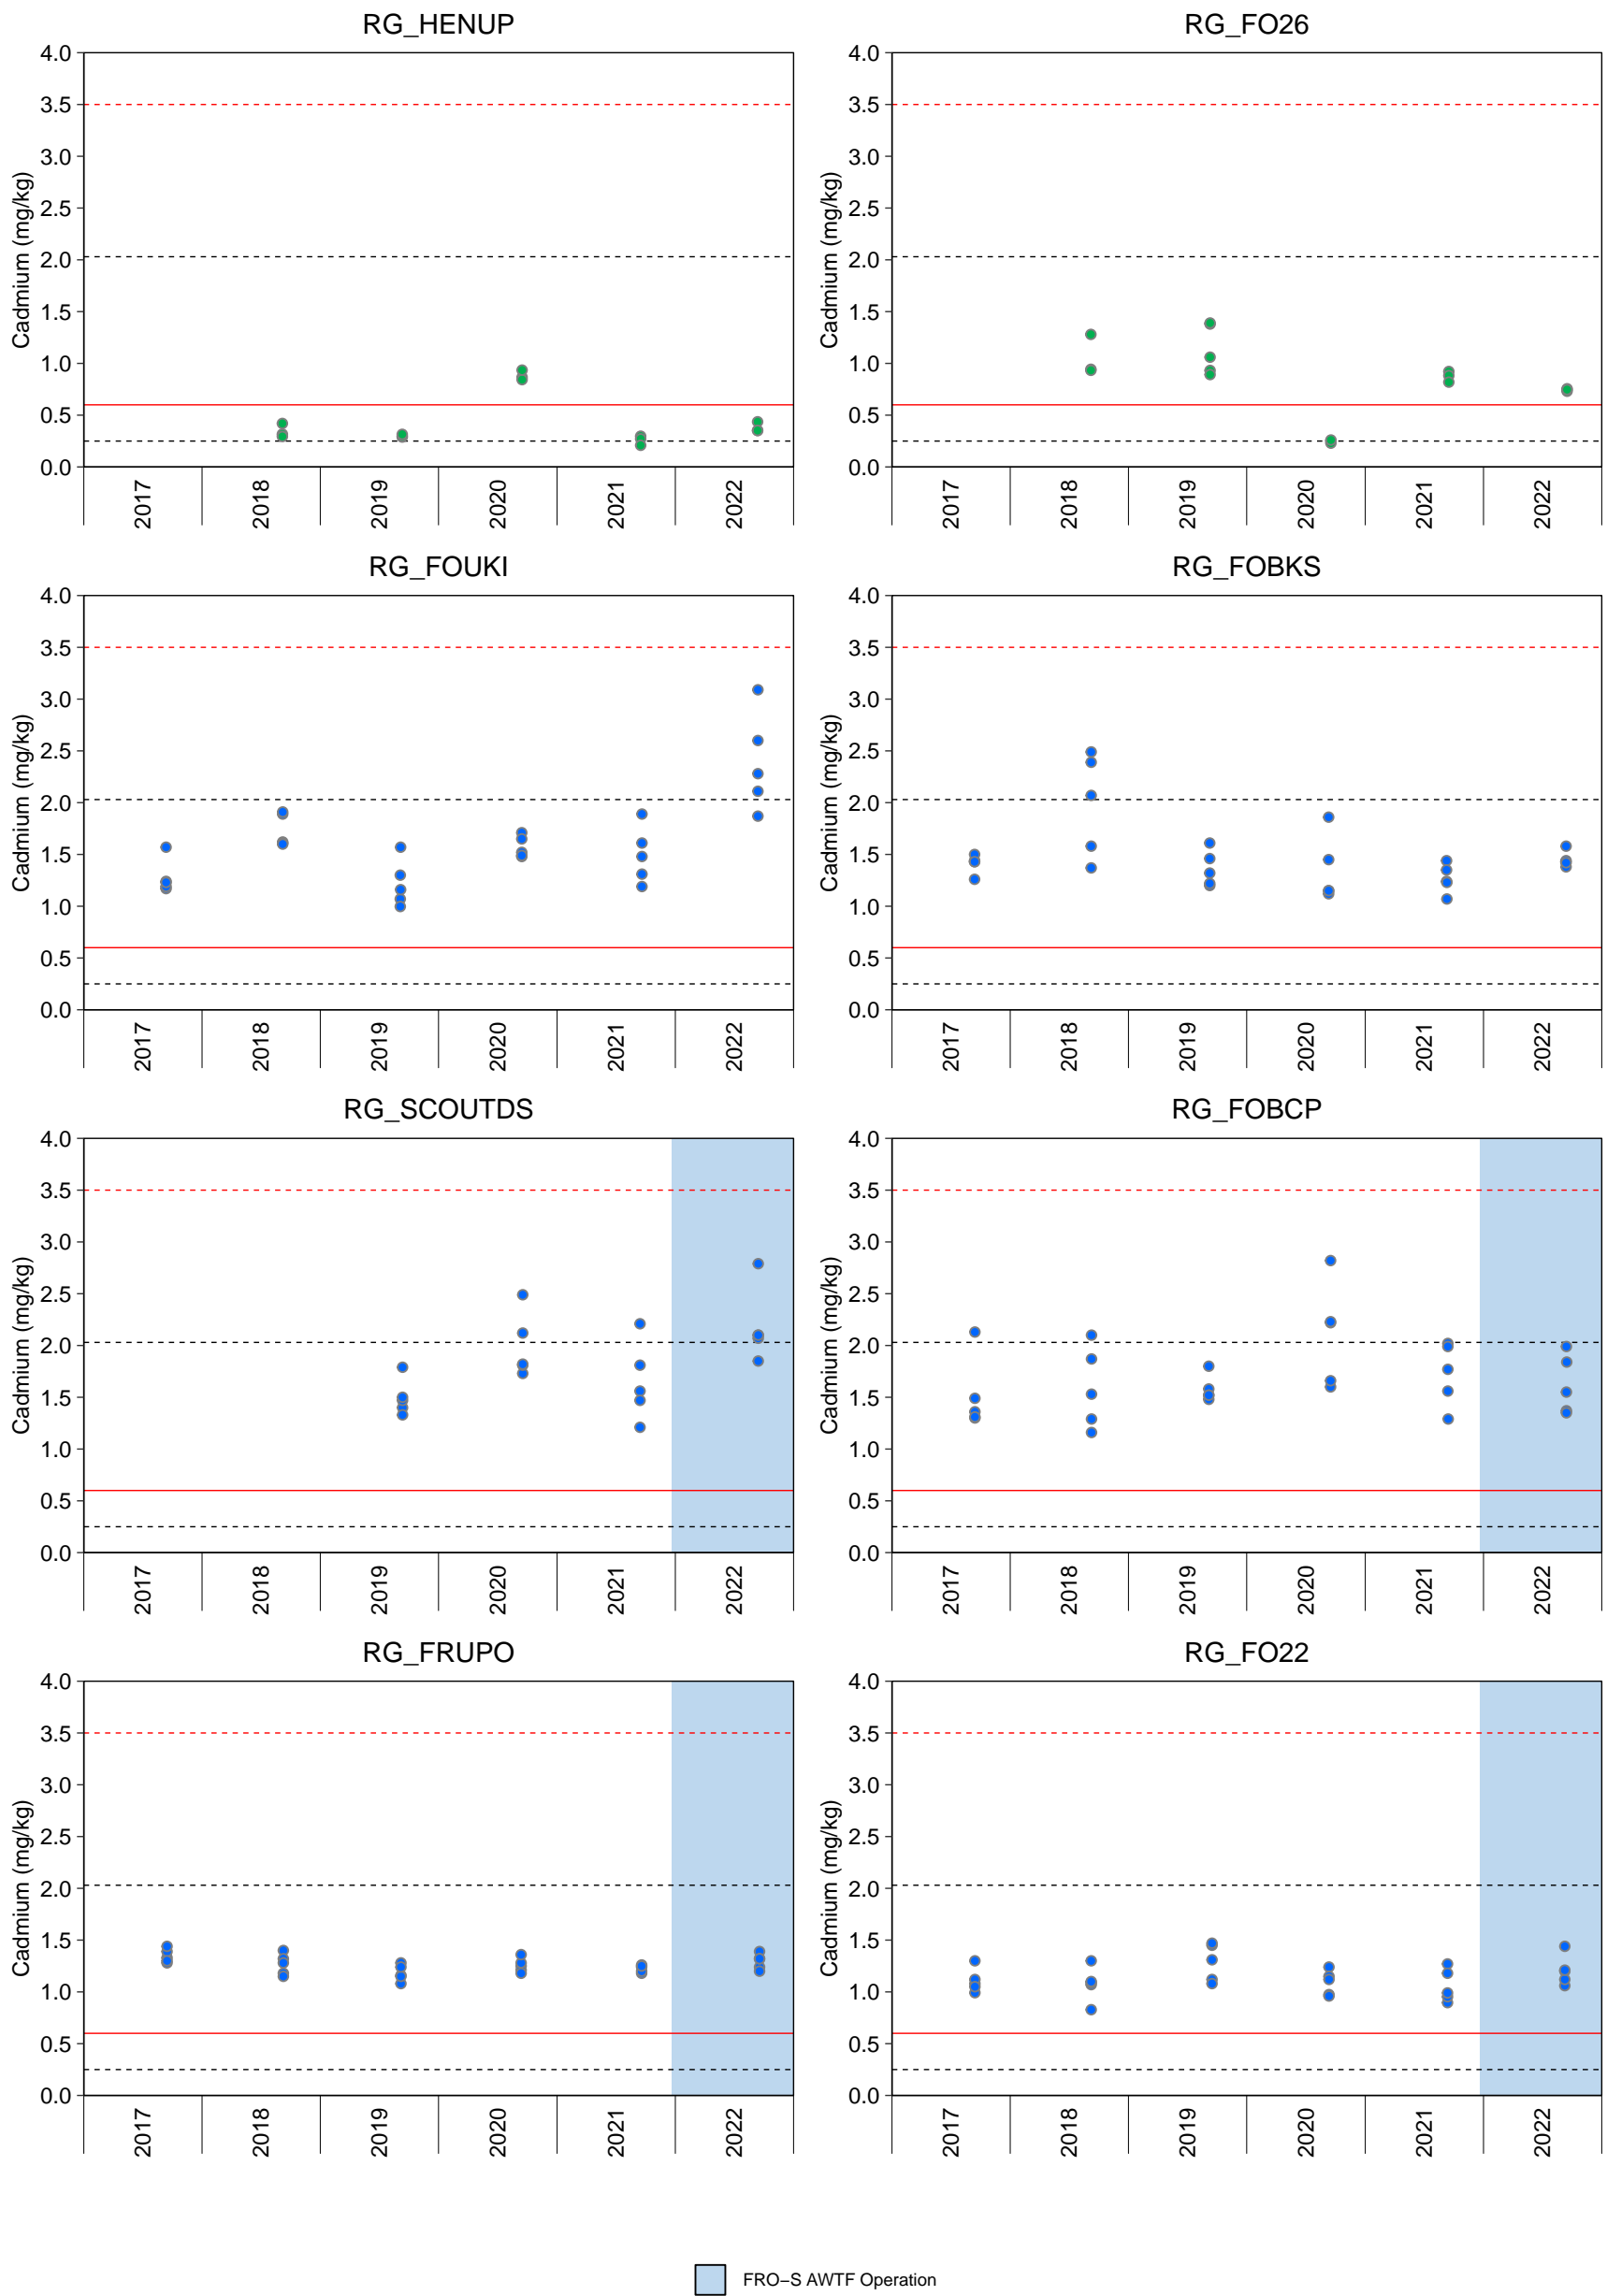

Figure .1: Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2022

Notes: Green represents reference stations and blue represents mine-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium; BC MOECCS 2021). Hashed black lines represent the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

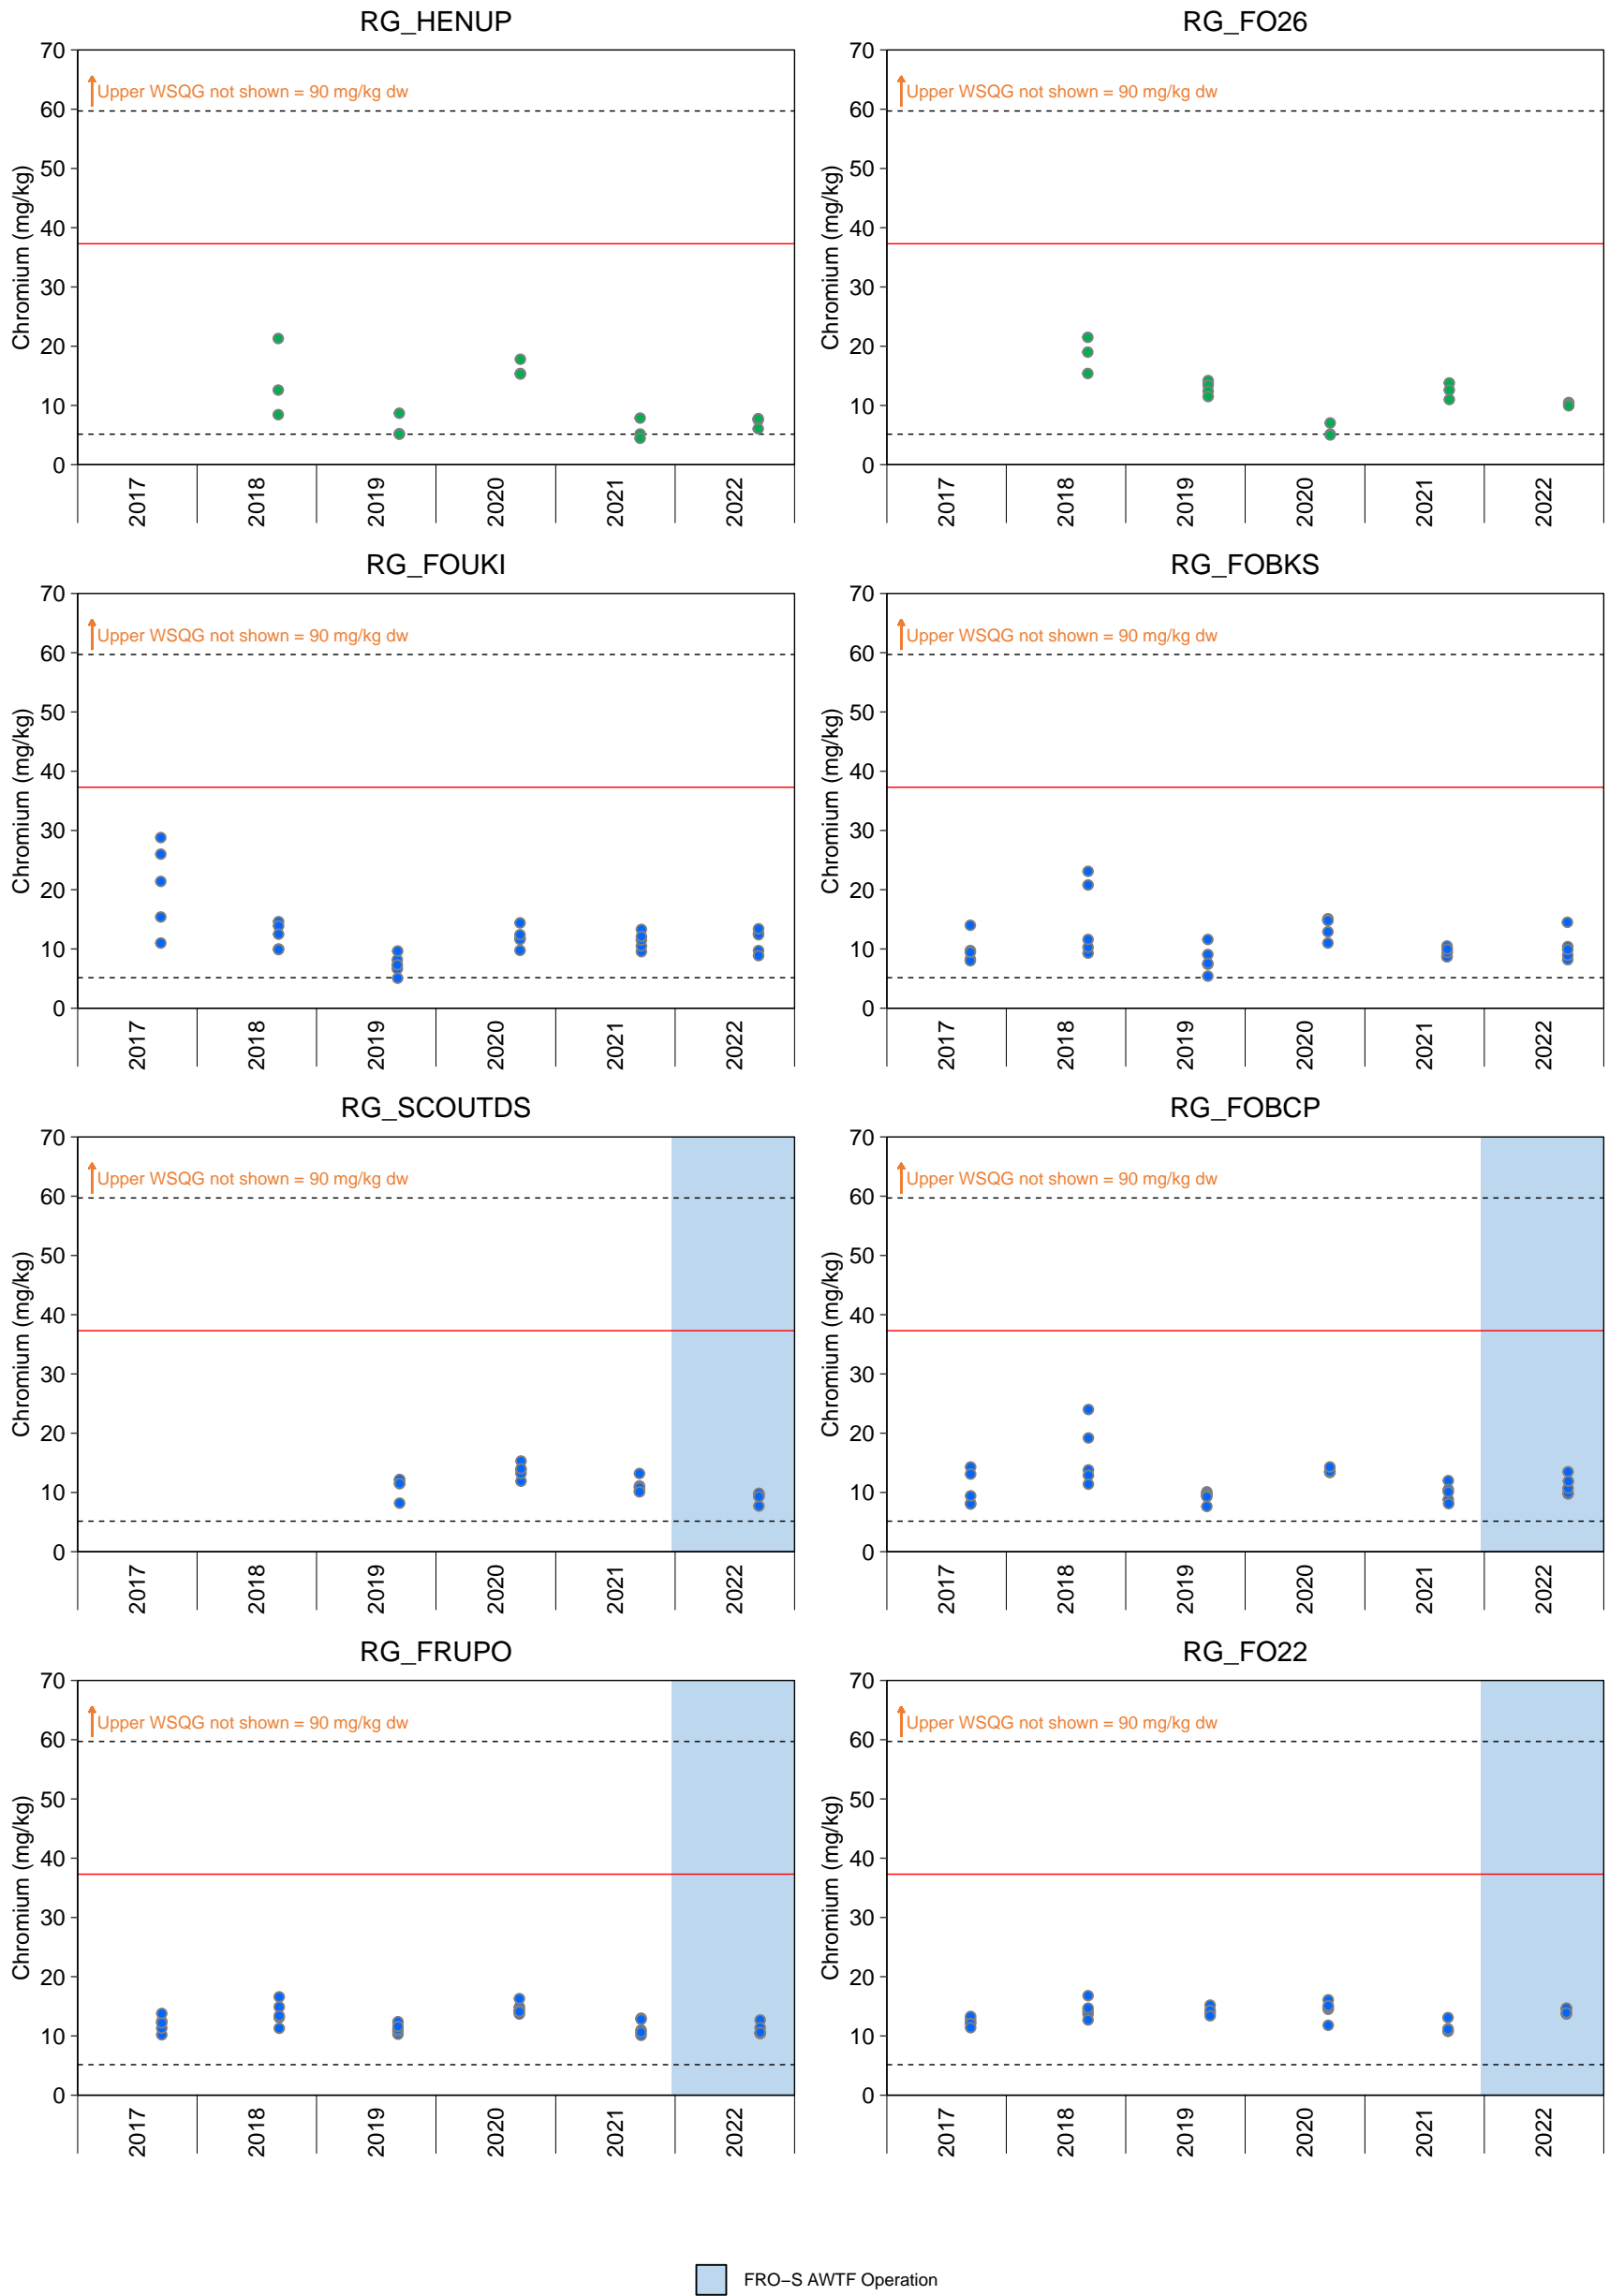

Figure .1: Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2022

Figure F.2:

7

Notes: Green represents reference stations and blue represents mine-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium; BCMOECSS 2021). Hashed black lines represent the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

Figure F.3: Comparison of Sediment Composition, Metal and PAH Concentrations Upstream (RG_FOBKS) and Downstream of Treatment

Notes: Values at the Laboratory Reporting Limit (LRL) are plotted as open symbols at the LRL. RG_FOBKS was the biological monitoring area immediately upstream of FRO-S AWTF treatment (untreated water), while RG_SCOUTDS was immediately downstream of treatment. The blue shading represents FRO-S AWTF operation.

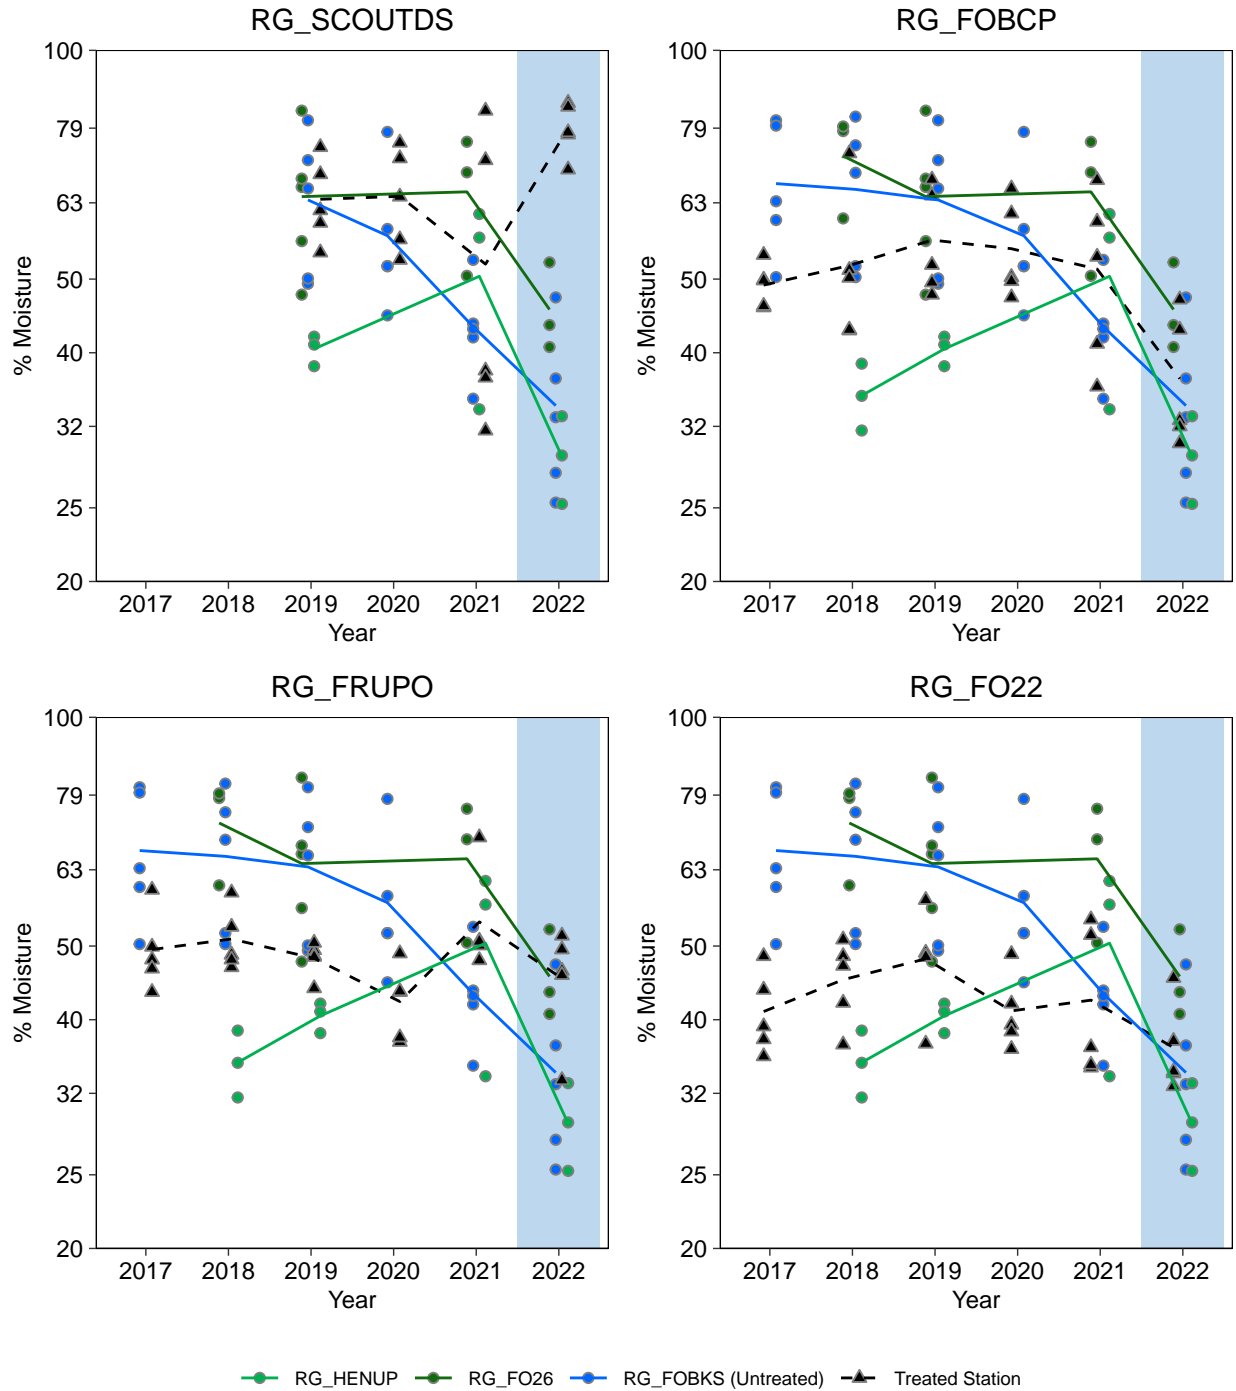

Figure F.3: Comparison of Sediment Composition, Metal and PAH Concentrations Upstream (RG_FOBKS) and Downstream of Treatment

P-Value for relevant BACI term < 0.1.
 Increase in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25%.
 Decrease in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25%.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = $(MCT_{Treated, after} - MCT_{Predicted, after}) / MCT_{Predicted, after} * 100\%$, where $MCT_{Predicted, After} = MCT_{Untreated, after} + (MCT_{Treated, Before} - MCT_{Untreated, Before})$ and MCT = Measure of Central Tendency. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (i.e., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

■ Decrease in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25%.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = $(MCT_{Treated, after} - MCT_{Predicted, after}) / MCT_{Predicted, after} * 100\%$, where $MCT_{Predicted, After} = MCT_{Untreated, after} + (MCT_{Treated, Before} - MCT_{Untreated, Before})$ and MCT = Measure of Central Tendency. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (i.e., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

P-Value for relevant BACI term < 0.1.
 Increase in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25 %.
 Decrease in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25%.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = $(MCT_{Treated, after} - MCT_{Predicted, after}) / MCT_{Predicted, after} * 100\%$, where $MCT_{Predicted, After} = MCT_{Untreated, after} + (MCT_{Treated, Before} - MCT_{Untreated, Before})$ and MCT = Measure of Central Tendency. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (i.e., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

Notes: "-" indicates that no calcite monitoring was completed.
 CI represents calcite index determined by presence and CI' represents calcite index determined by fraction of rock having calcite.

APPENDIX G

**BENTHIC
INVERTEBRATES**

Figure G.1: Benthic Invertebrate Abundance and Richness, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.2: Benthic Invertebrate % EPT and % Ephemeroptera, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.3: Benthic Invertebrate % Plecoptera and % Trichoptera, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.4: Benthic Invertebrate % Chironomidae and EPT Abundance, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.5: Benthic Invertebrate Ephemeroptera Abundance and Plecoptera Abundance, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.6: Benthic Invertebrate Trichoptera Abundance and Chironomidae Abundance, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.7: Benthic Invertebrate Baetidae Abundance and Heptageniidae Abundance, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.8: Benthic Invertebrate Ephemerelellidae Abundance and Autotrophic Heterotrophic Index, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.9: Benthic Invertebrate Filtering Collector Index and Predator Index, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.10: Benthic Invertebrate Shredder Index and Hyporheic to Benthic Index, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

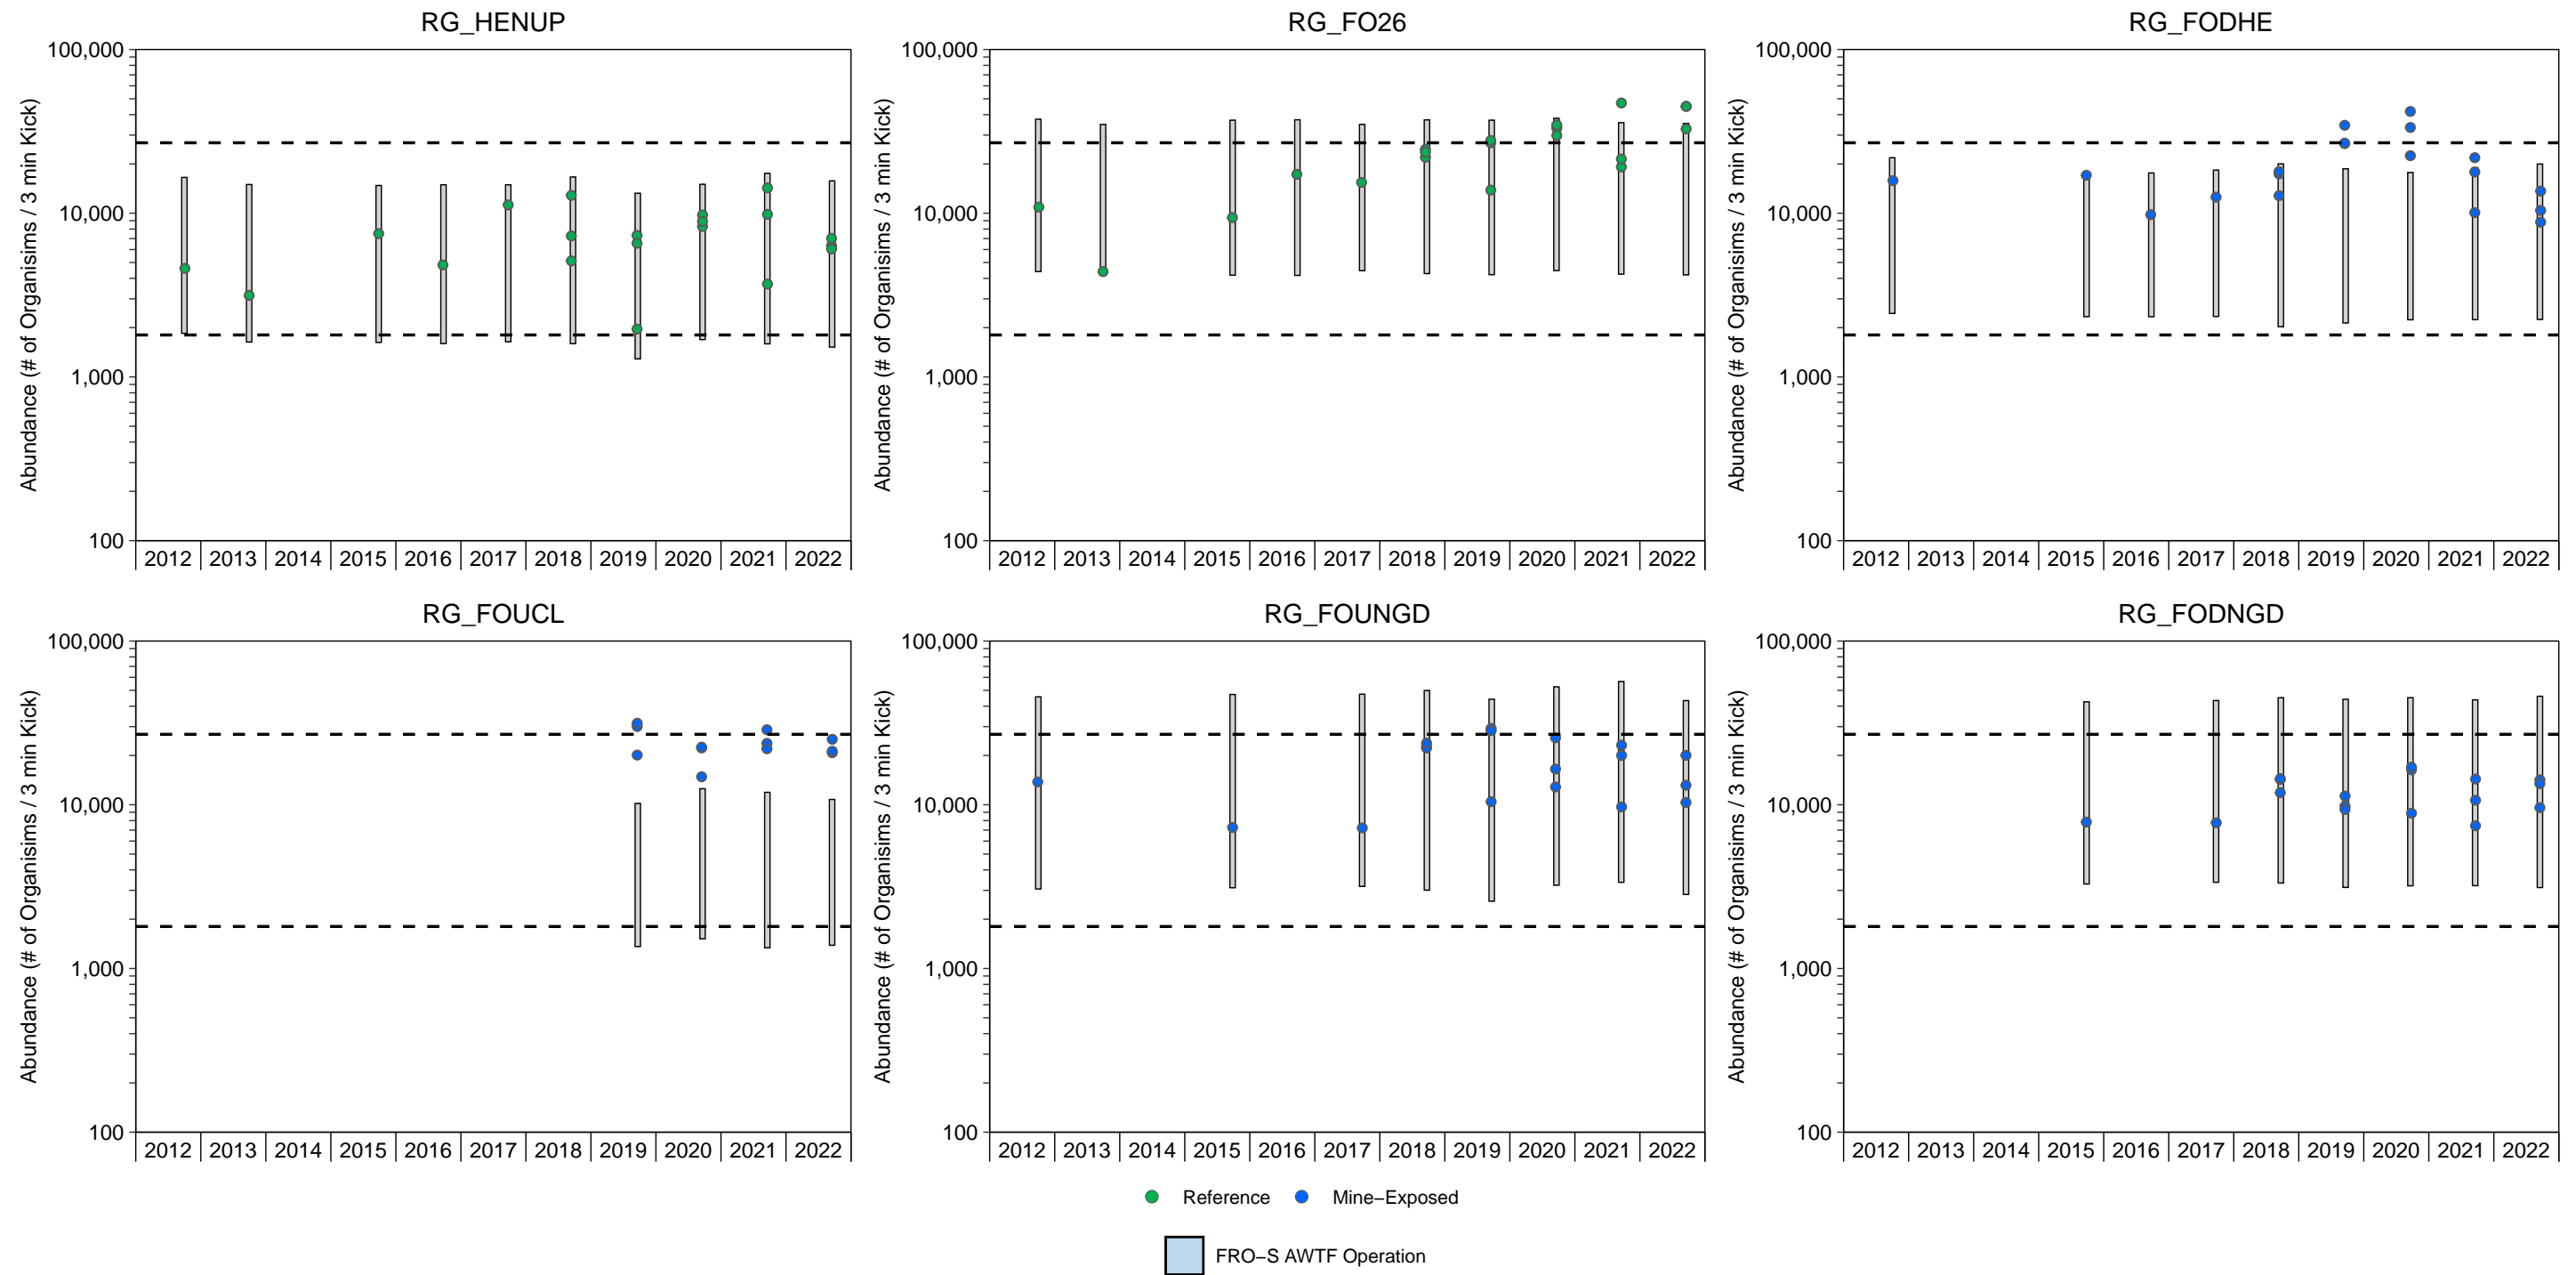

Figure G.11: Benthic Invertebrate Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

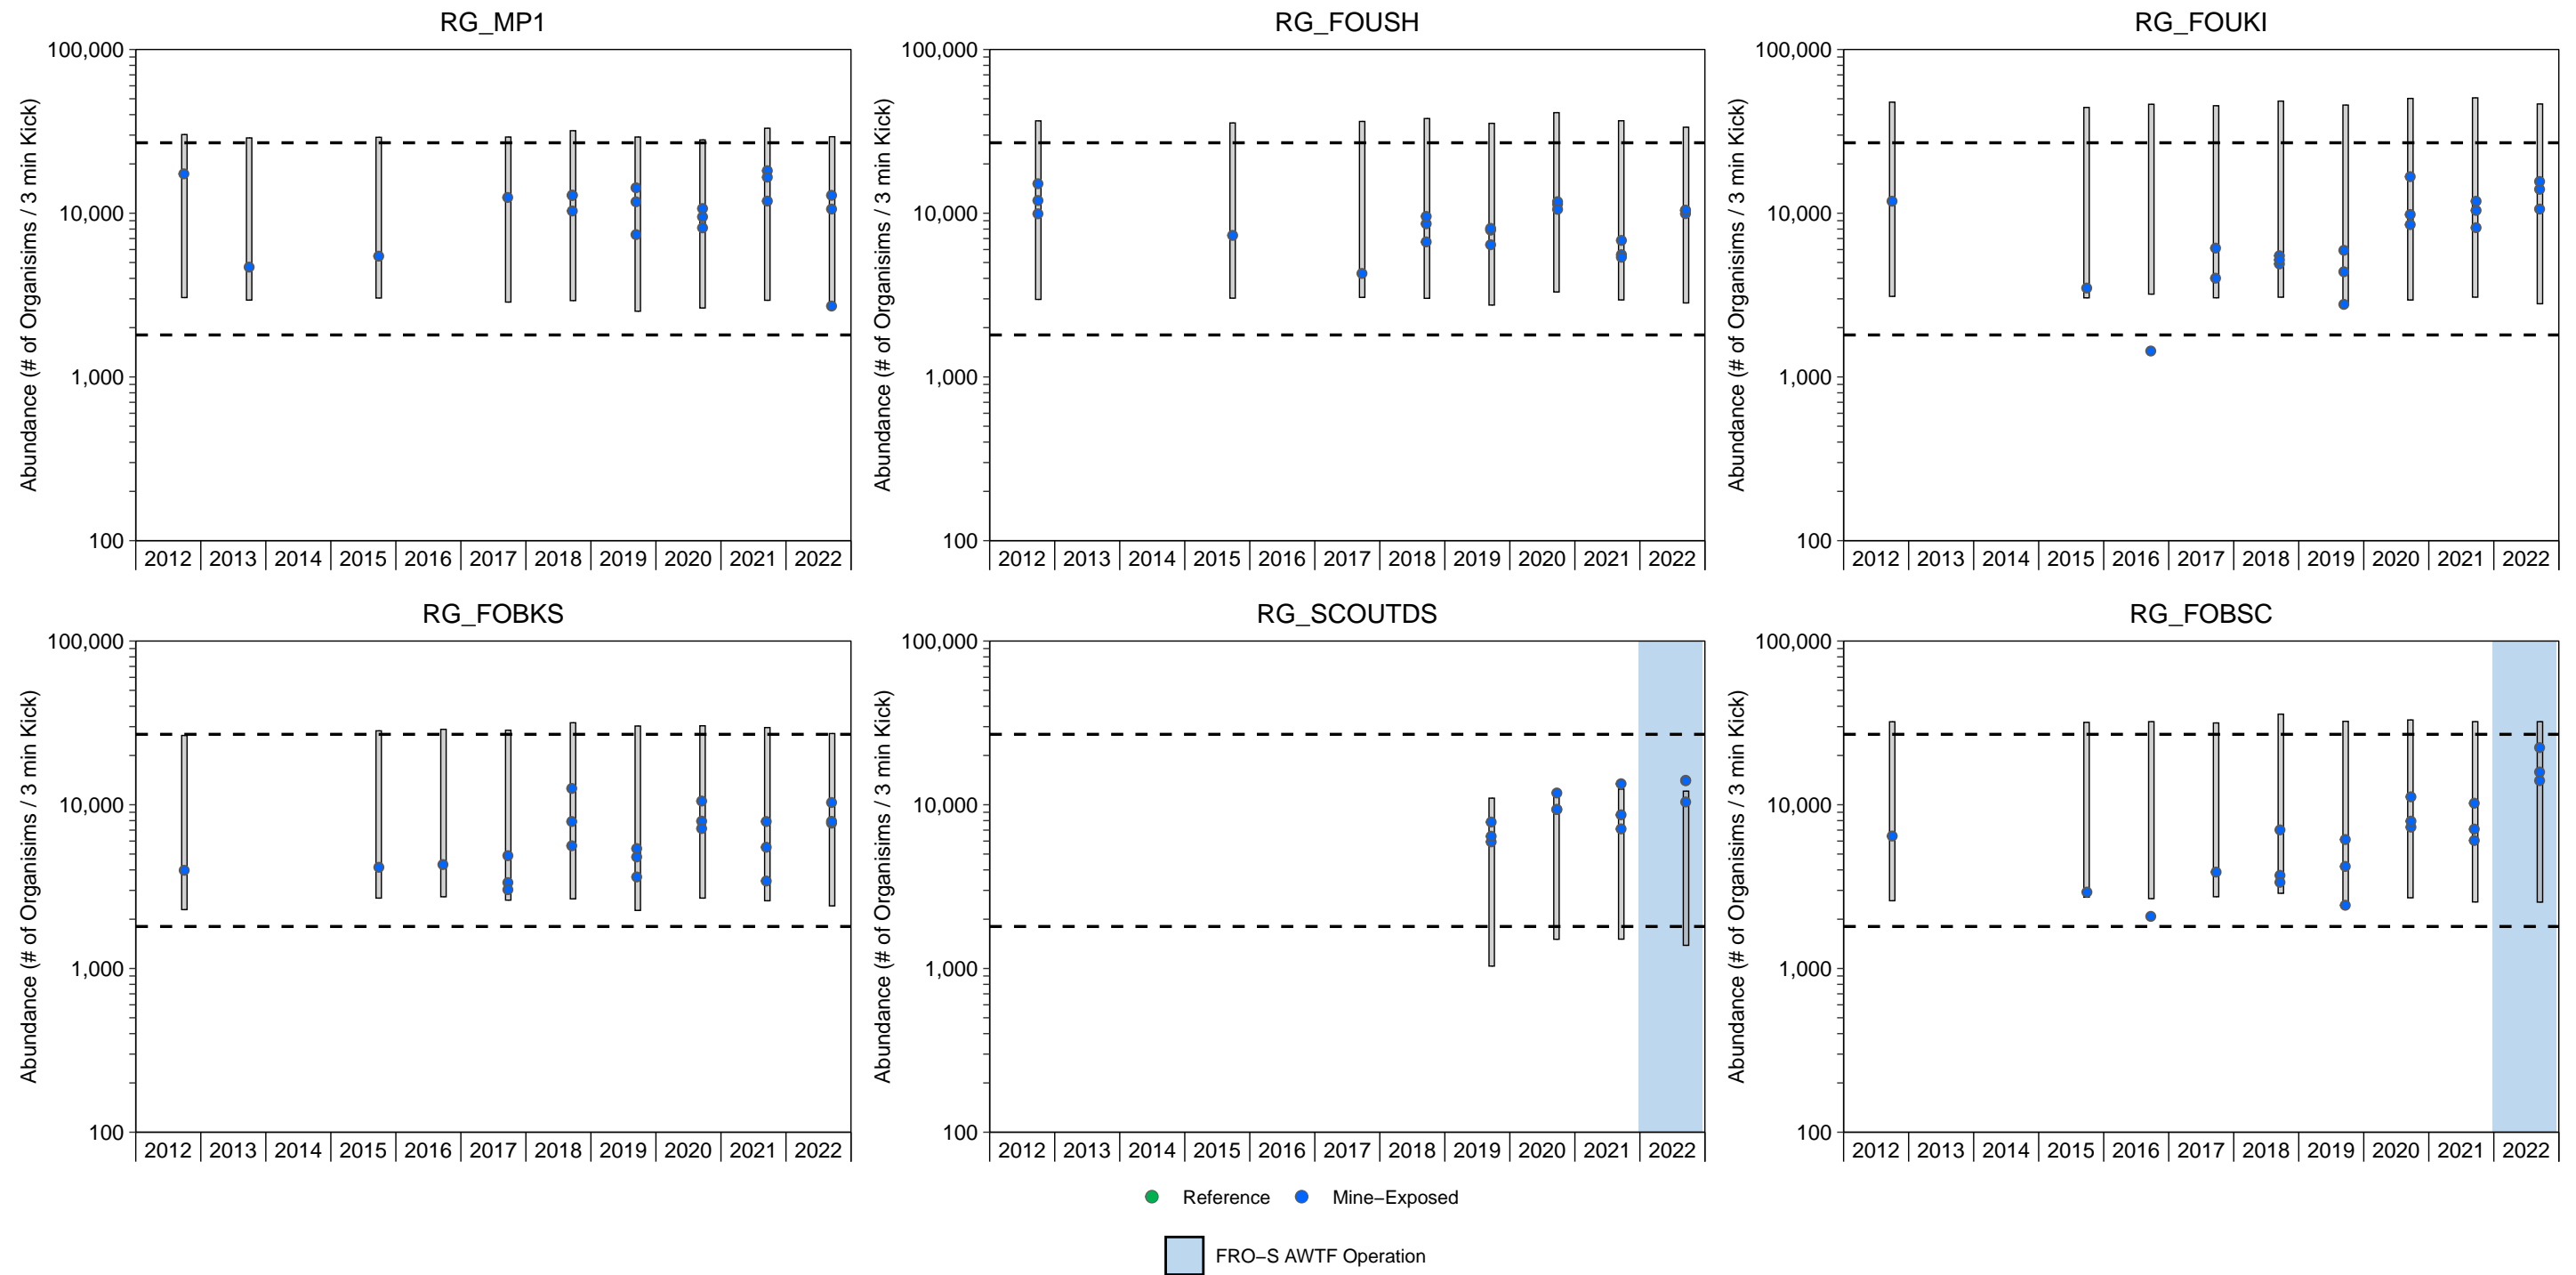

Figure G.11: Benthic Invertebrate Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

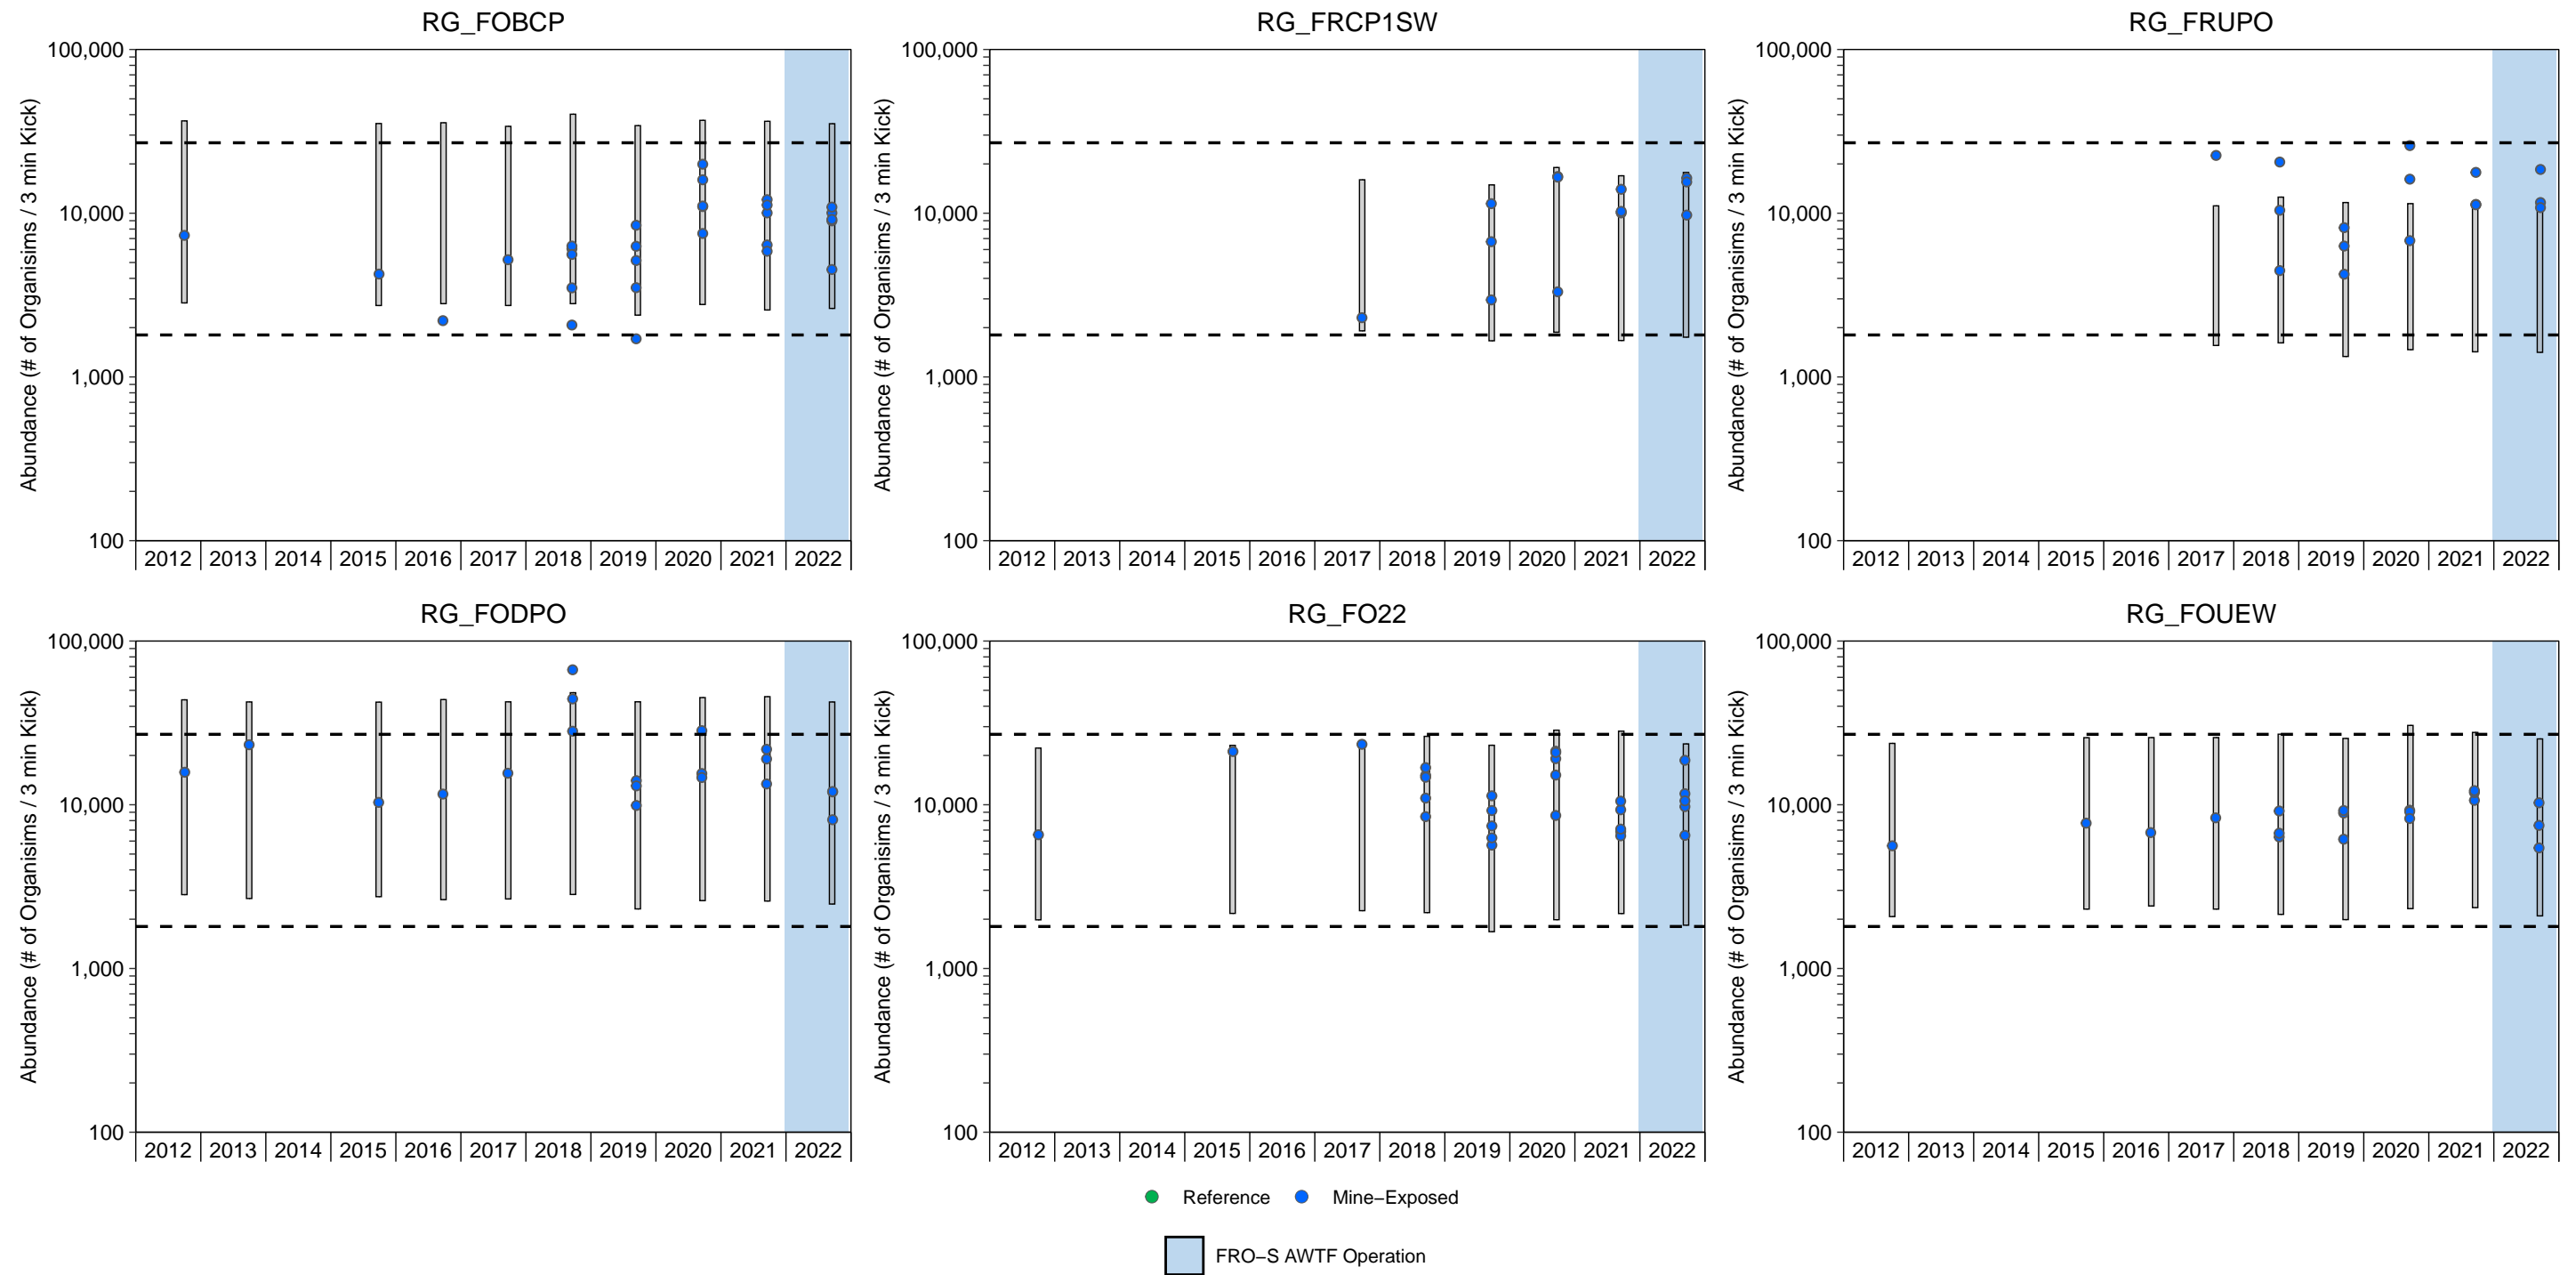

Figure G.11: Benthic Invertebrate Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

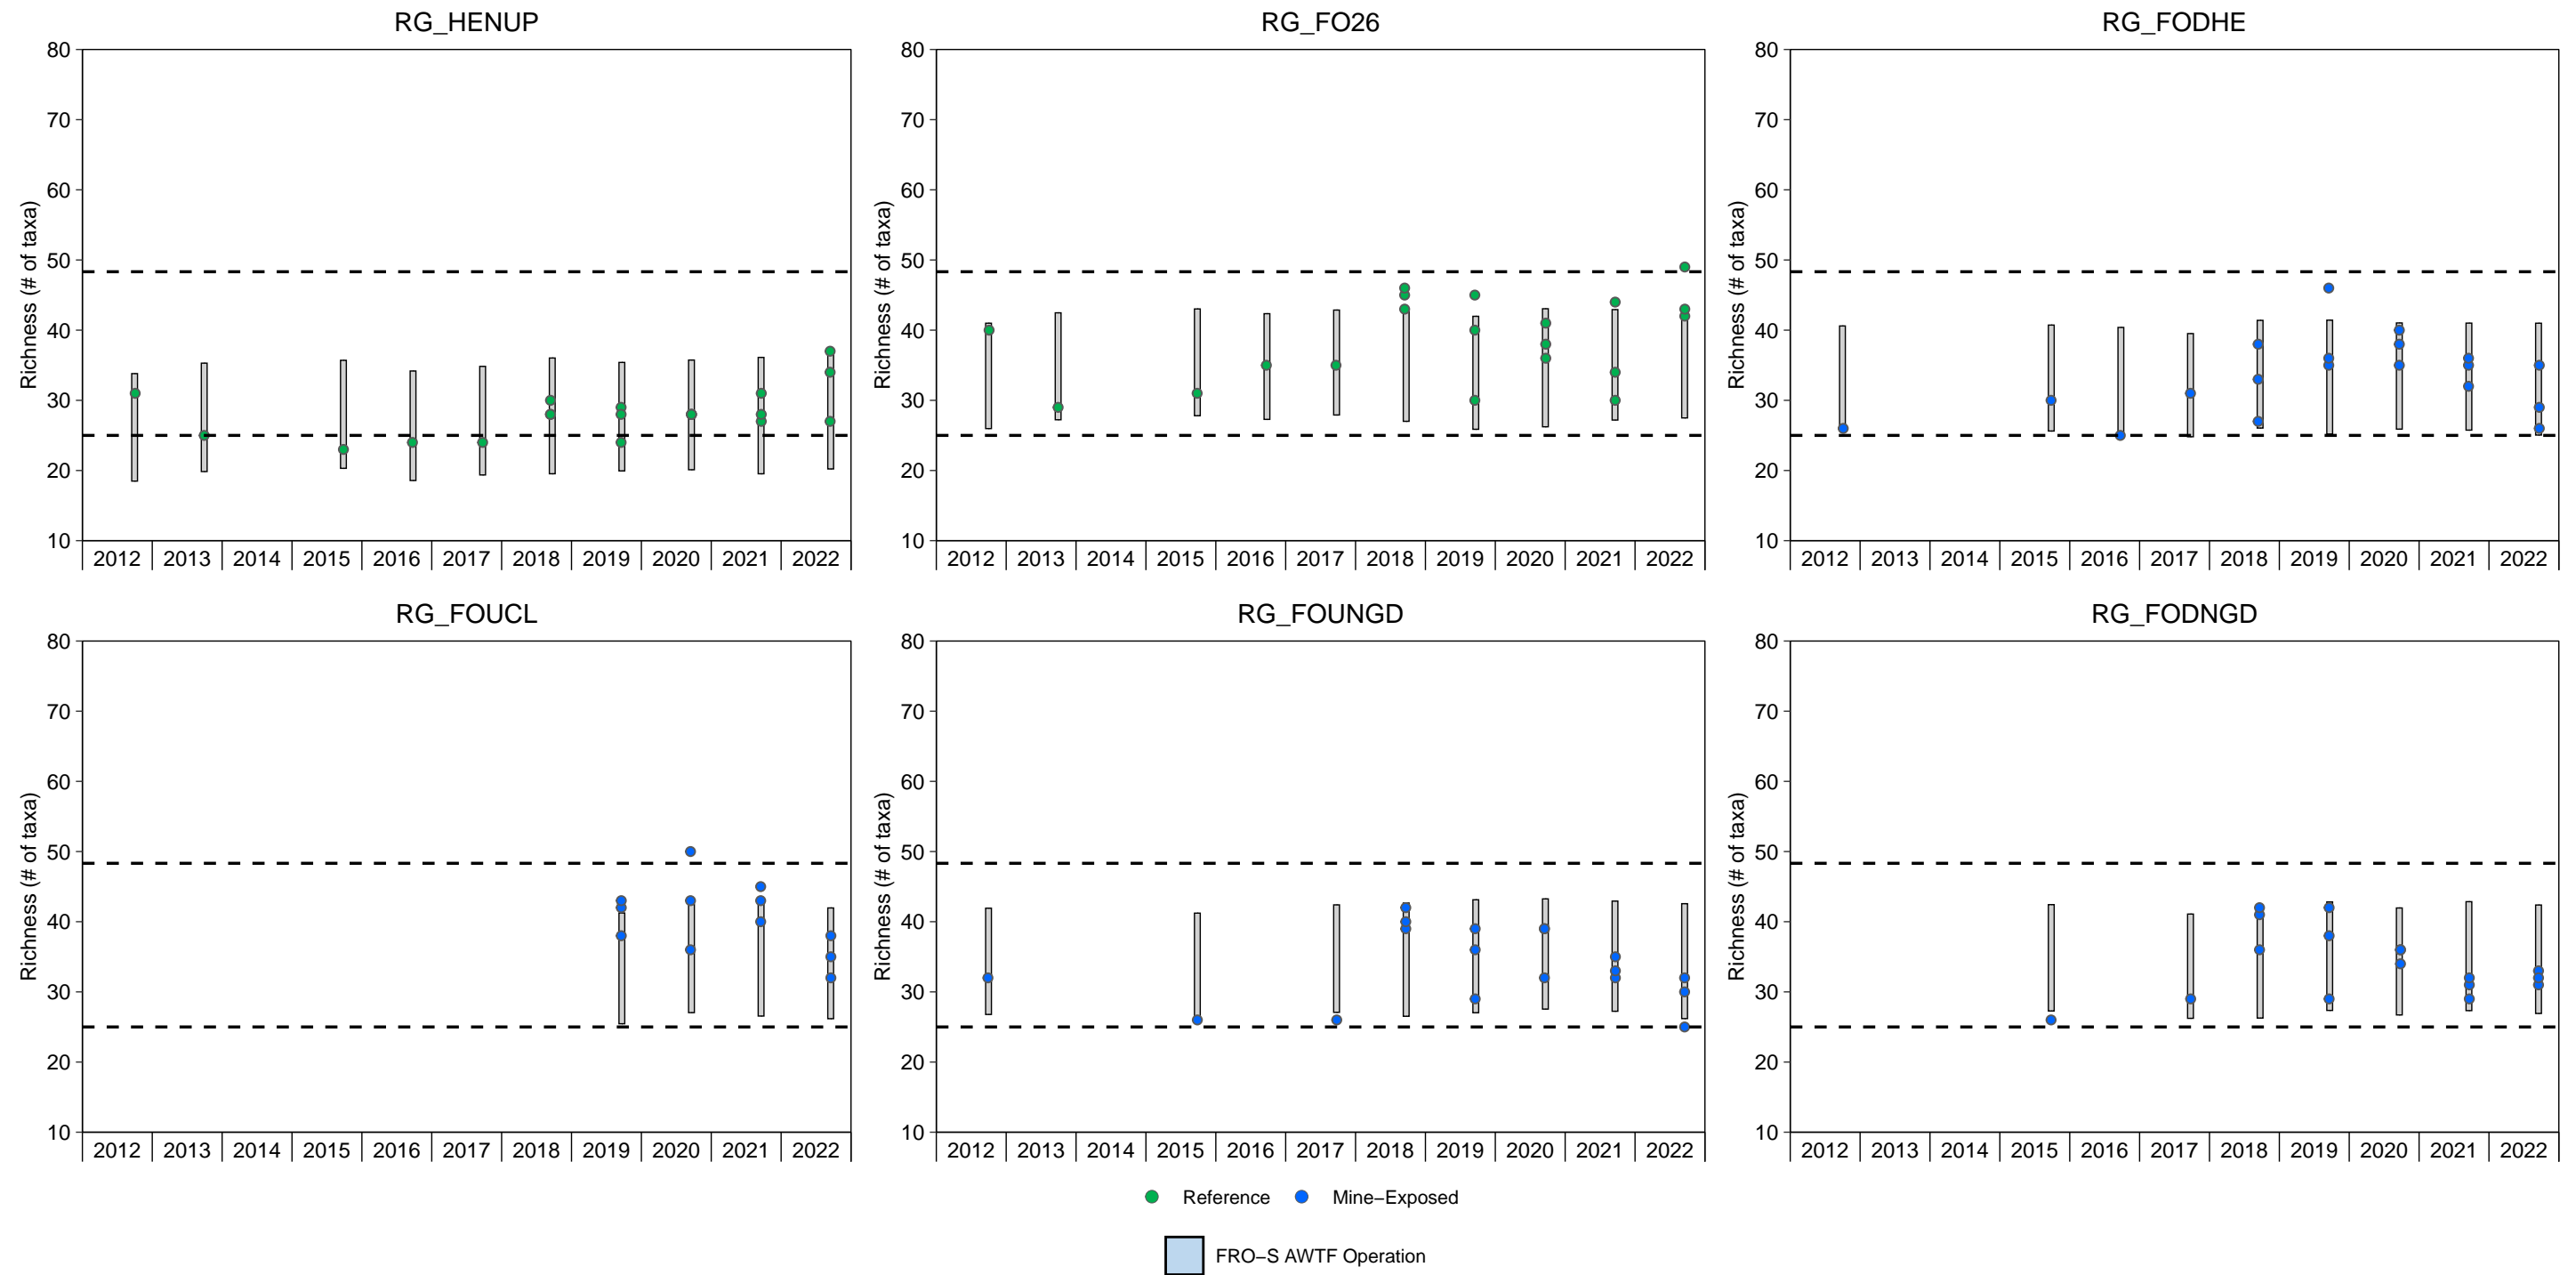

Figure G.12: Benthic Invertebrate Richness in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

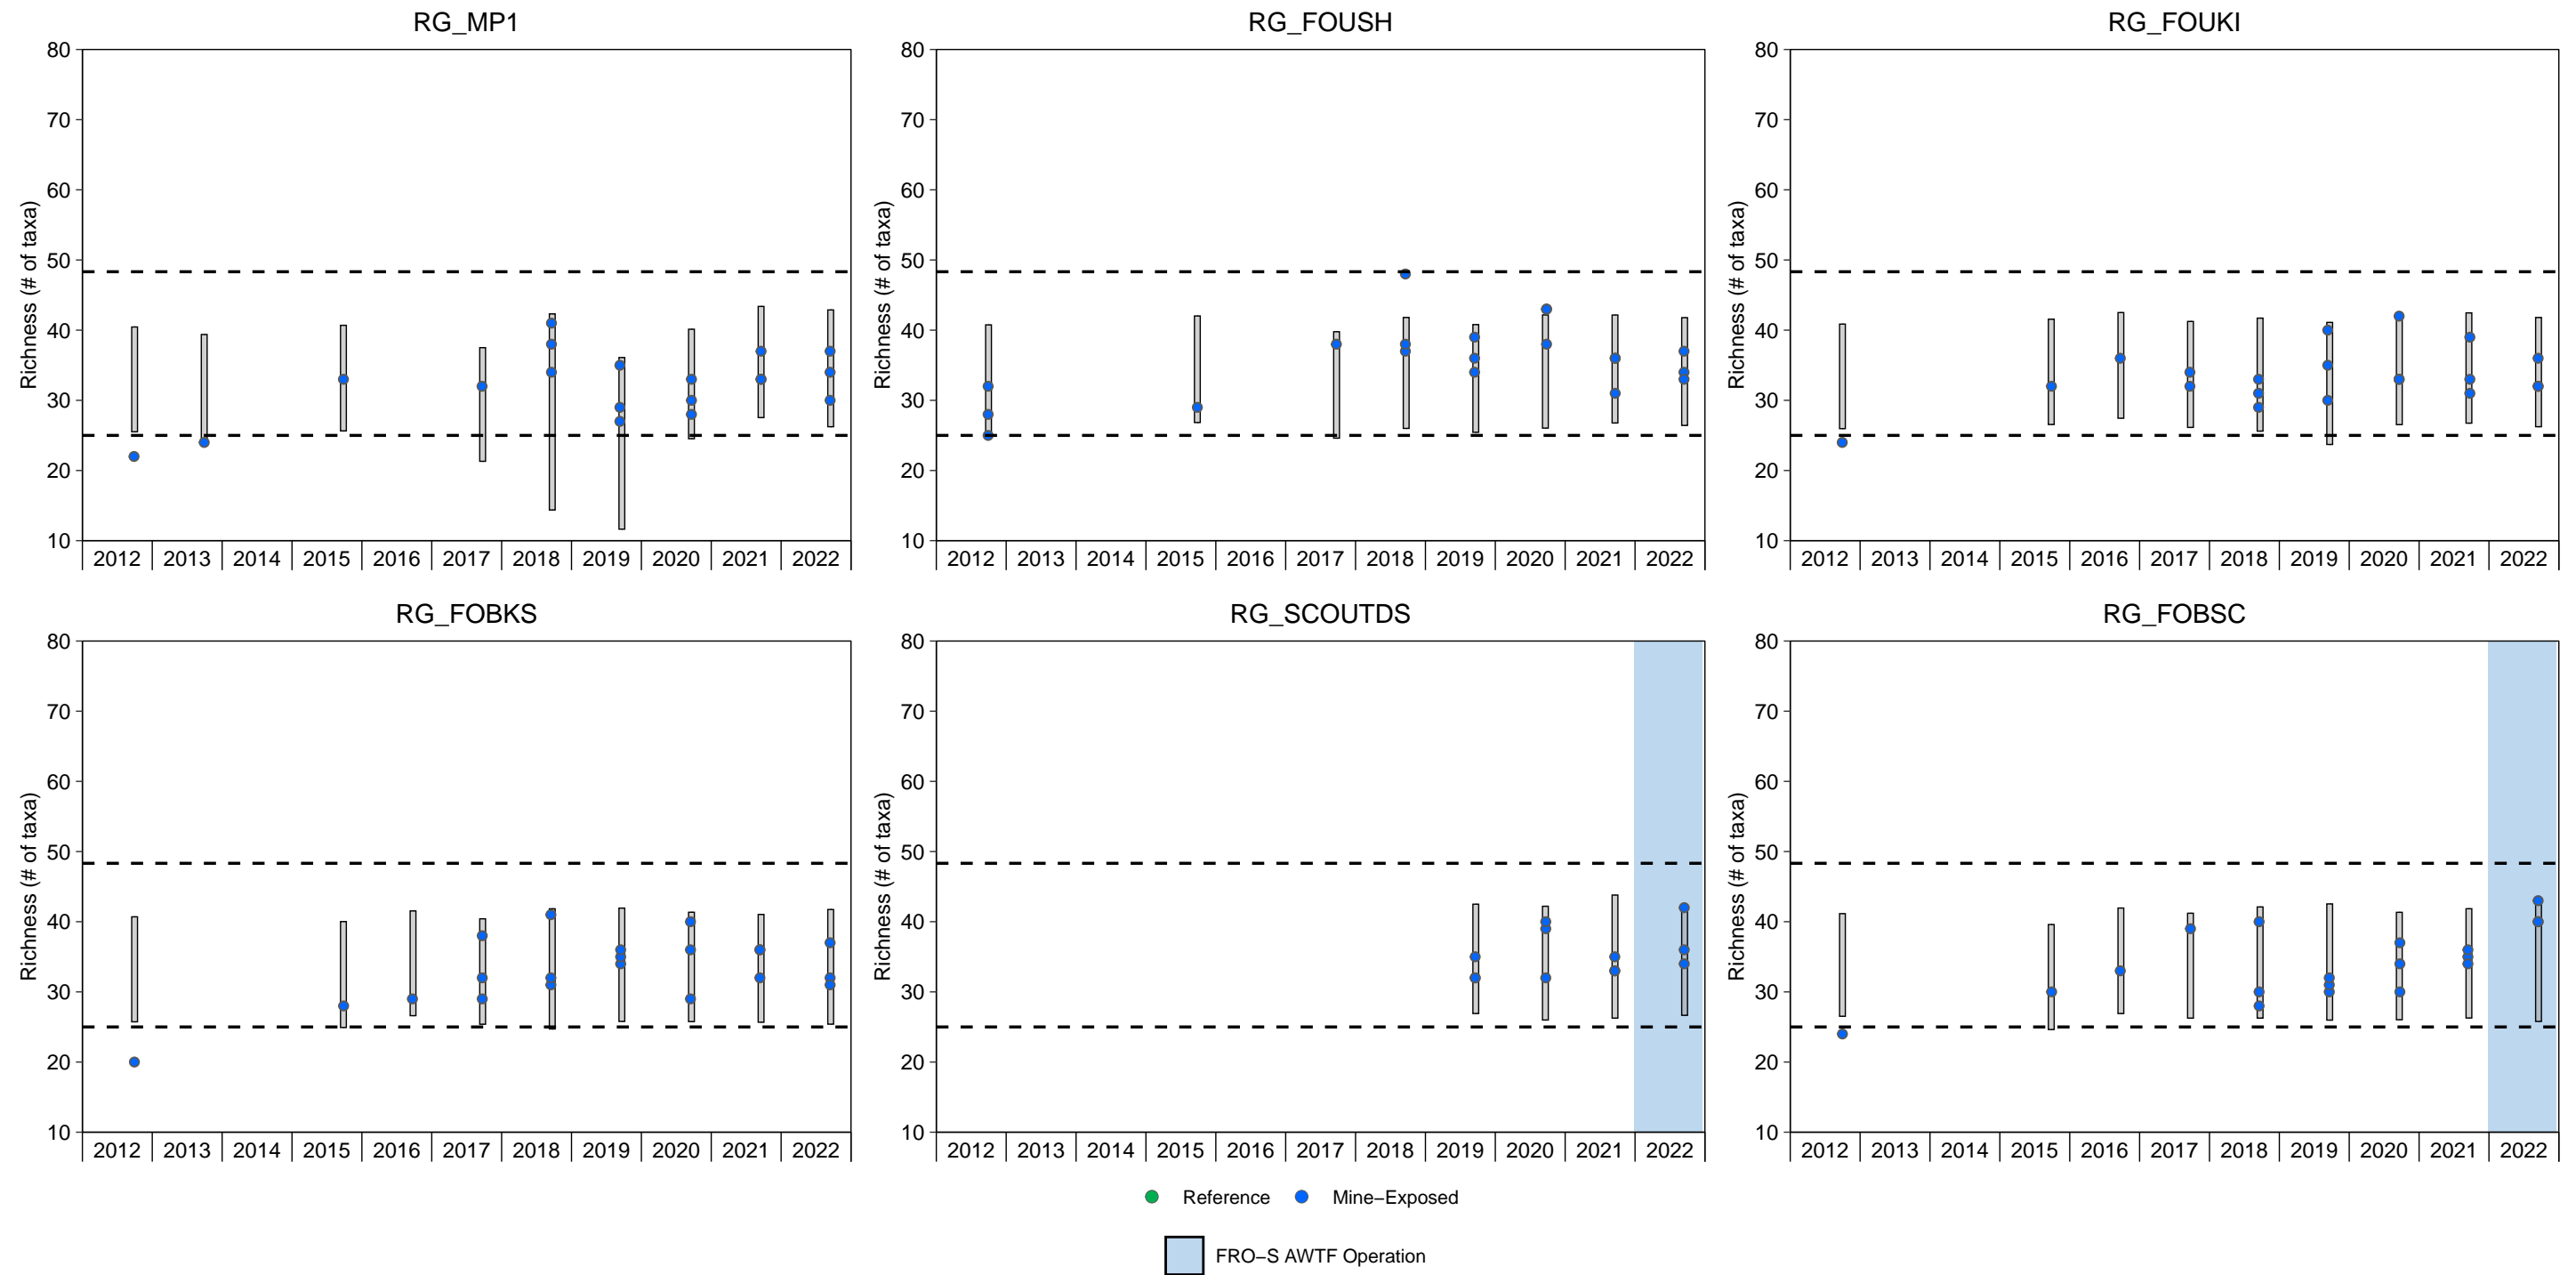

Figure G.12: Benthic Invertebrate Richness in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

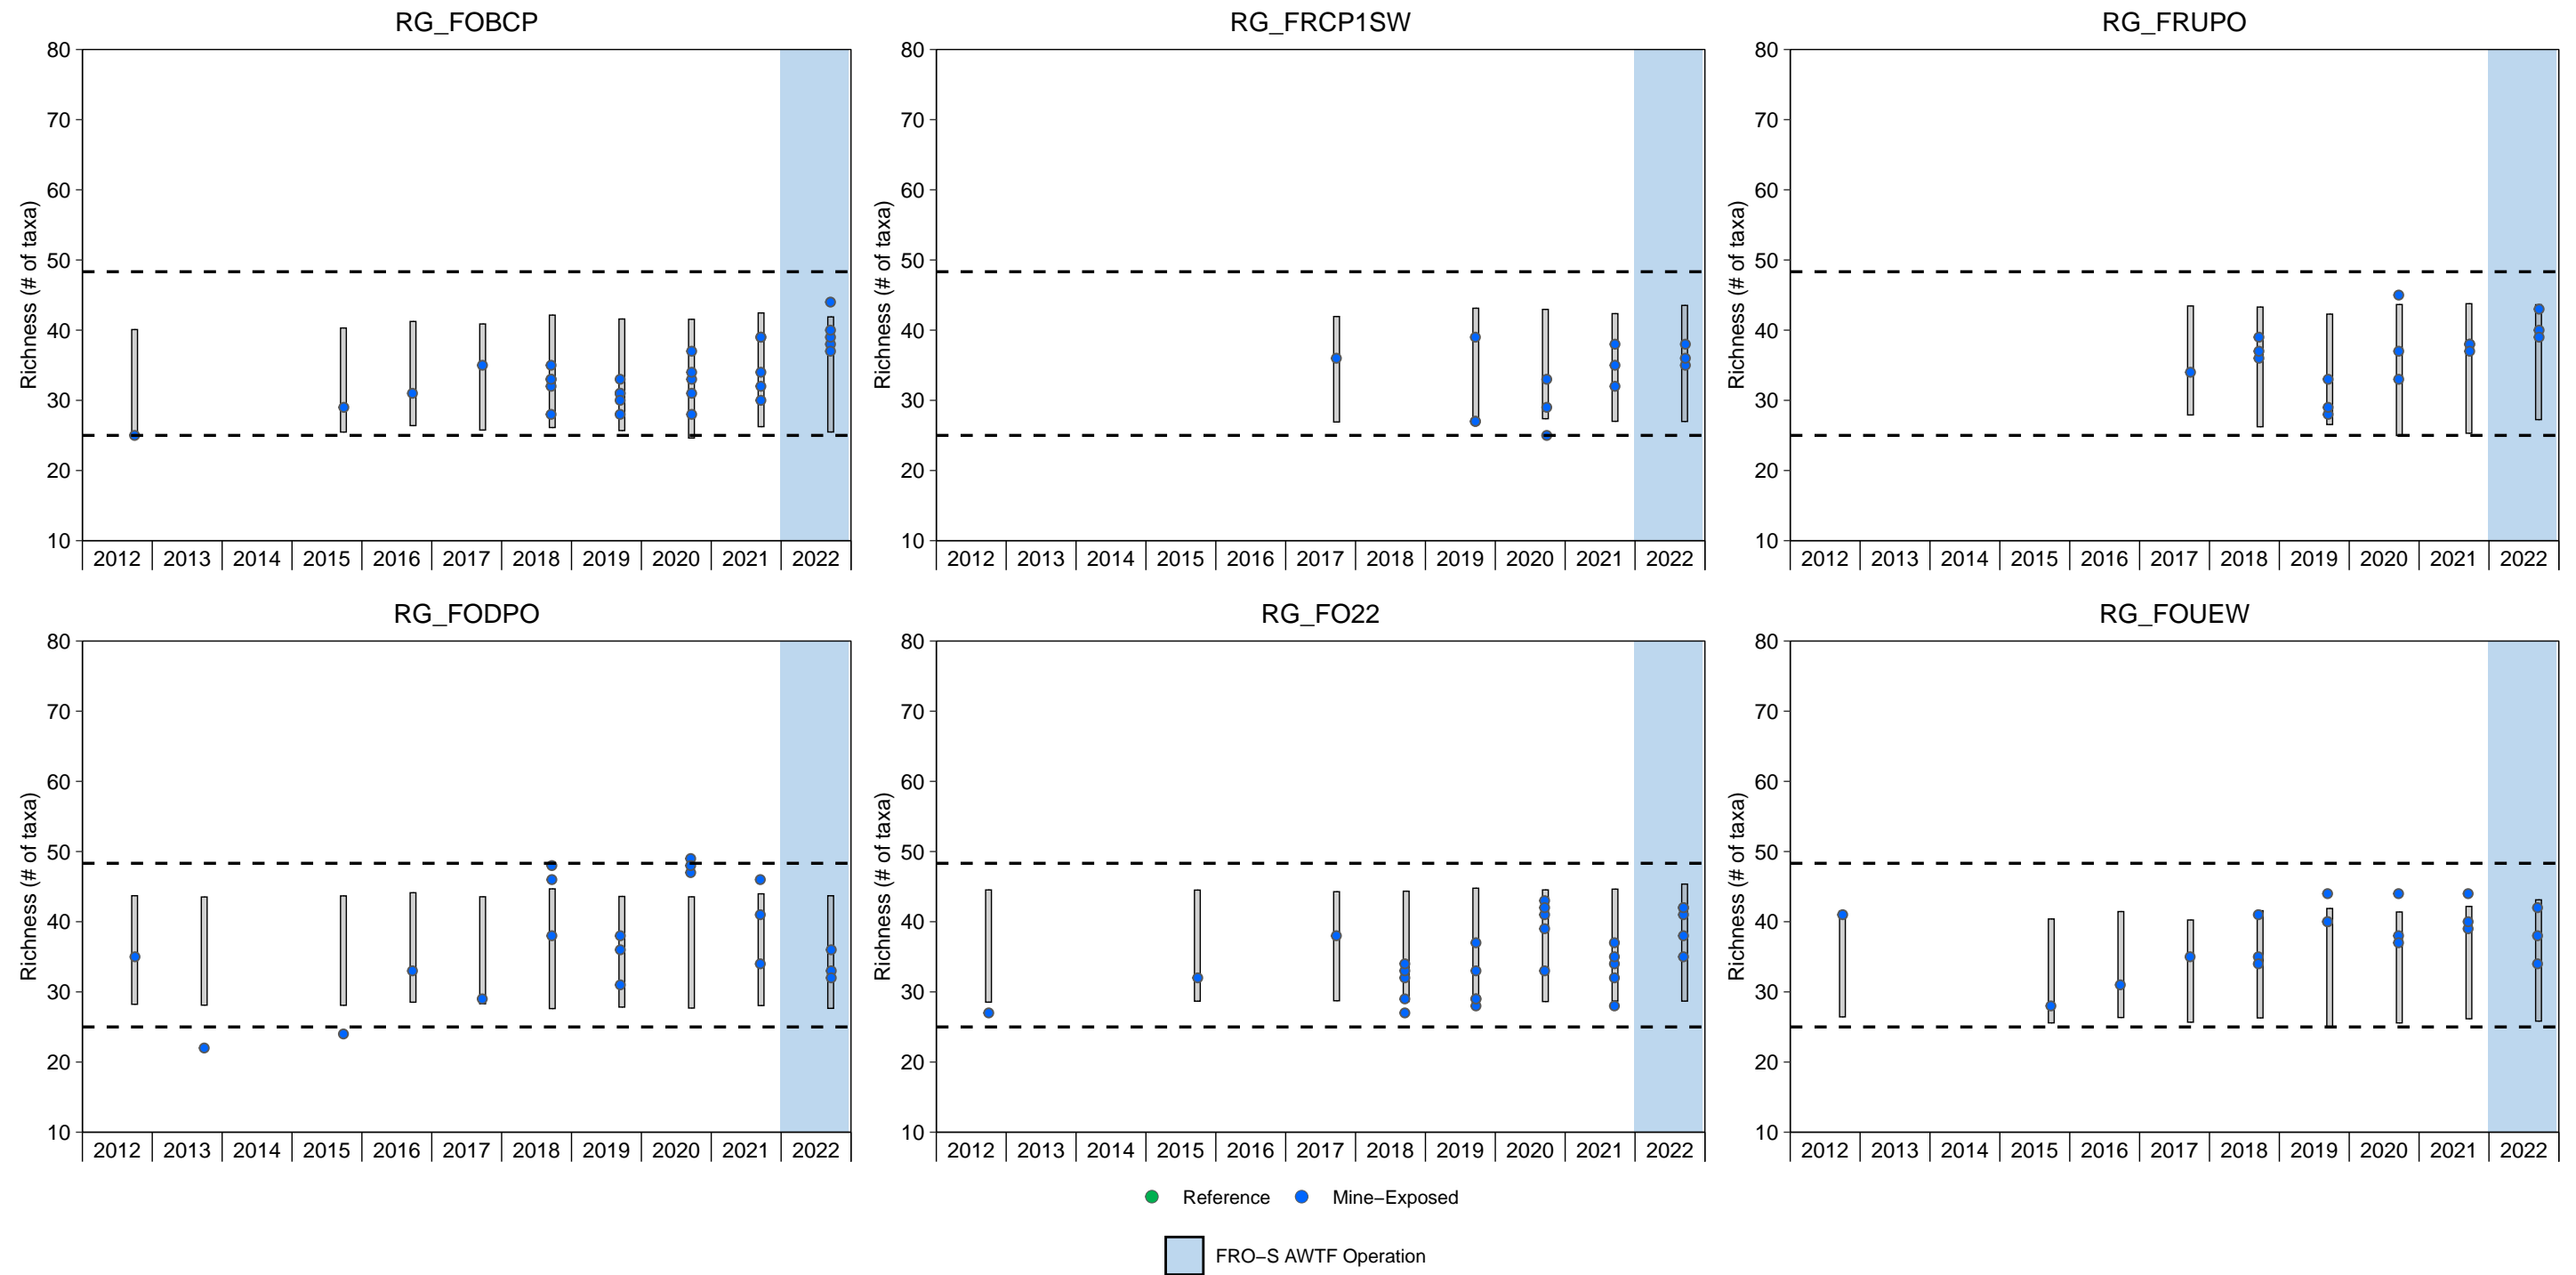

Figure G.12: Benthic Invertebrate Richness in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

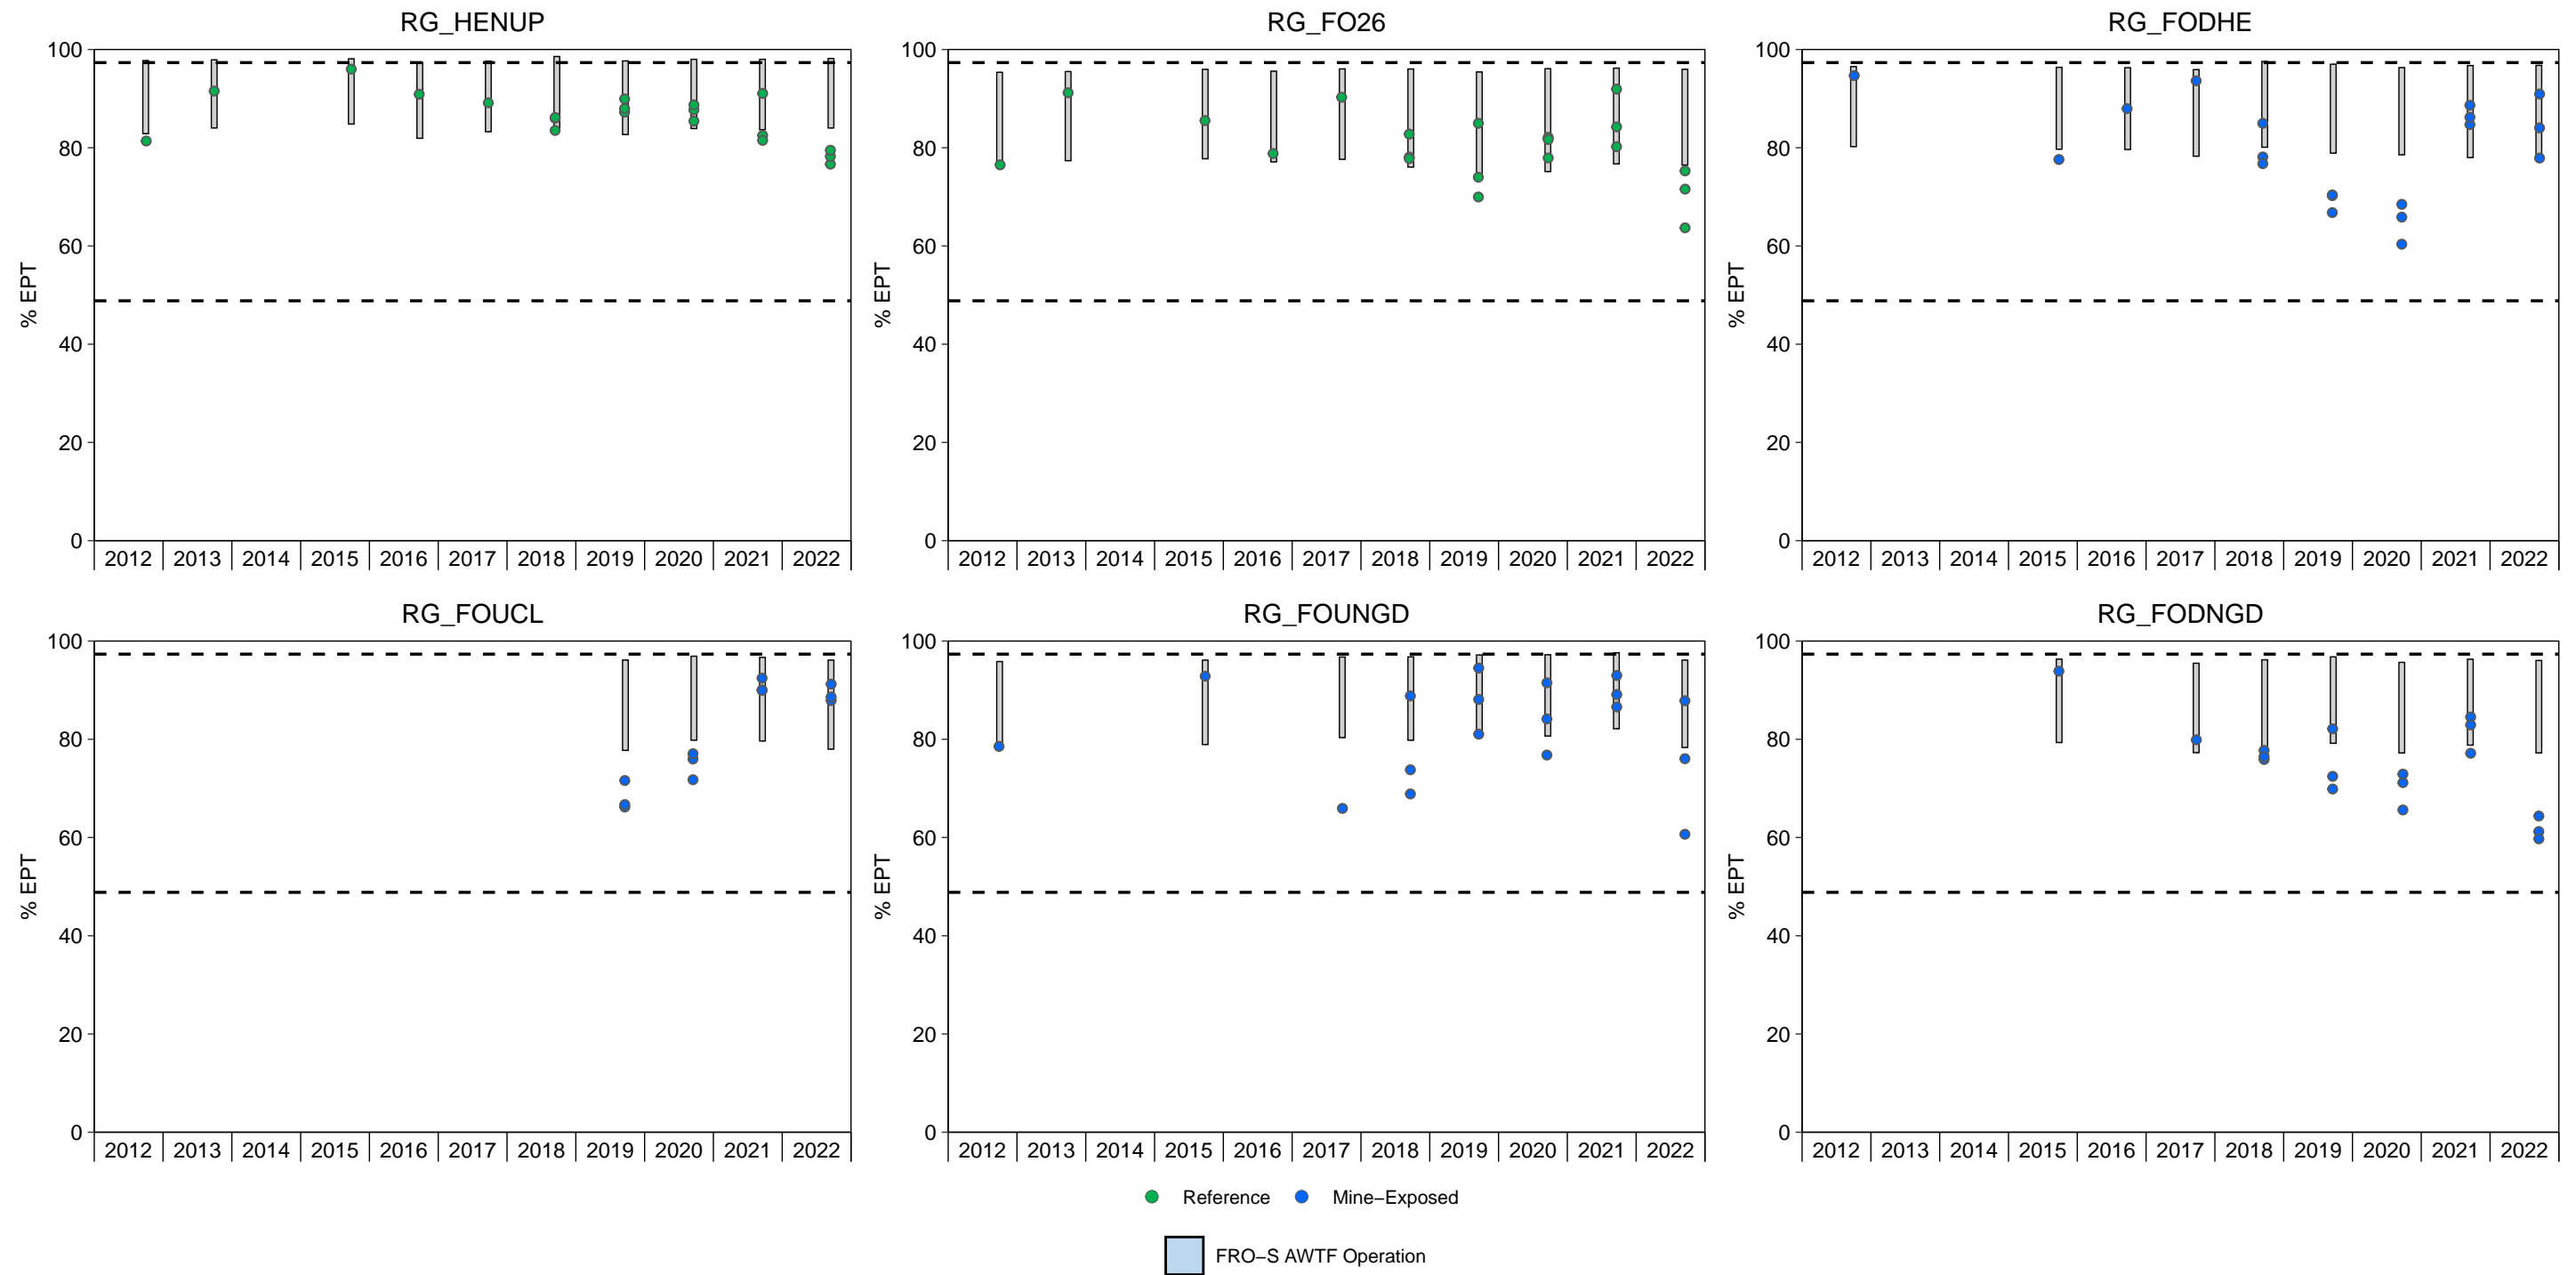

Figure G.13: Benthic Invertebrate % EPT in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

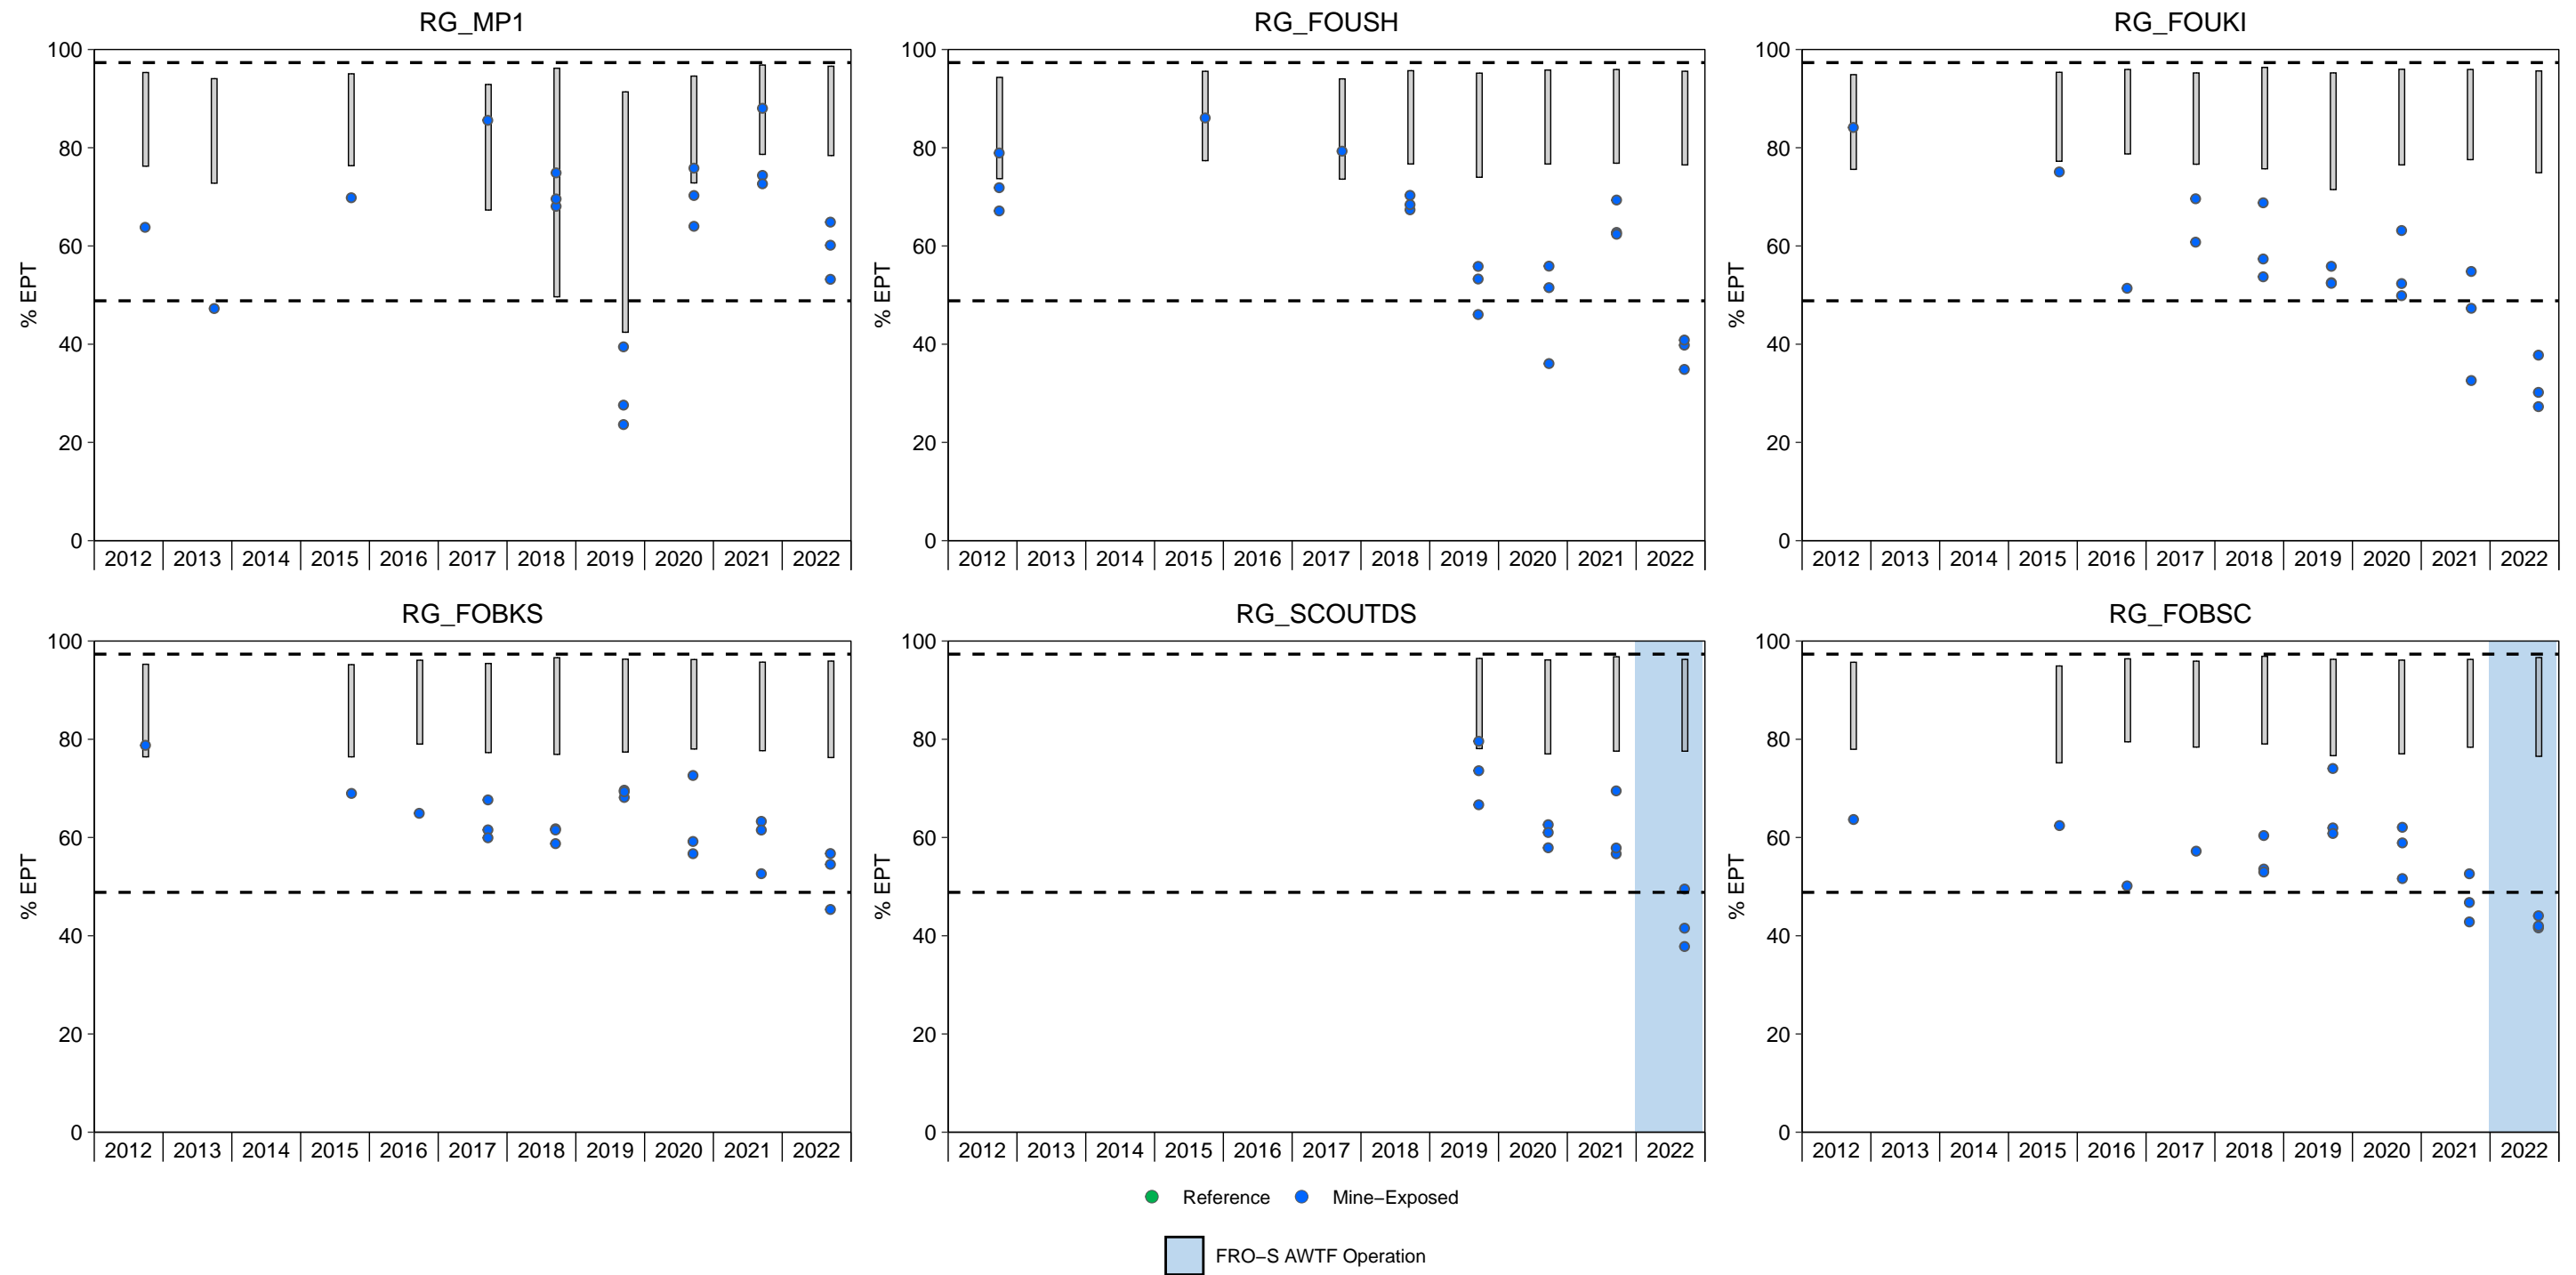

Figure G.13: Benthic Invertebrate % EPT in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.13: Benthic Invertebrate % EPT in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

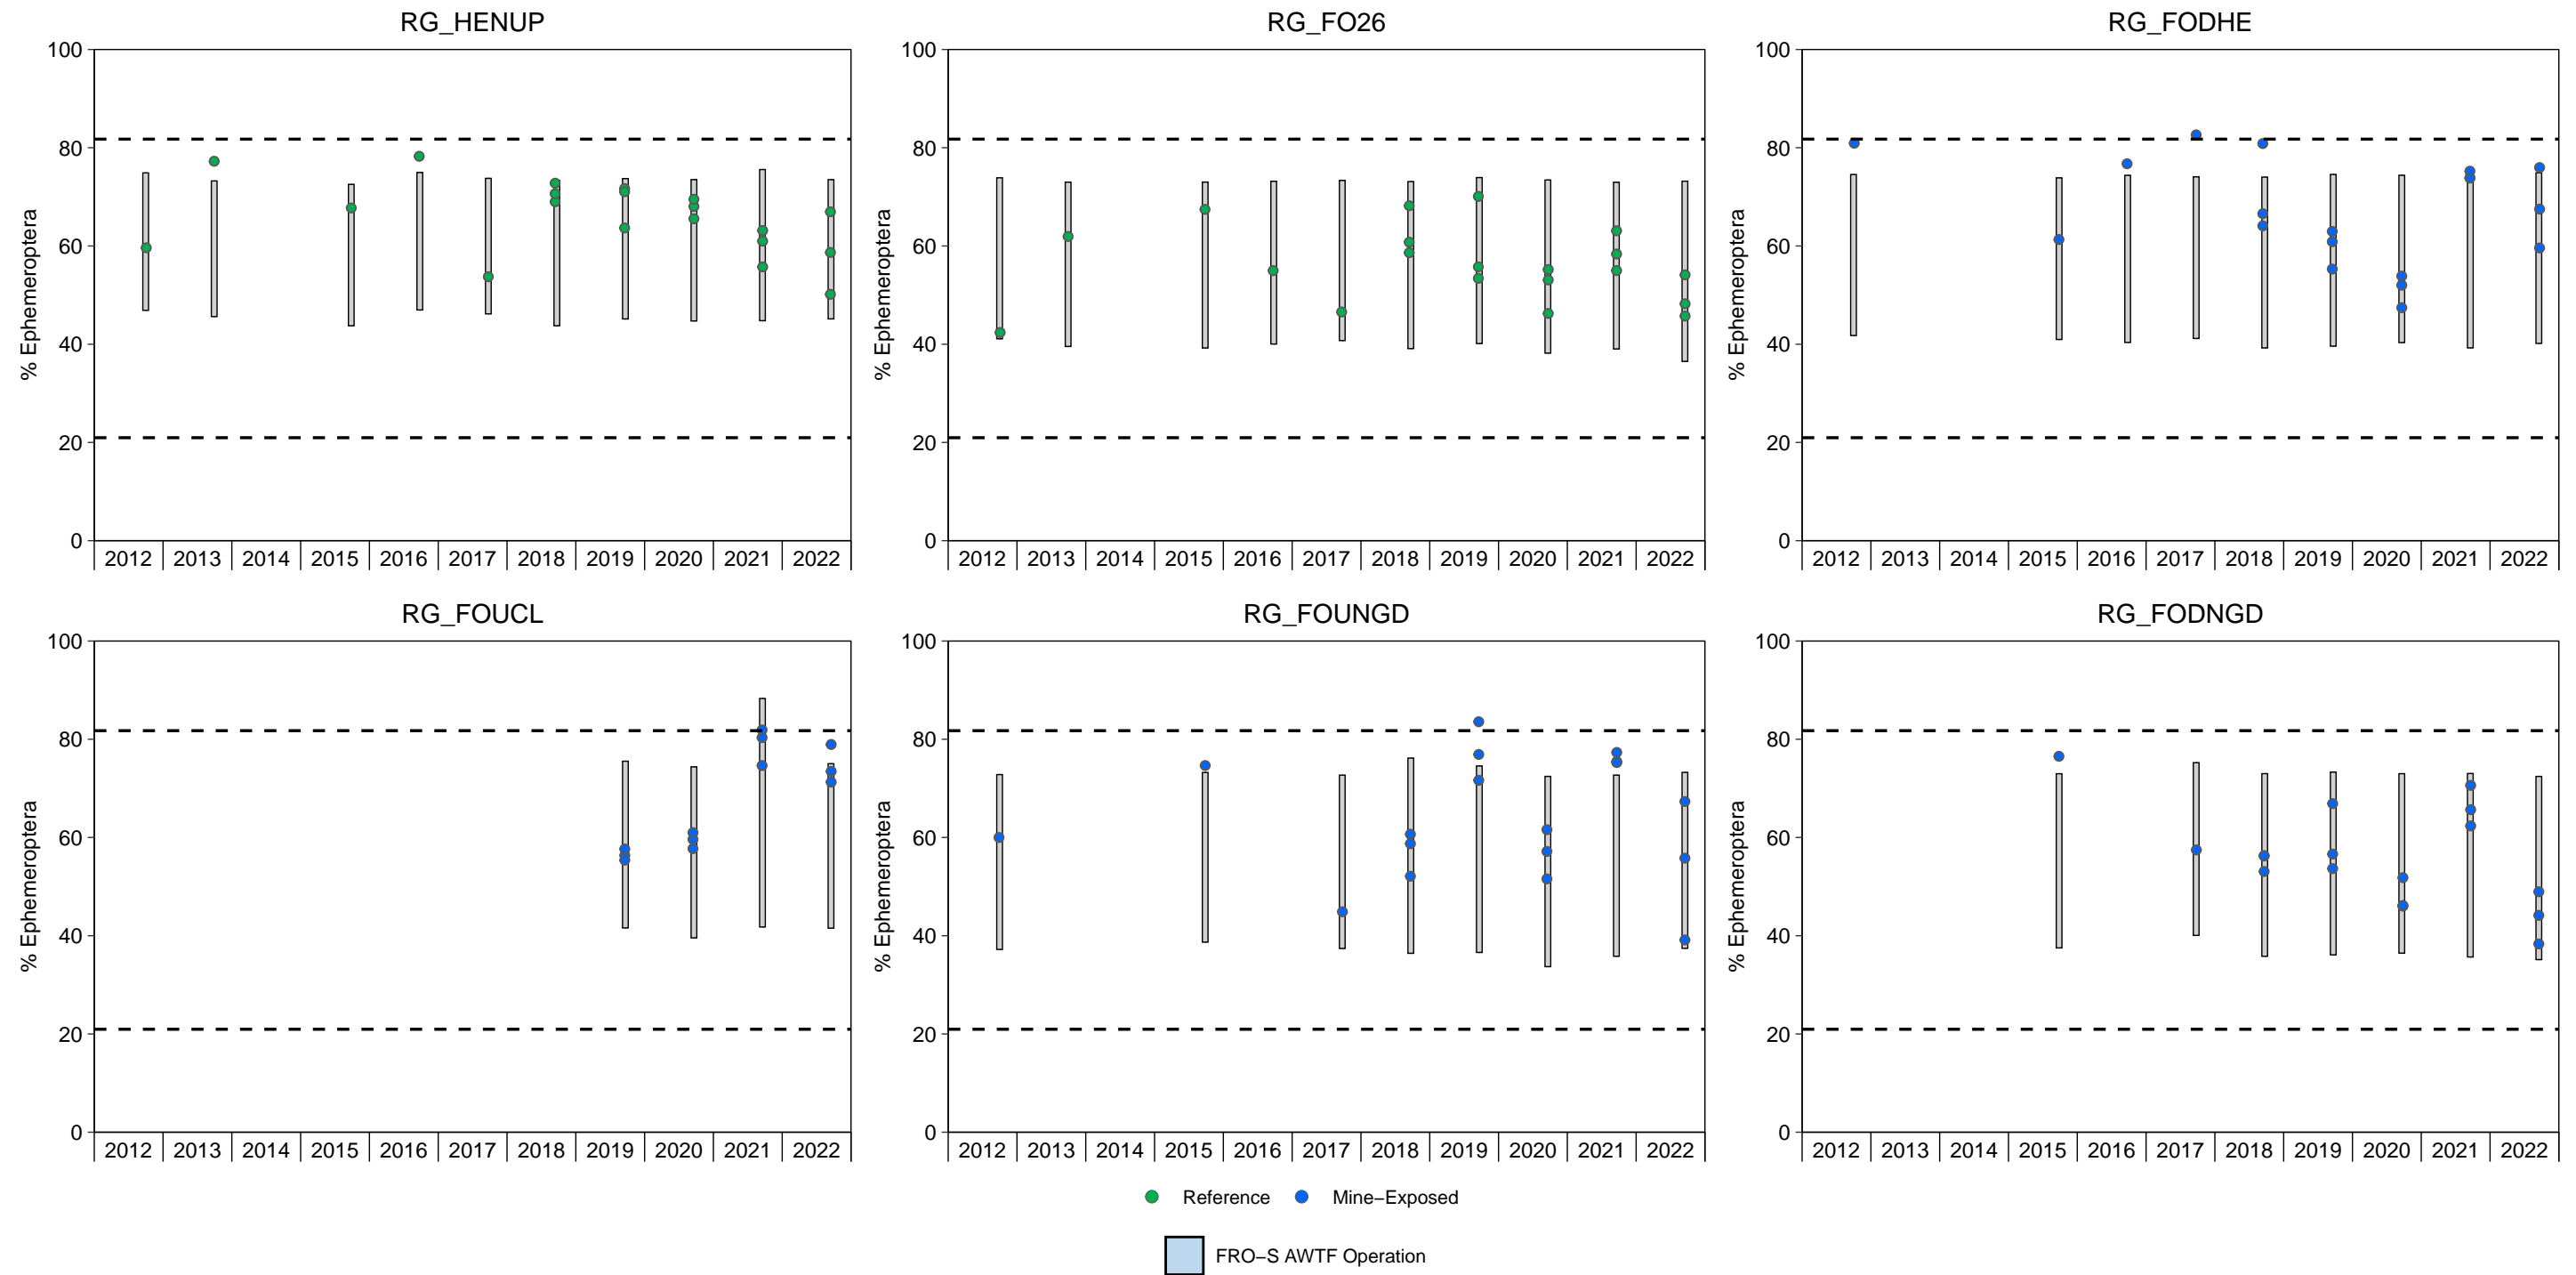

Figure G.14: Benthic Invertebrate % Ephemeroptera in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

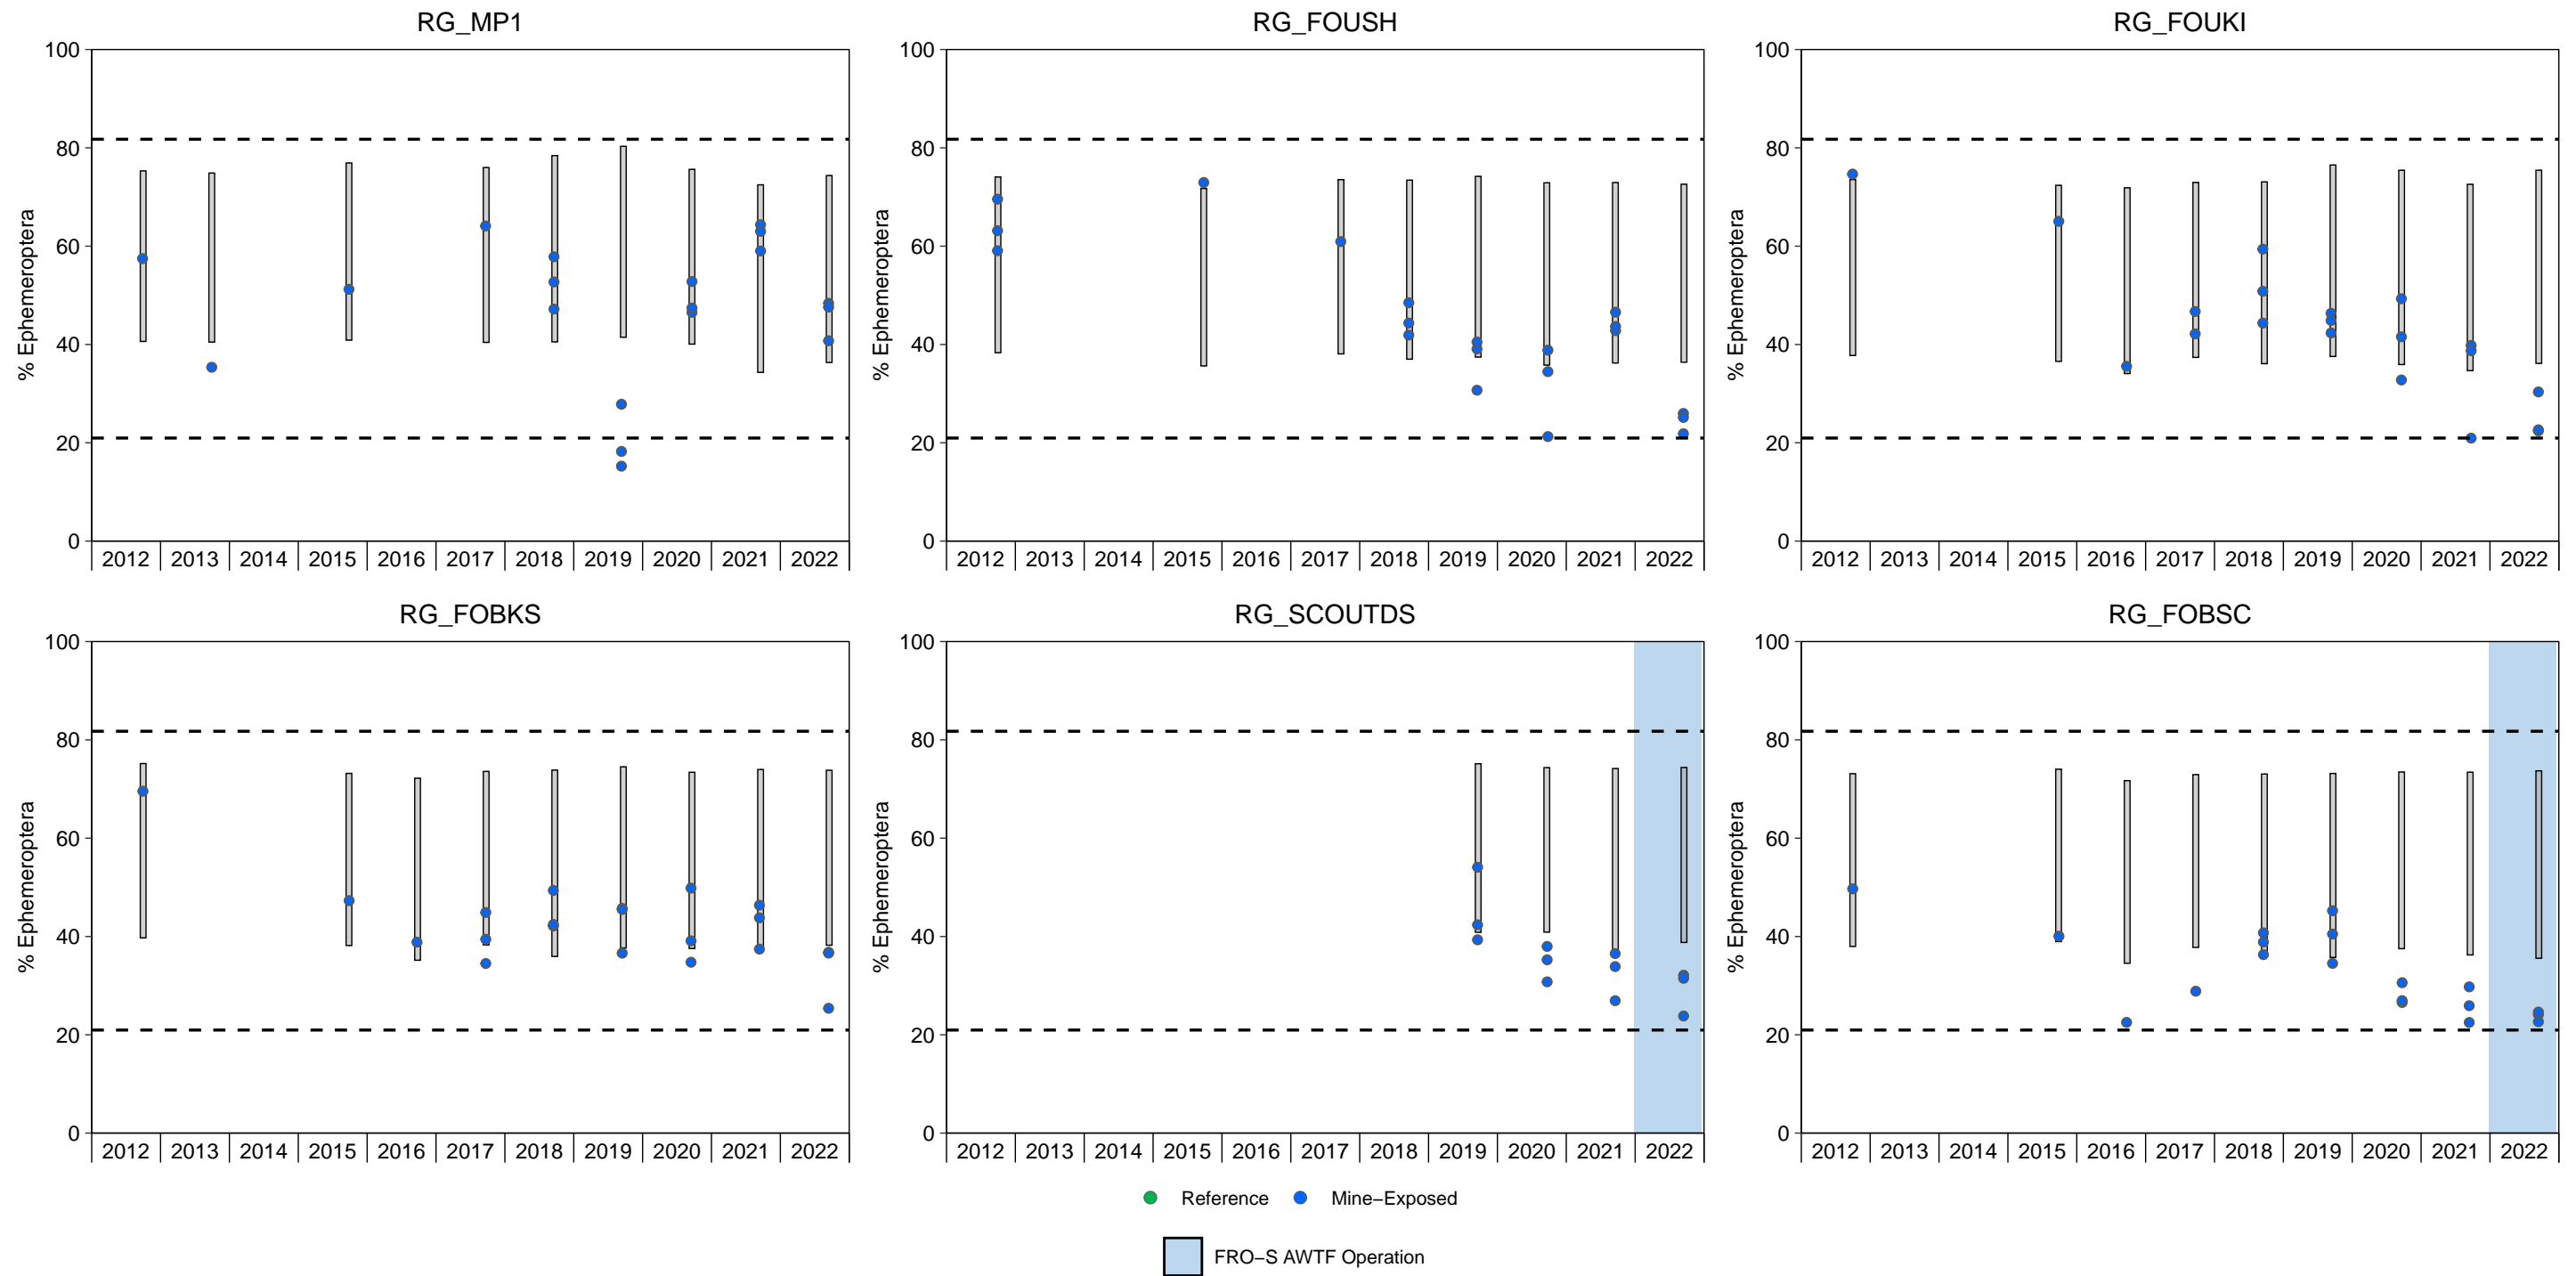

Figure G.14: Benthic Invertebrate % Ephemeroptera in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

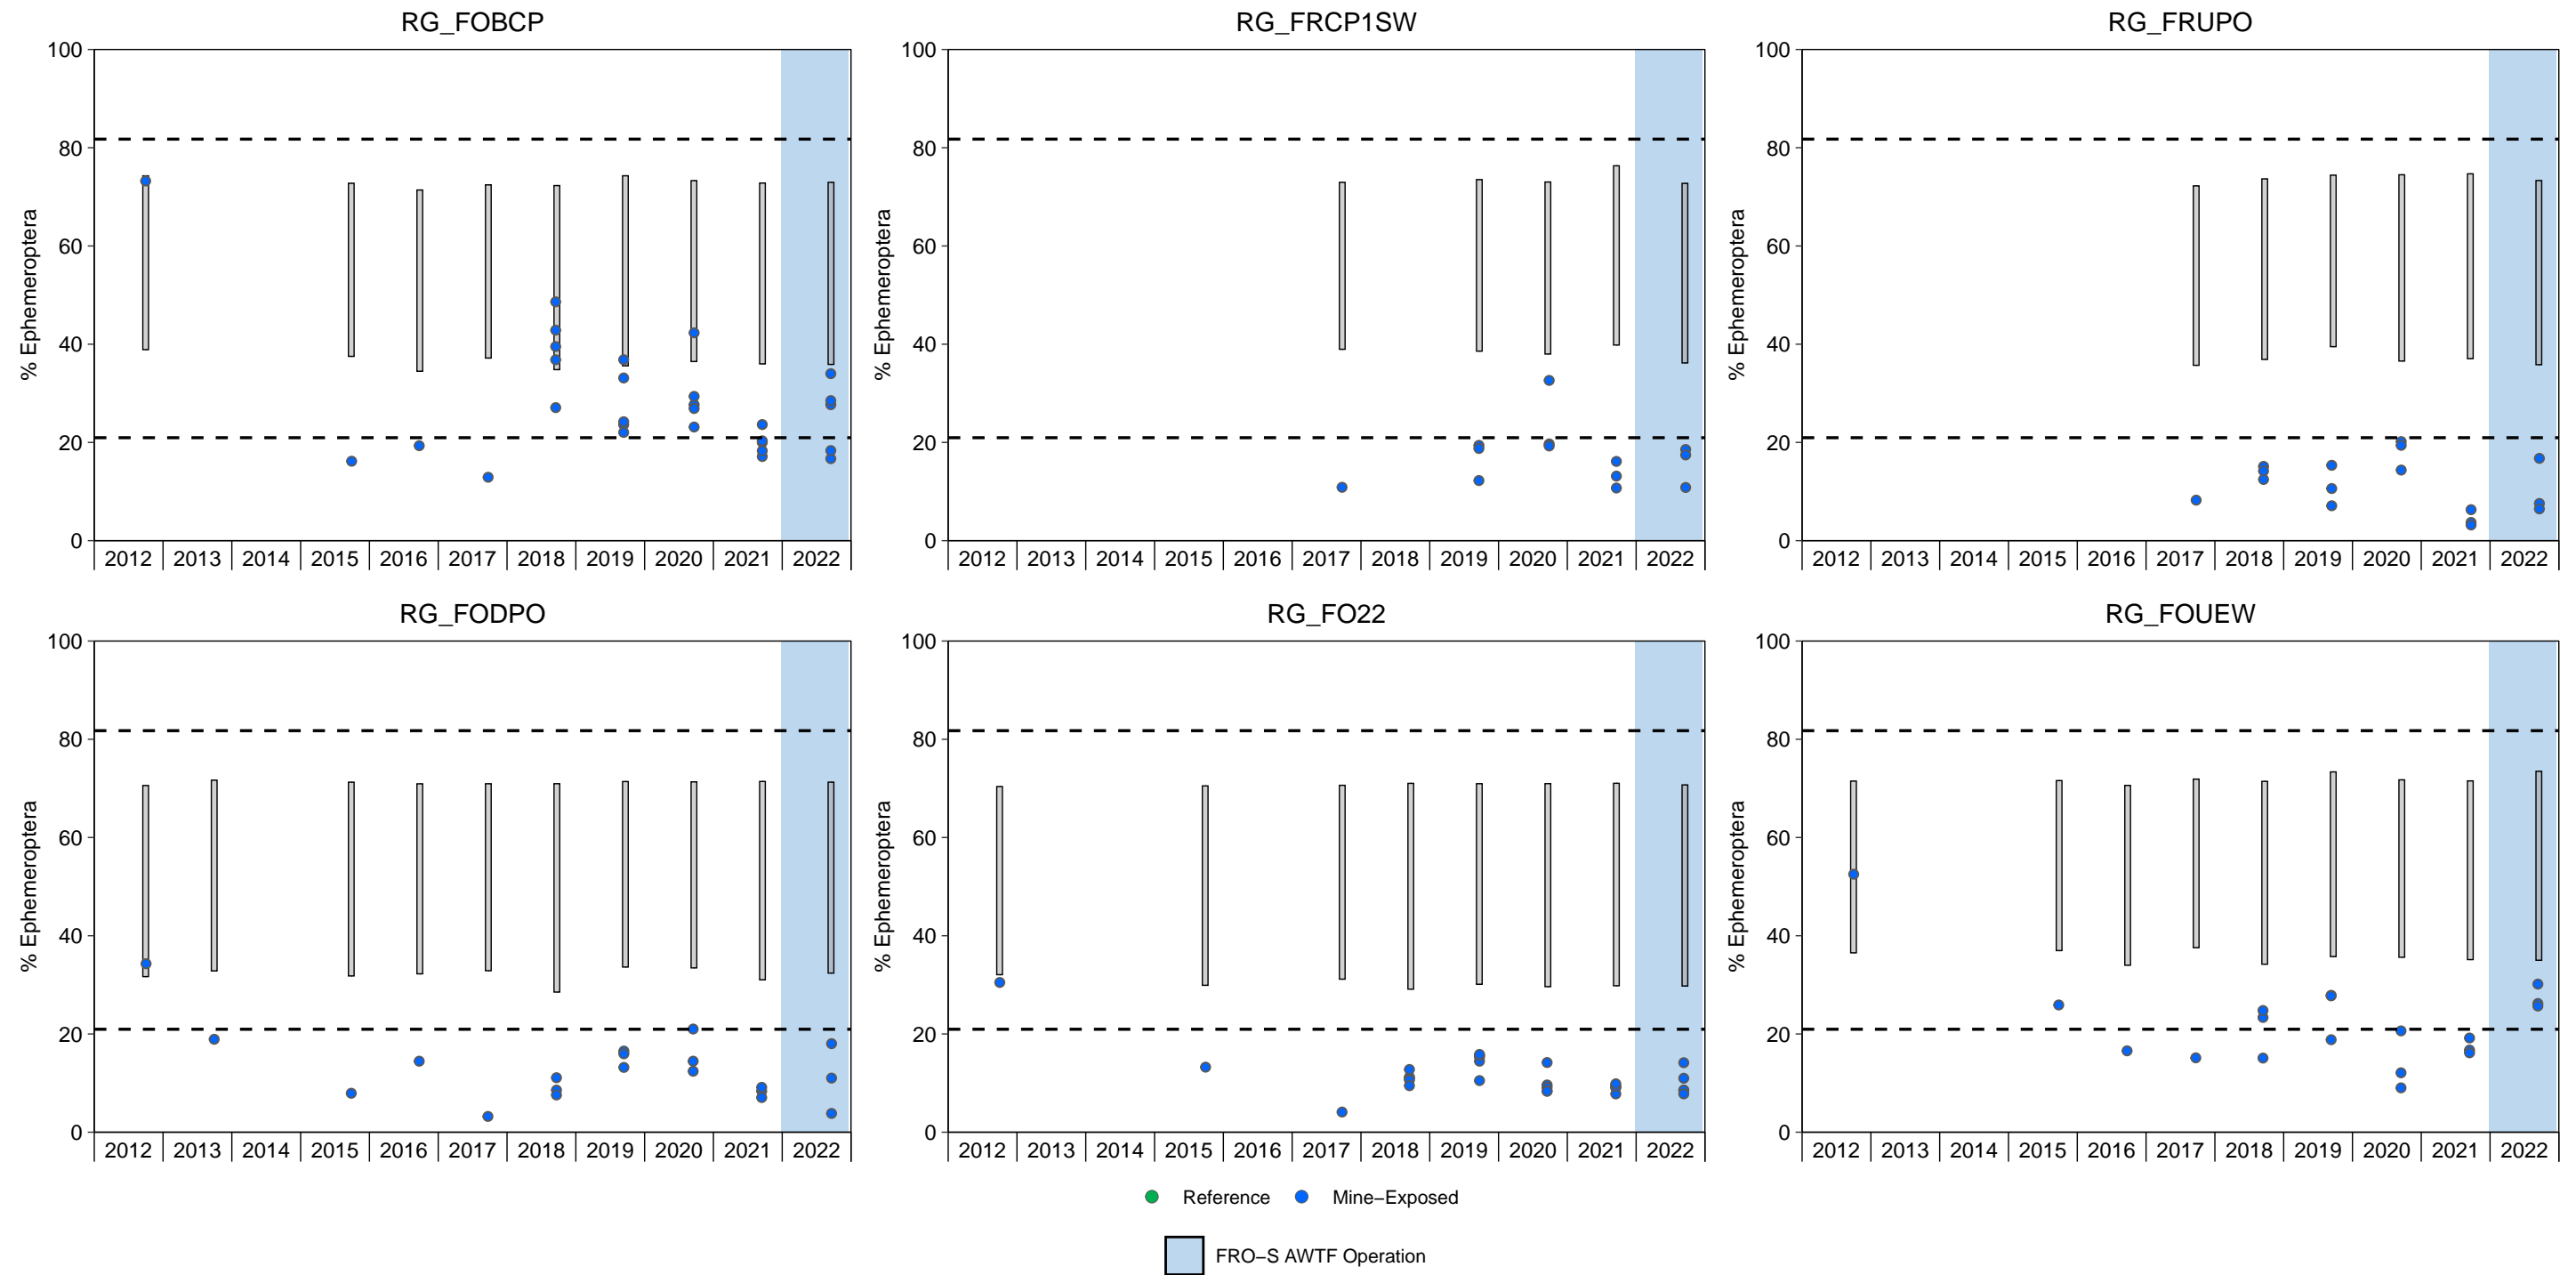

Figure G.14: Benthic Invertebrate % Ephemeroptera in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

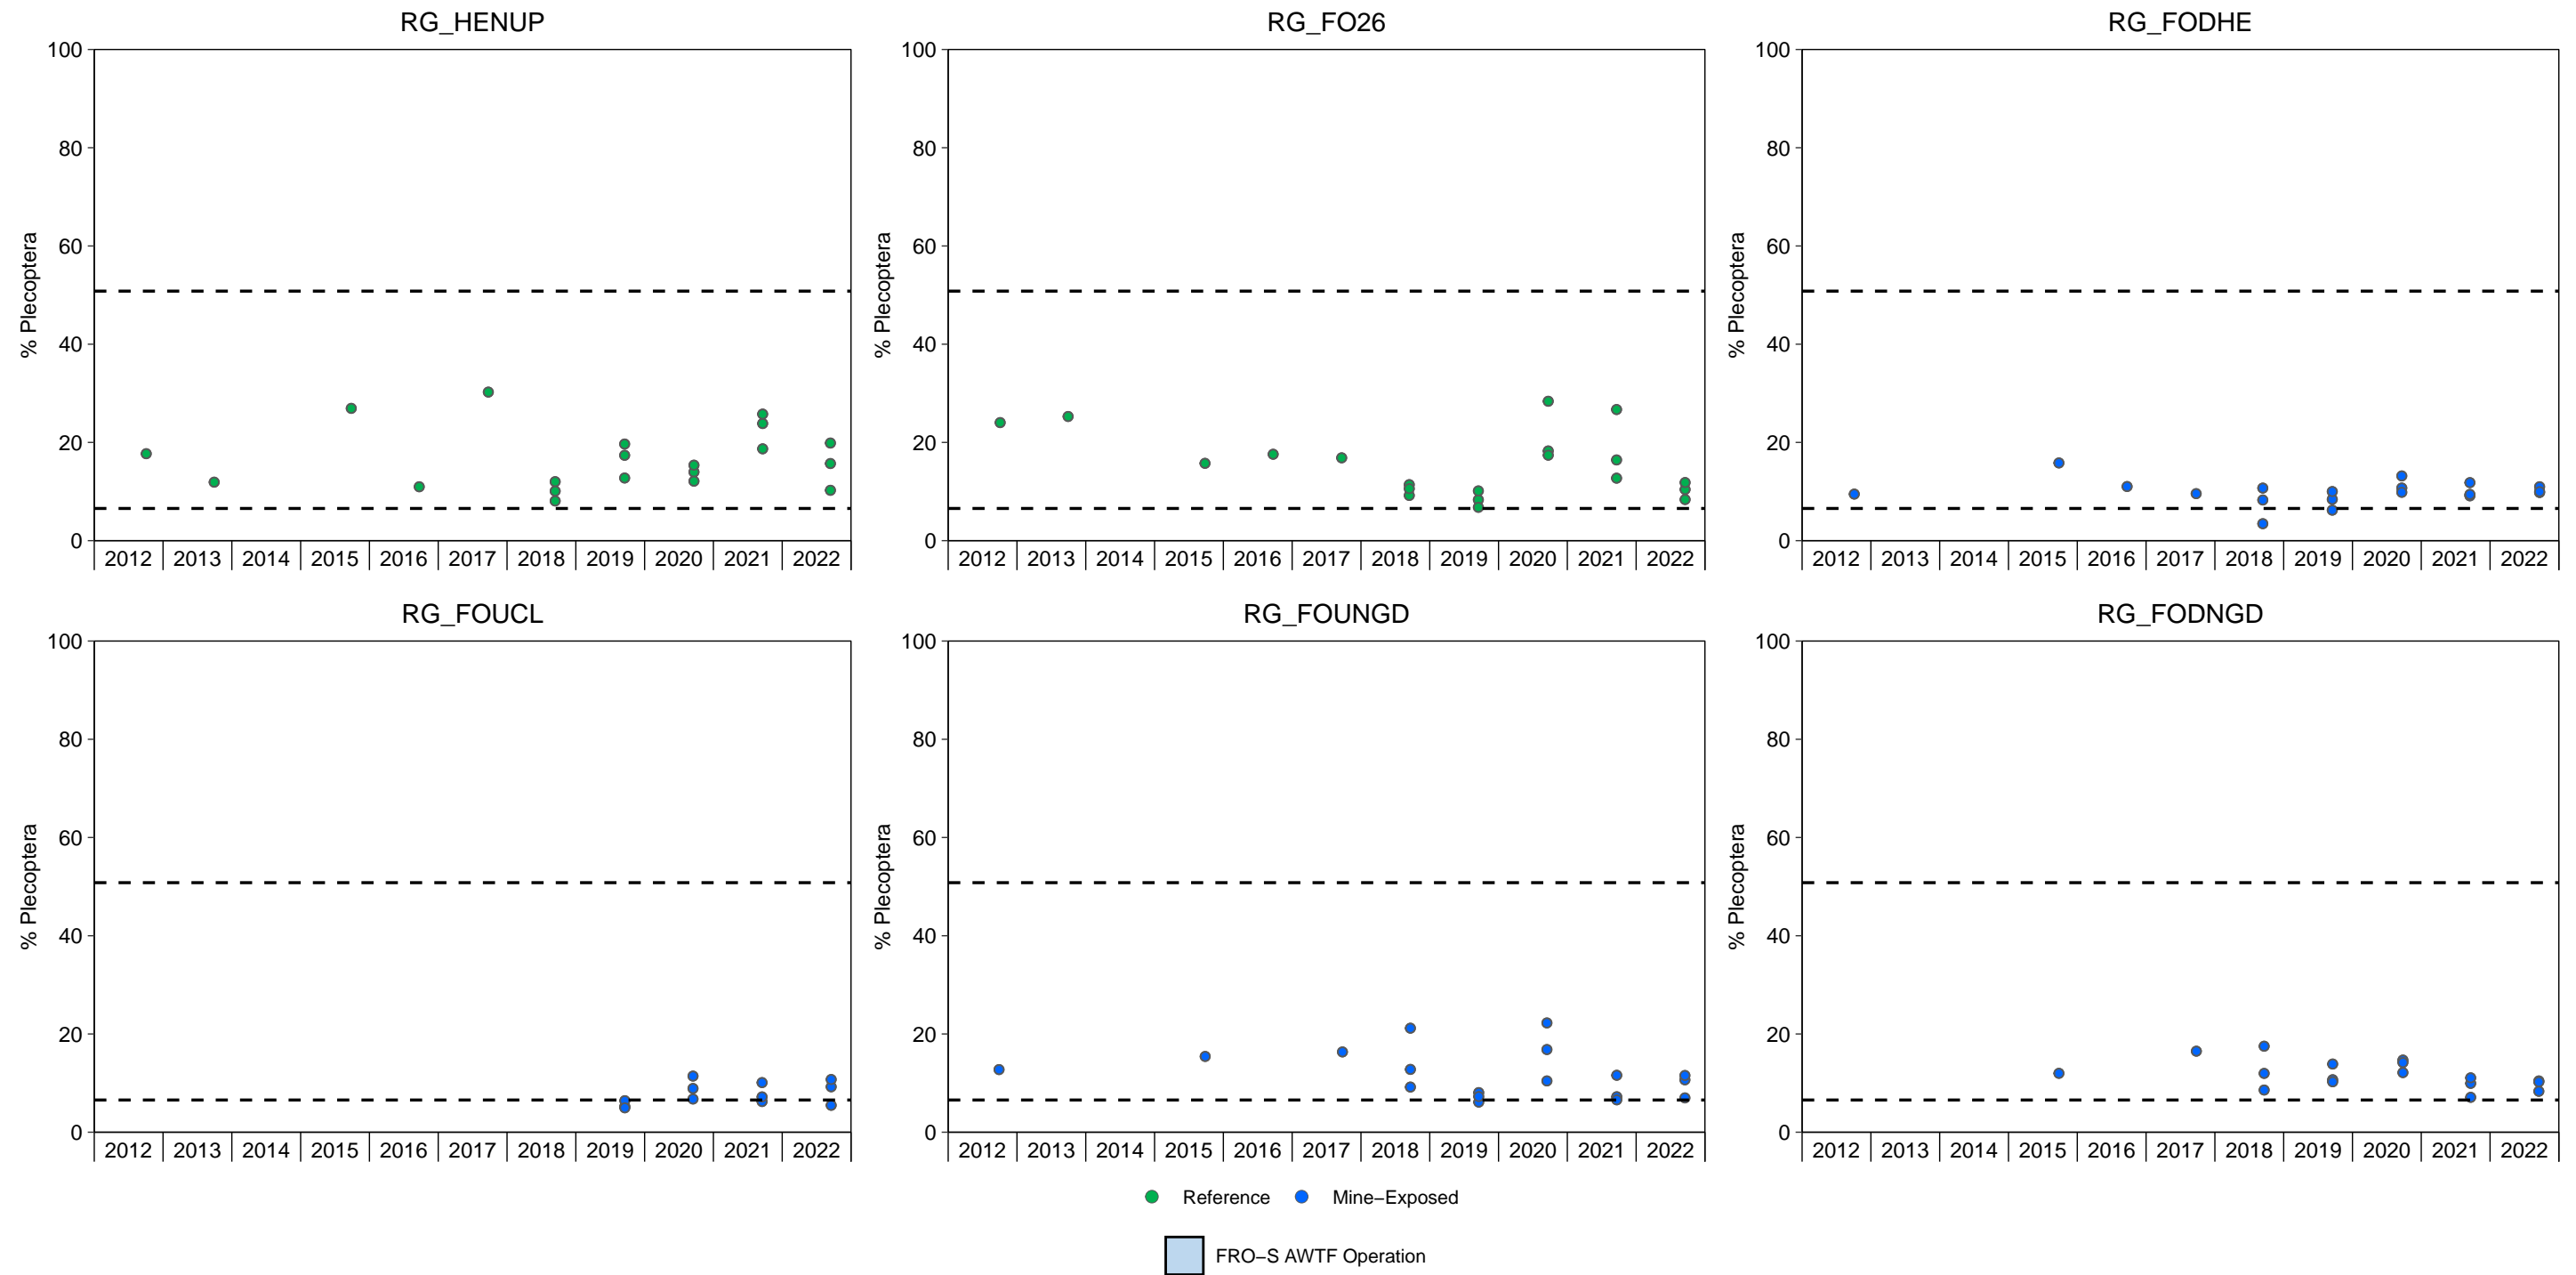

Figure G.15: Benthic Invertebrate % Plecoptera in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

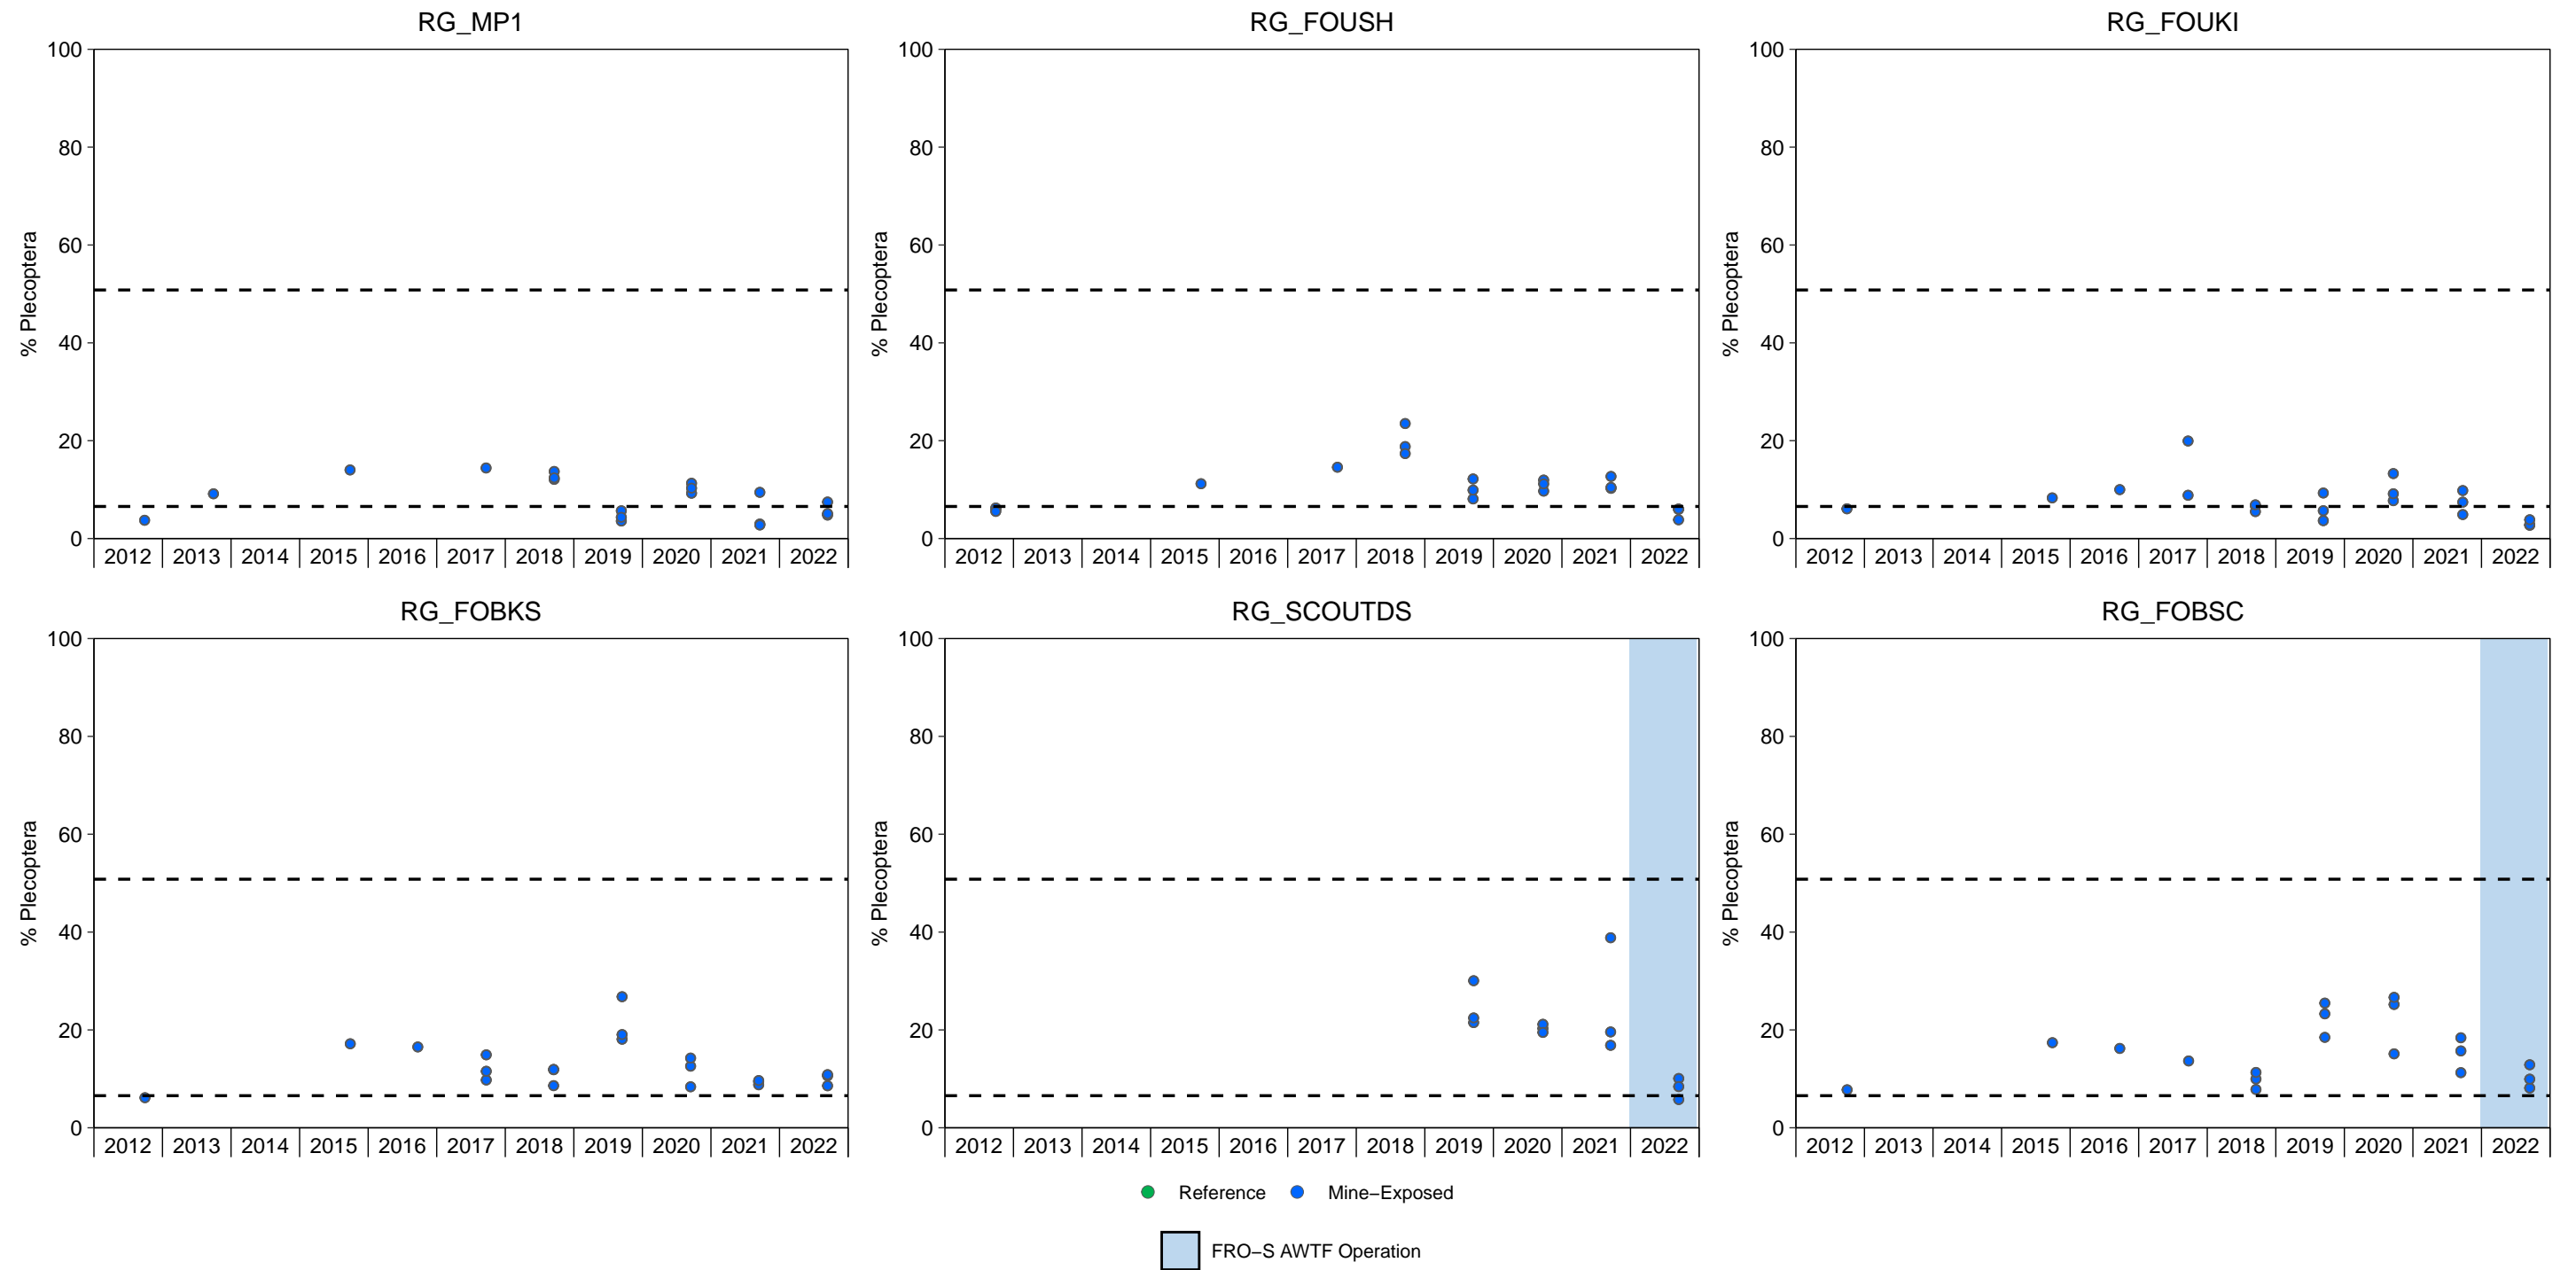

Figure G.15: Benthic Invertebrate % Plecoptera in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

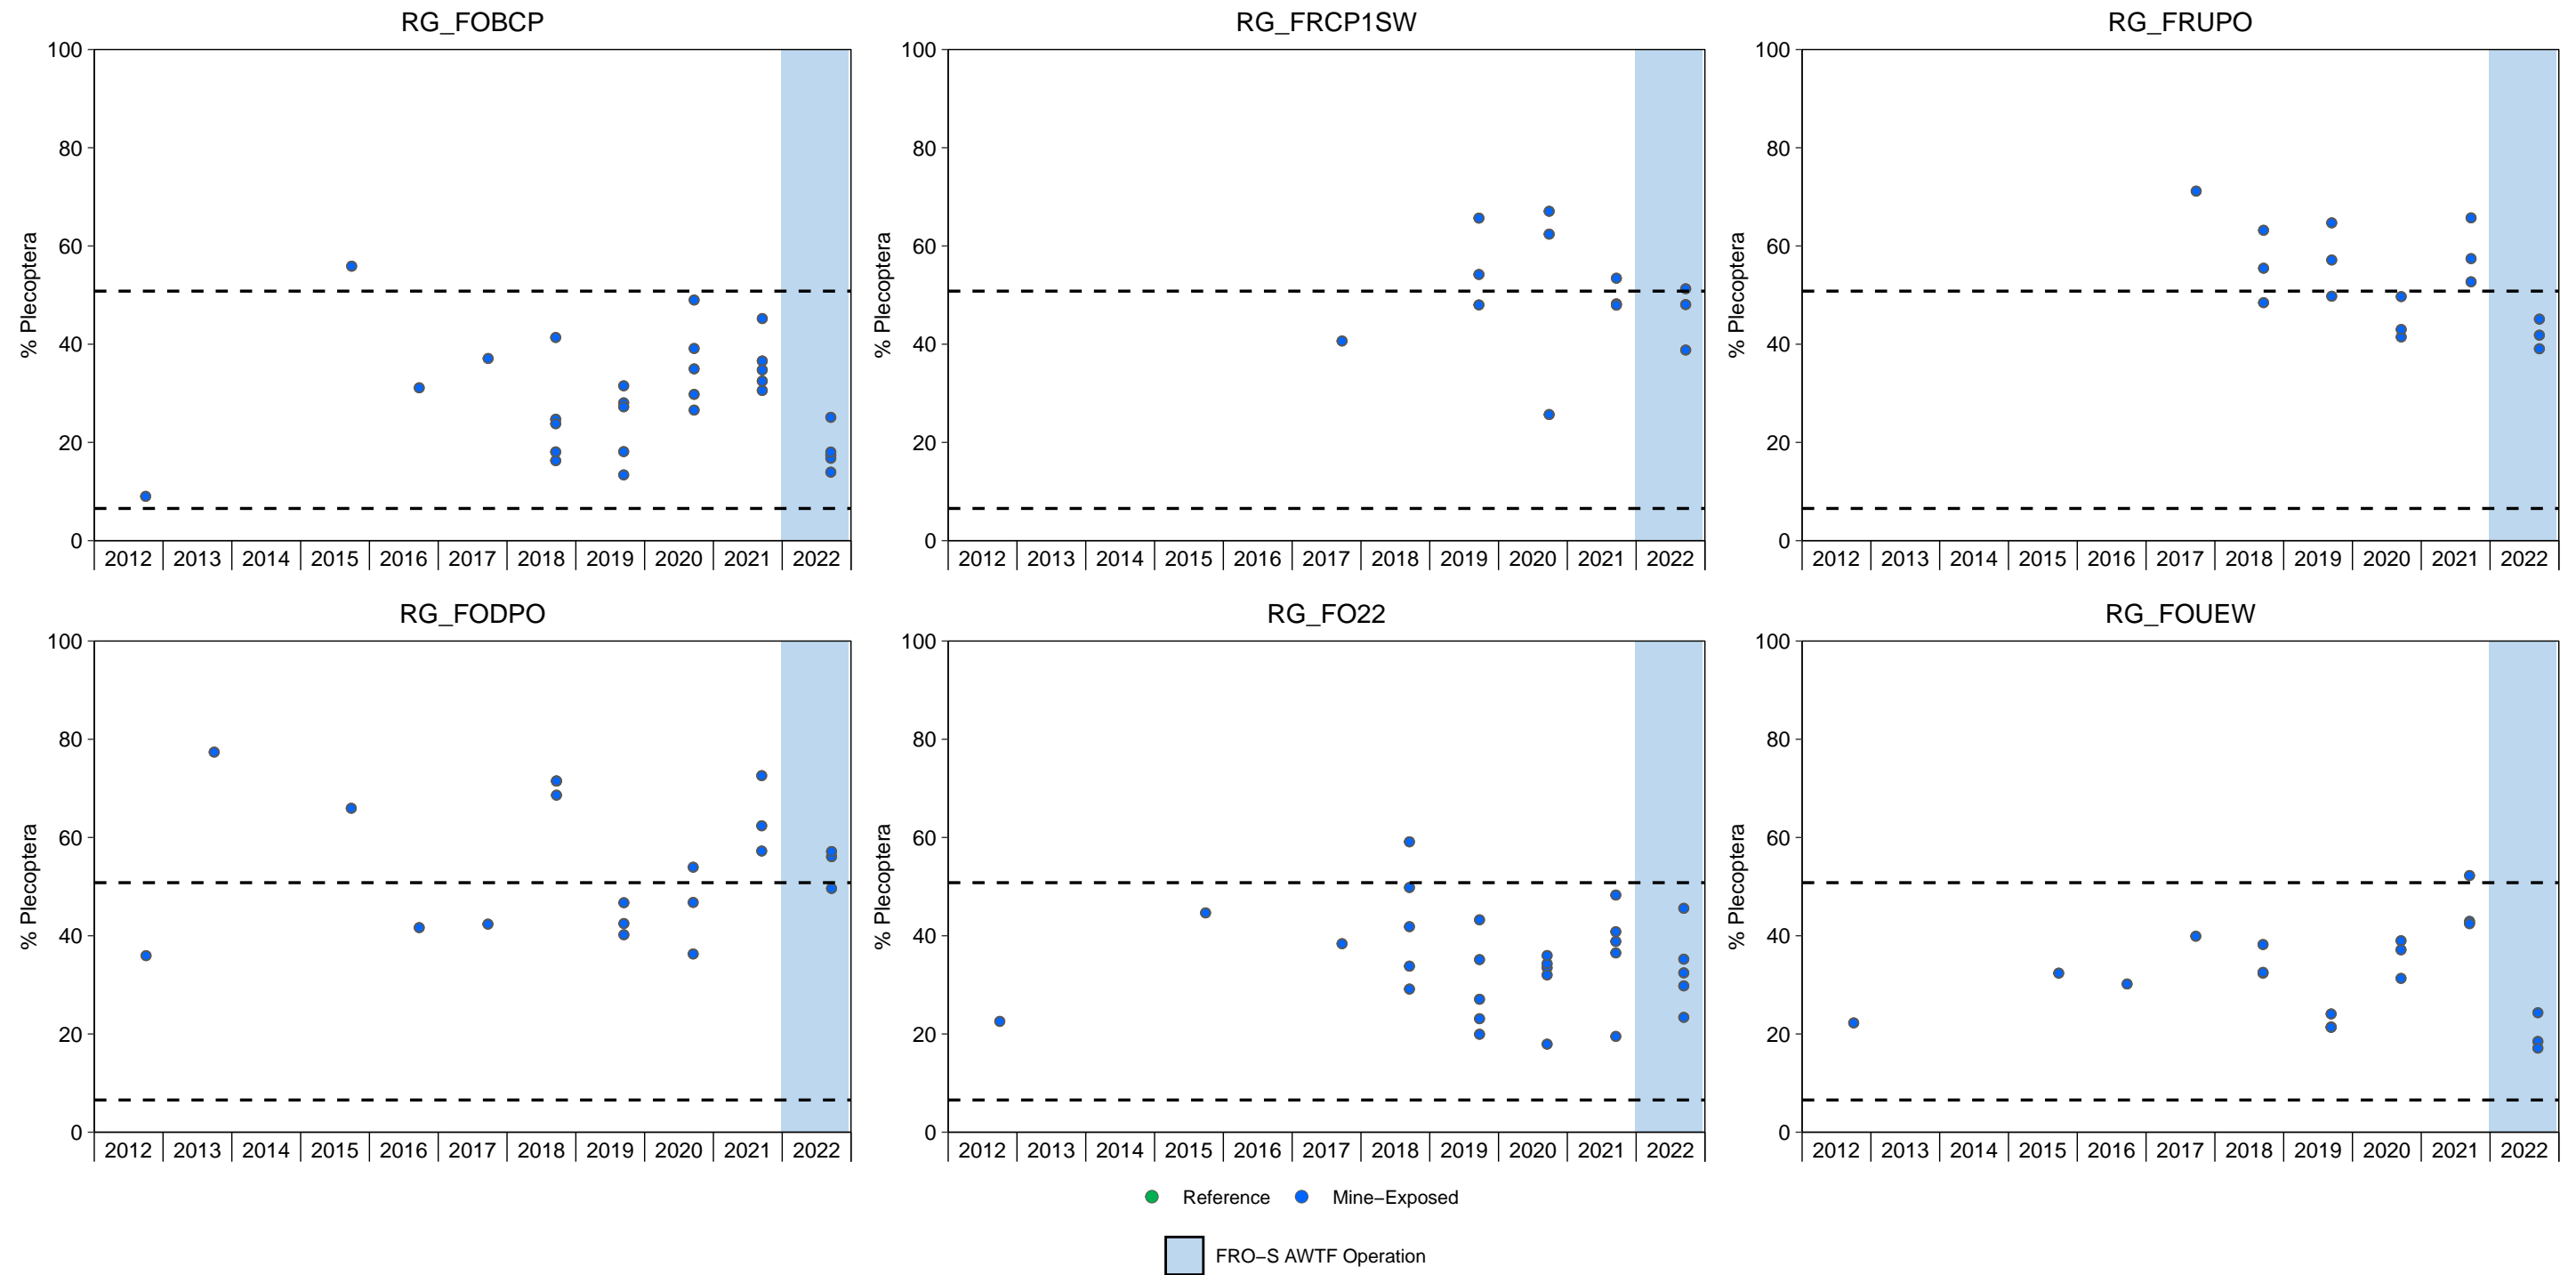

Figure G.15: Benthic Invertebrate % Plecoptera in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

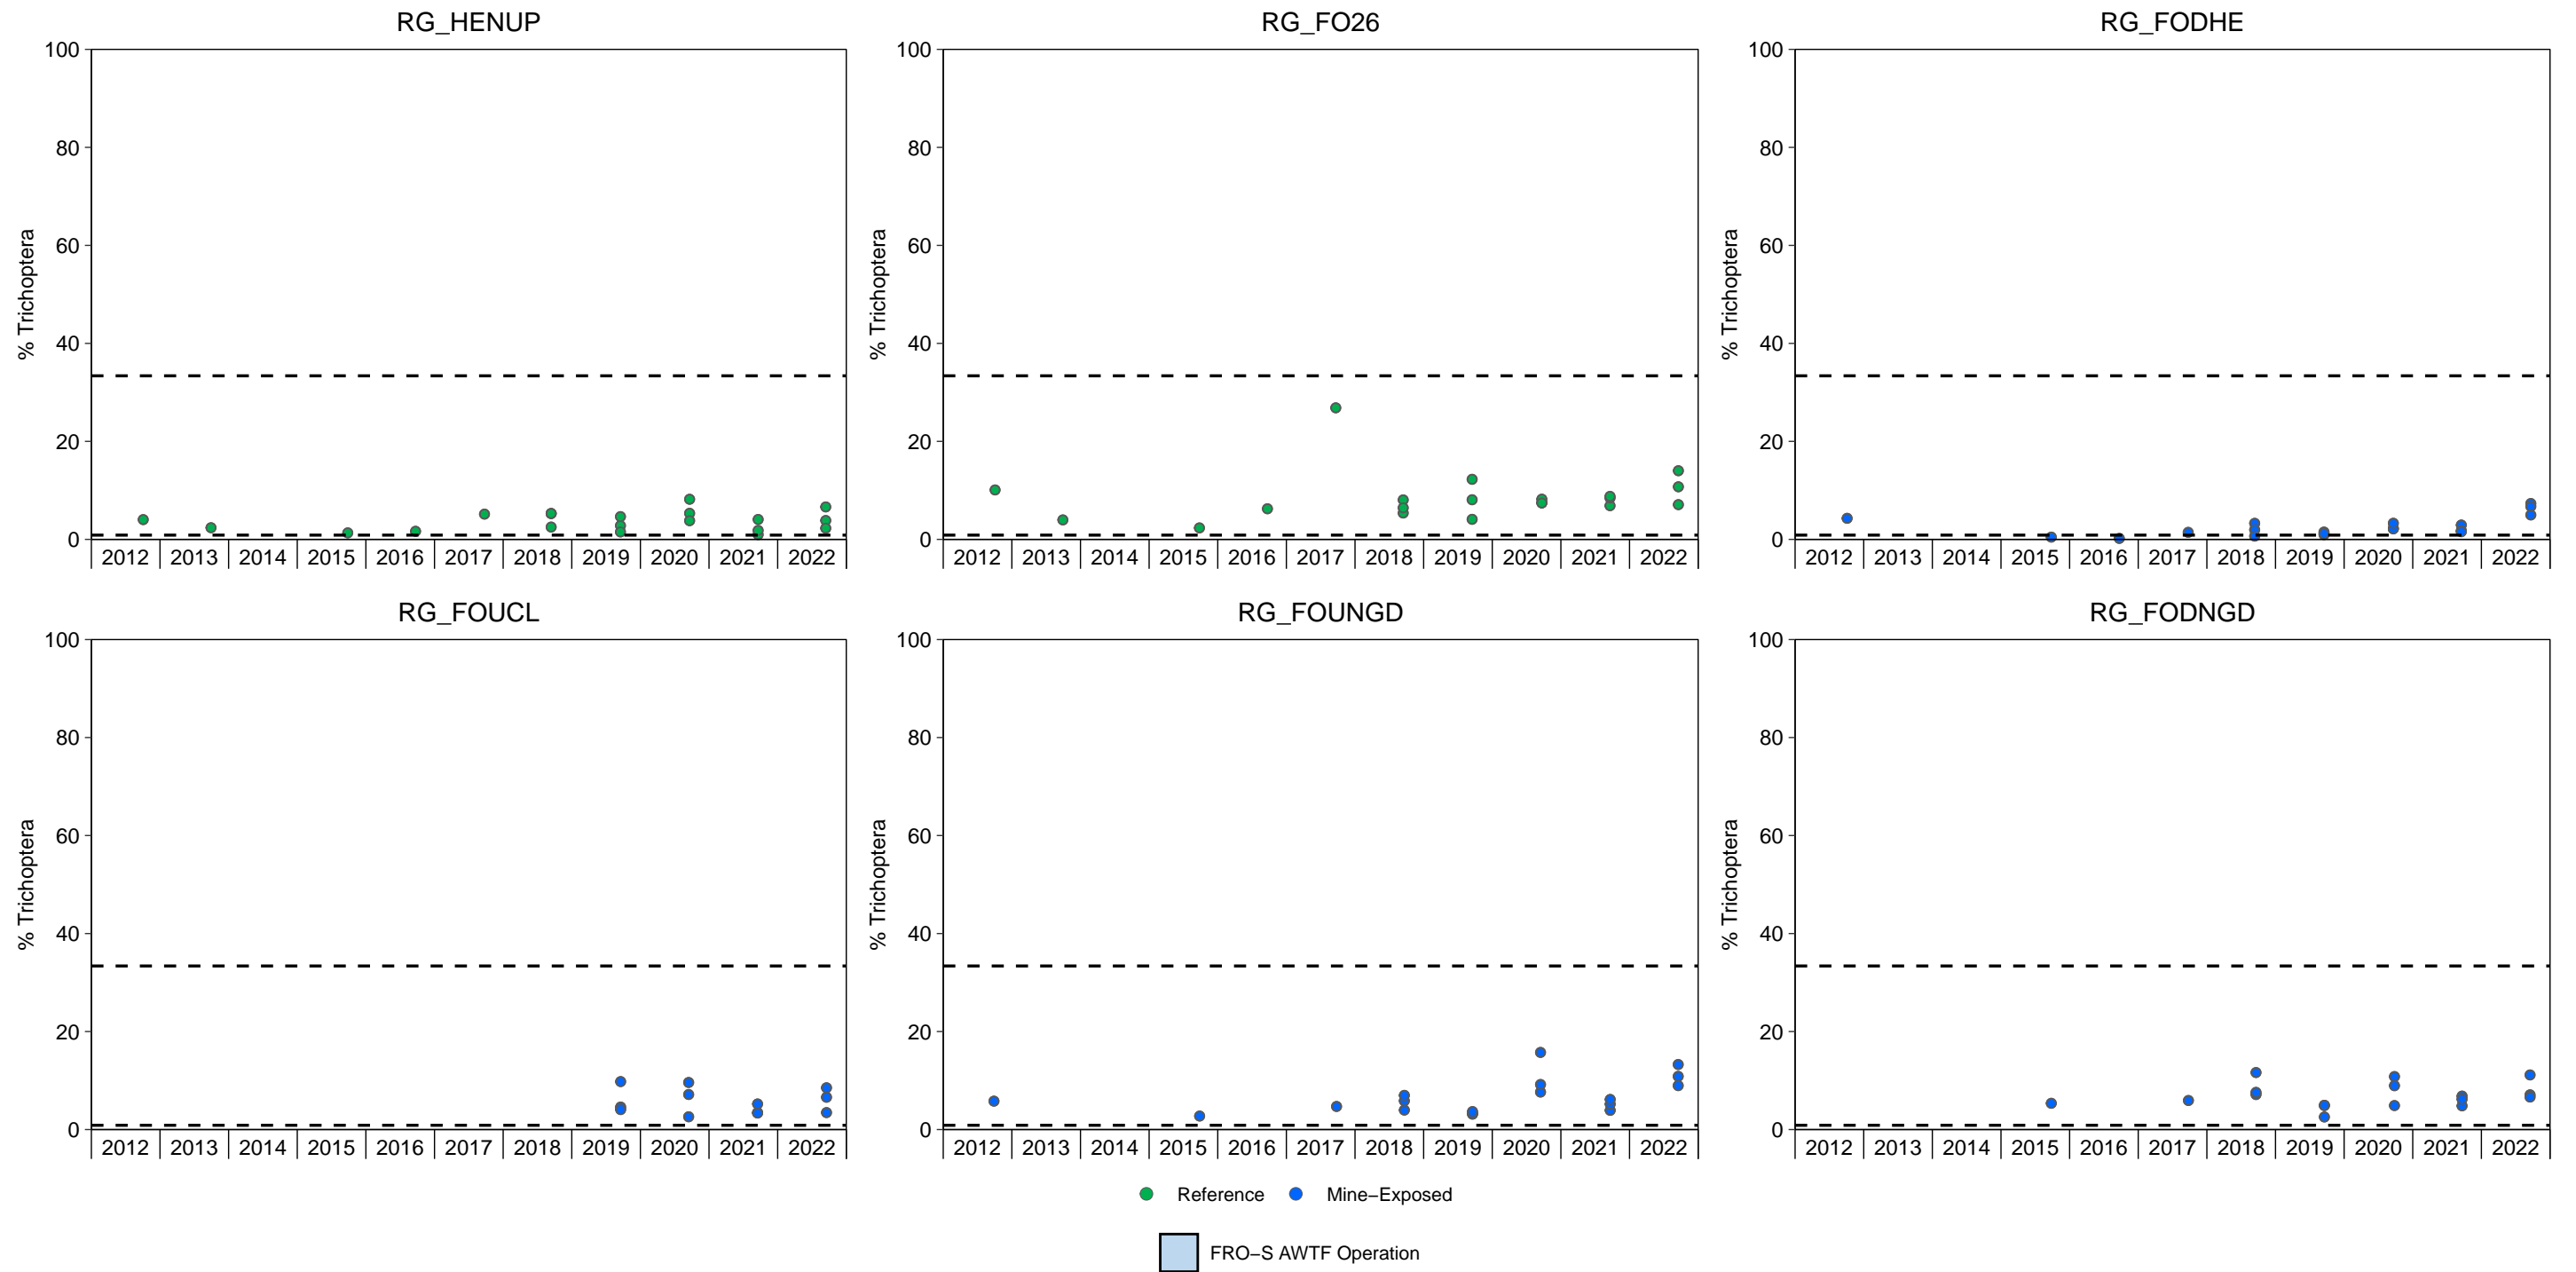

Figure G.16: Benthic Invertebrate % Trichoptera in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

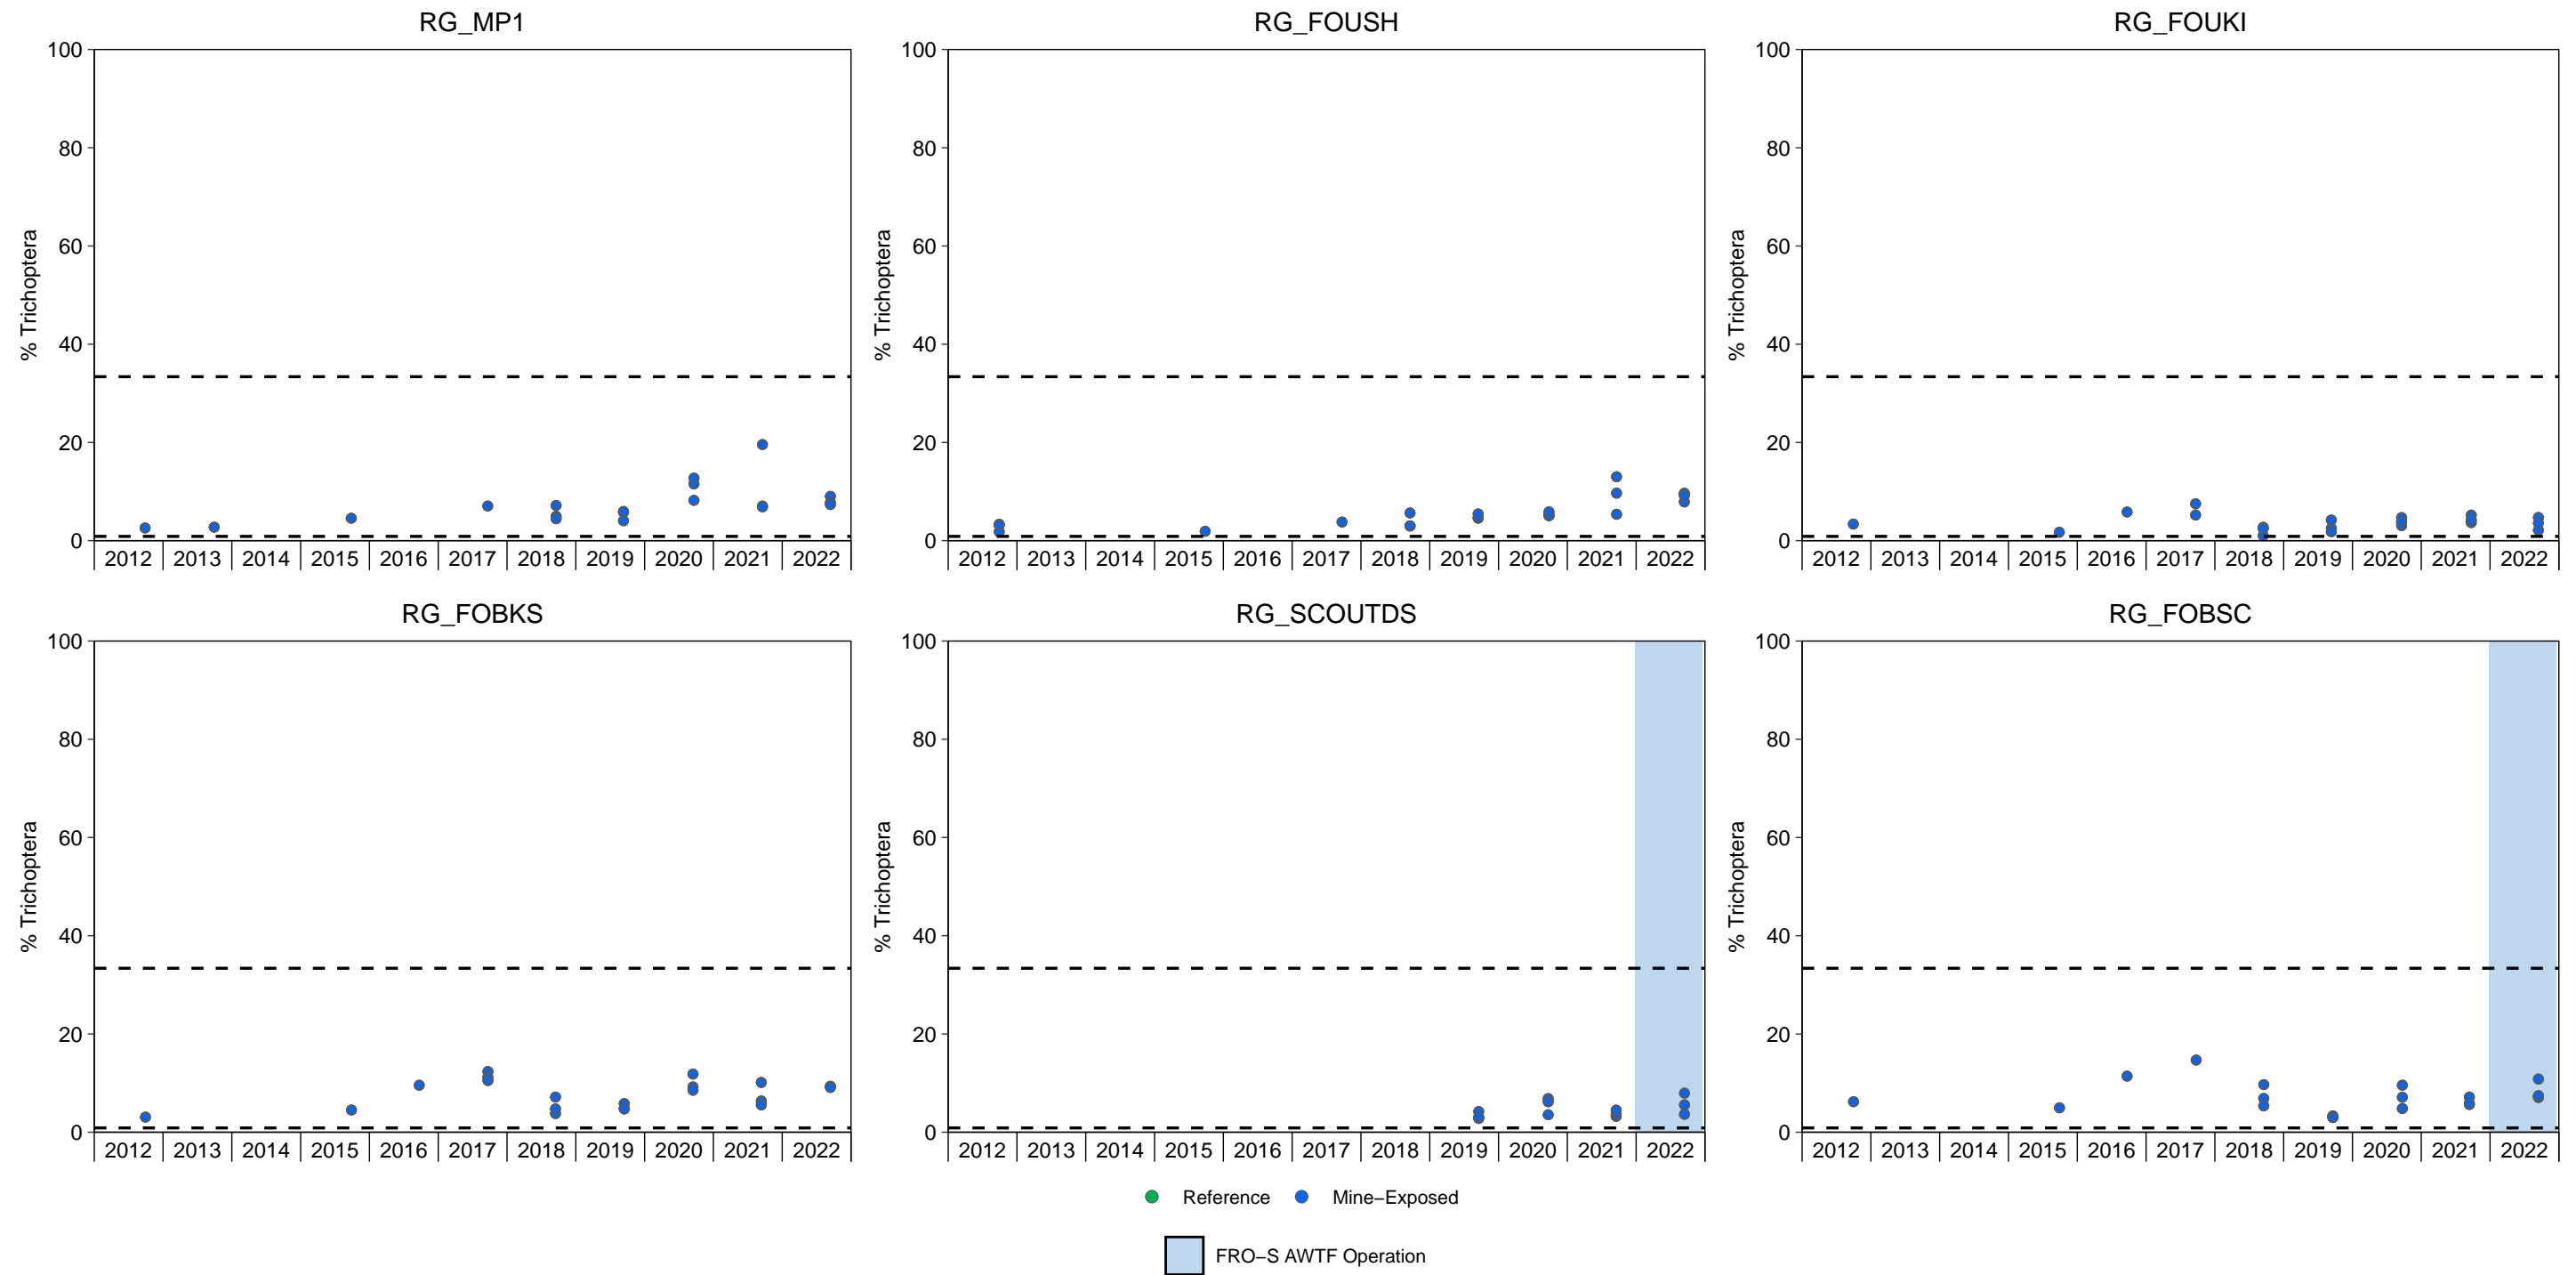

Figure G.16: Benthic Invertebrate % Trichoptera in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

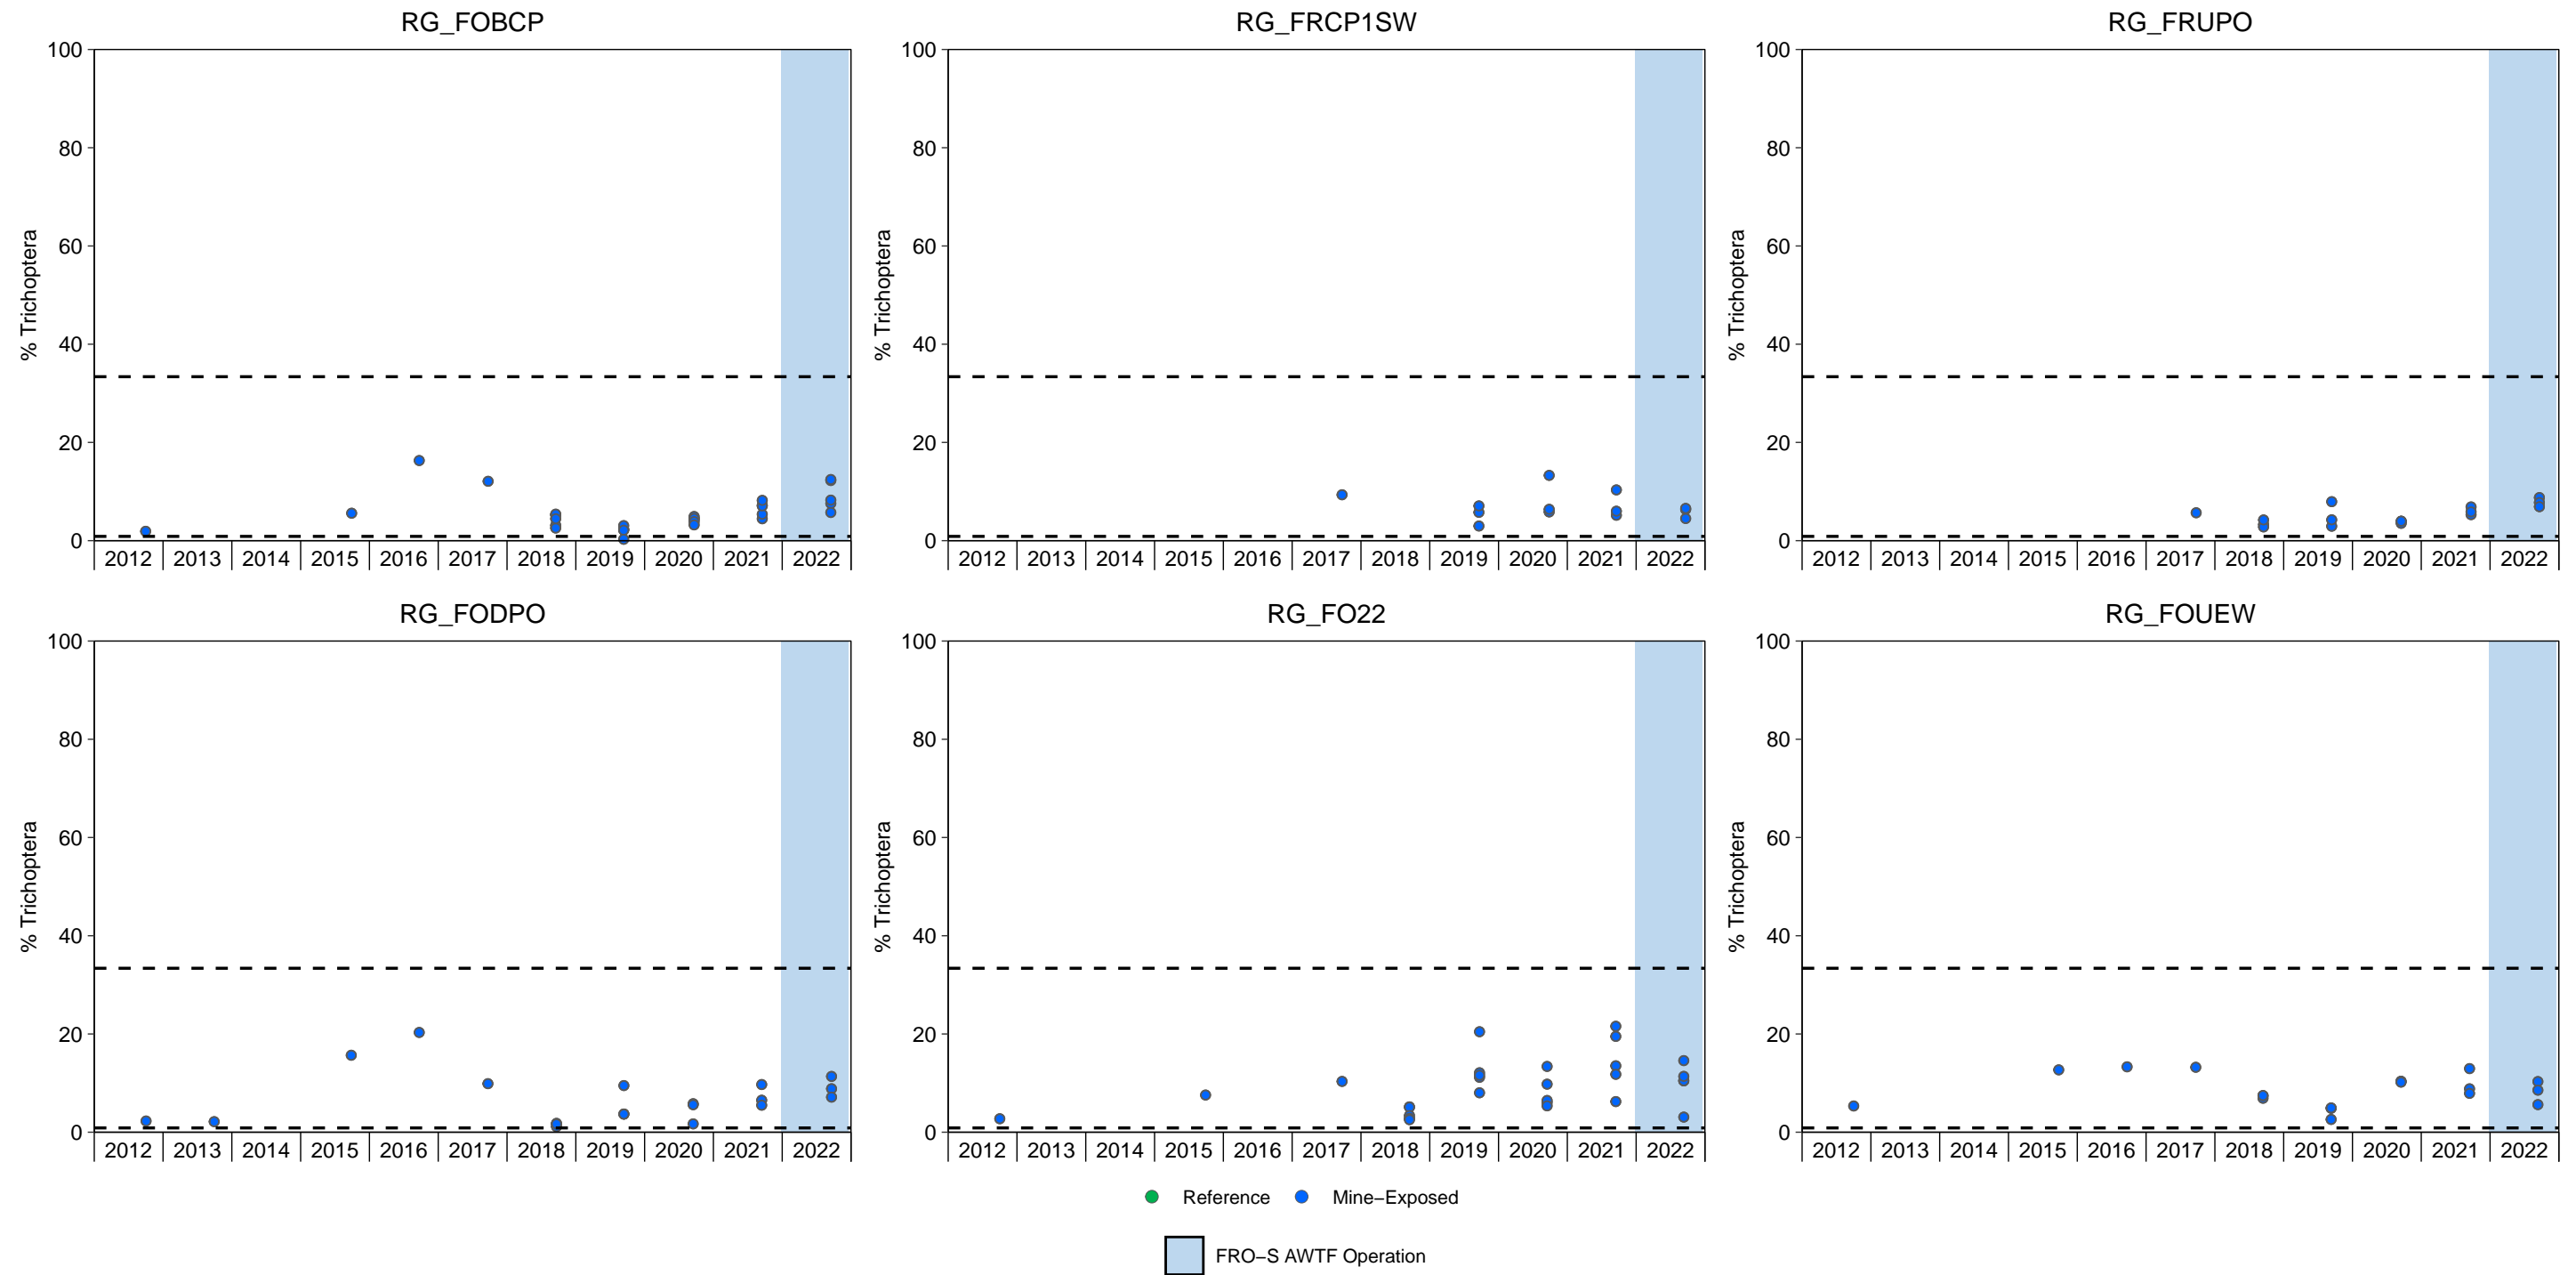

Figure G.16: Benthic Invertebrate % Trichoptera in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

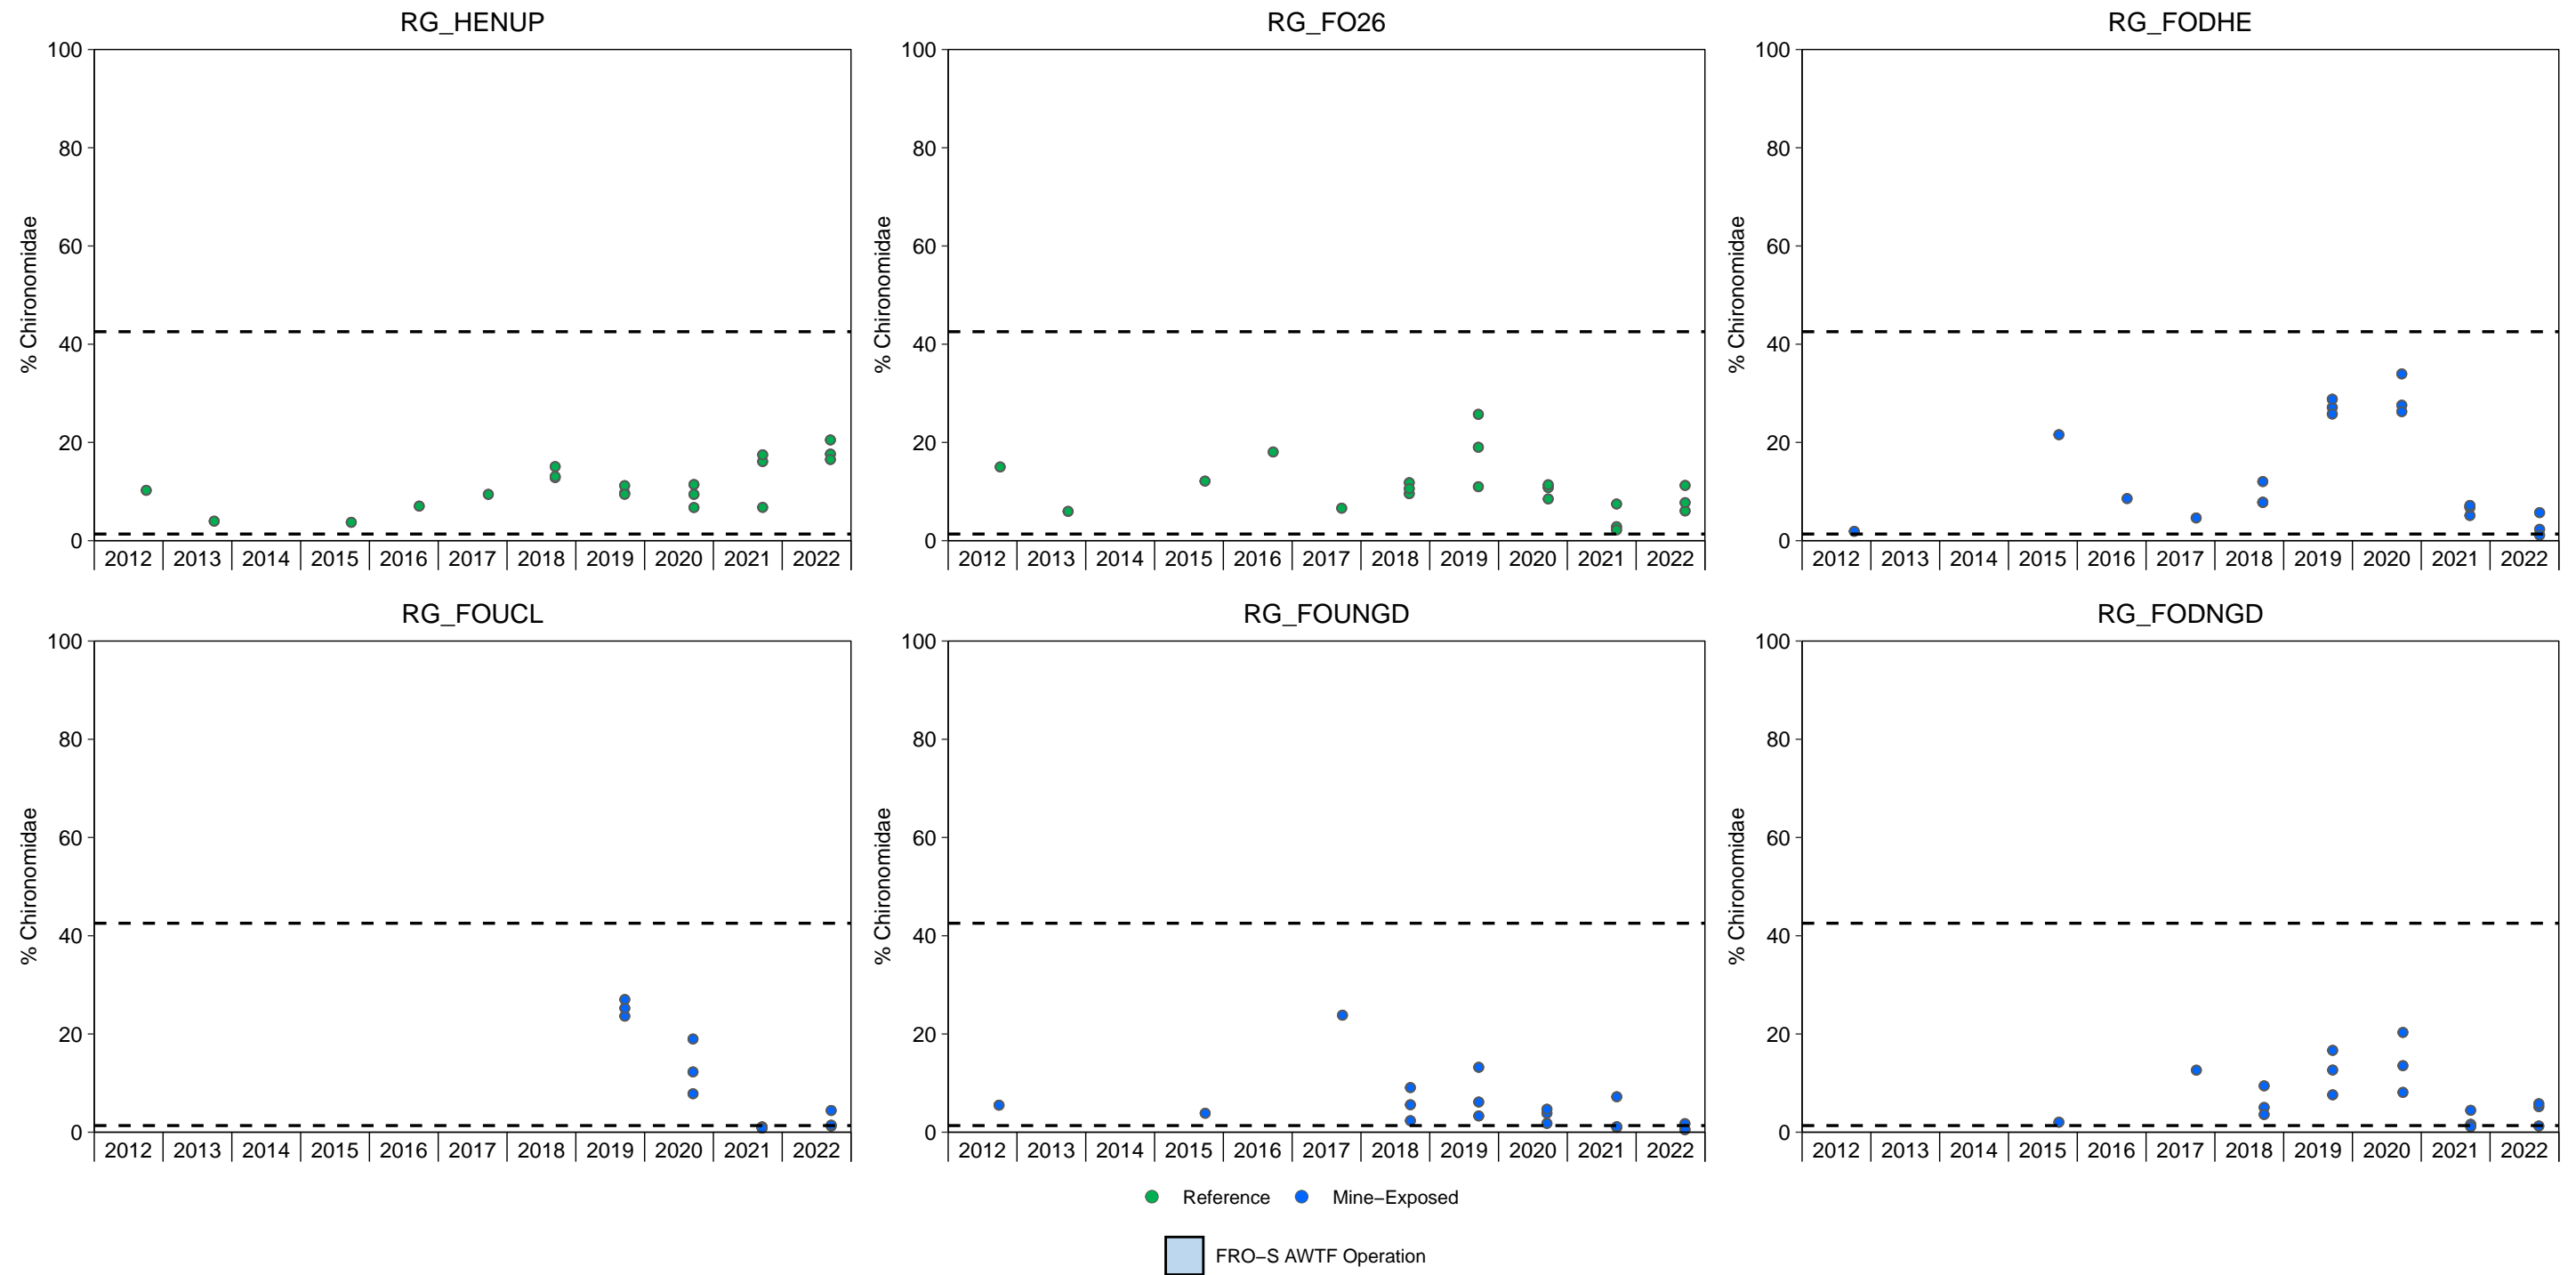

Figure G.17: Benthic Invertebrate % Chironomidae in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

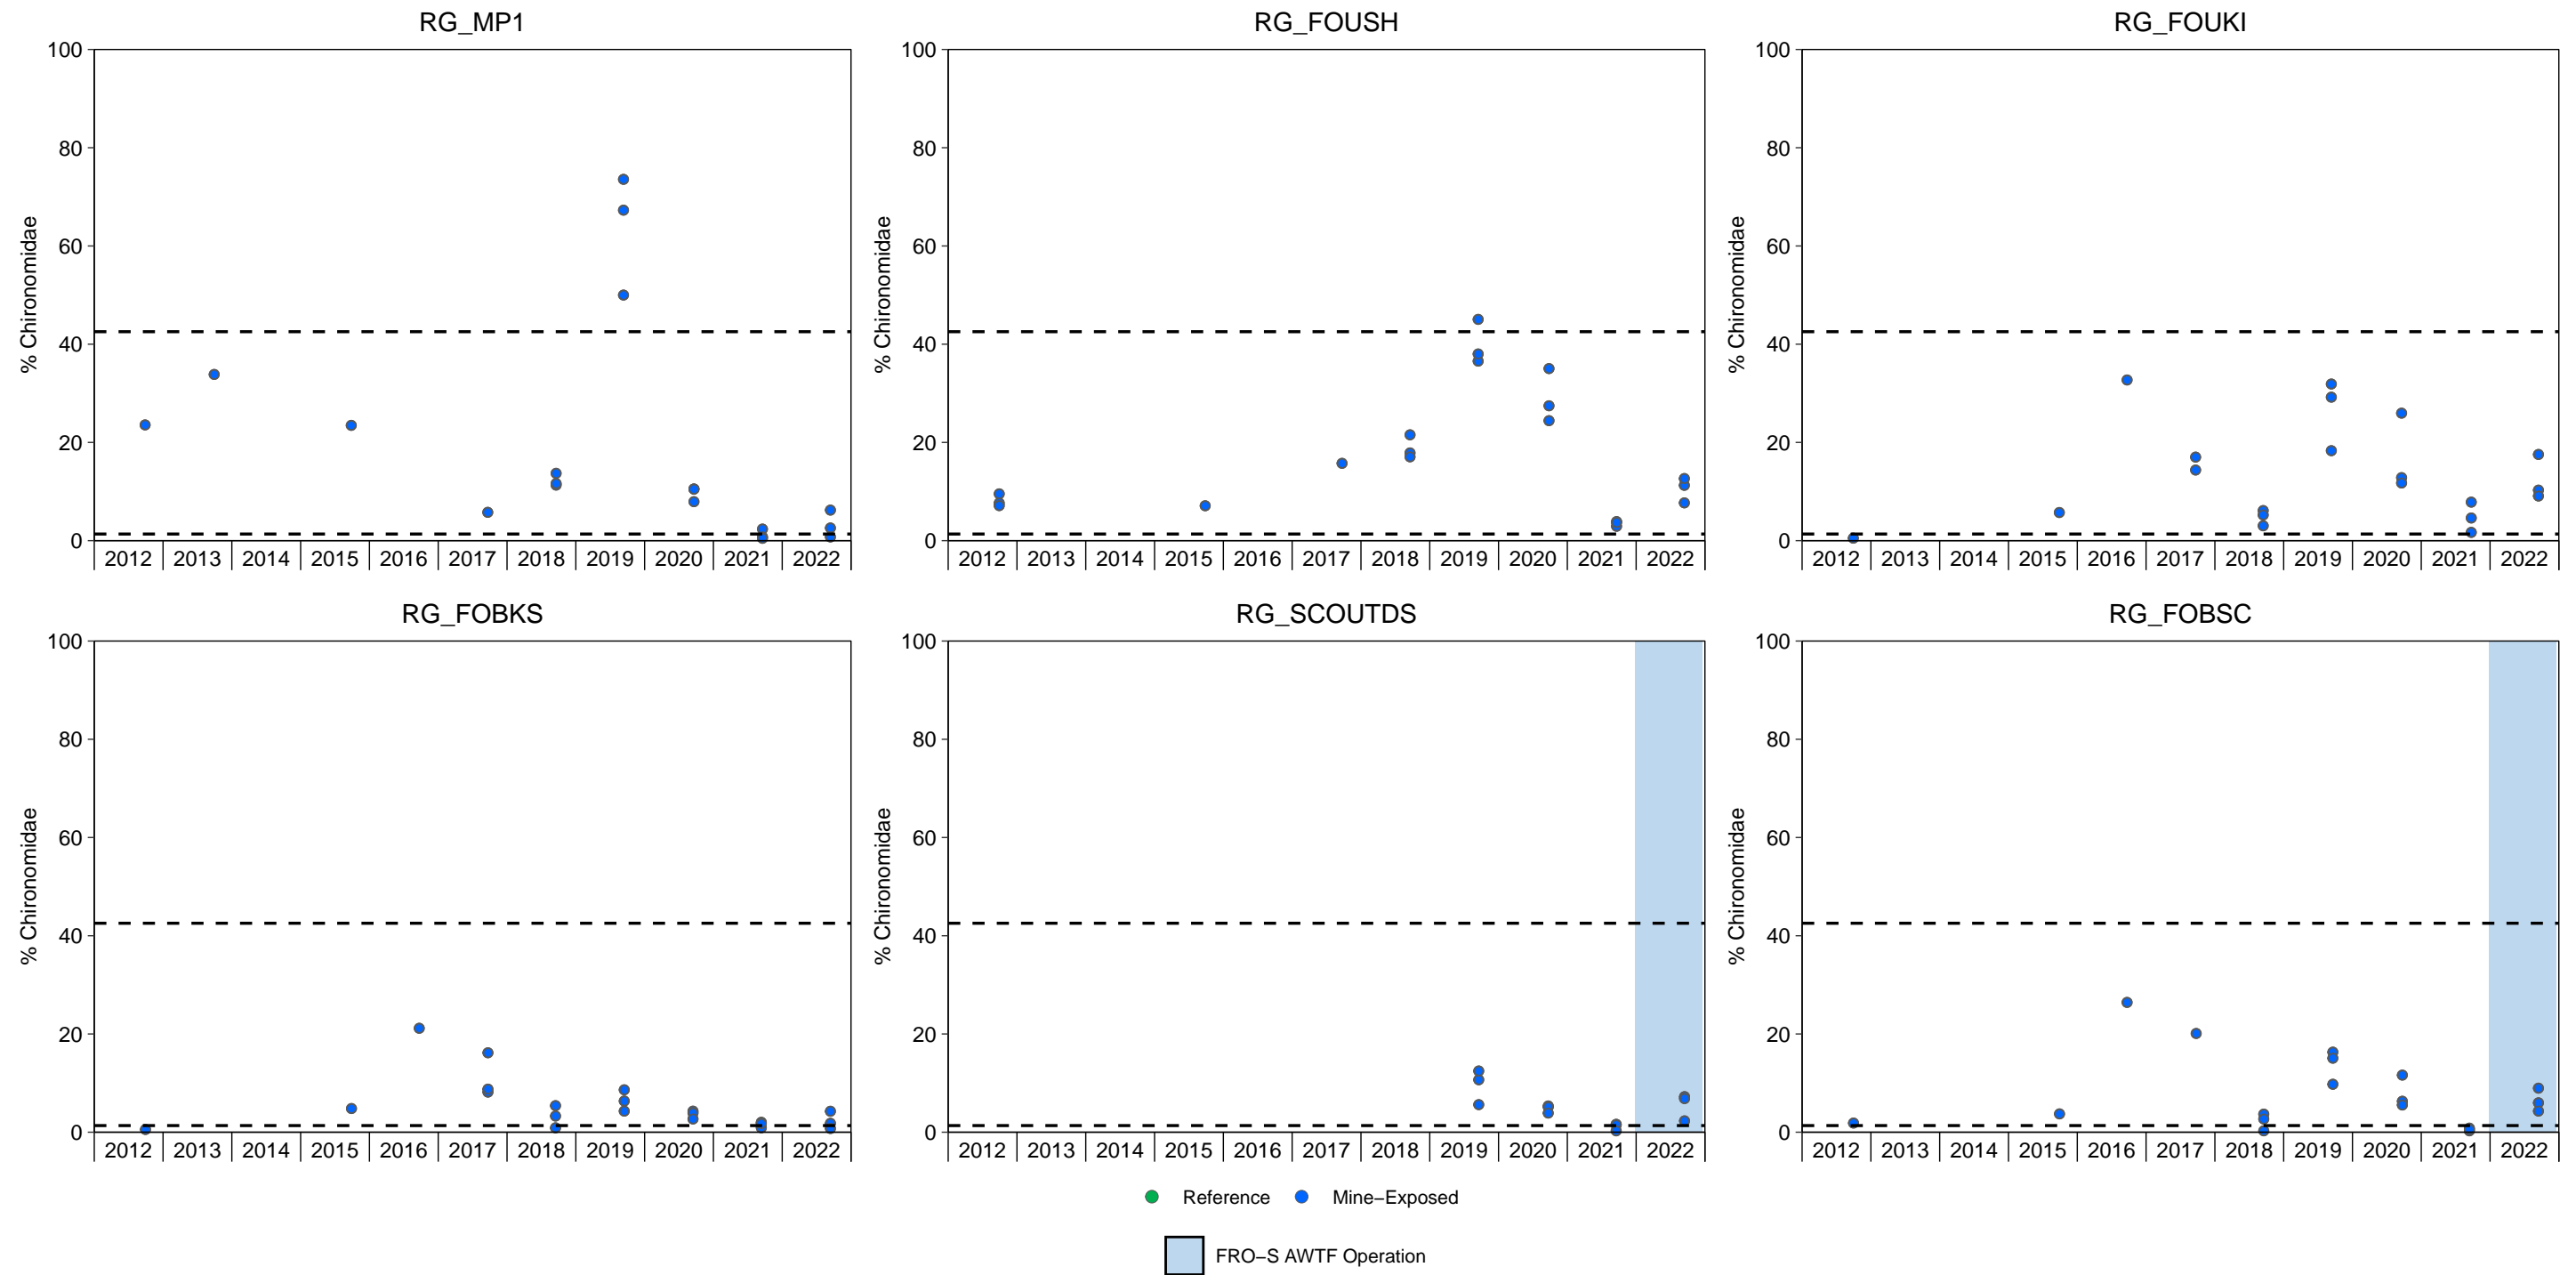

Figure G.17: Benthic Invertebrate % Chironomidae in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

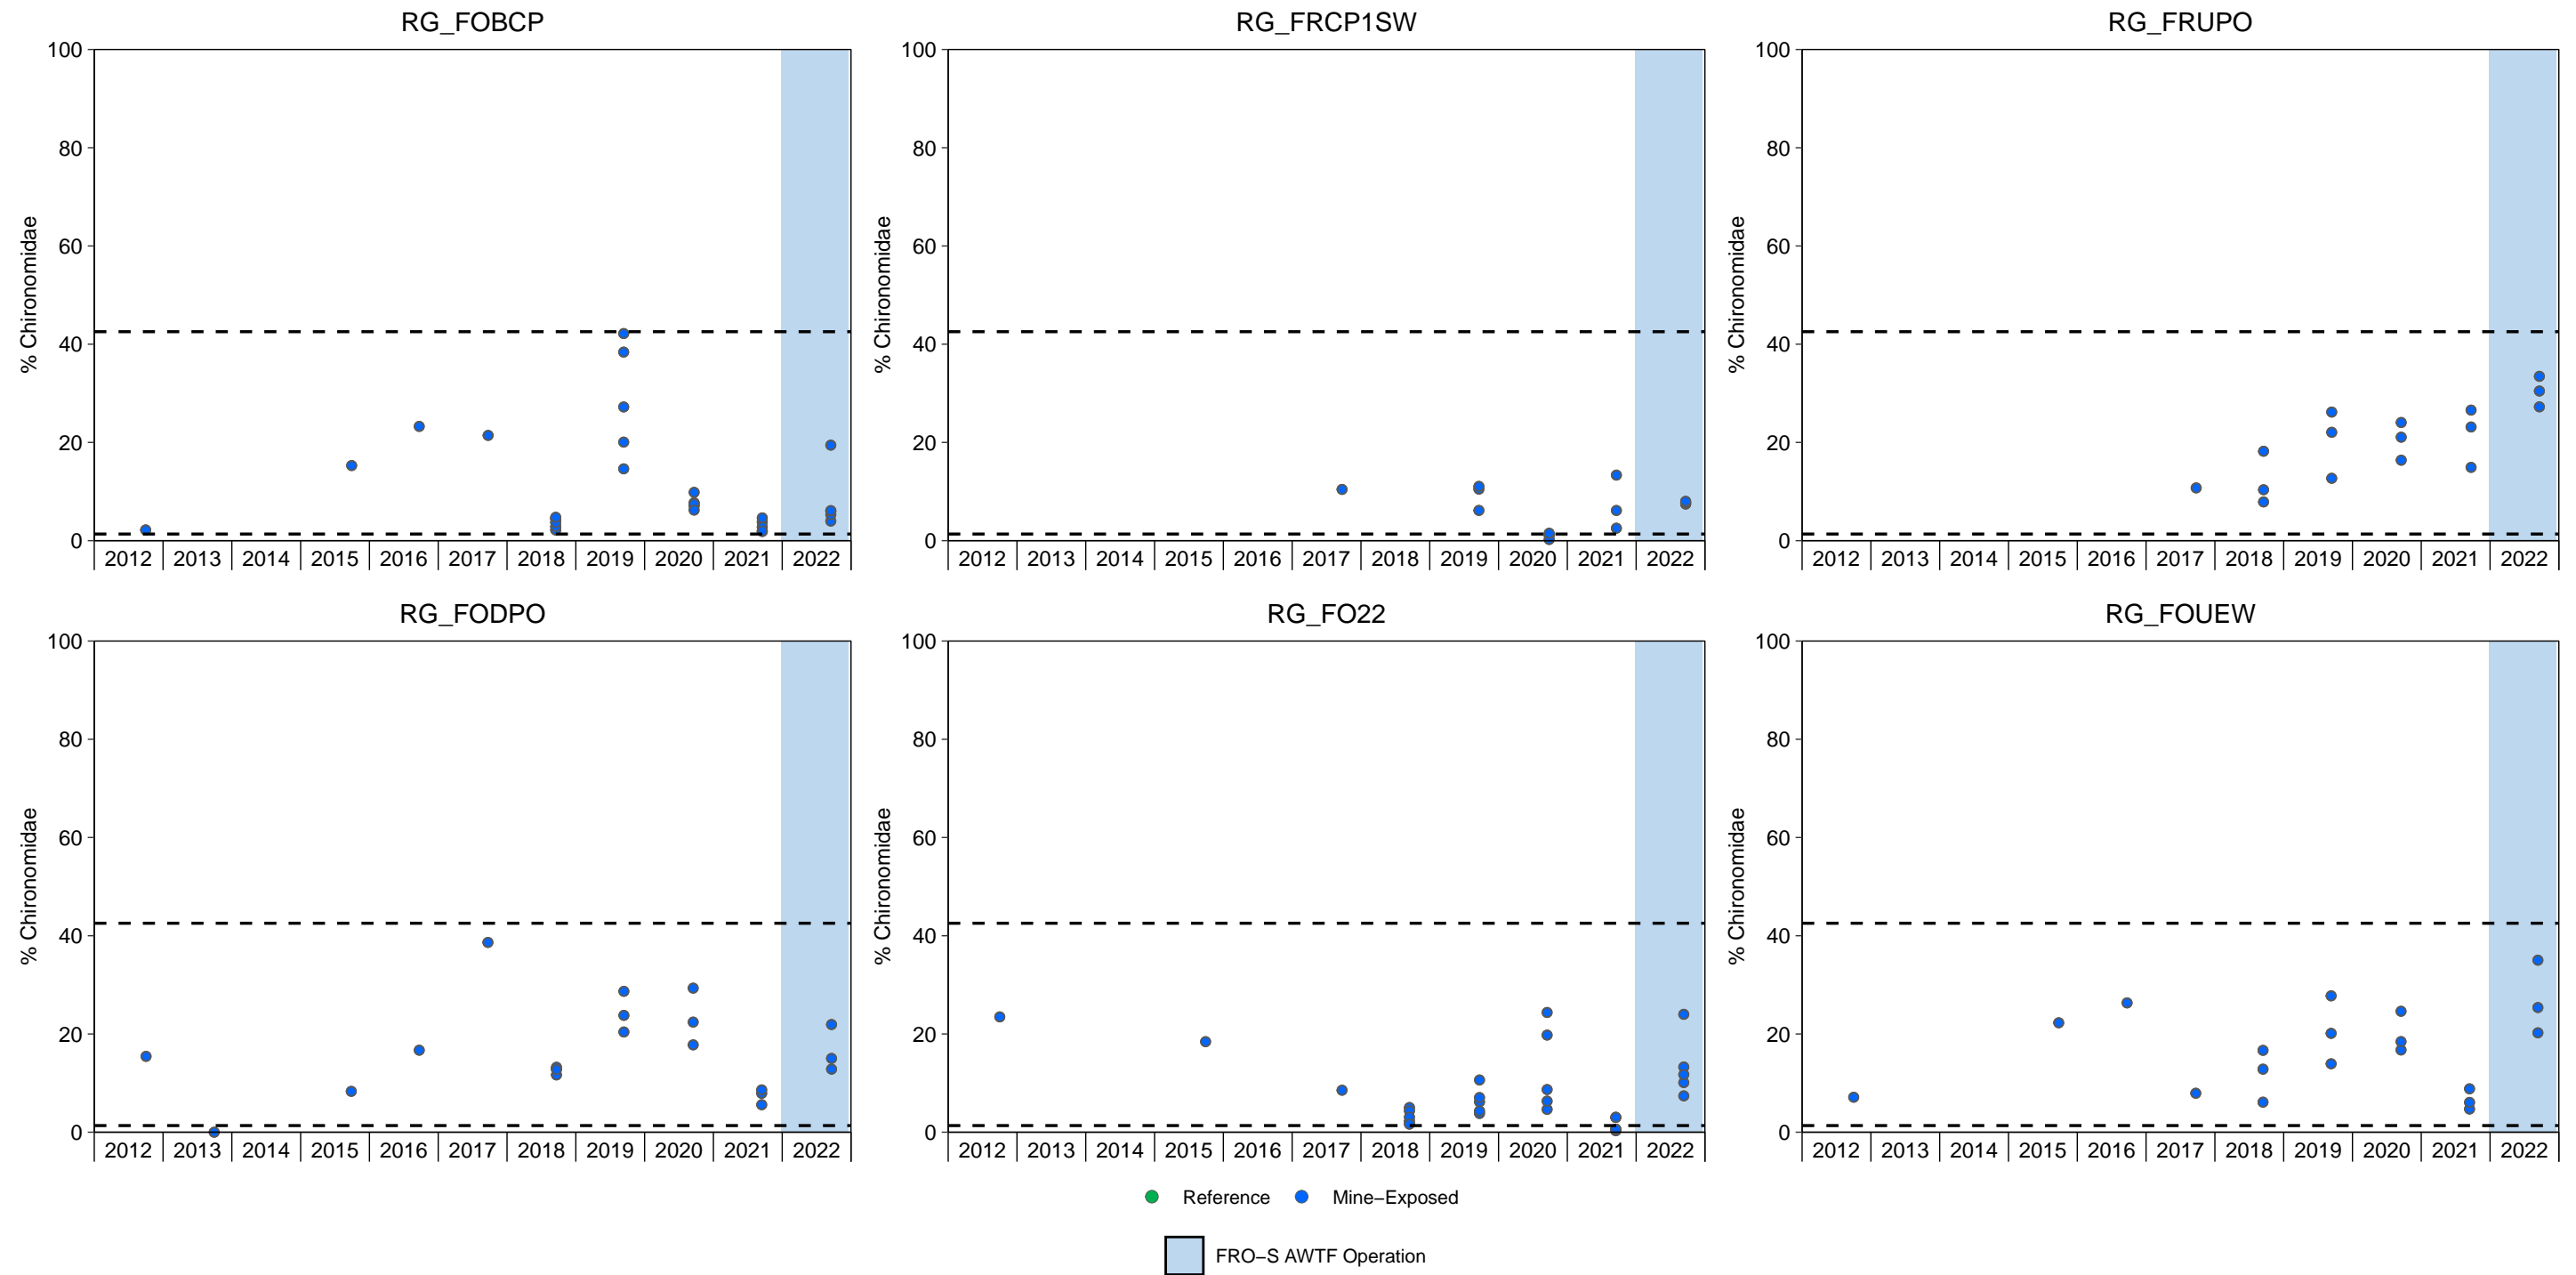

Figure G.17: Benthic Invertebrate % Chironomidae in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

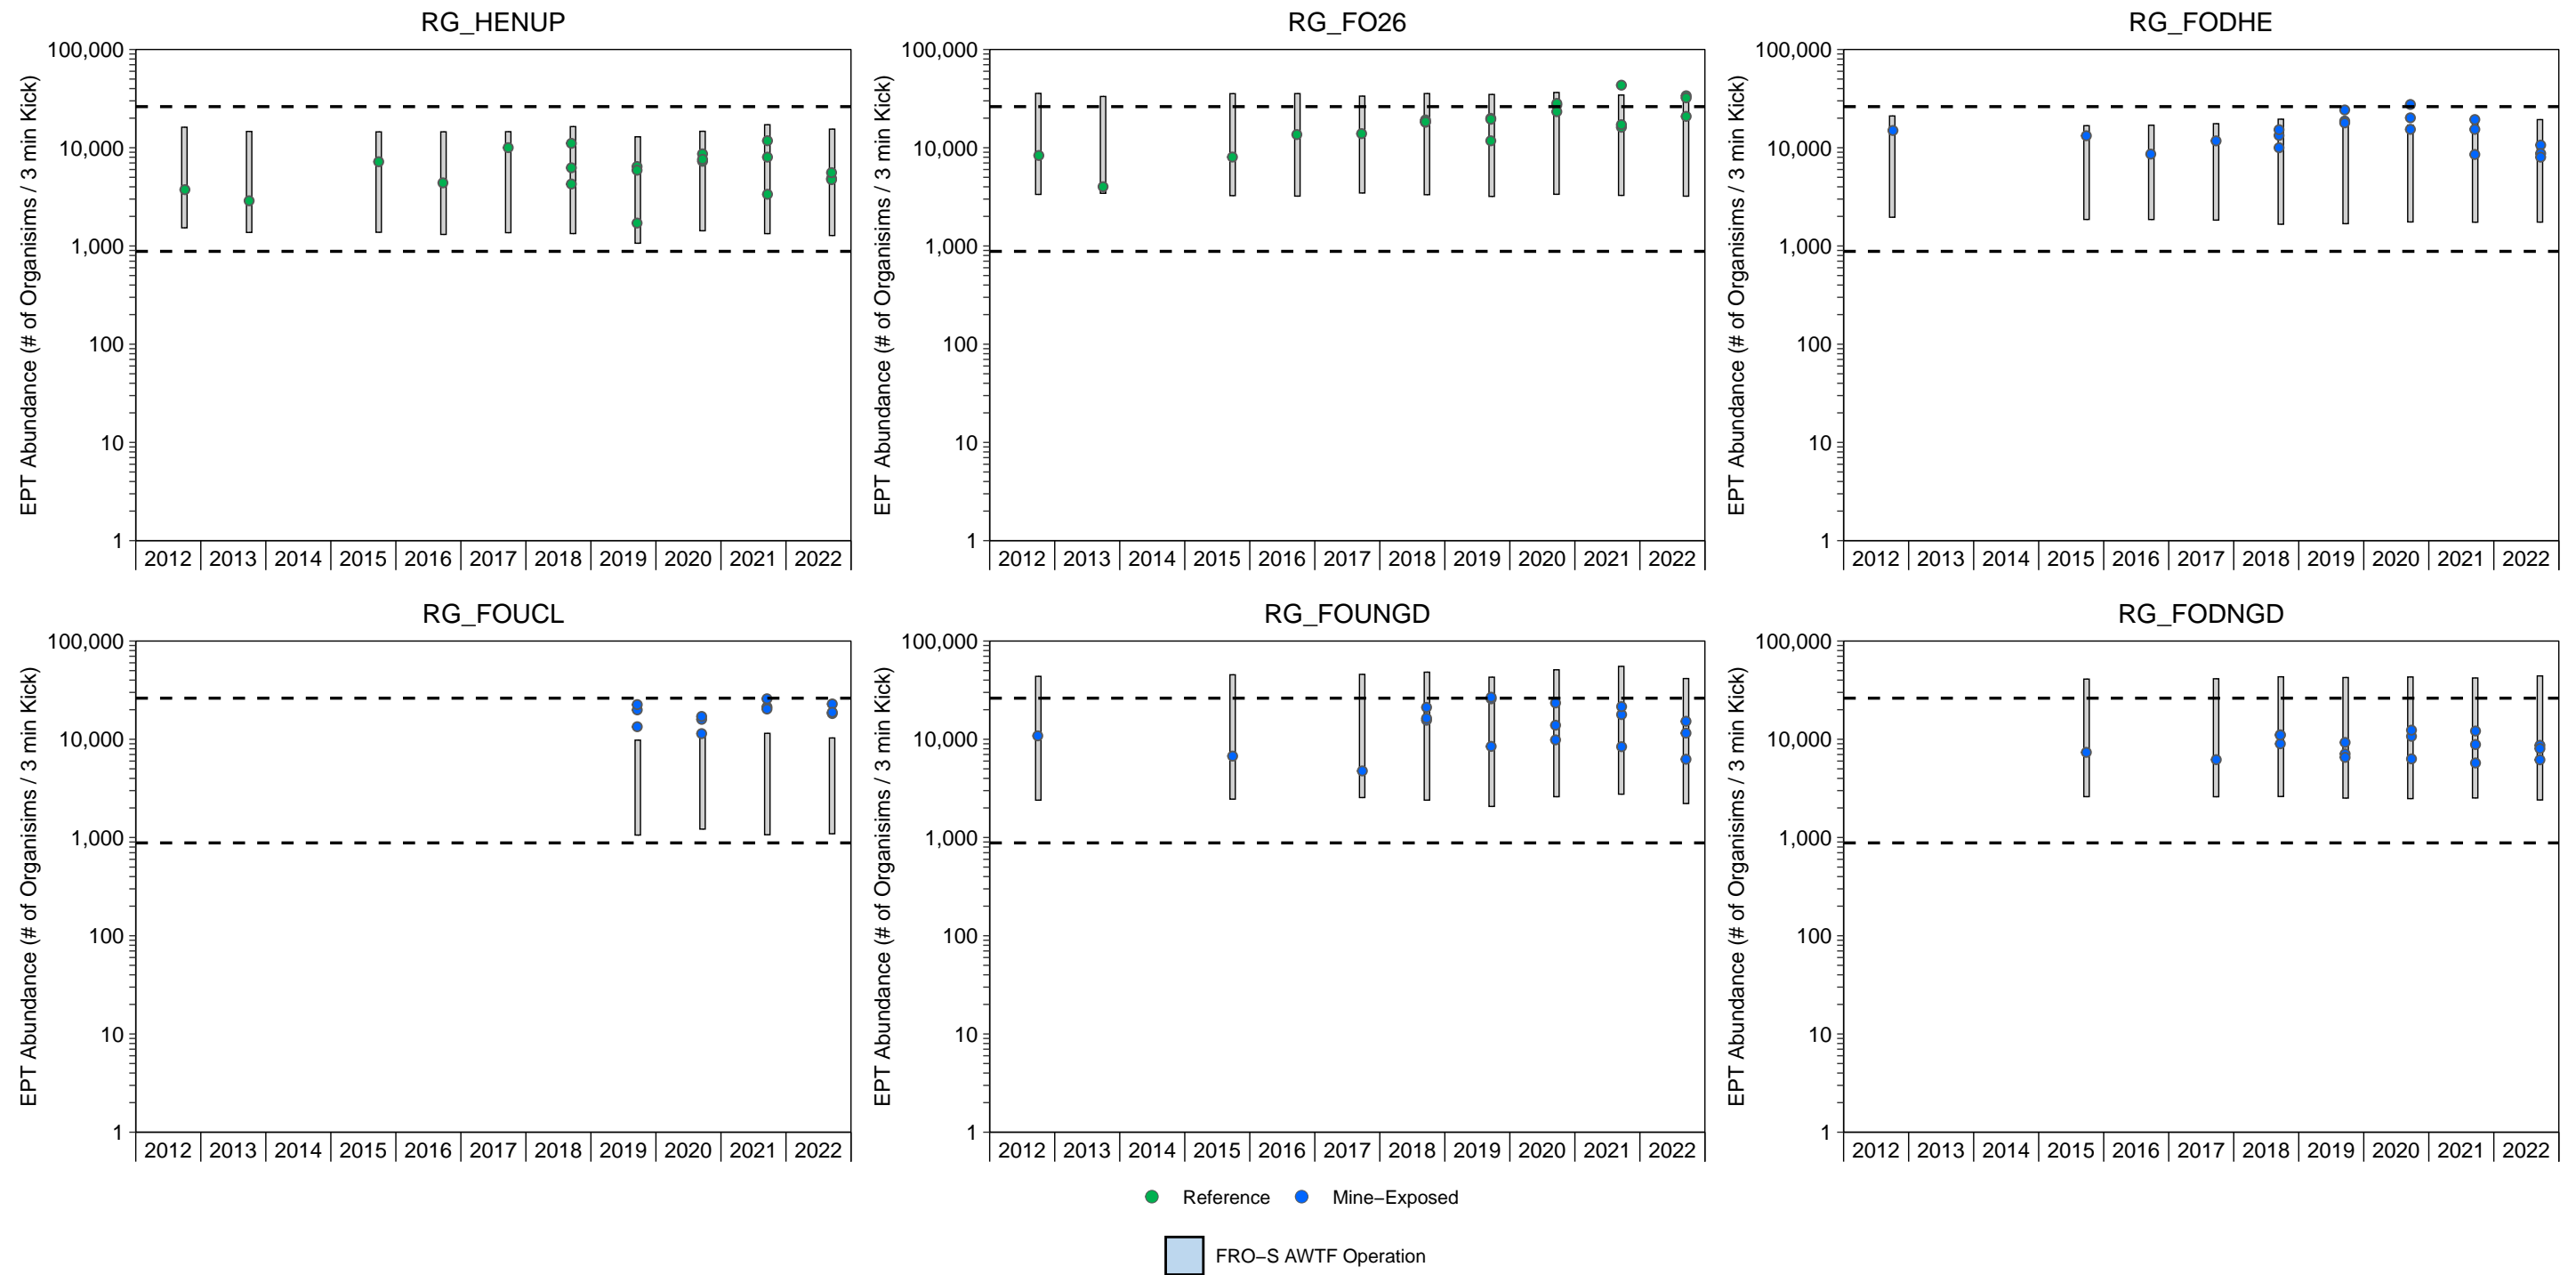

Figure G.18: Benthic Invertebrate EPT Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

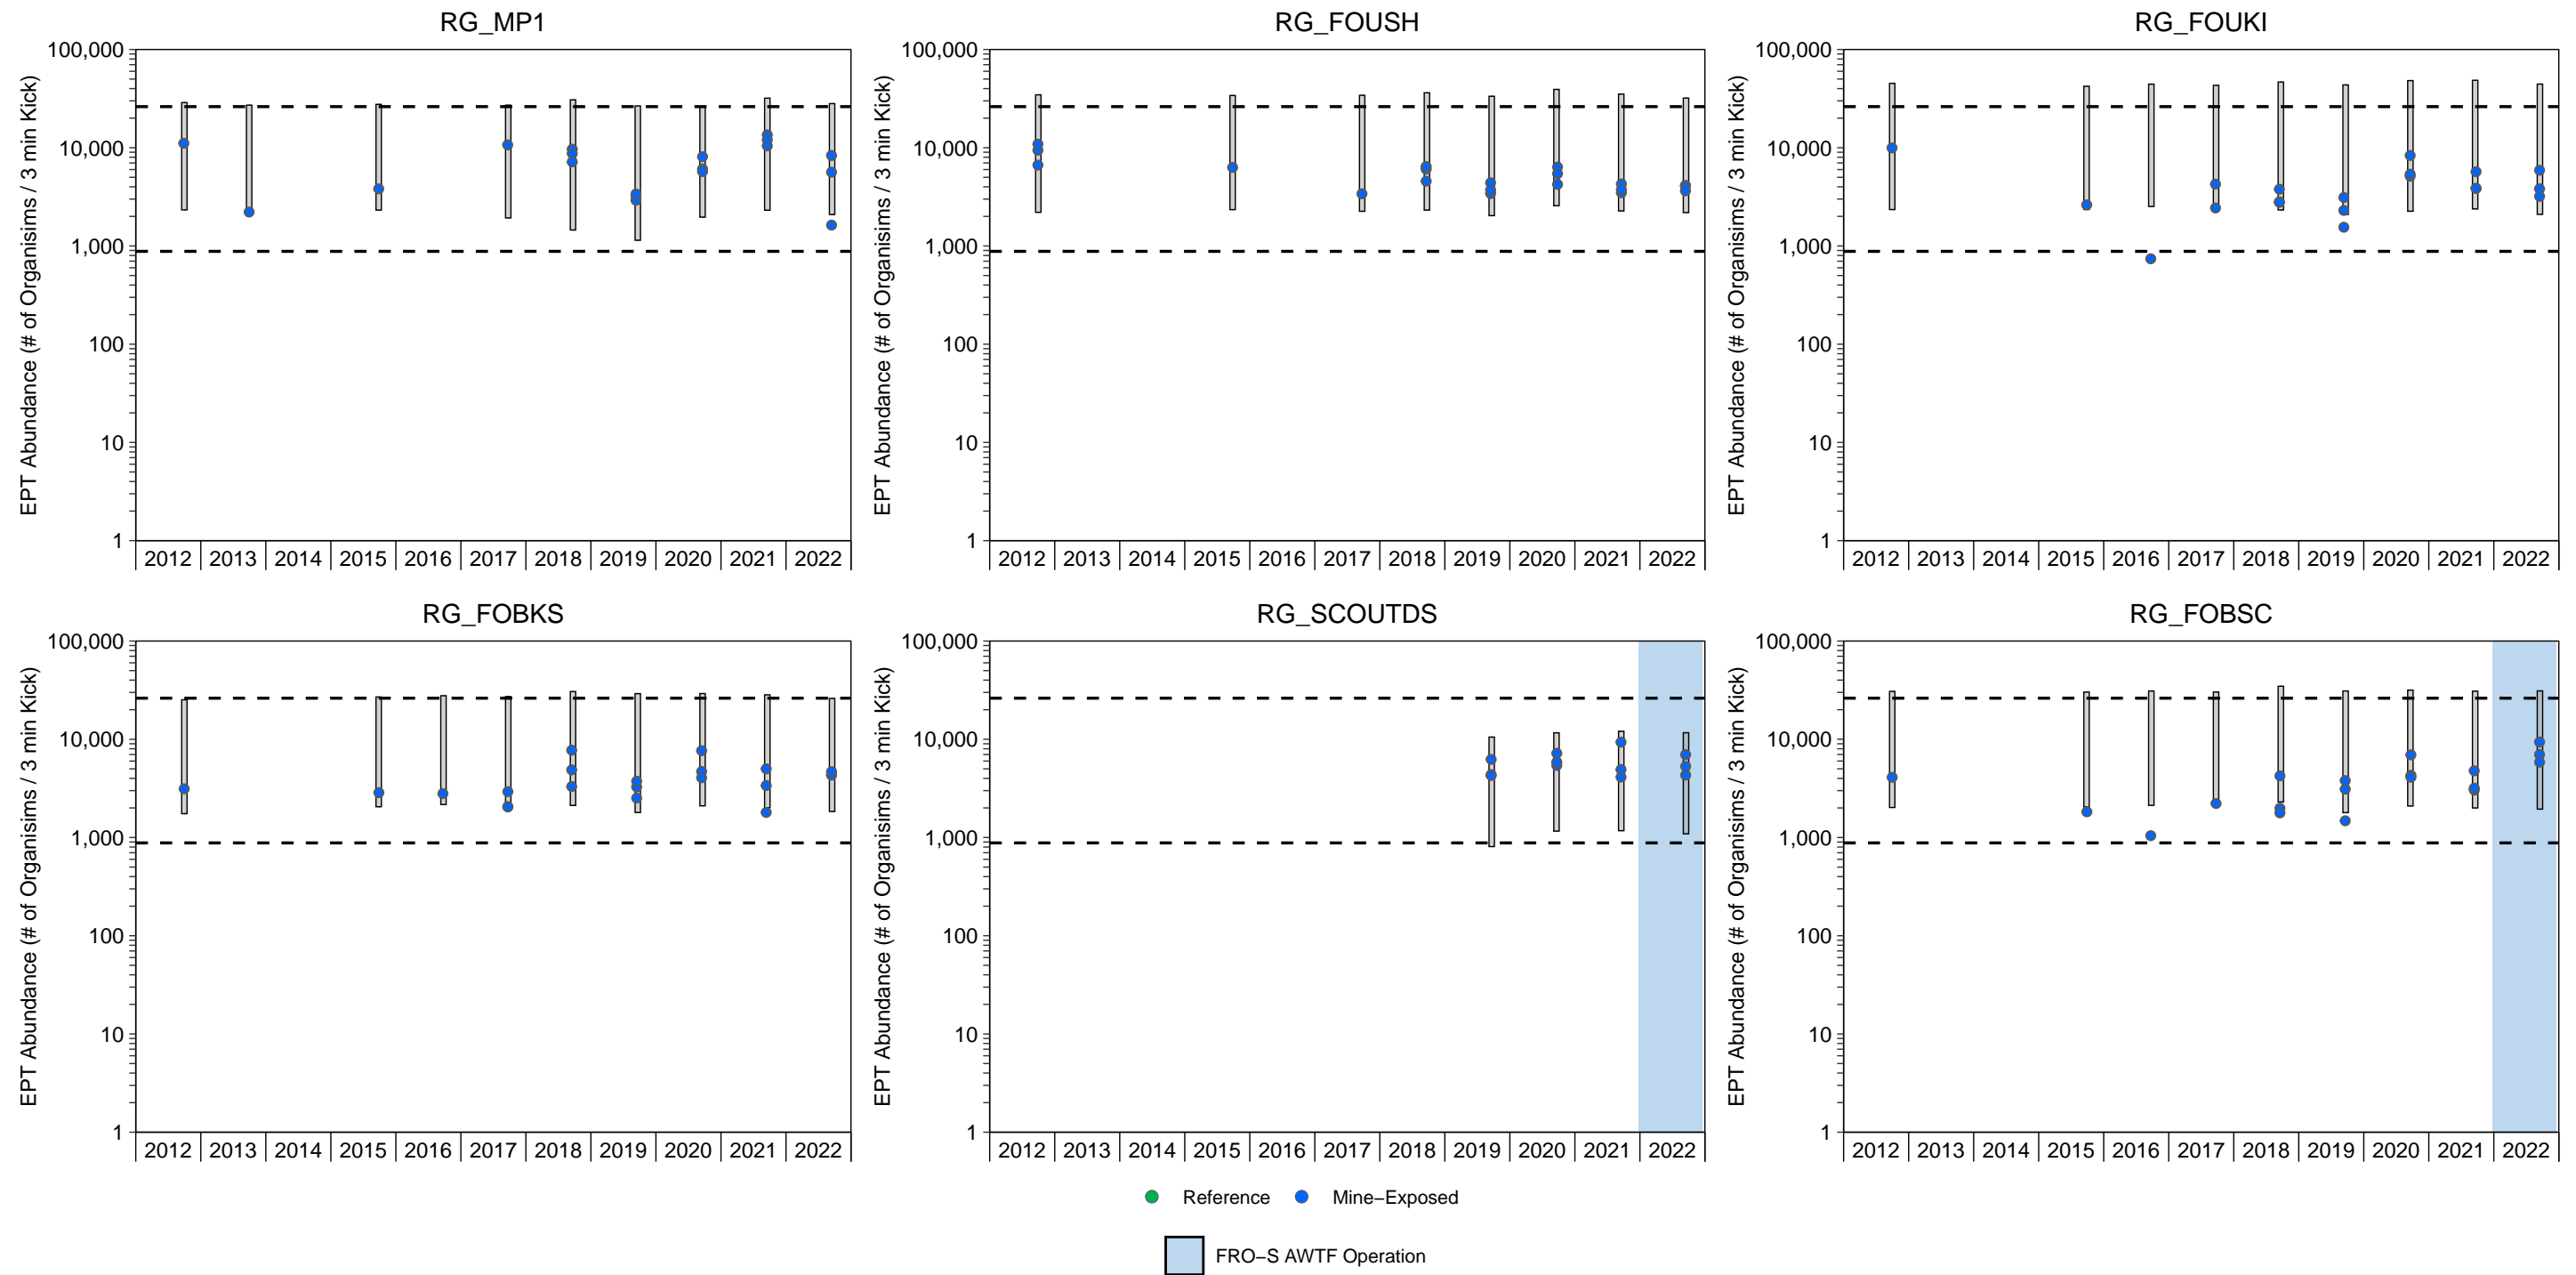

Figure G.18: Benthic Invertebrate EPT Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

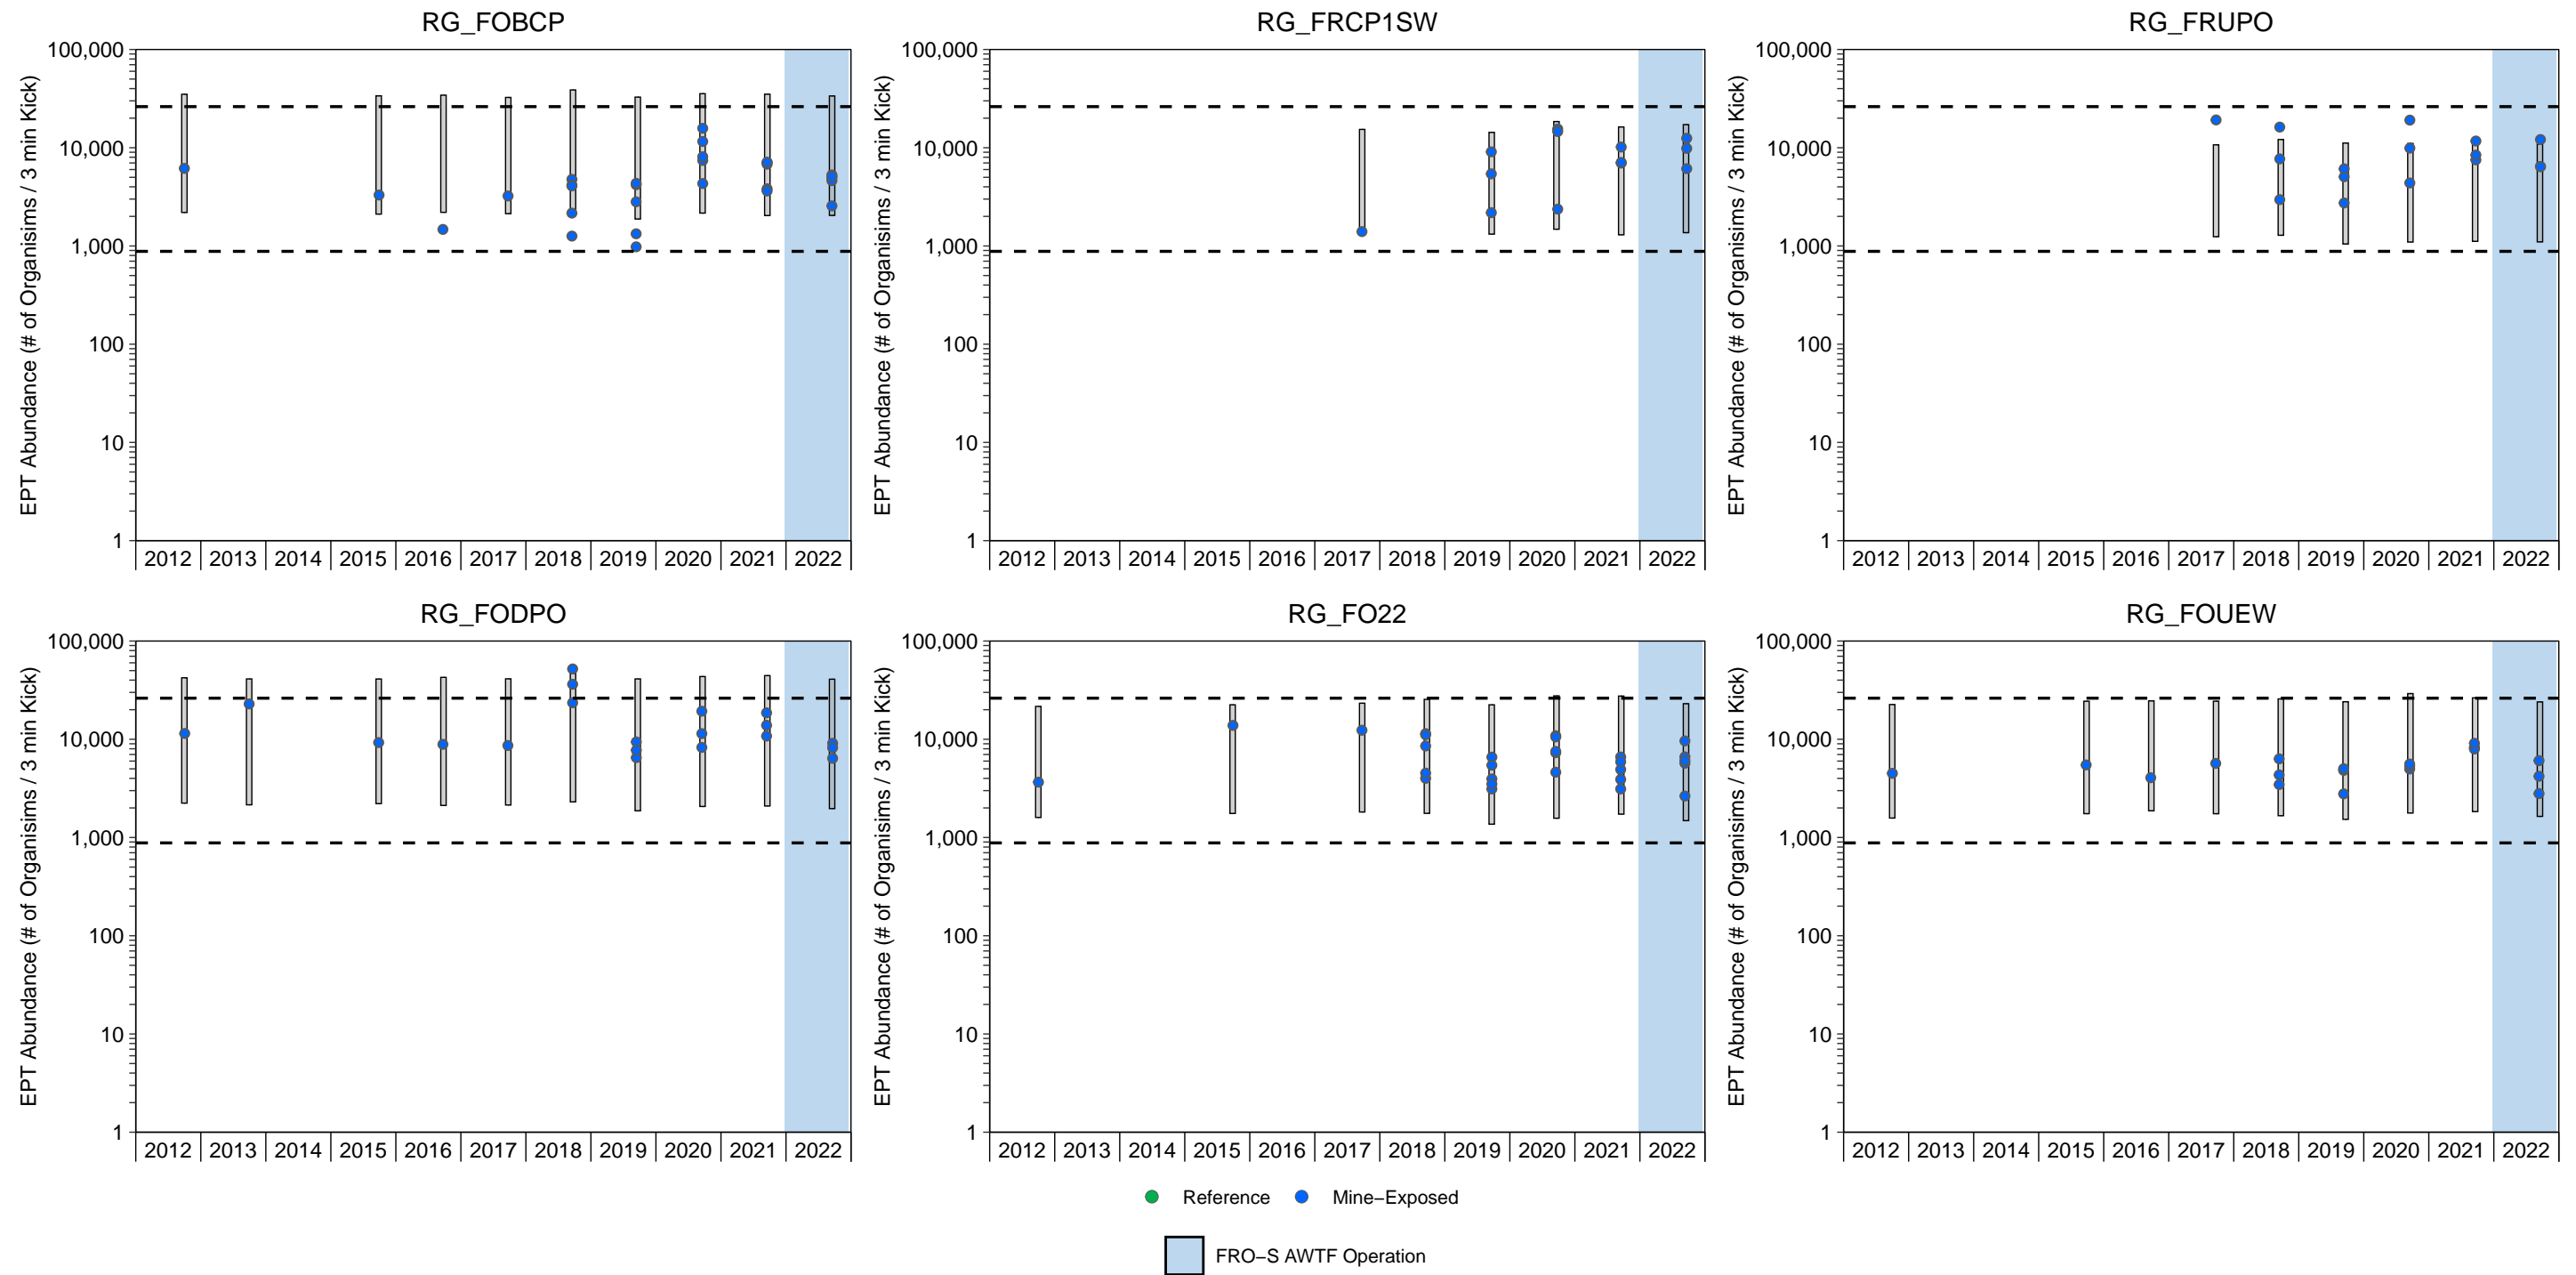

Figure G.18: Benthic Invertebrate EPT Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

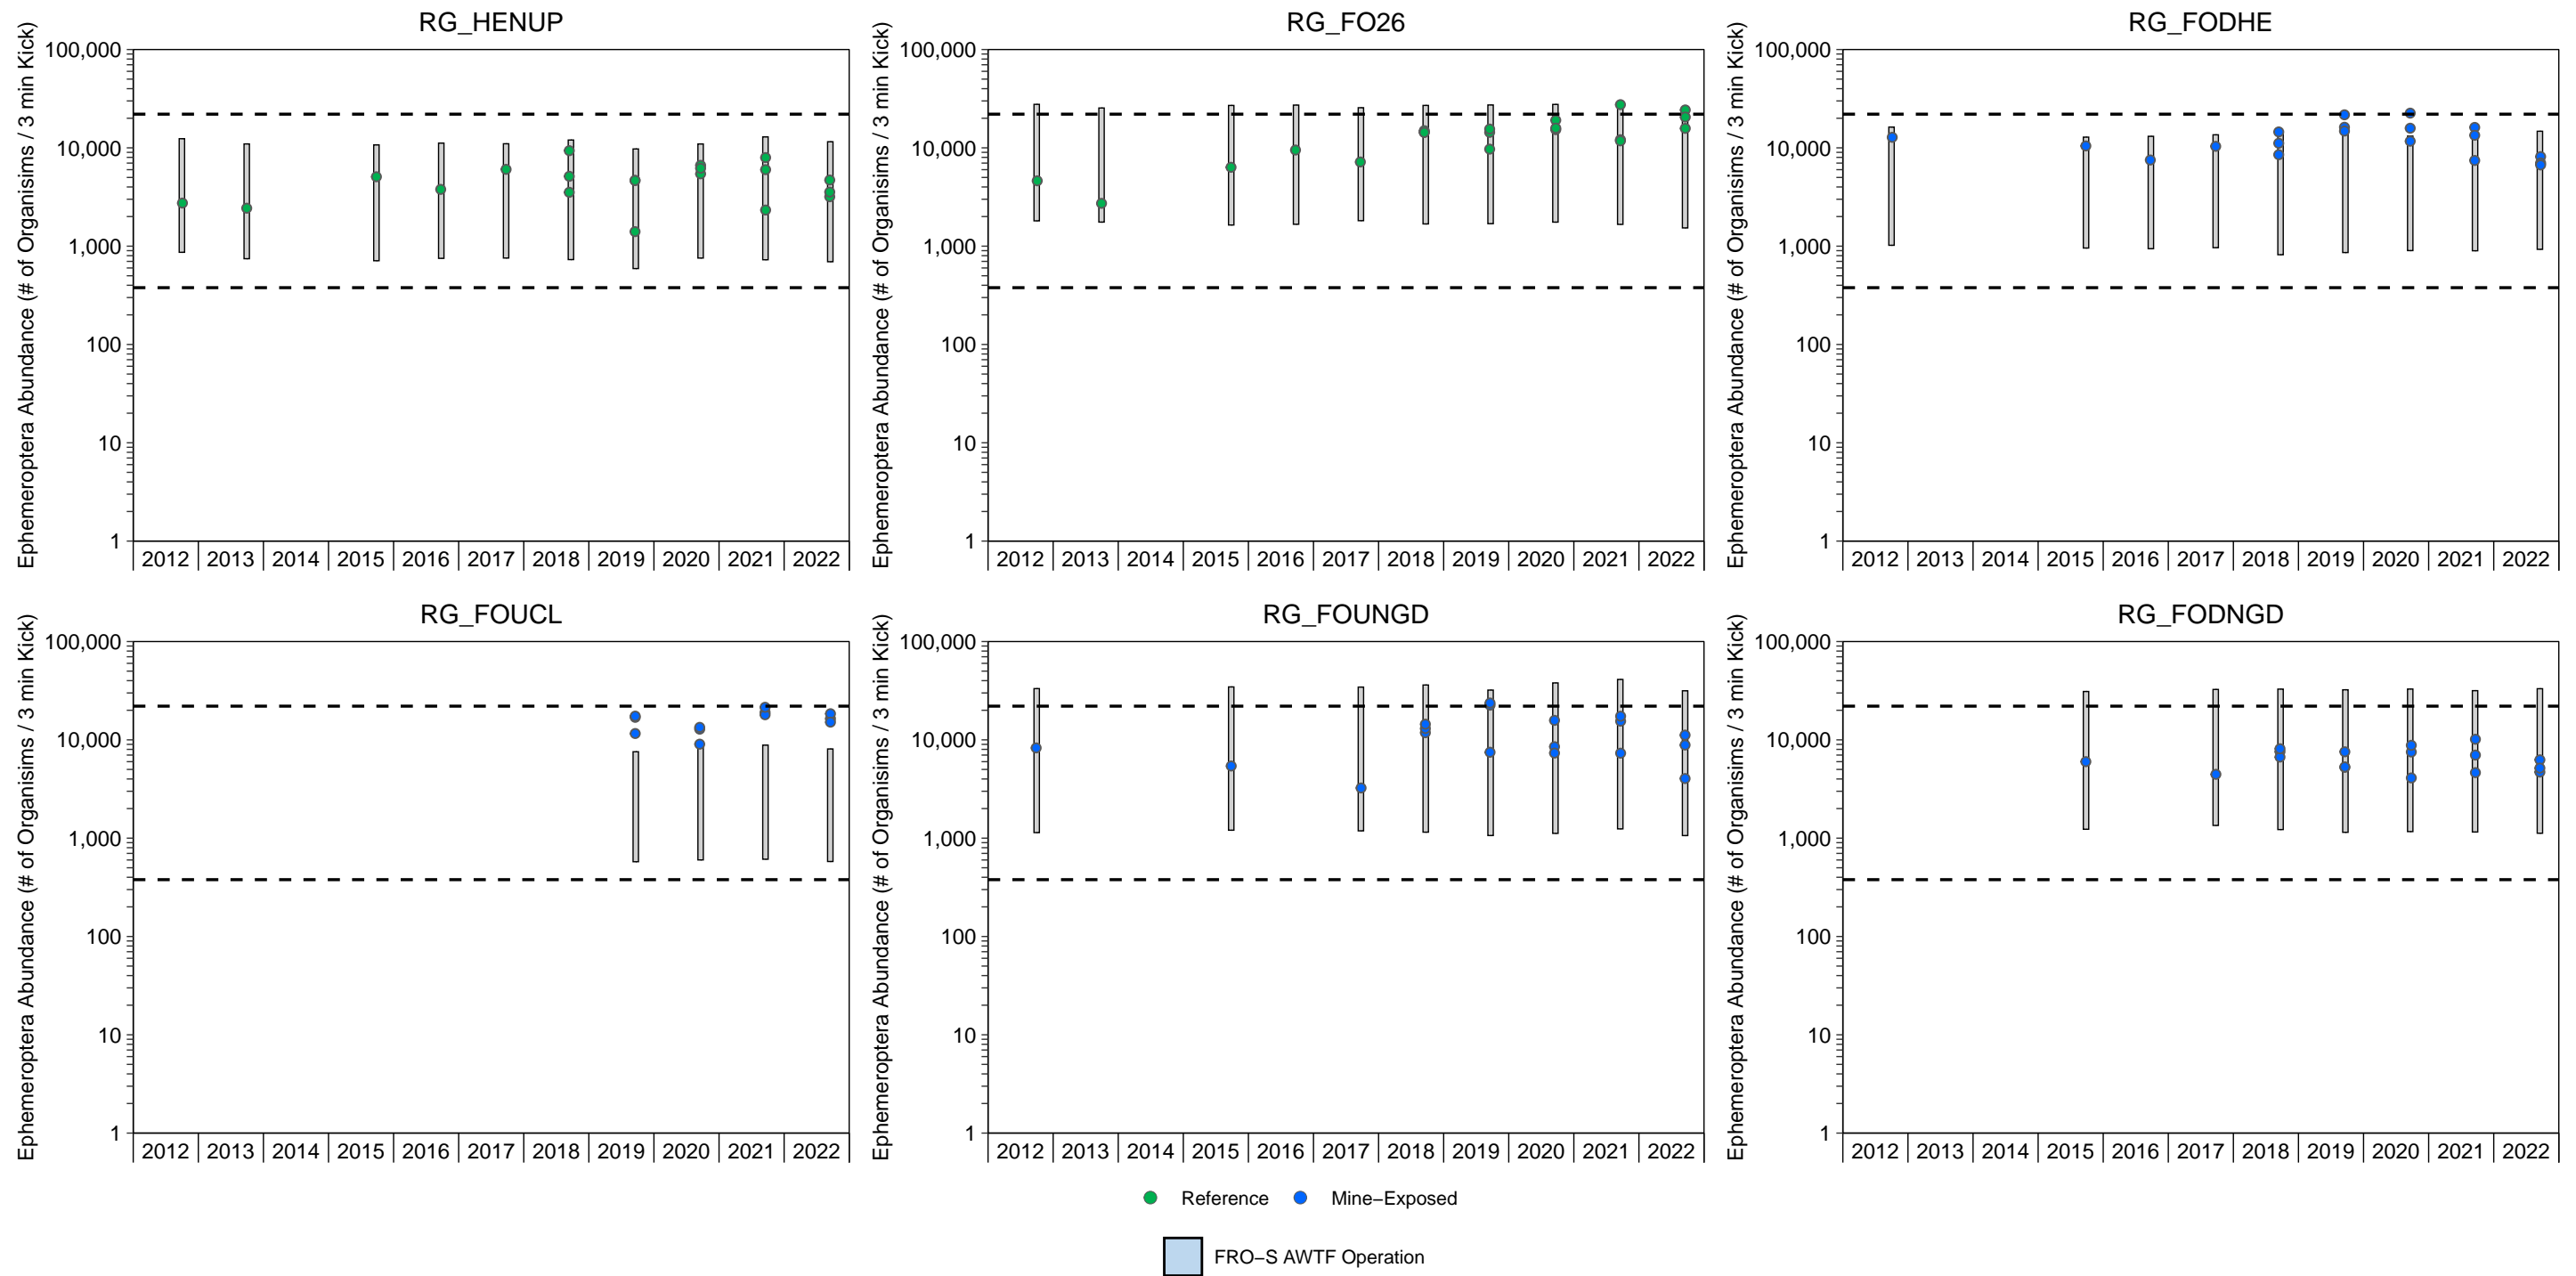

Figure G.19: Benthic Invertebrate Ephemeroptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

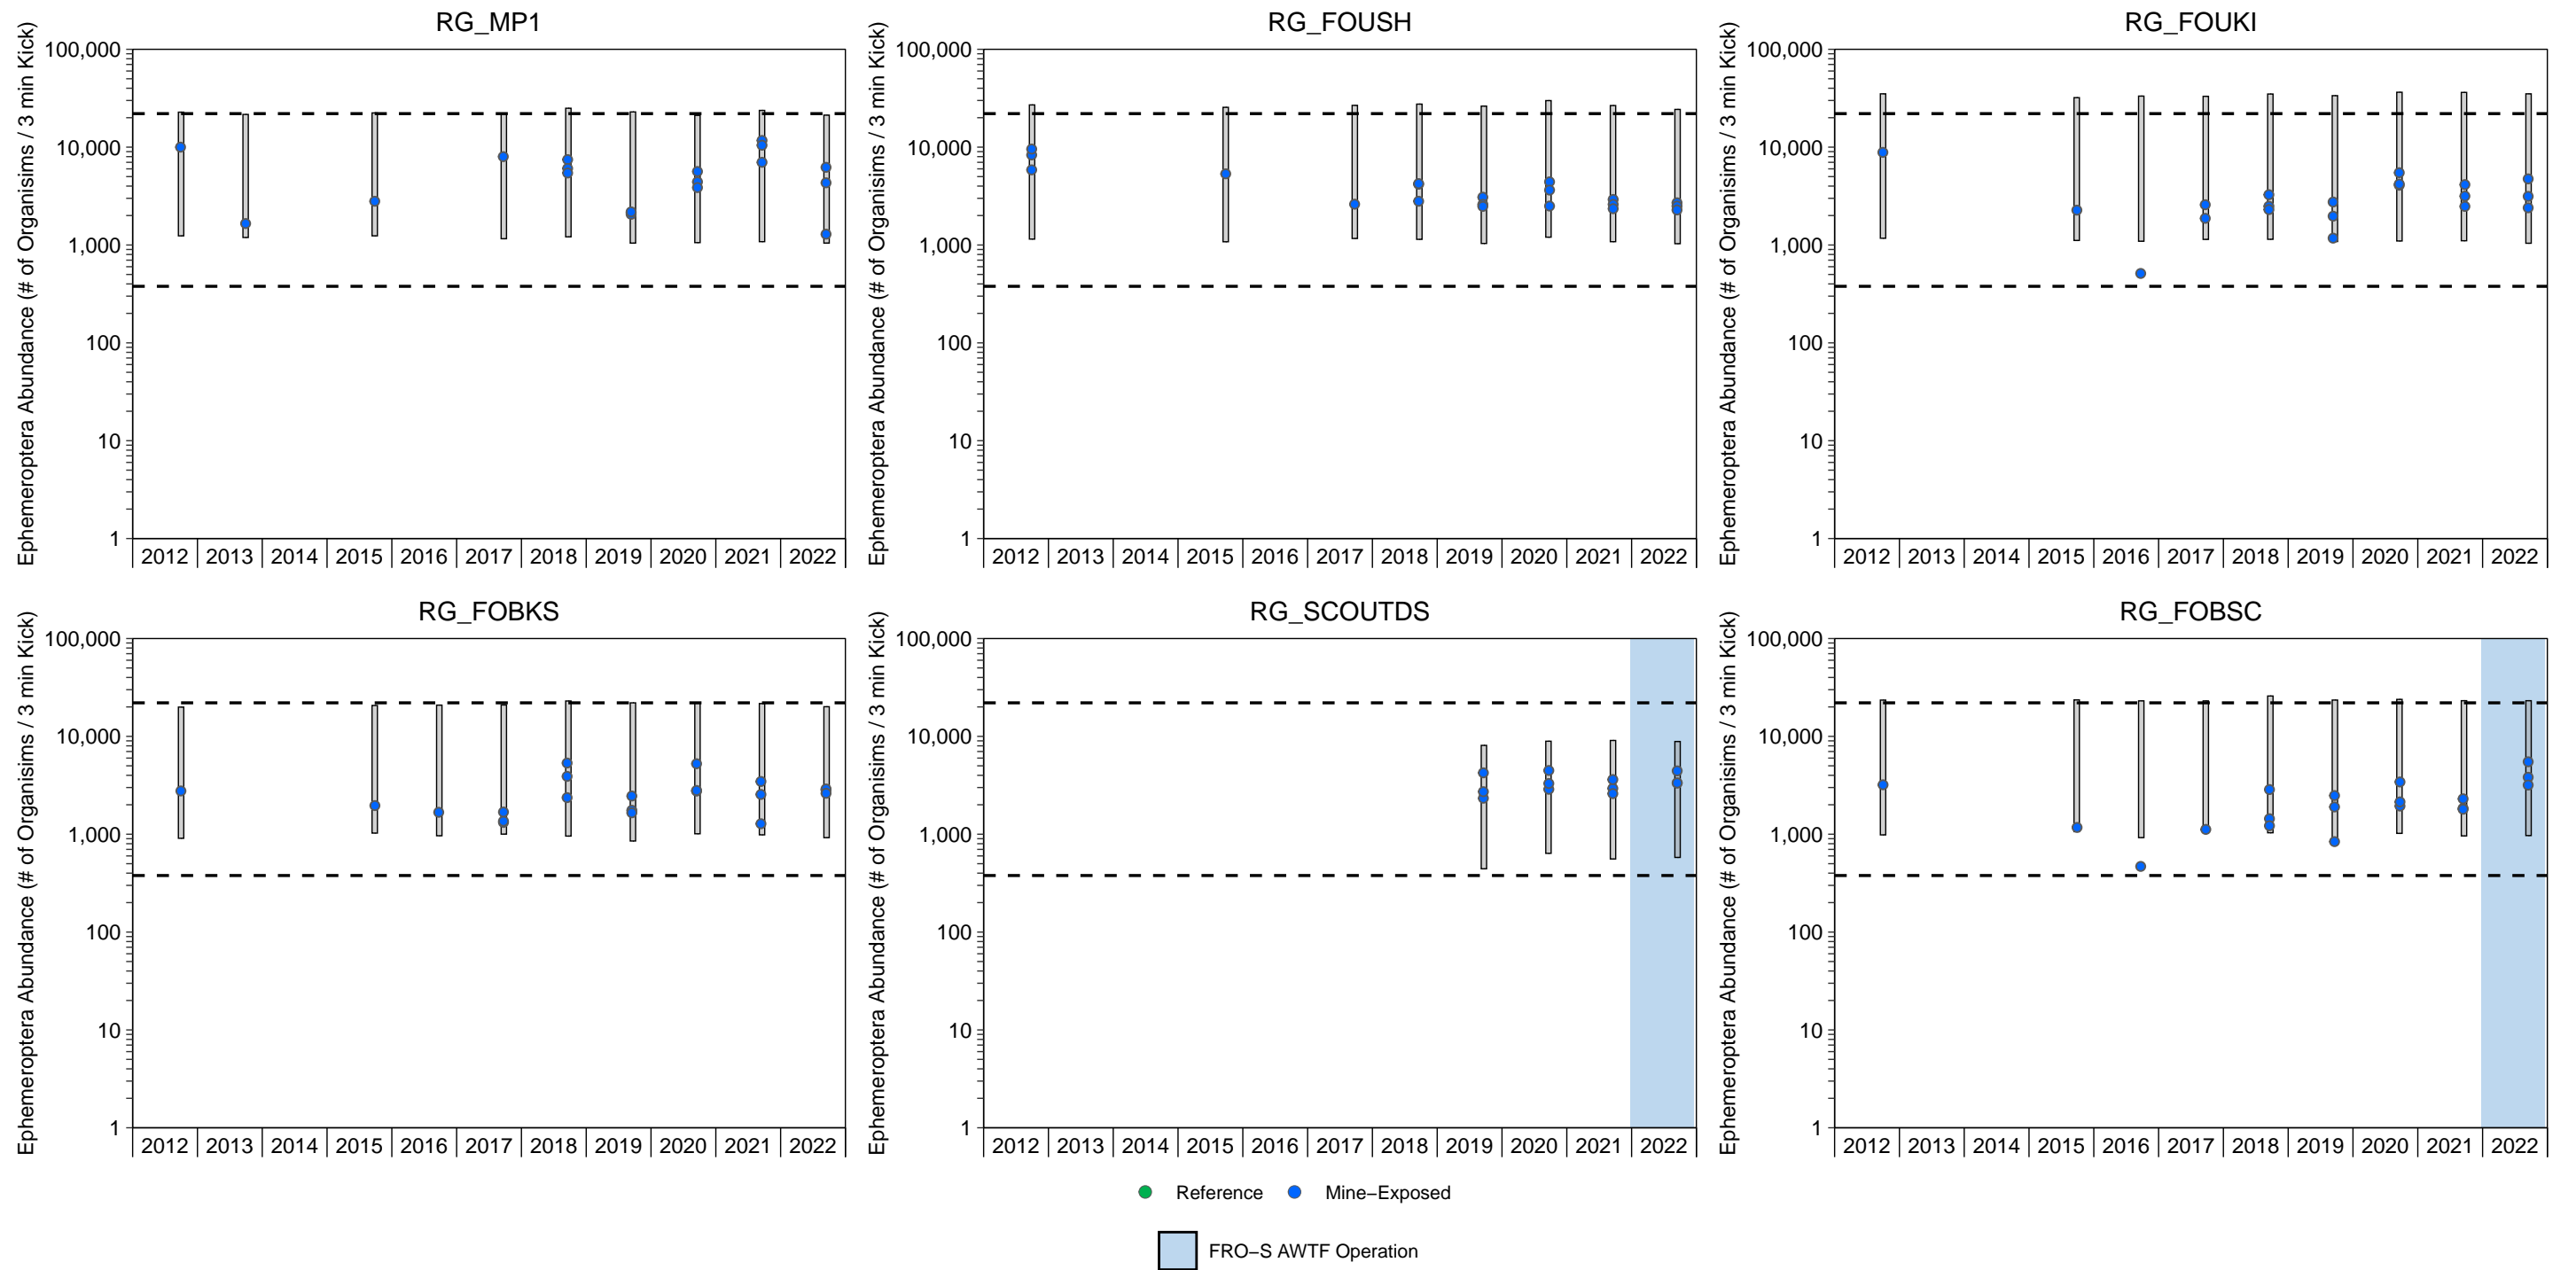

Figure G.19: Benthic Invertebrate Ephemeroptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

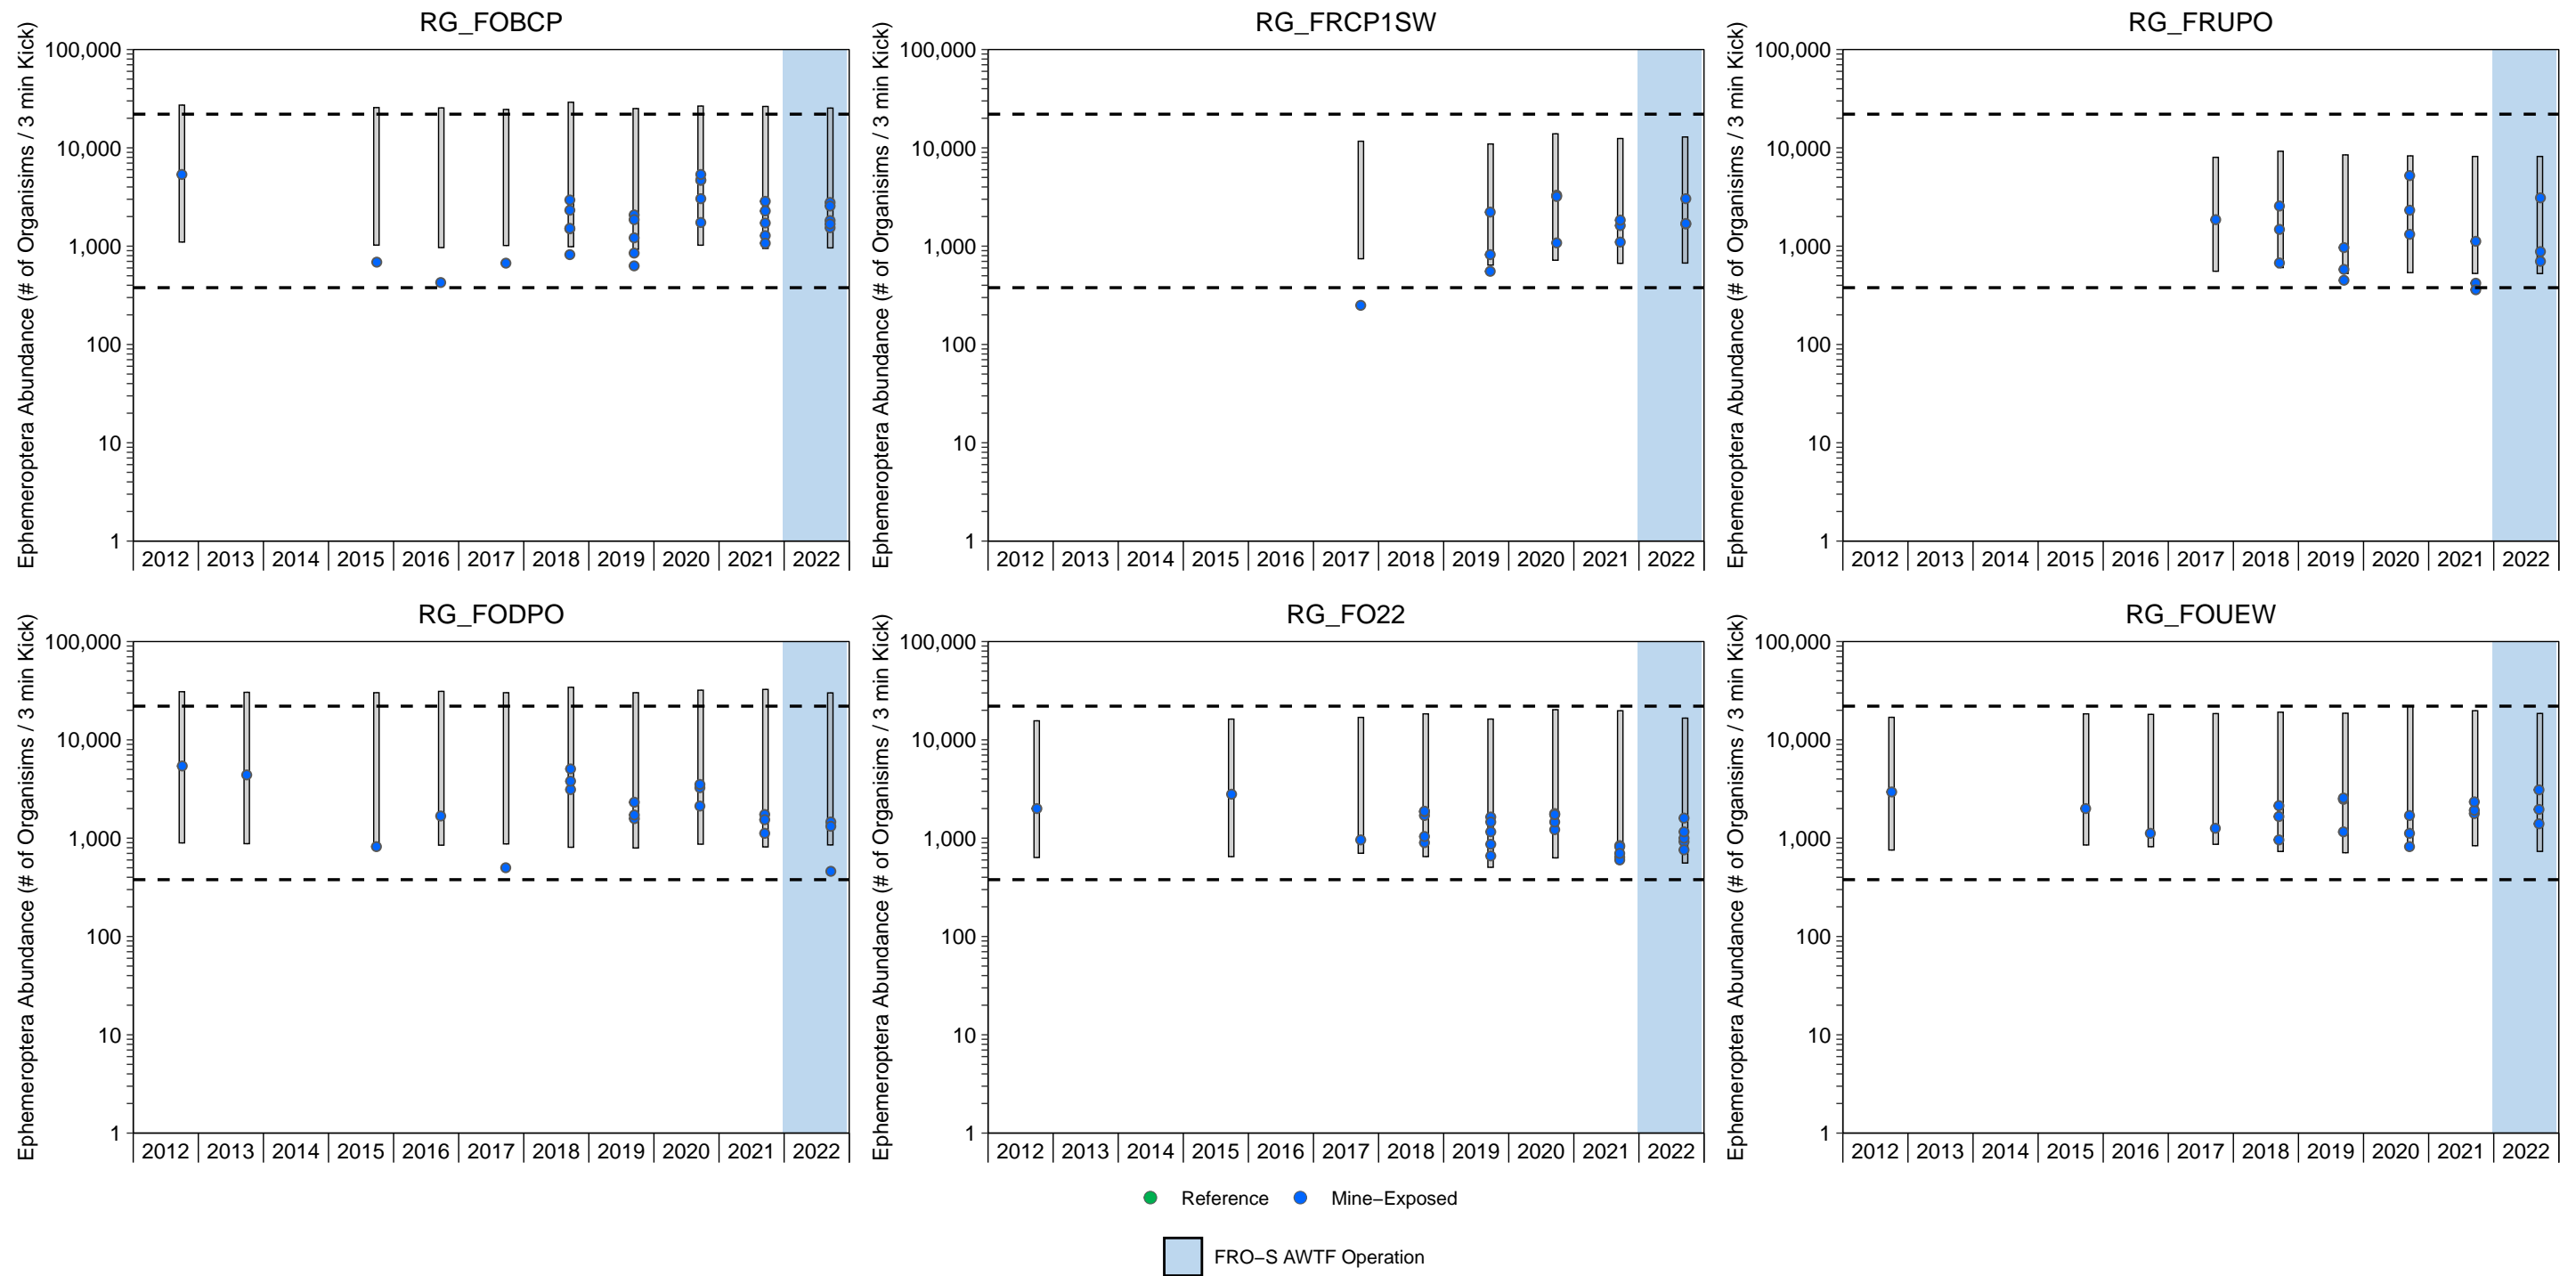

Figure G.19: Benthic Invertebrate Ephemeroptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.20: Benthic Invertebrate Plecoptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.20: Benthic Invertebrate Plecoptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

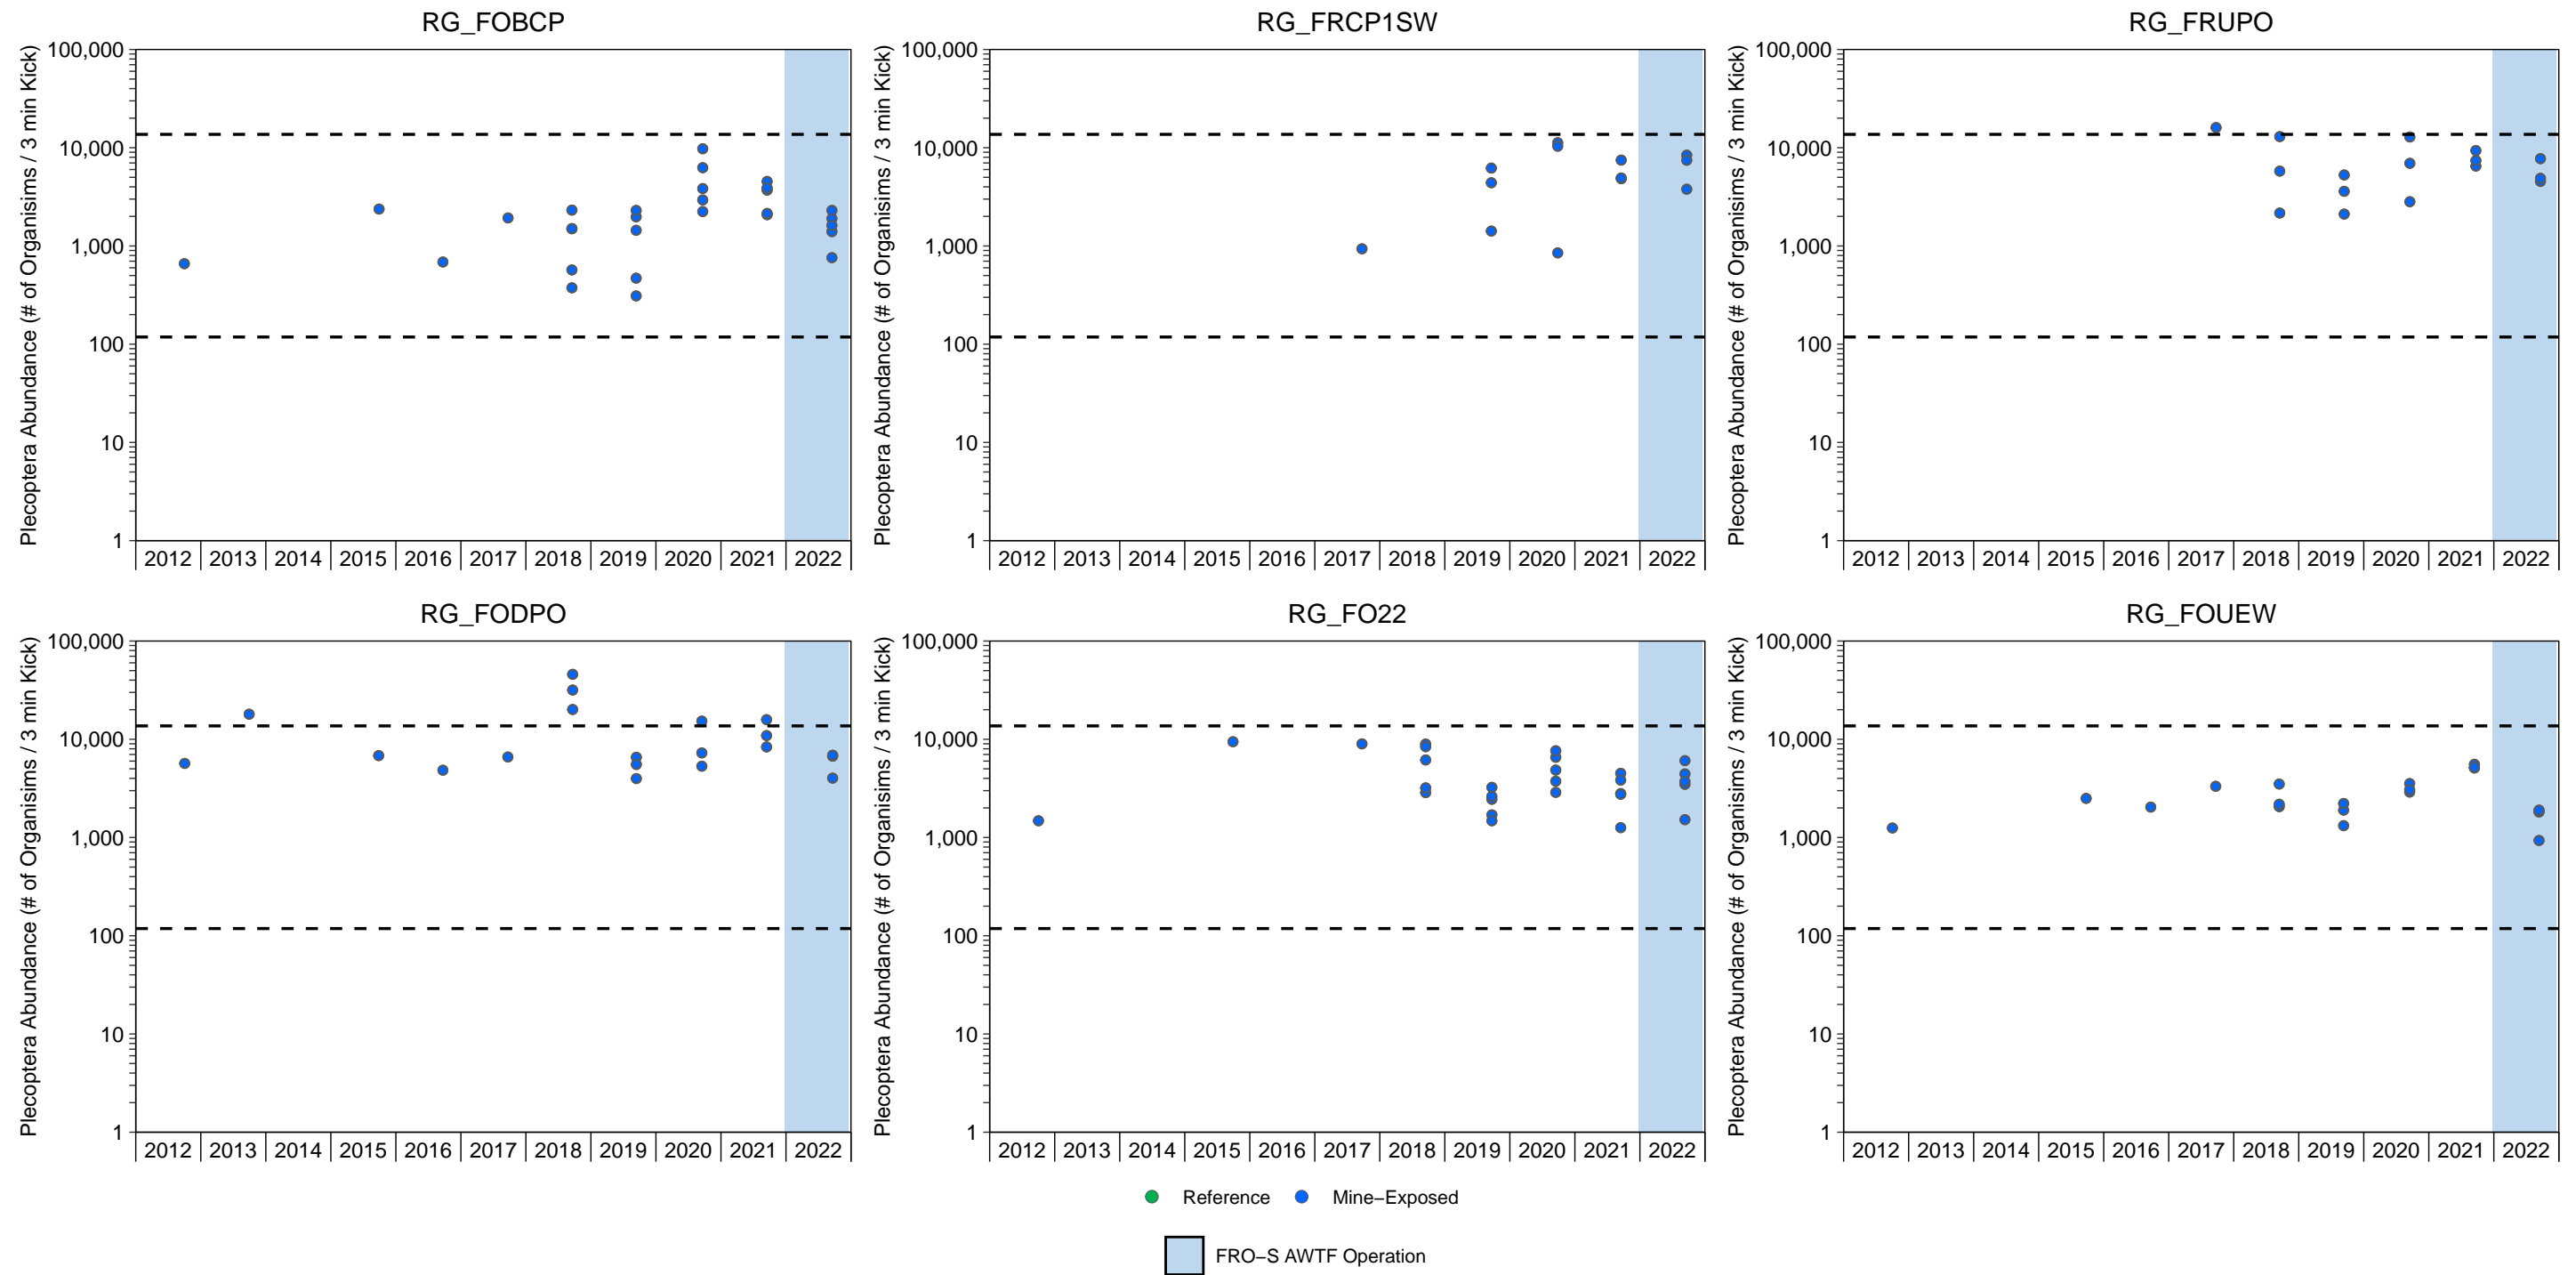

Figure G.20: Benthic Invertebrate Plecoptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

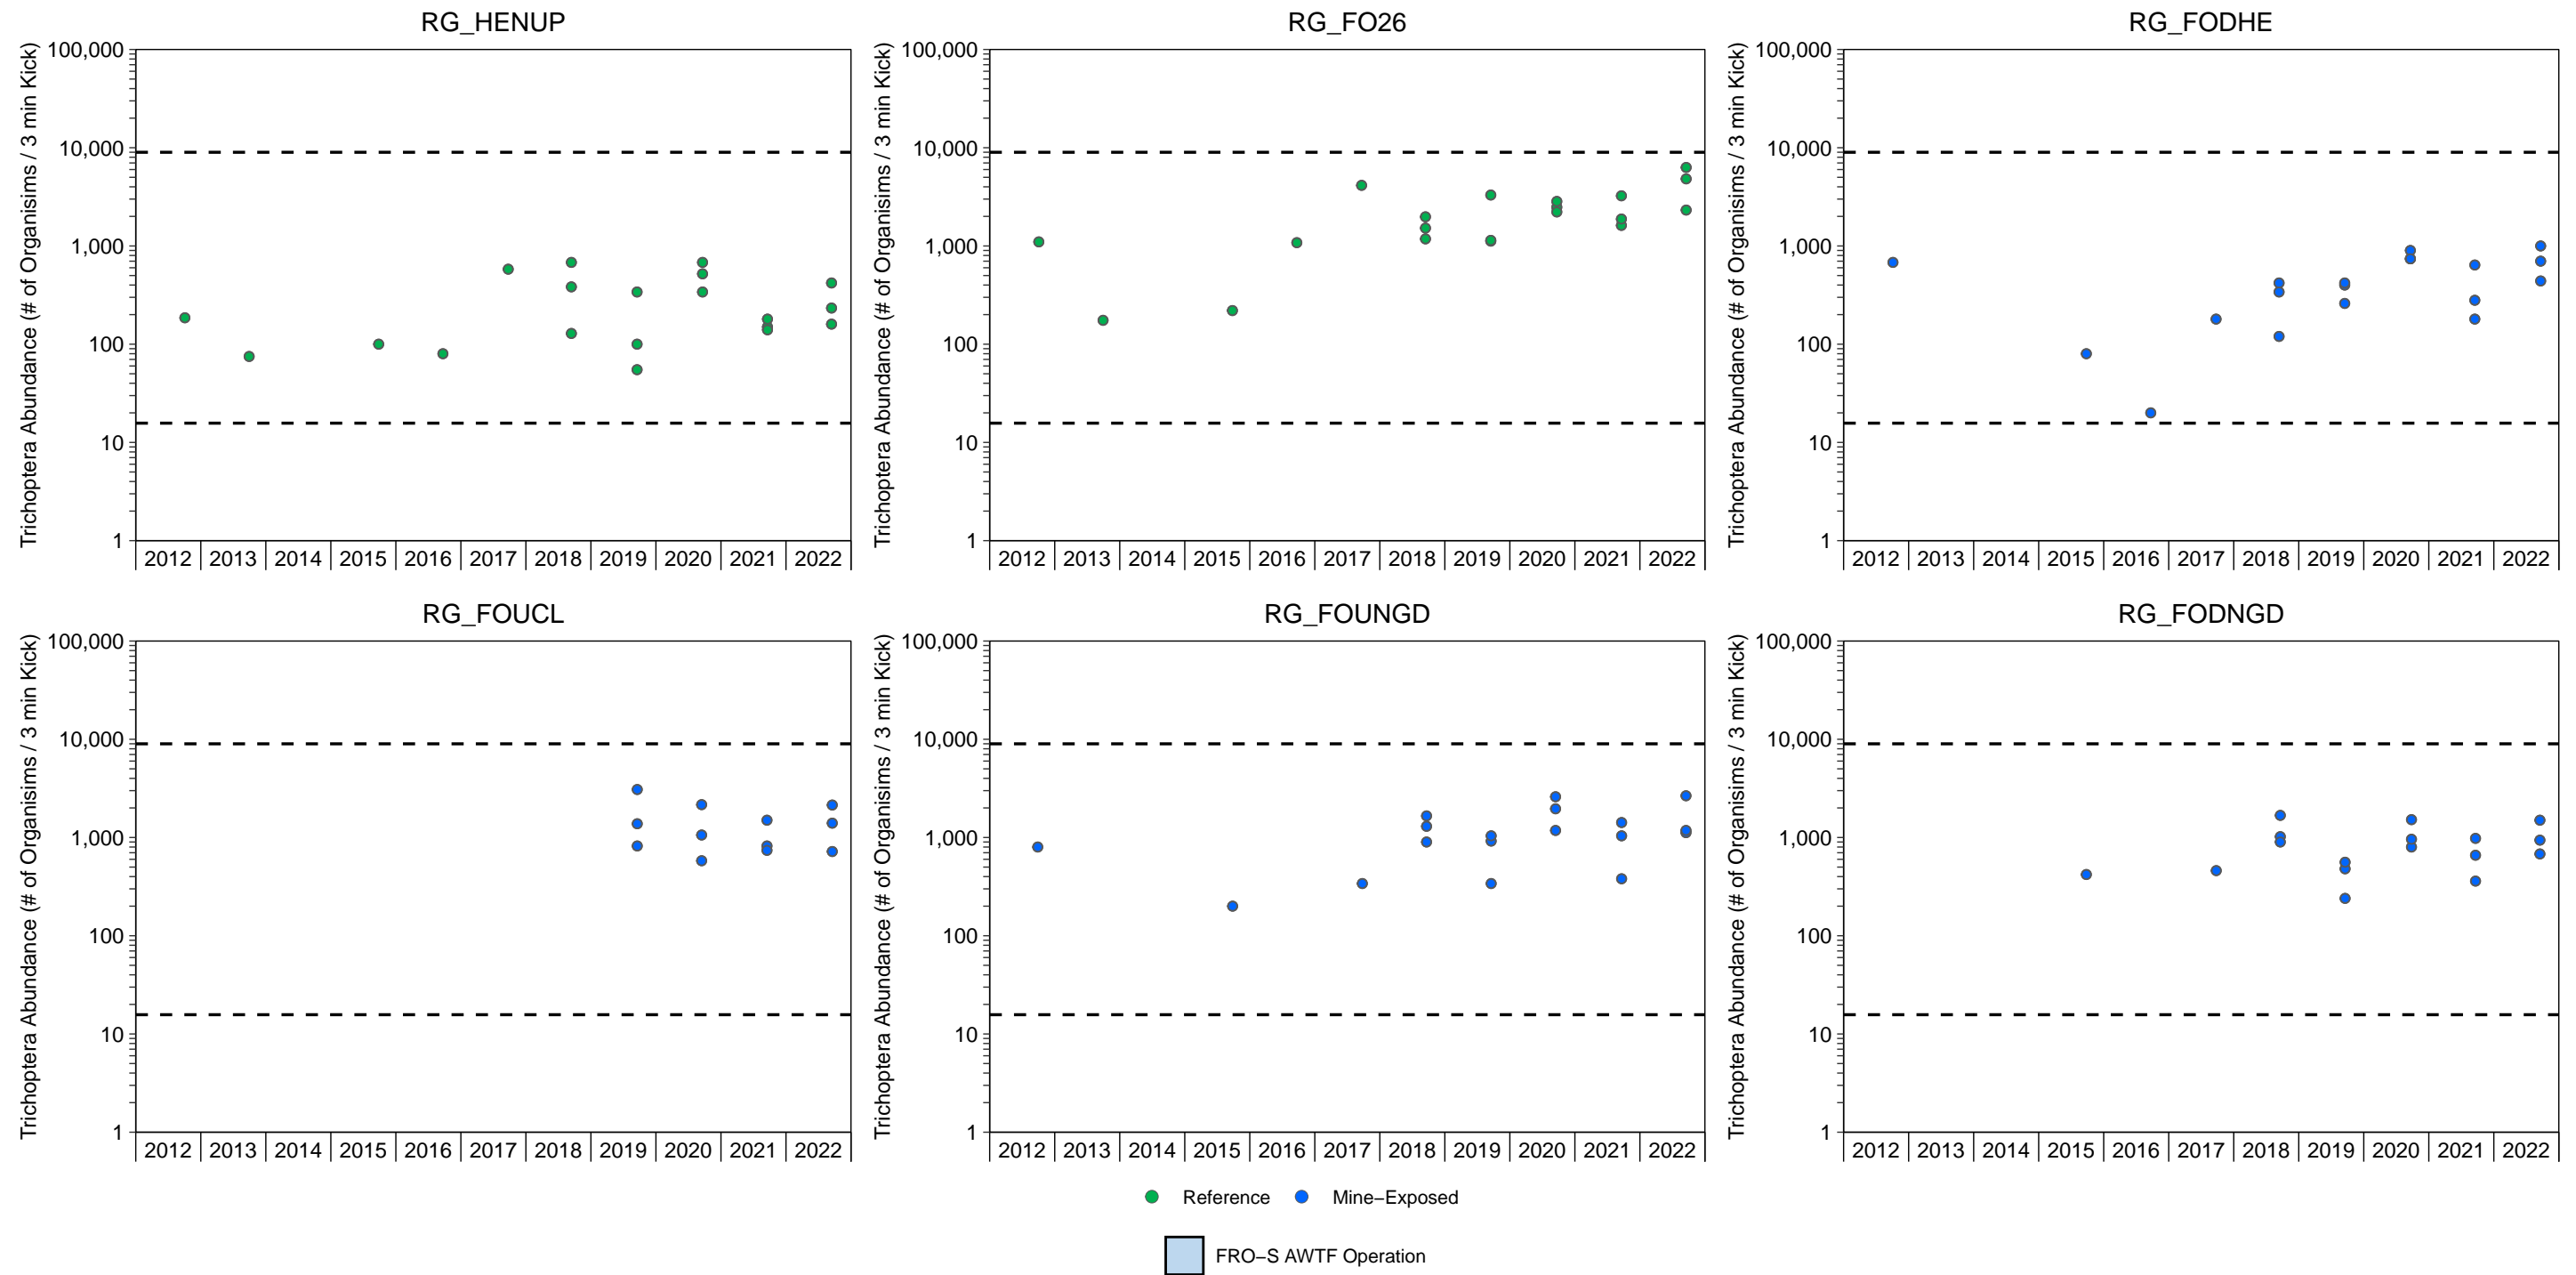

Figure G.21: Benthic Invertebrate Trichoptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.21: Benthic Invertebrate Trichoptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

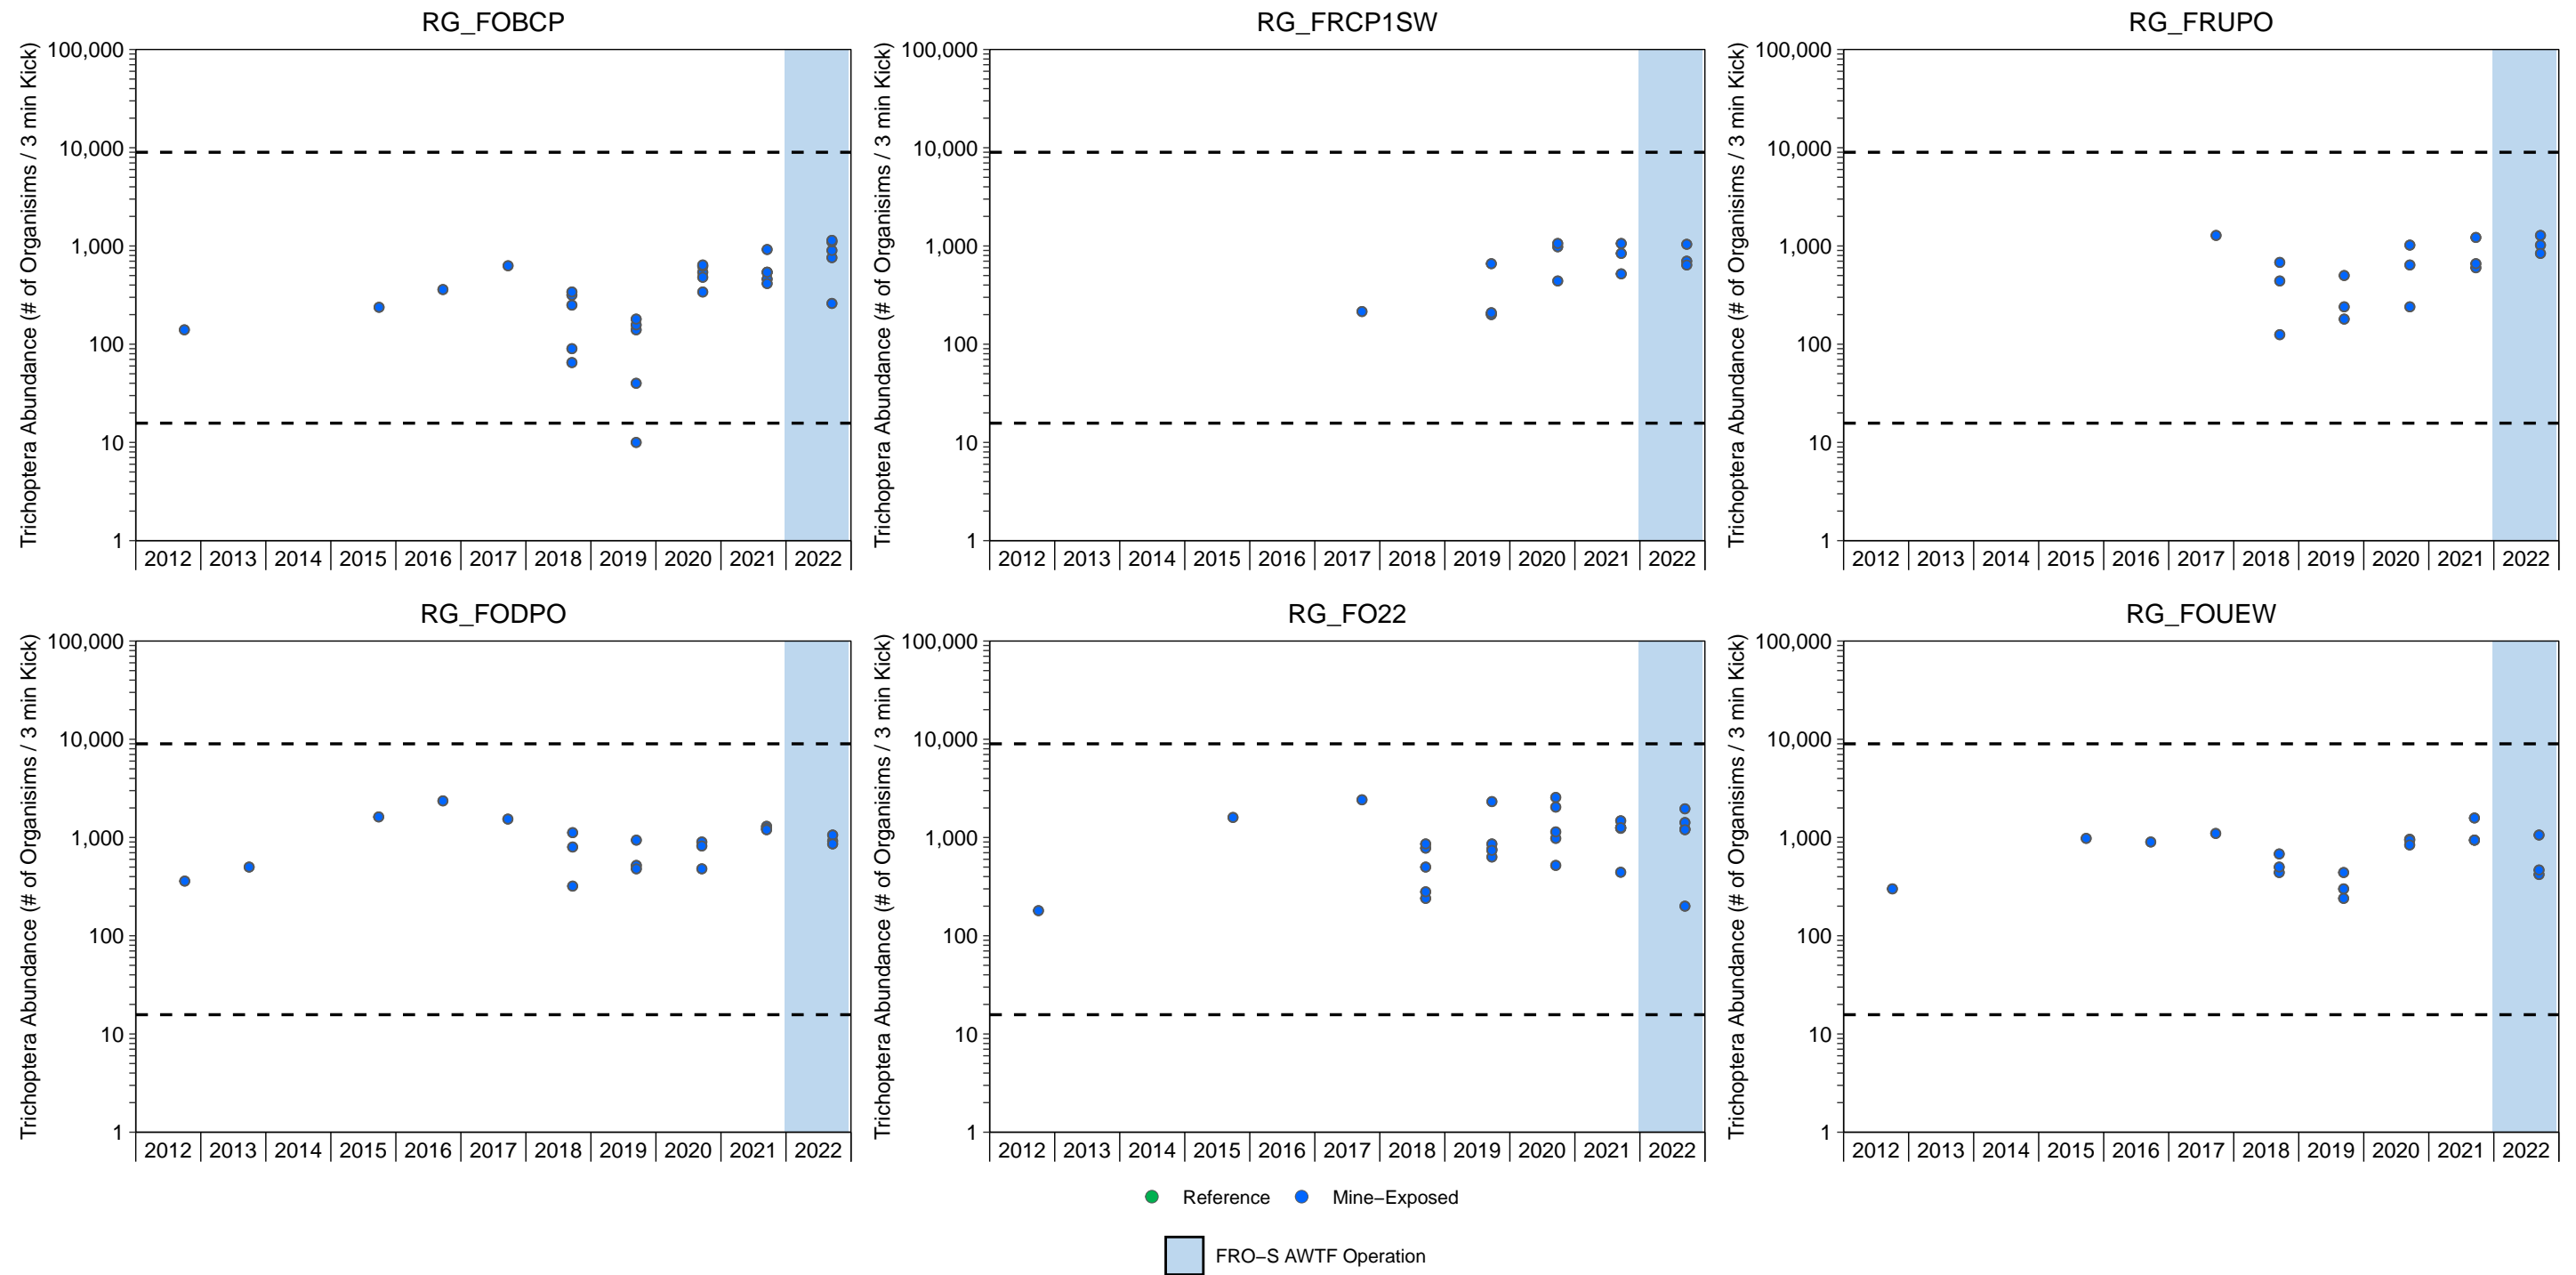

Figure G.21: Benthic Invertebrate Trichoptera Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

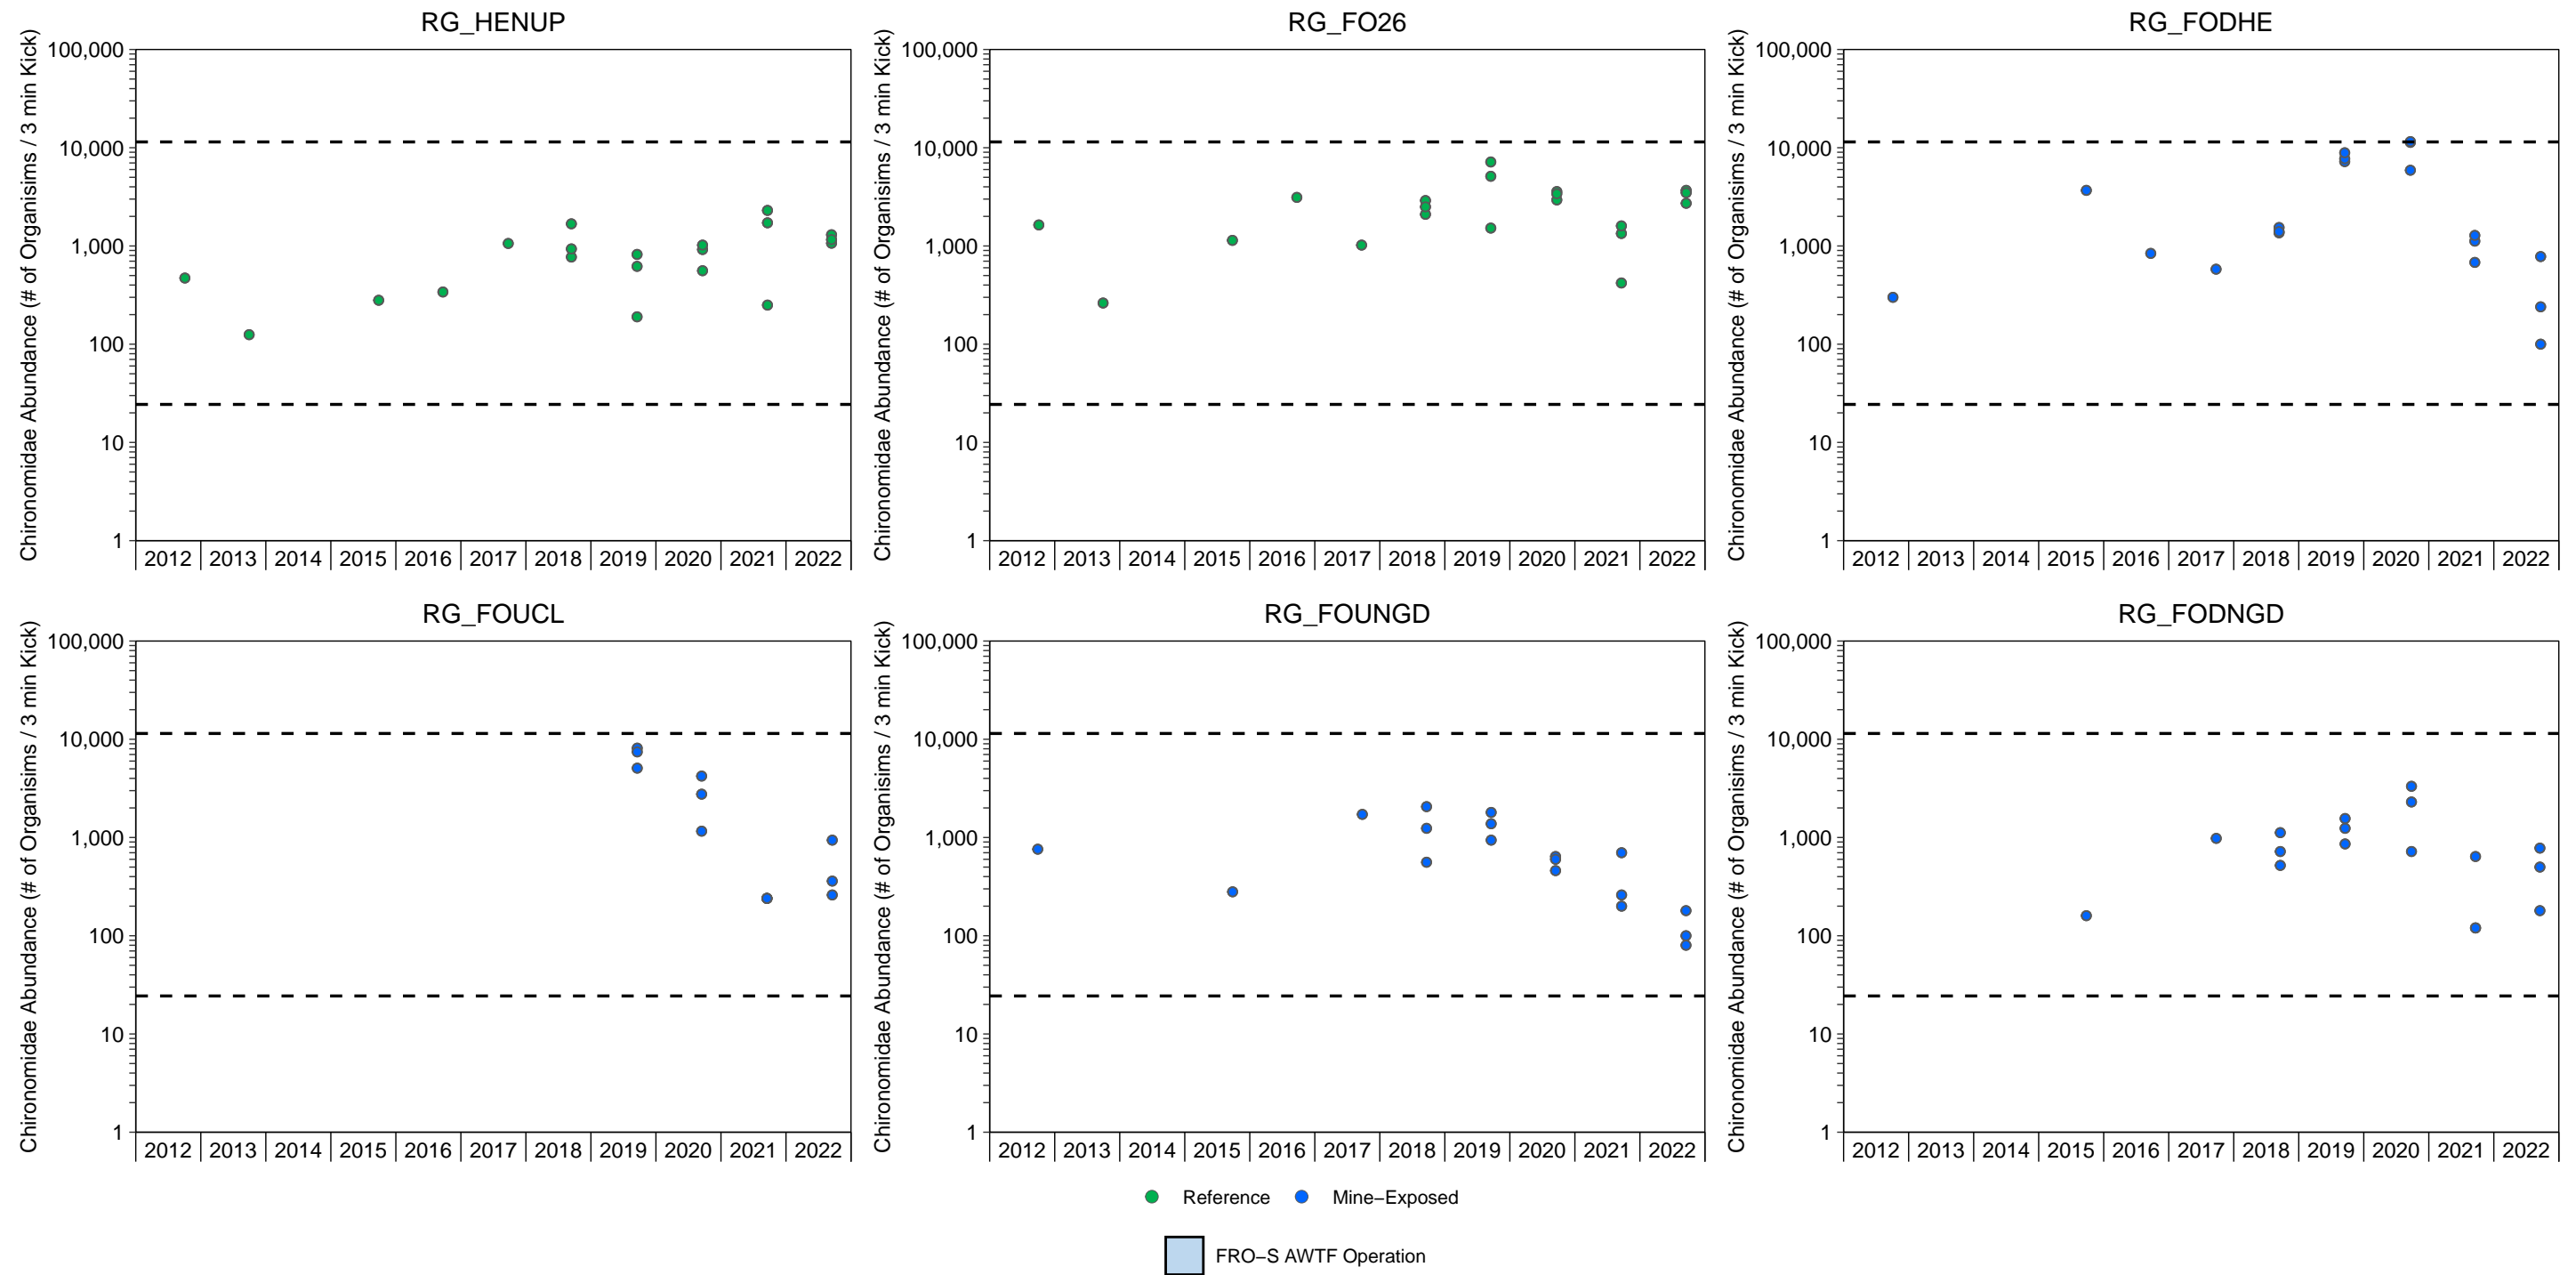

Figure G.22: Benthic Invertebrate Chironomidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.22: Benthic Invertebrate Chironomidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.22: Benthic Invertebrate Chironomidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

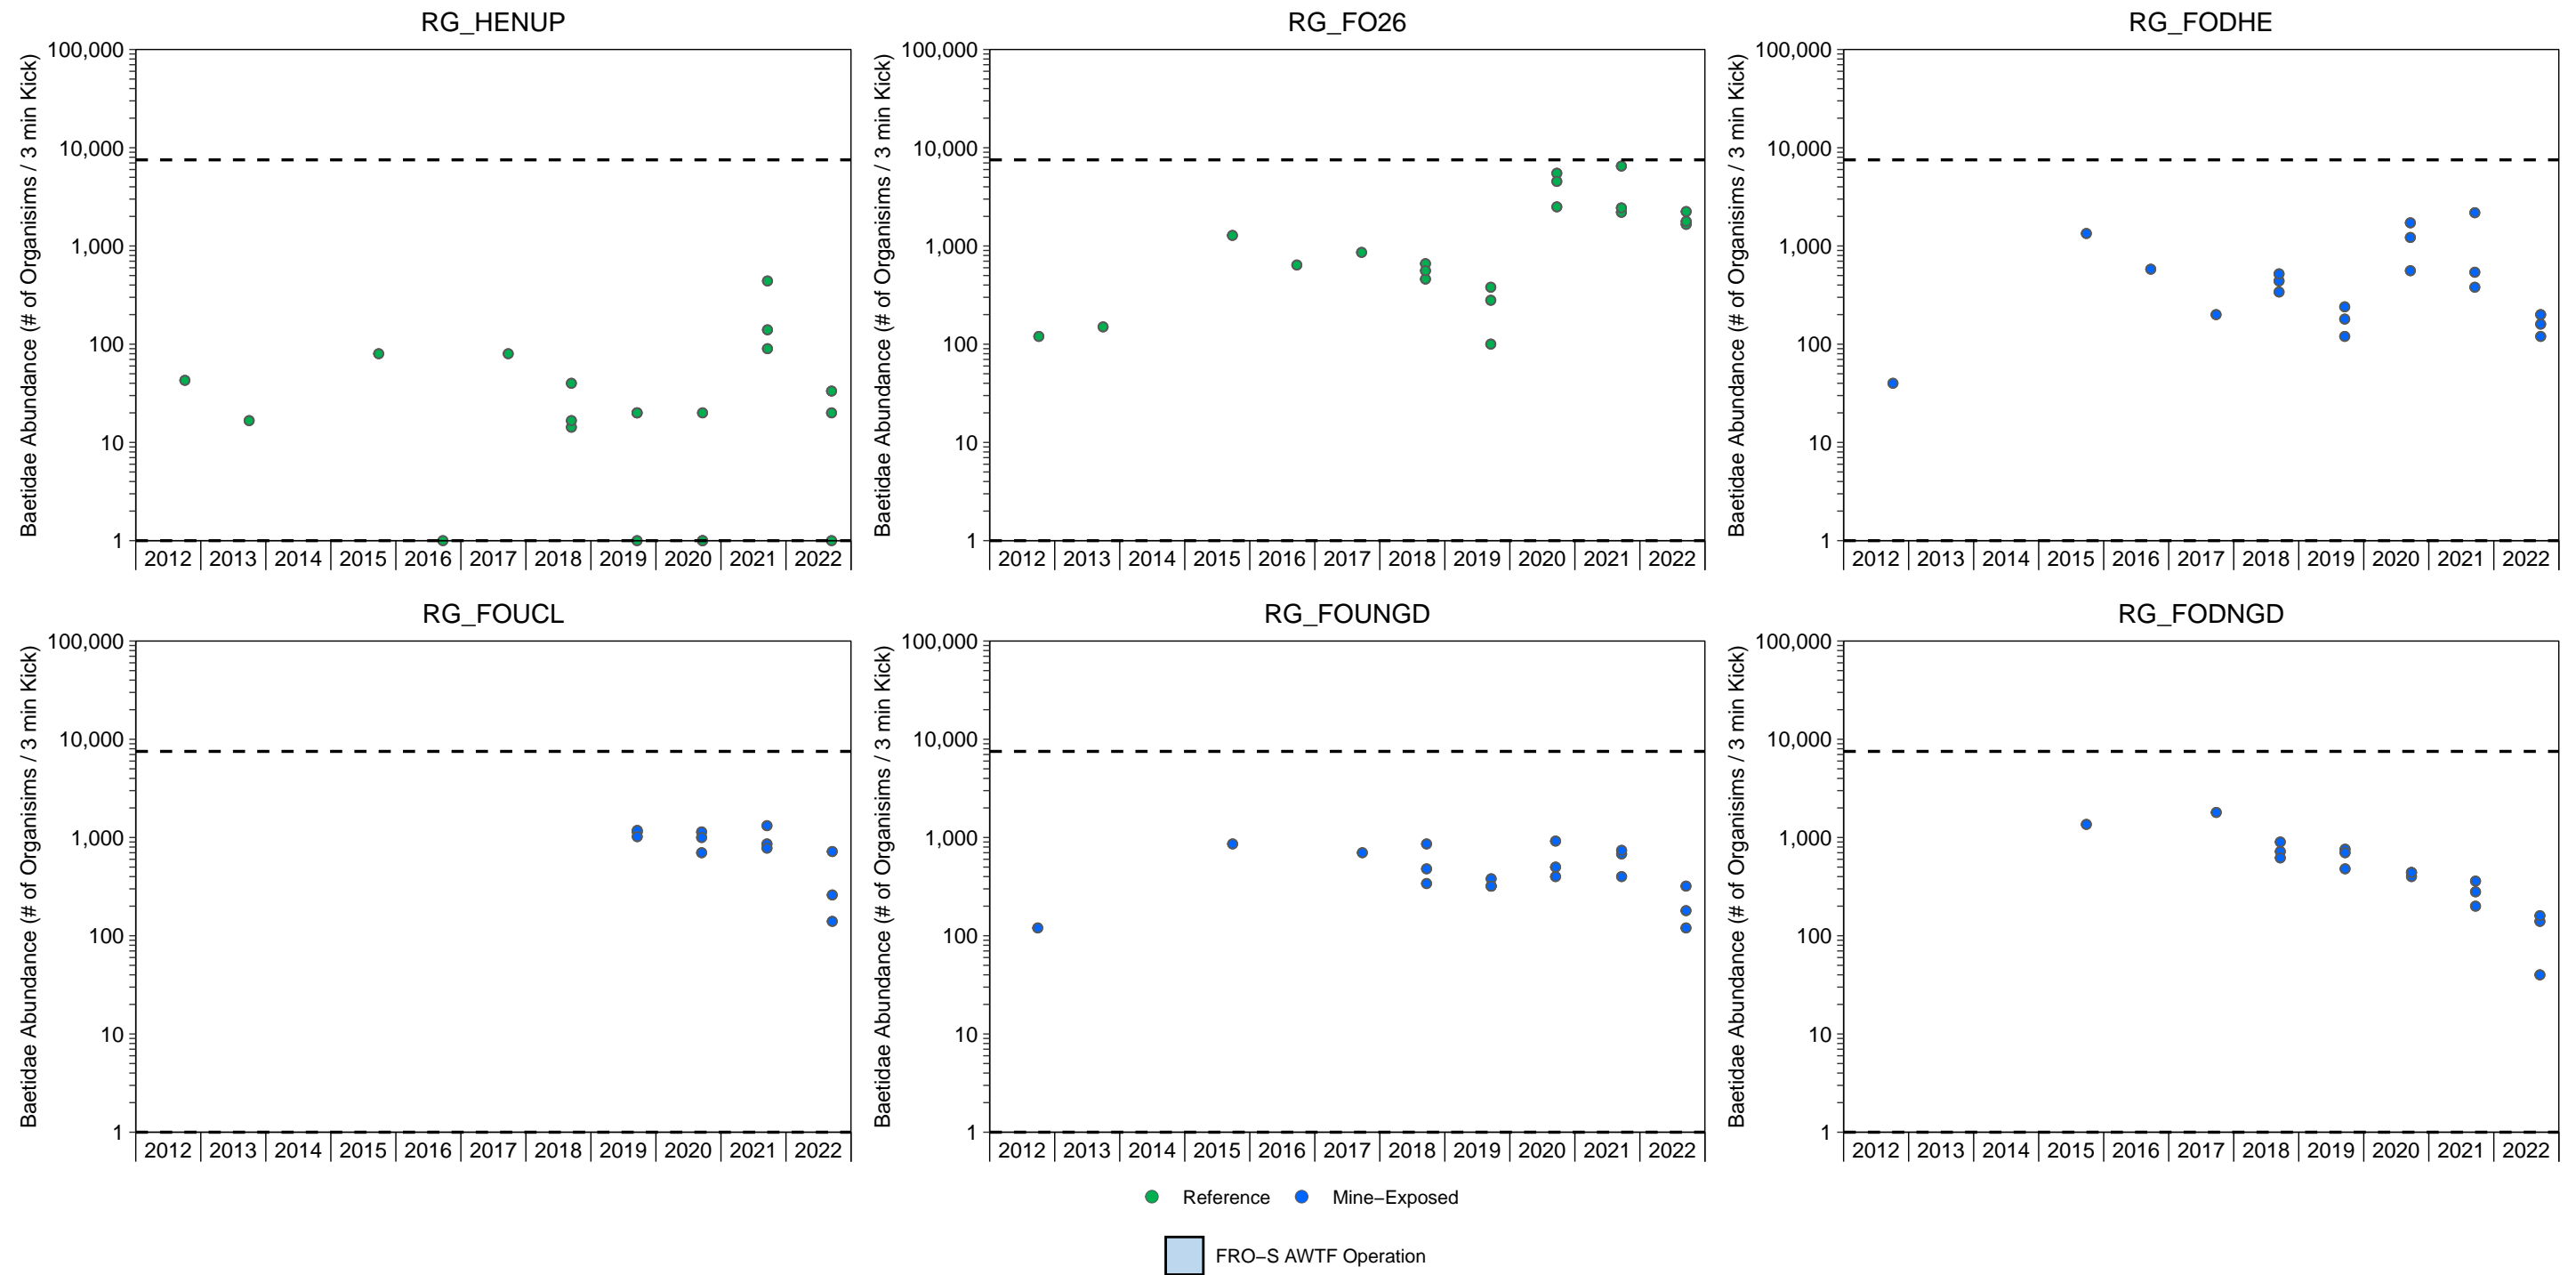

Figure G.23: Benthic Invertebrate Baetidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.23: Benthic Invertebrate Baetidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

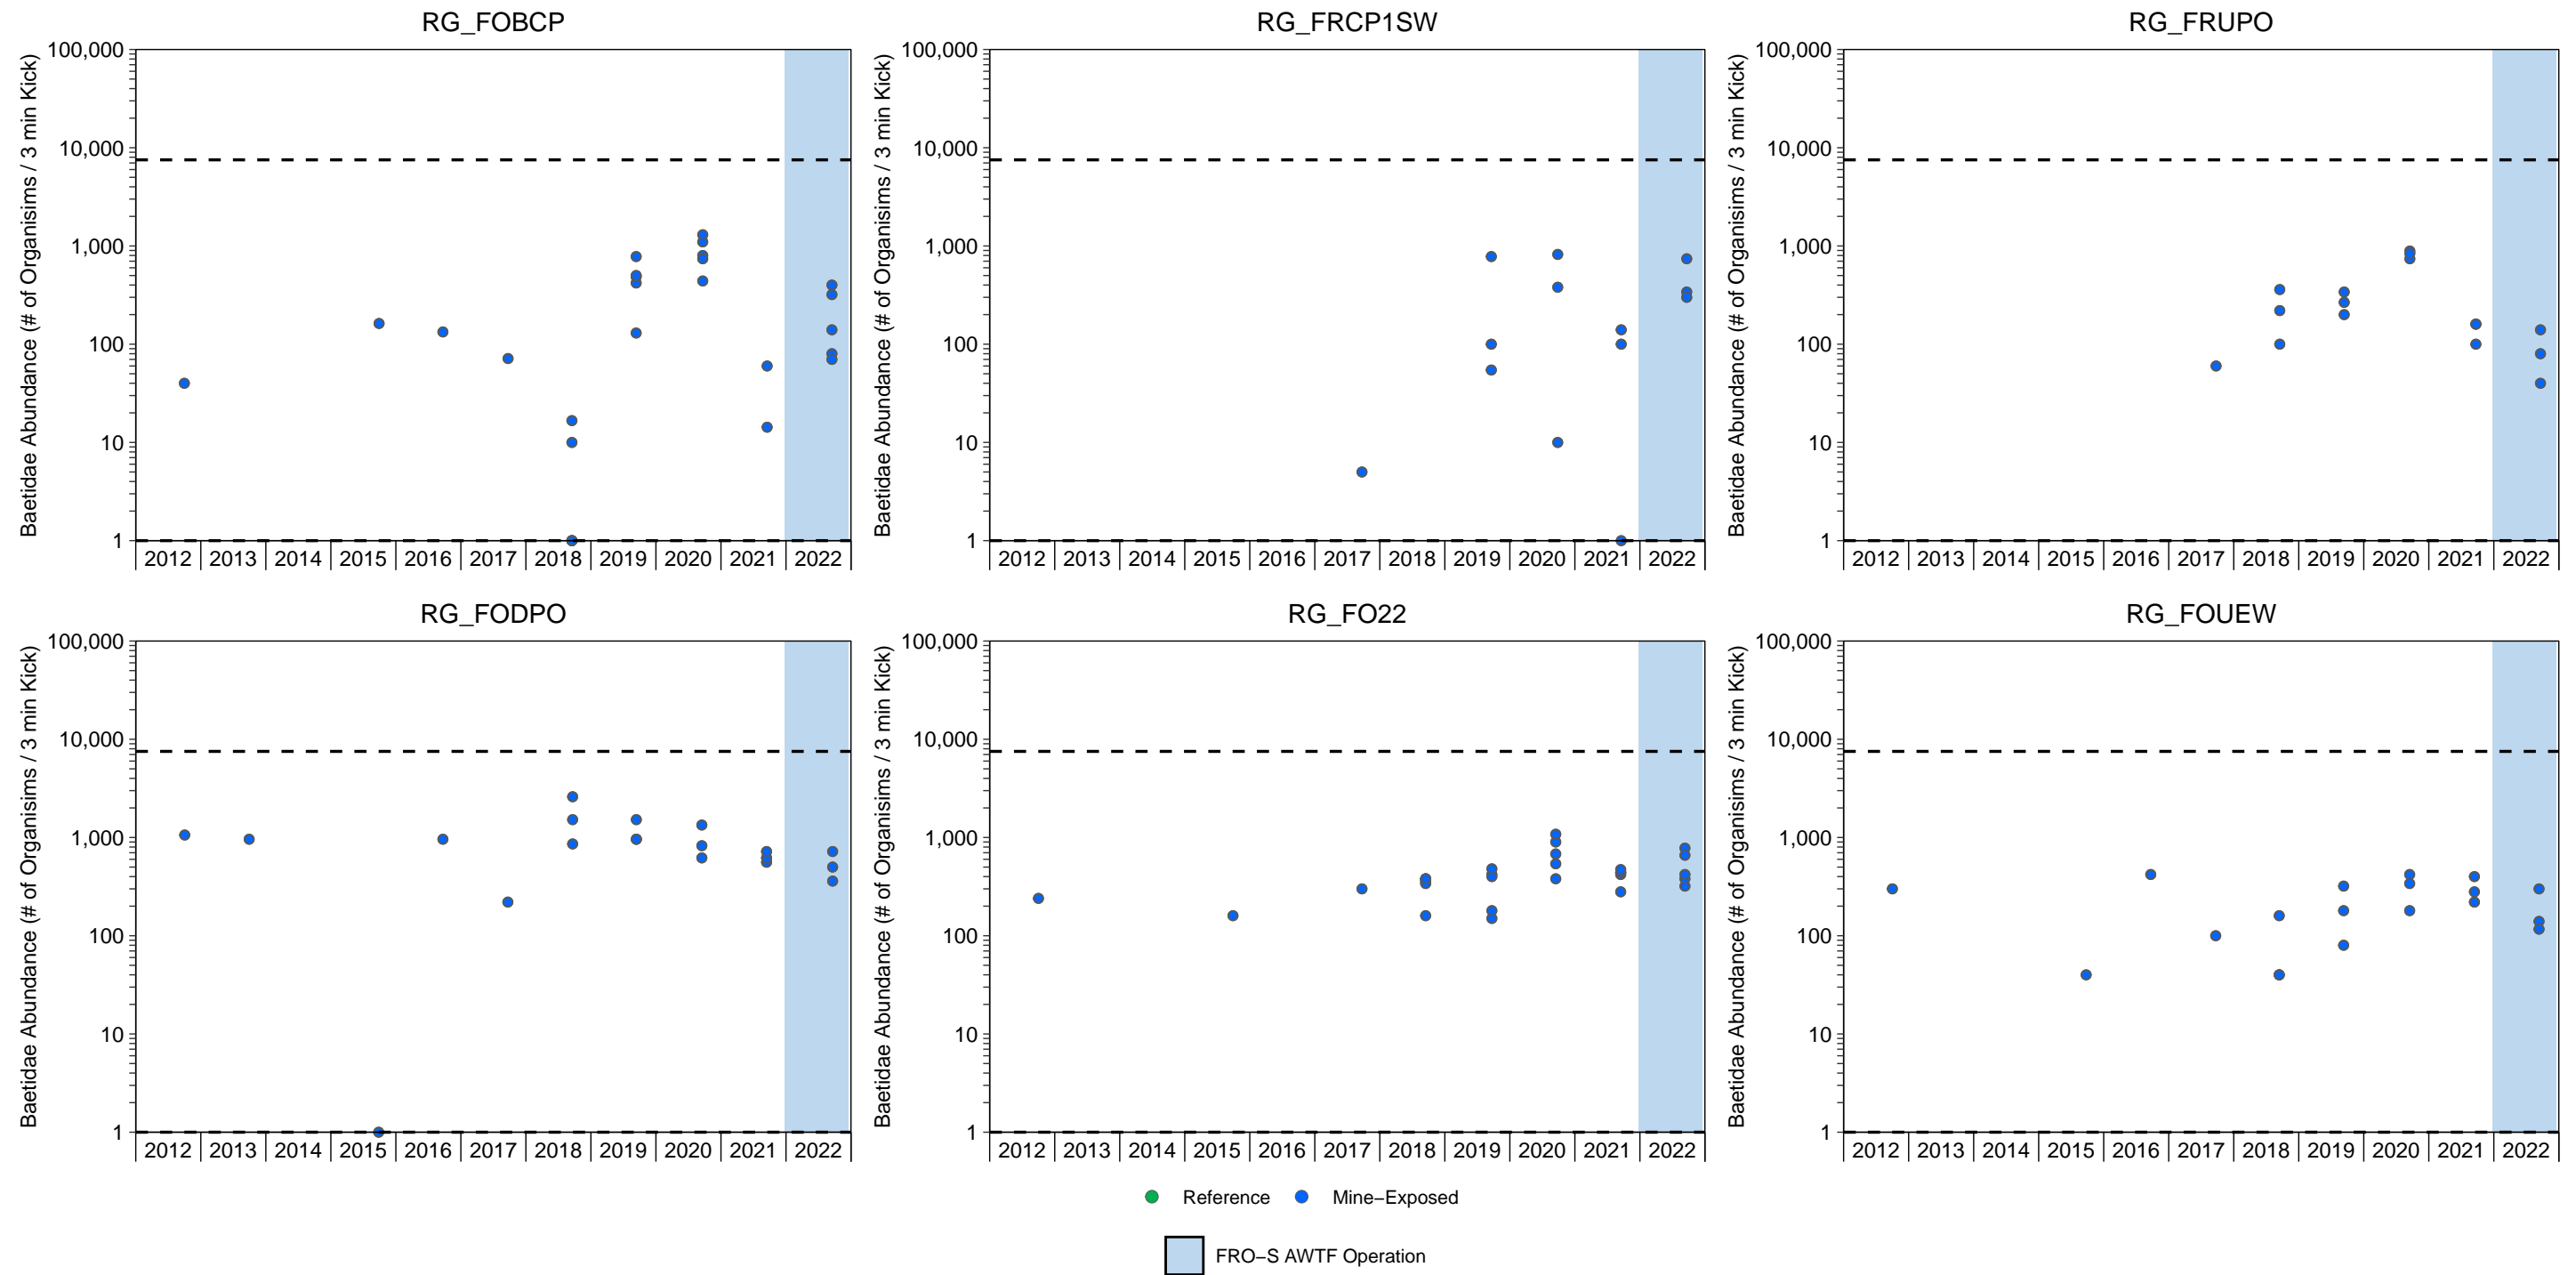

Figure G.23: Benthic Invertebrate Baetidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

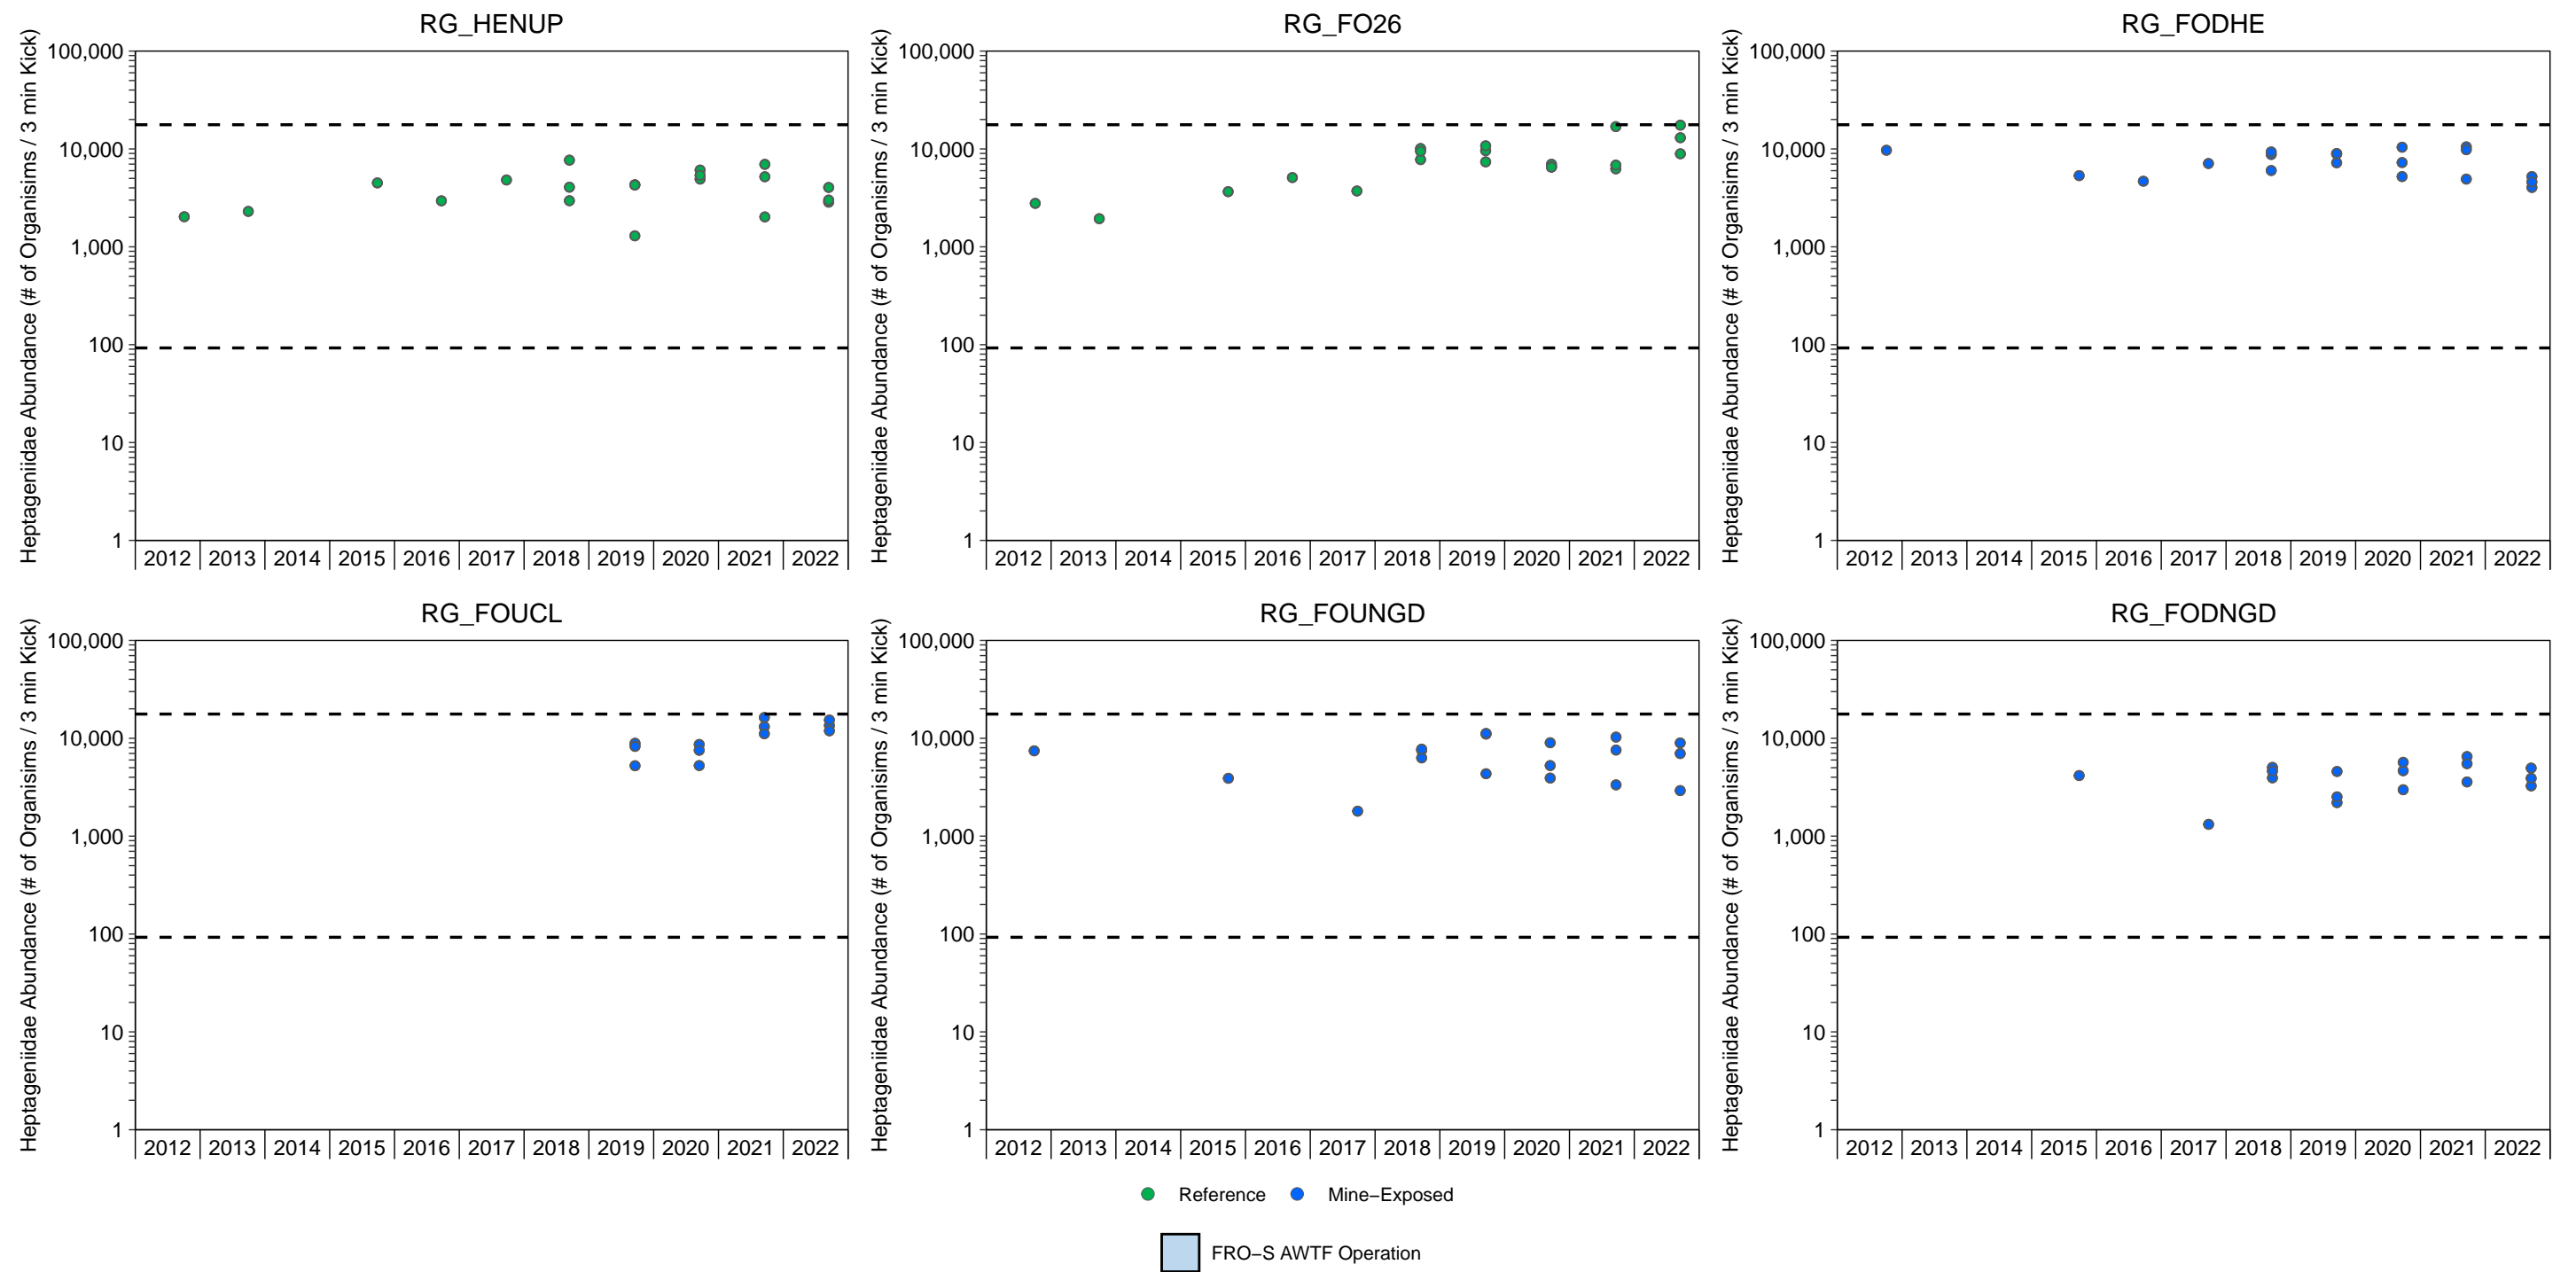

Figure G.24: Benthic Invertebrate Heptageniidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

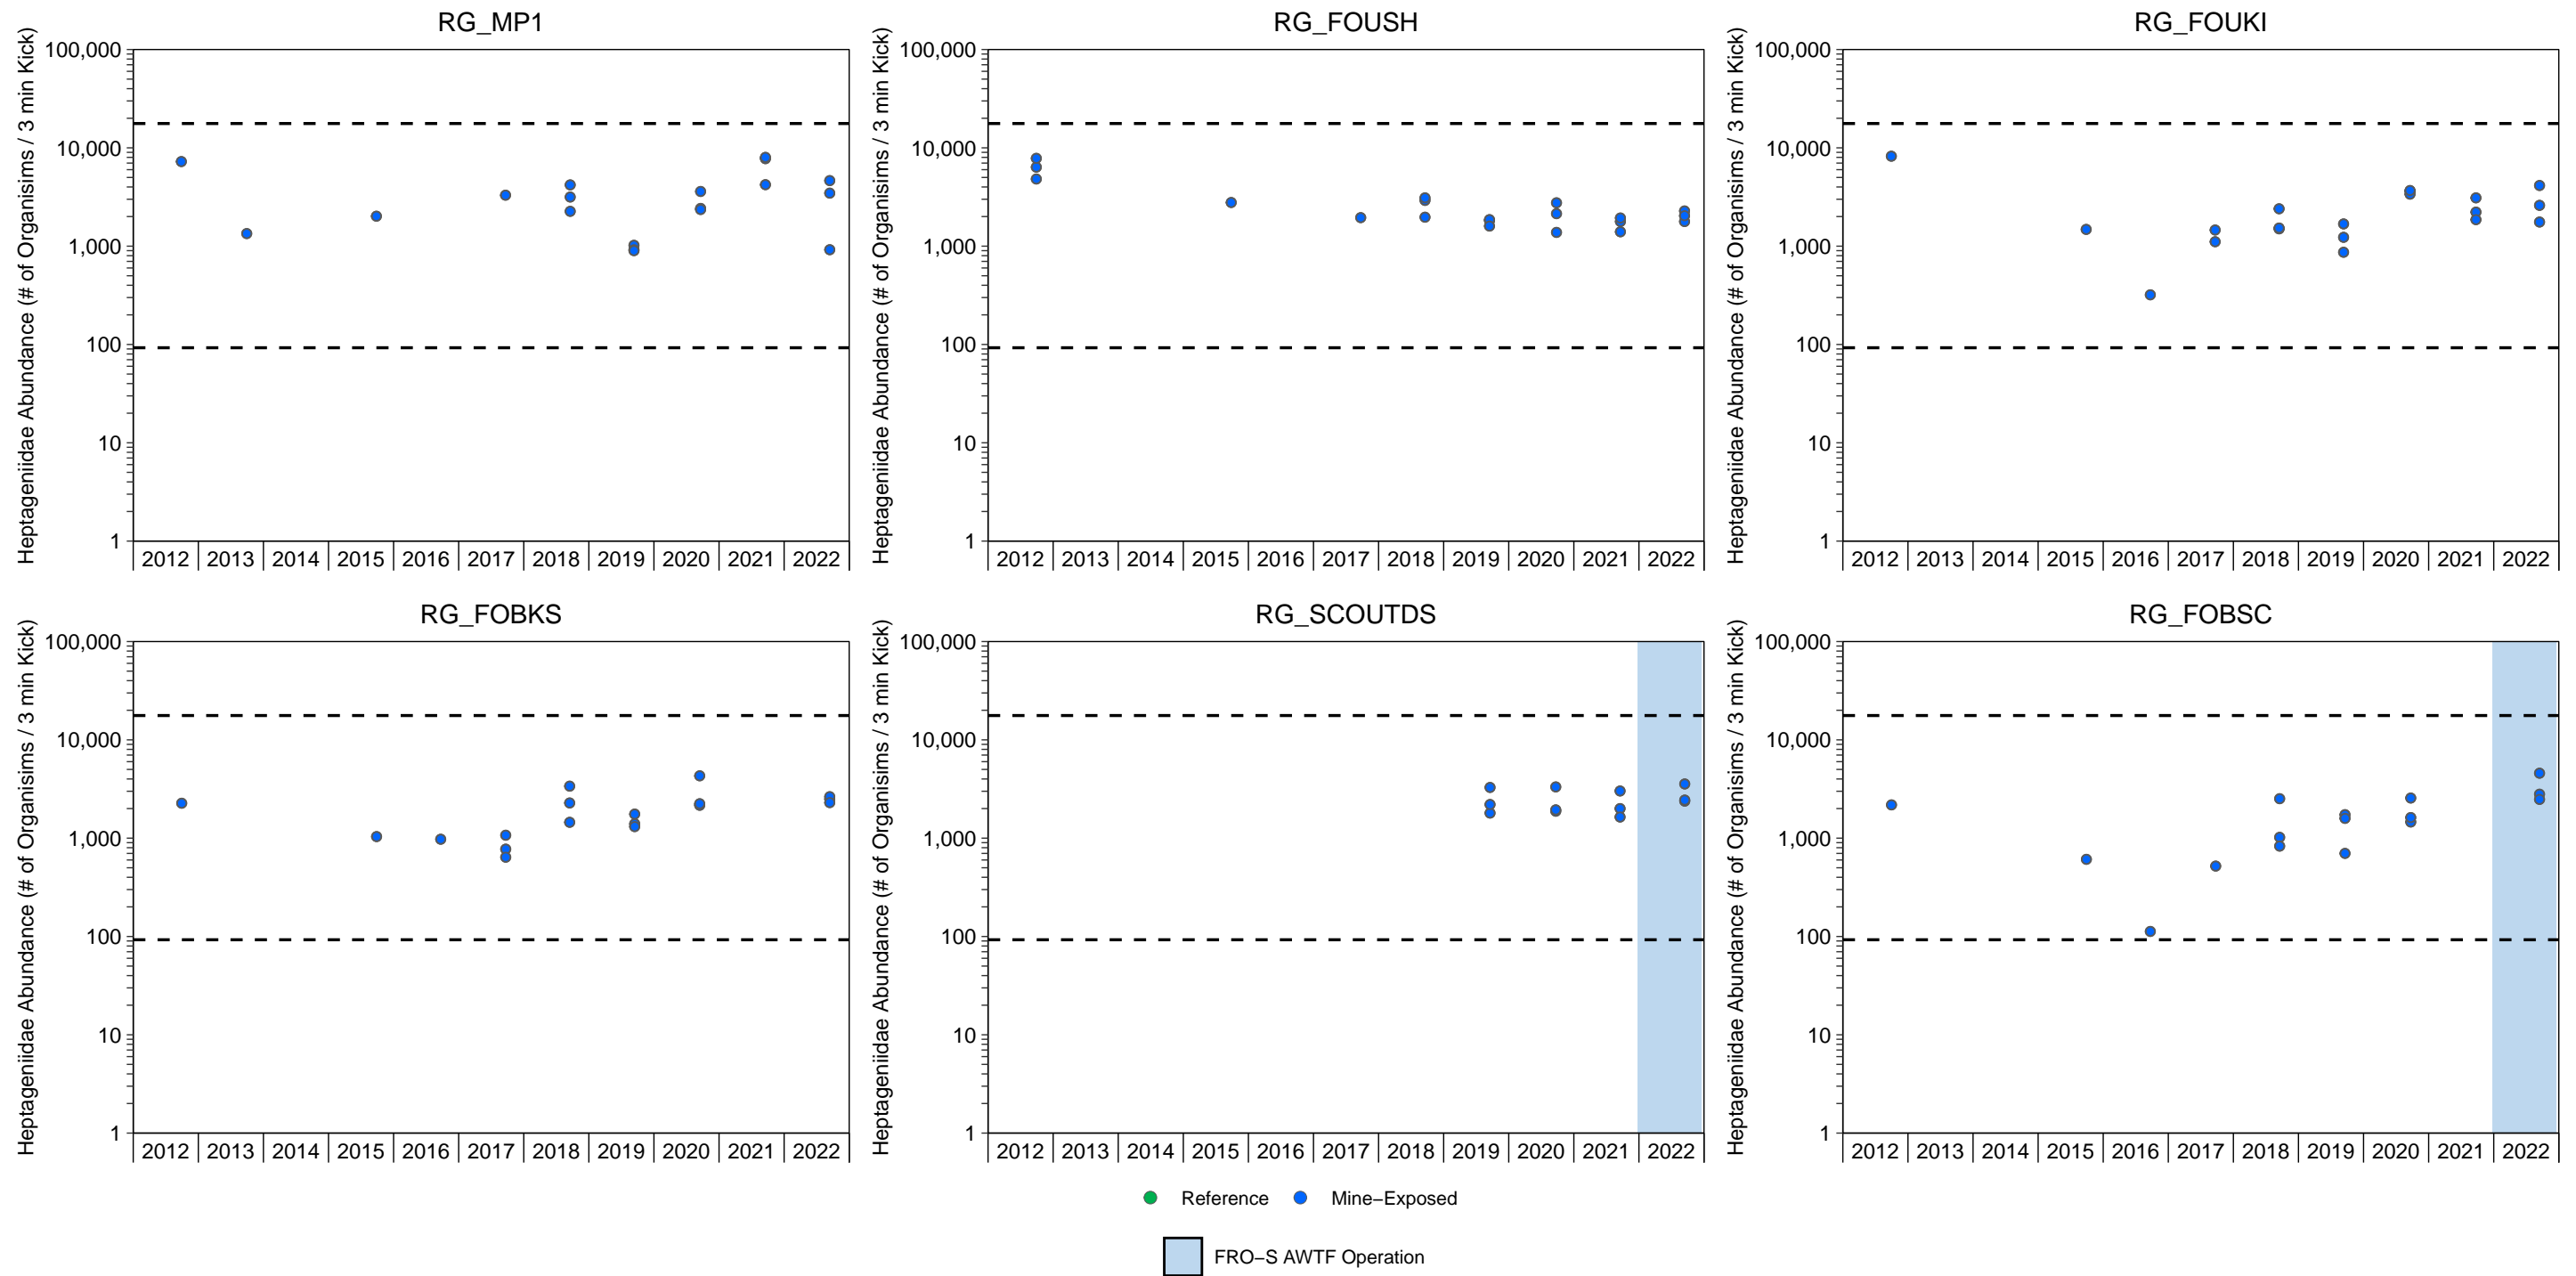

Figure G.24: Benthic Invertebrate Heptageniidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

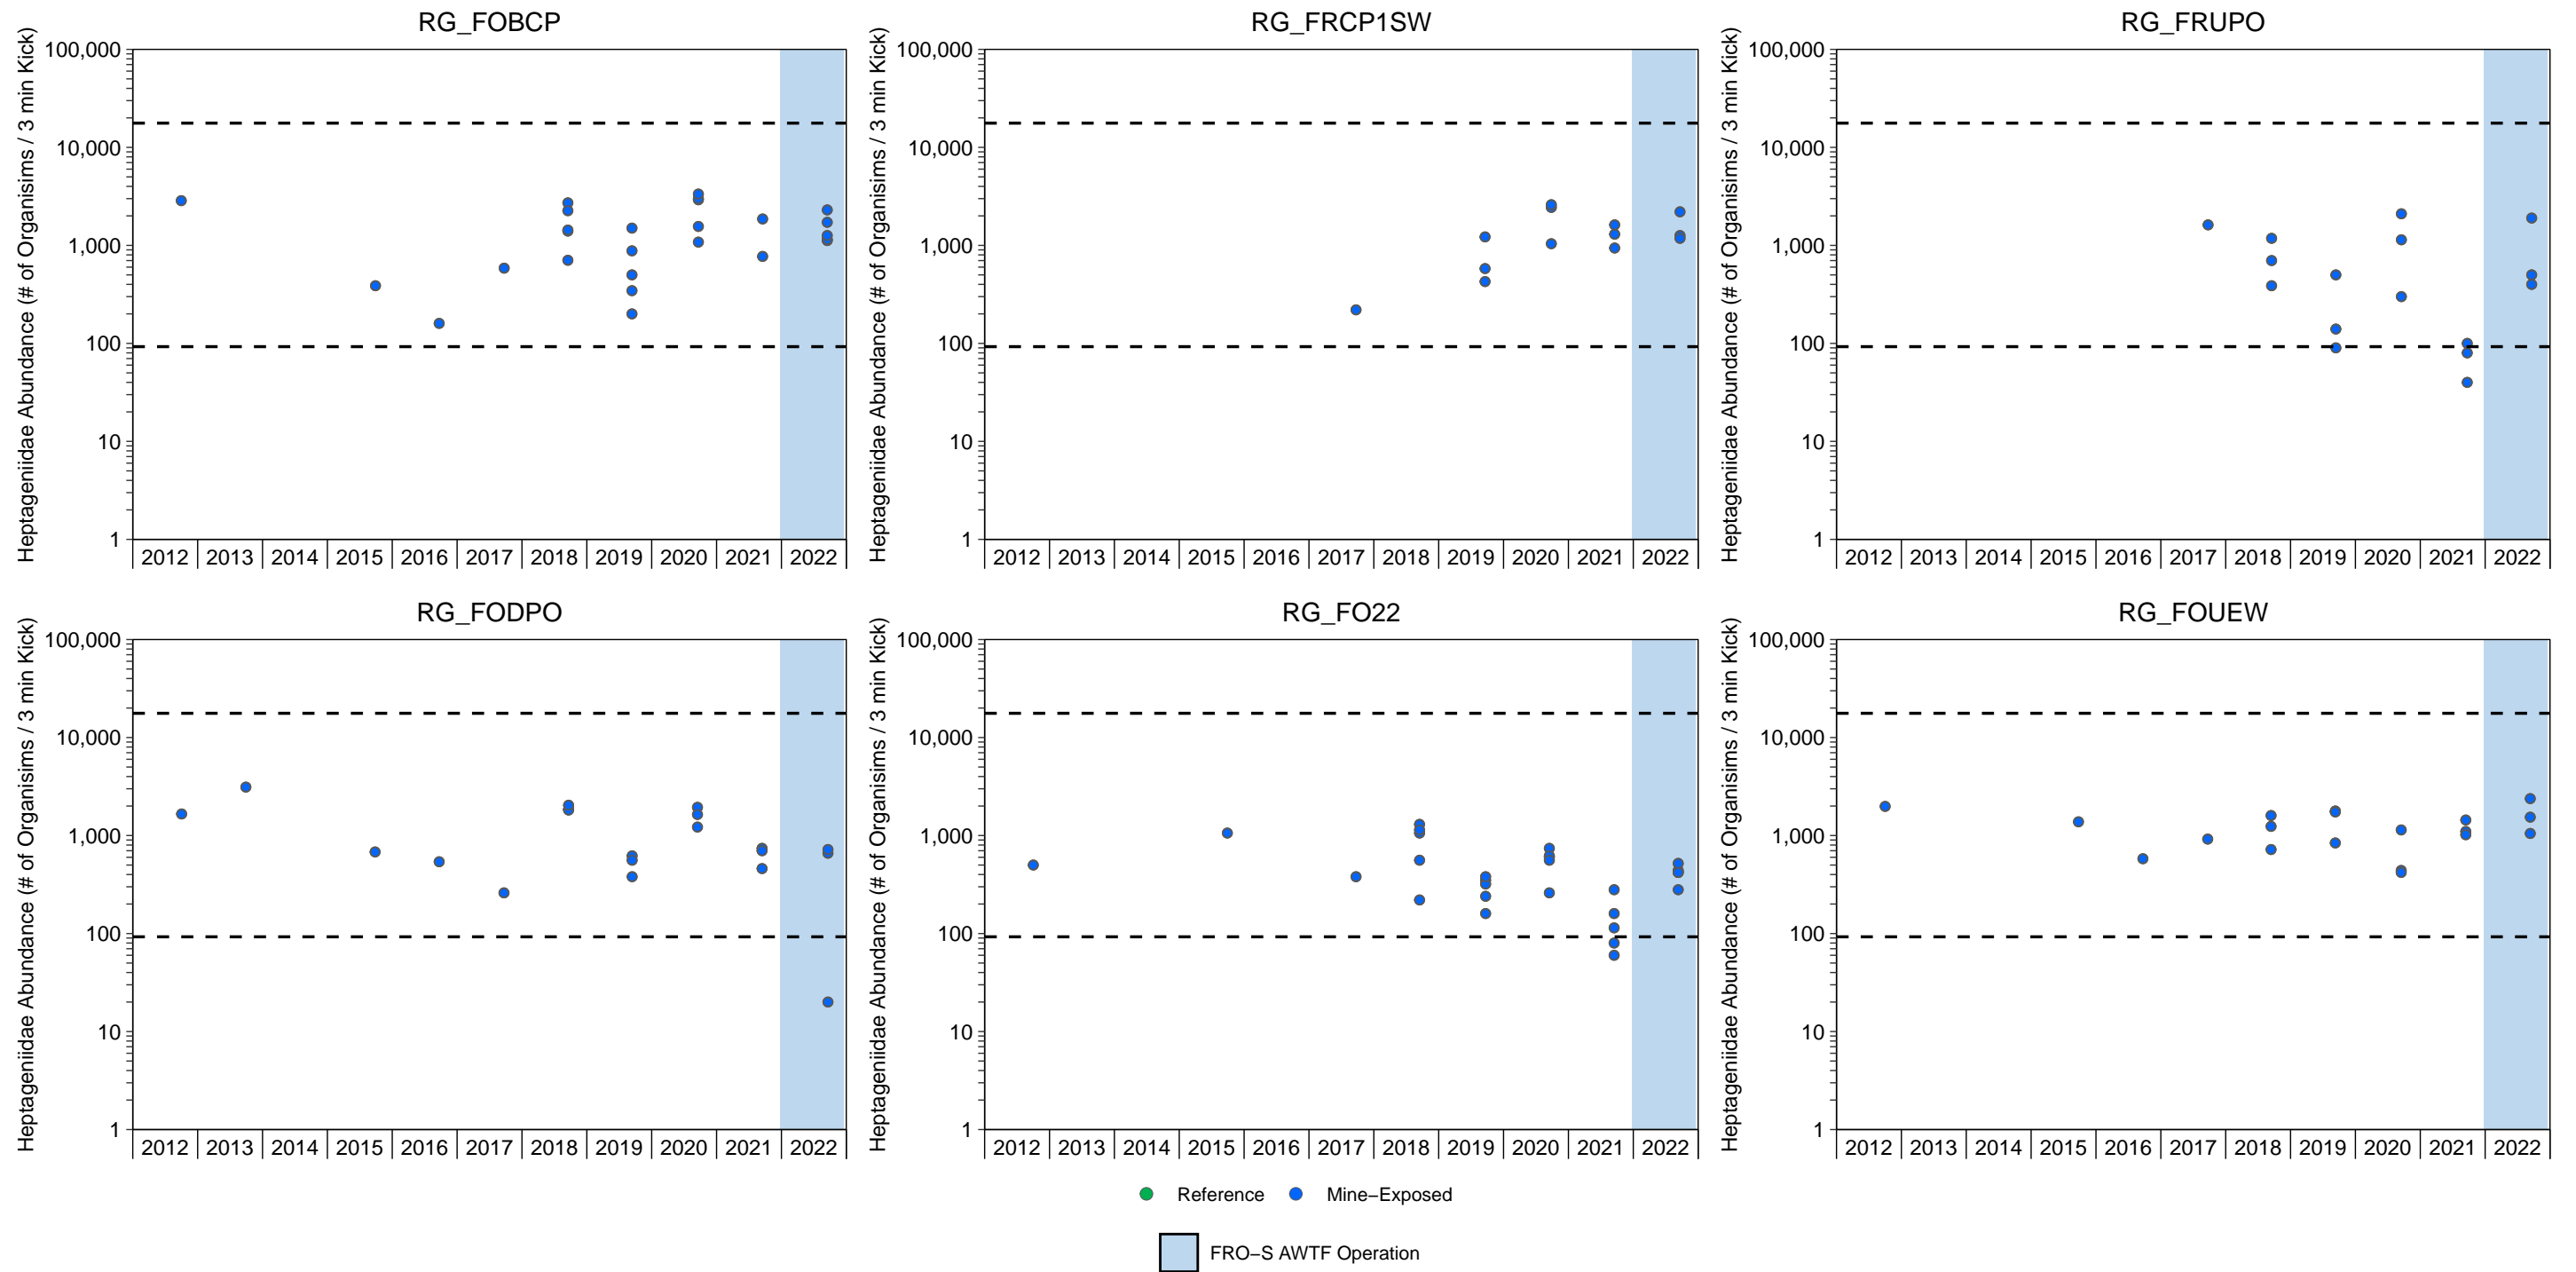

Figure G.24: Benthic Invertebrate Heptageniidae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

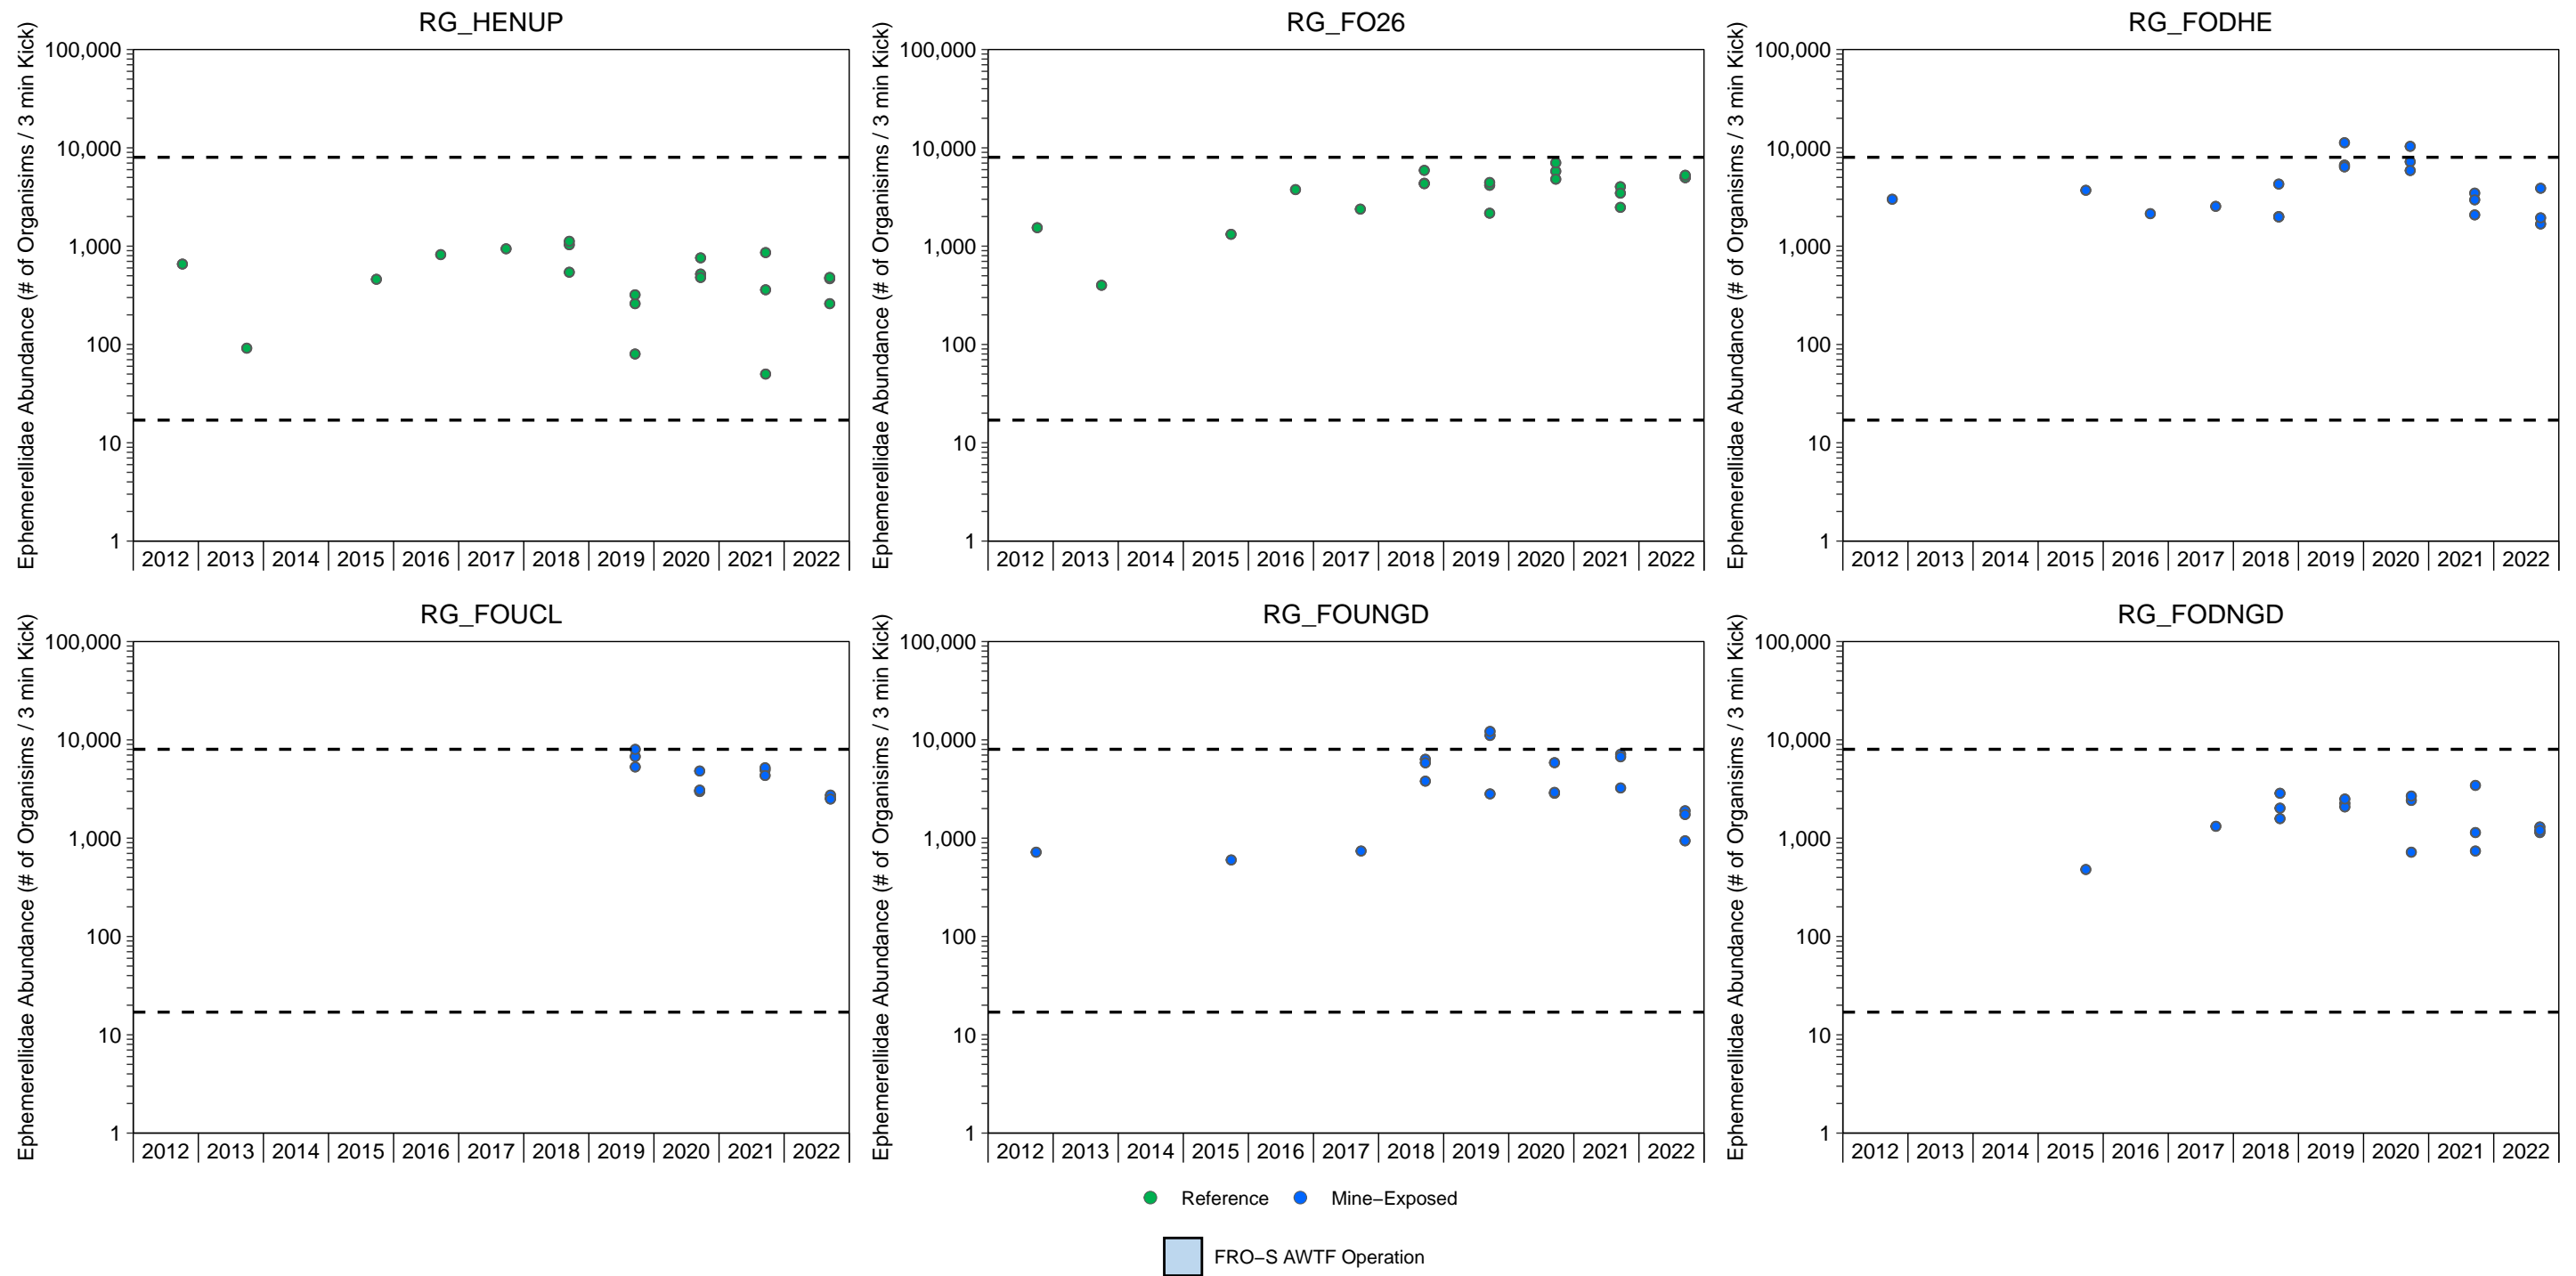

Figure G.25: Benthic Invertebrate Ephemereleidiae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.25: Benthic Invertebrate Ephemereleididae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

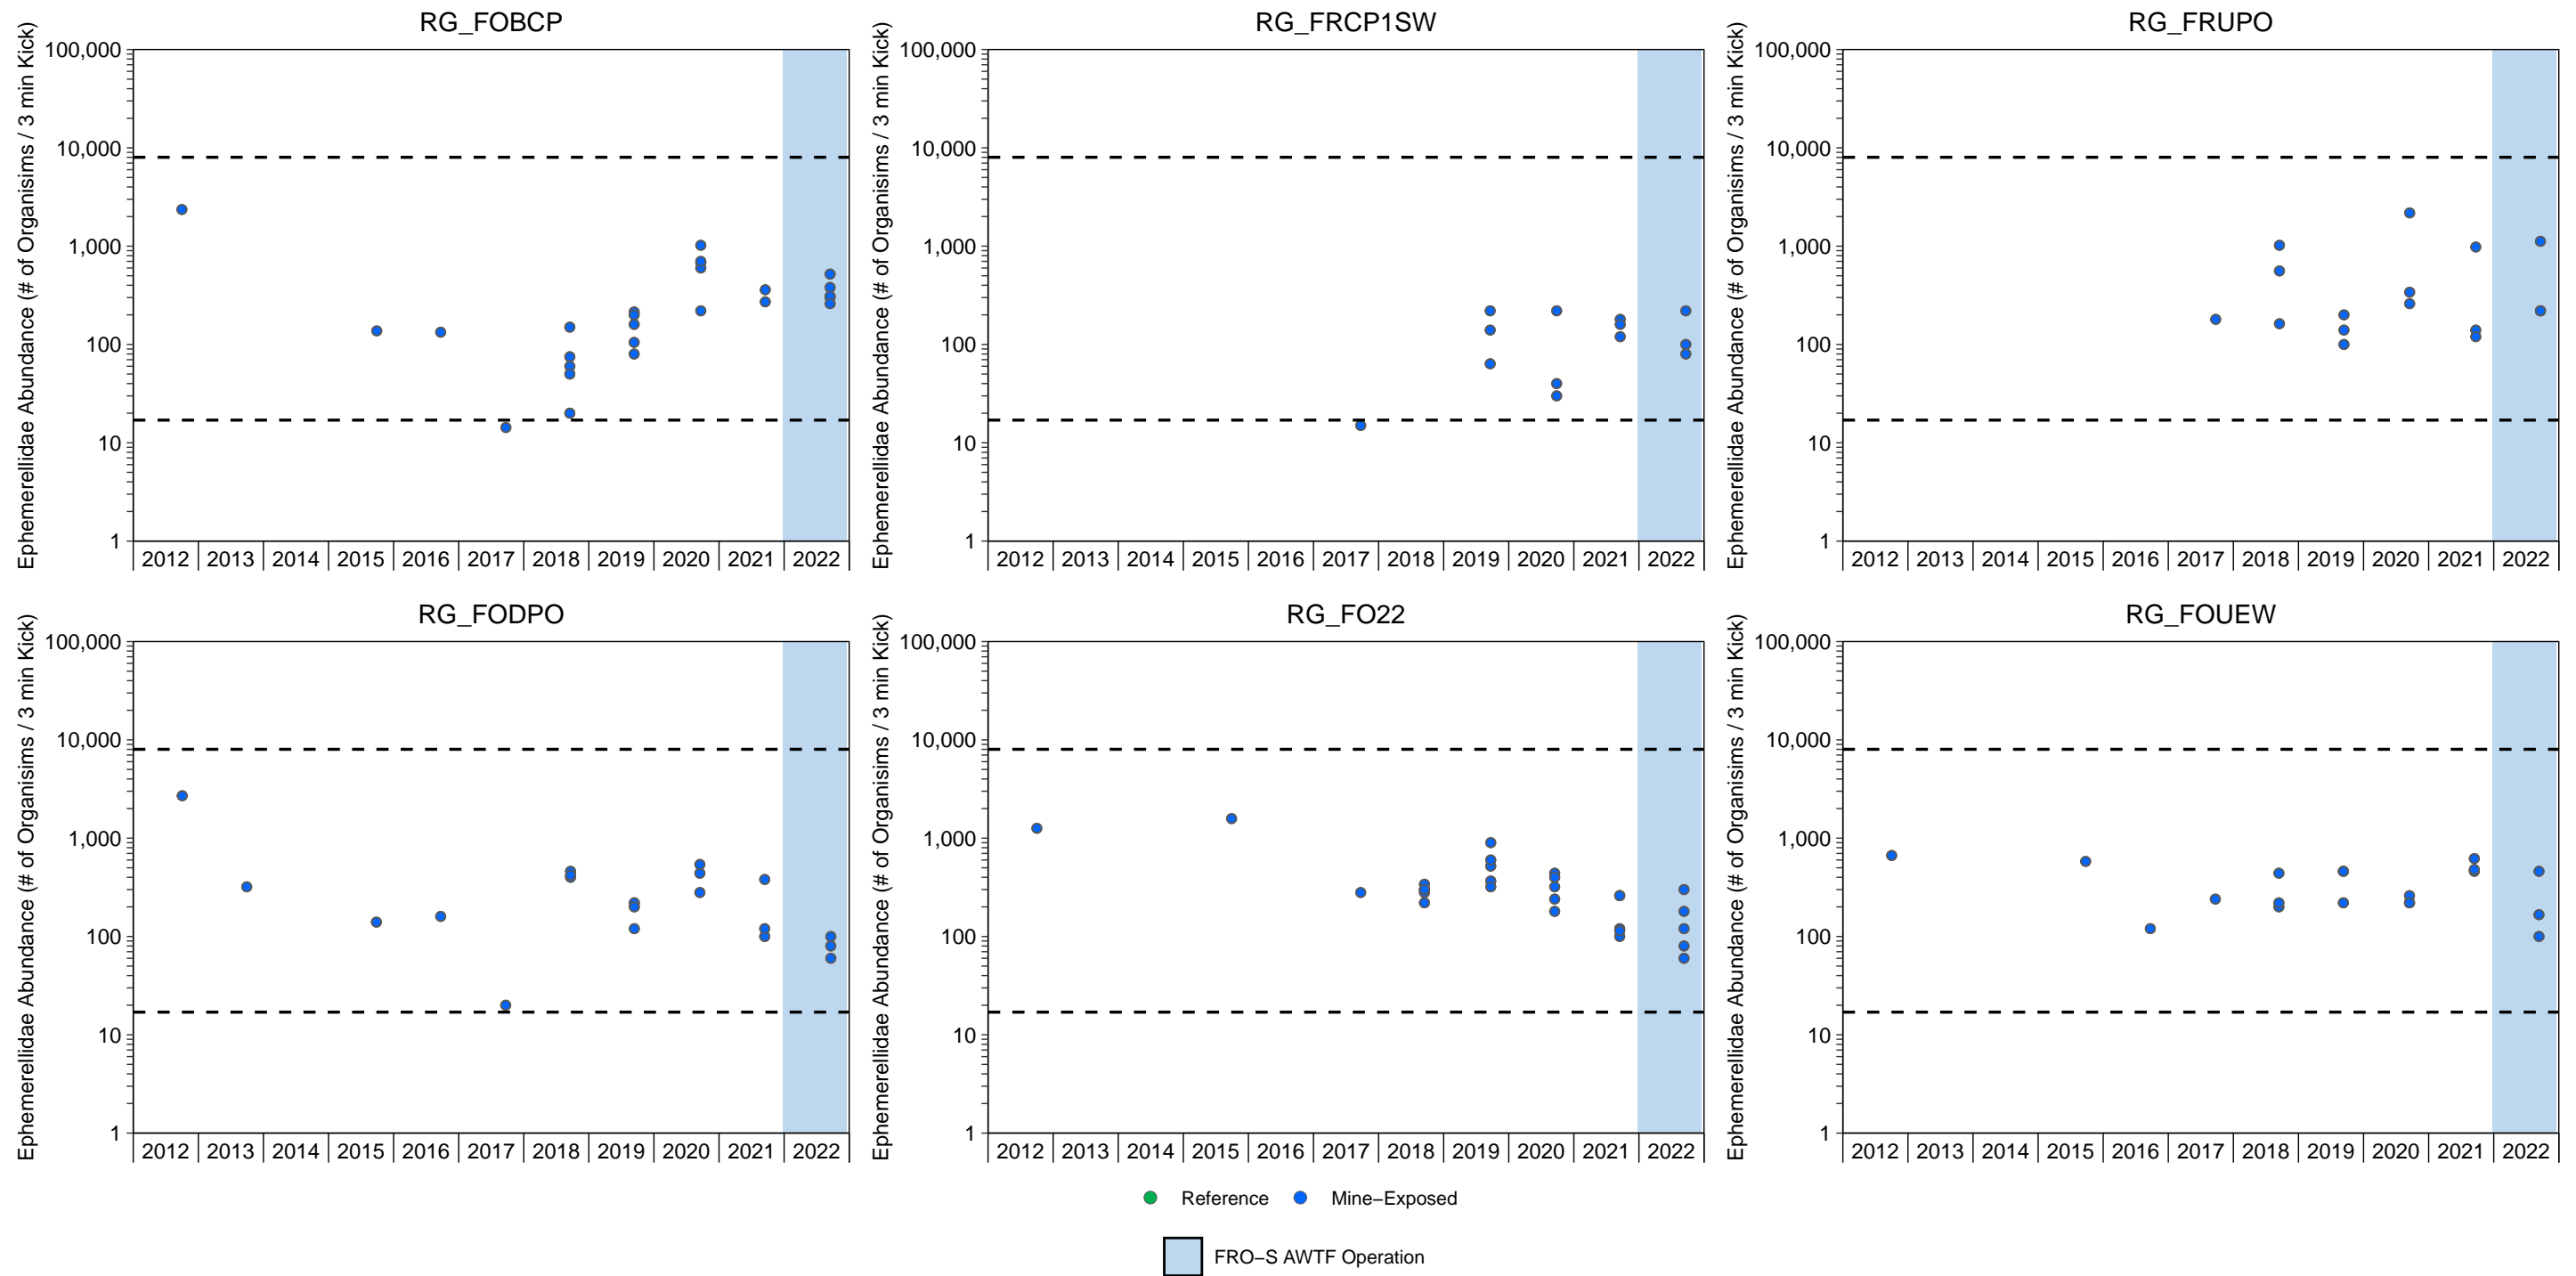

Figure G.25: Benthic Invertebrate Ephemereleididae Abundance in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.26: Benthic Invertebrate Autotrophic Heterotrophic Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.26: Benthic Invertebrate Autotrophic Heterotrophic Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.26: Benthic Invertebrate Autotrophic Heterotrophic Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

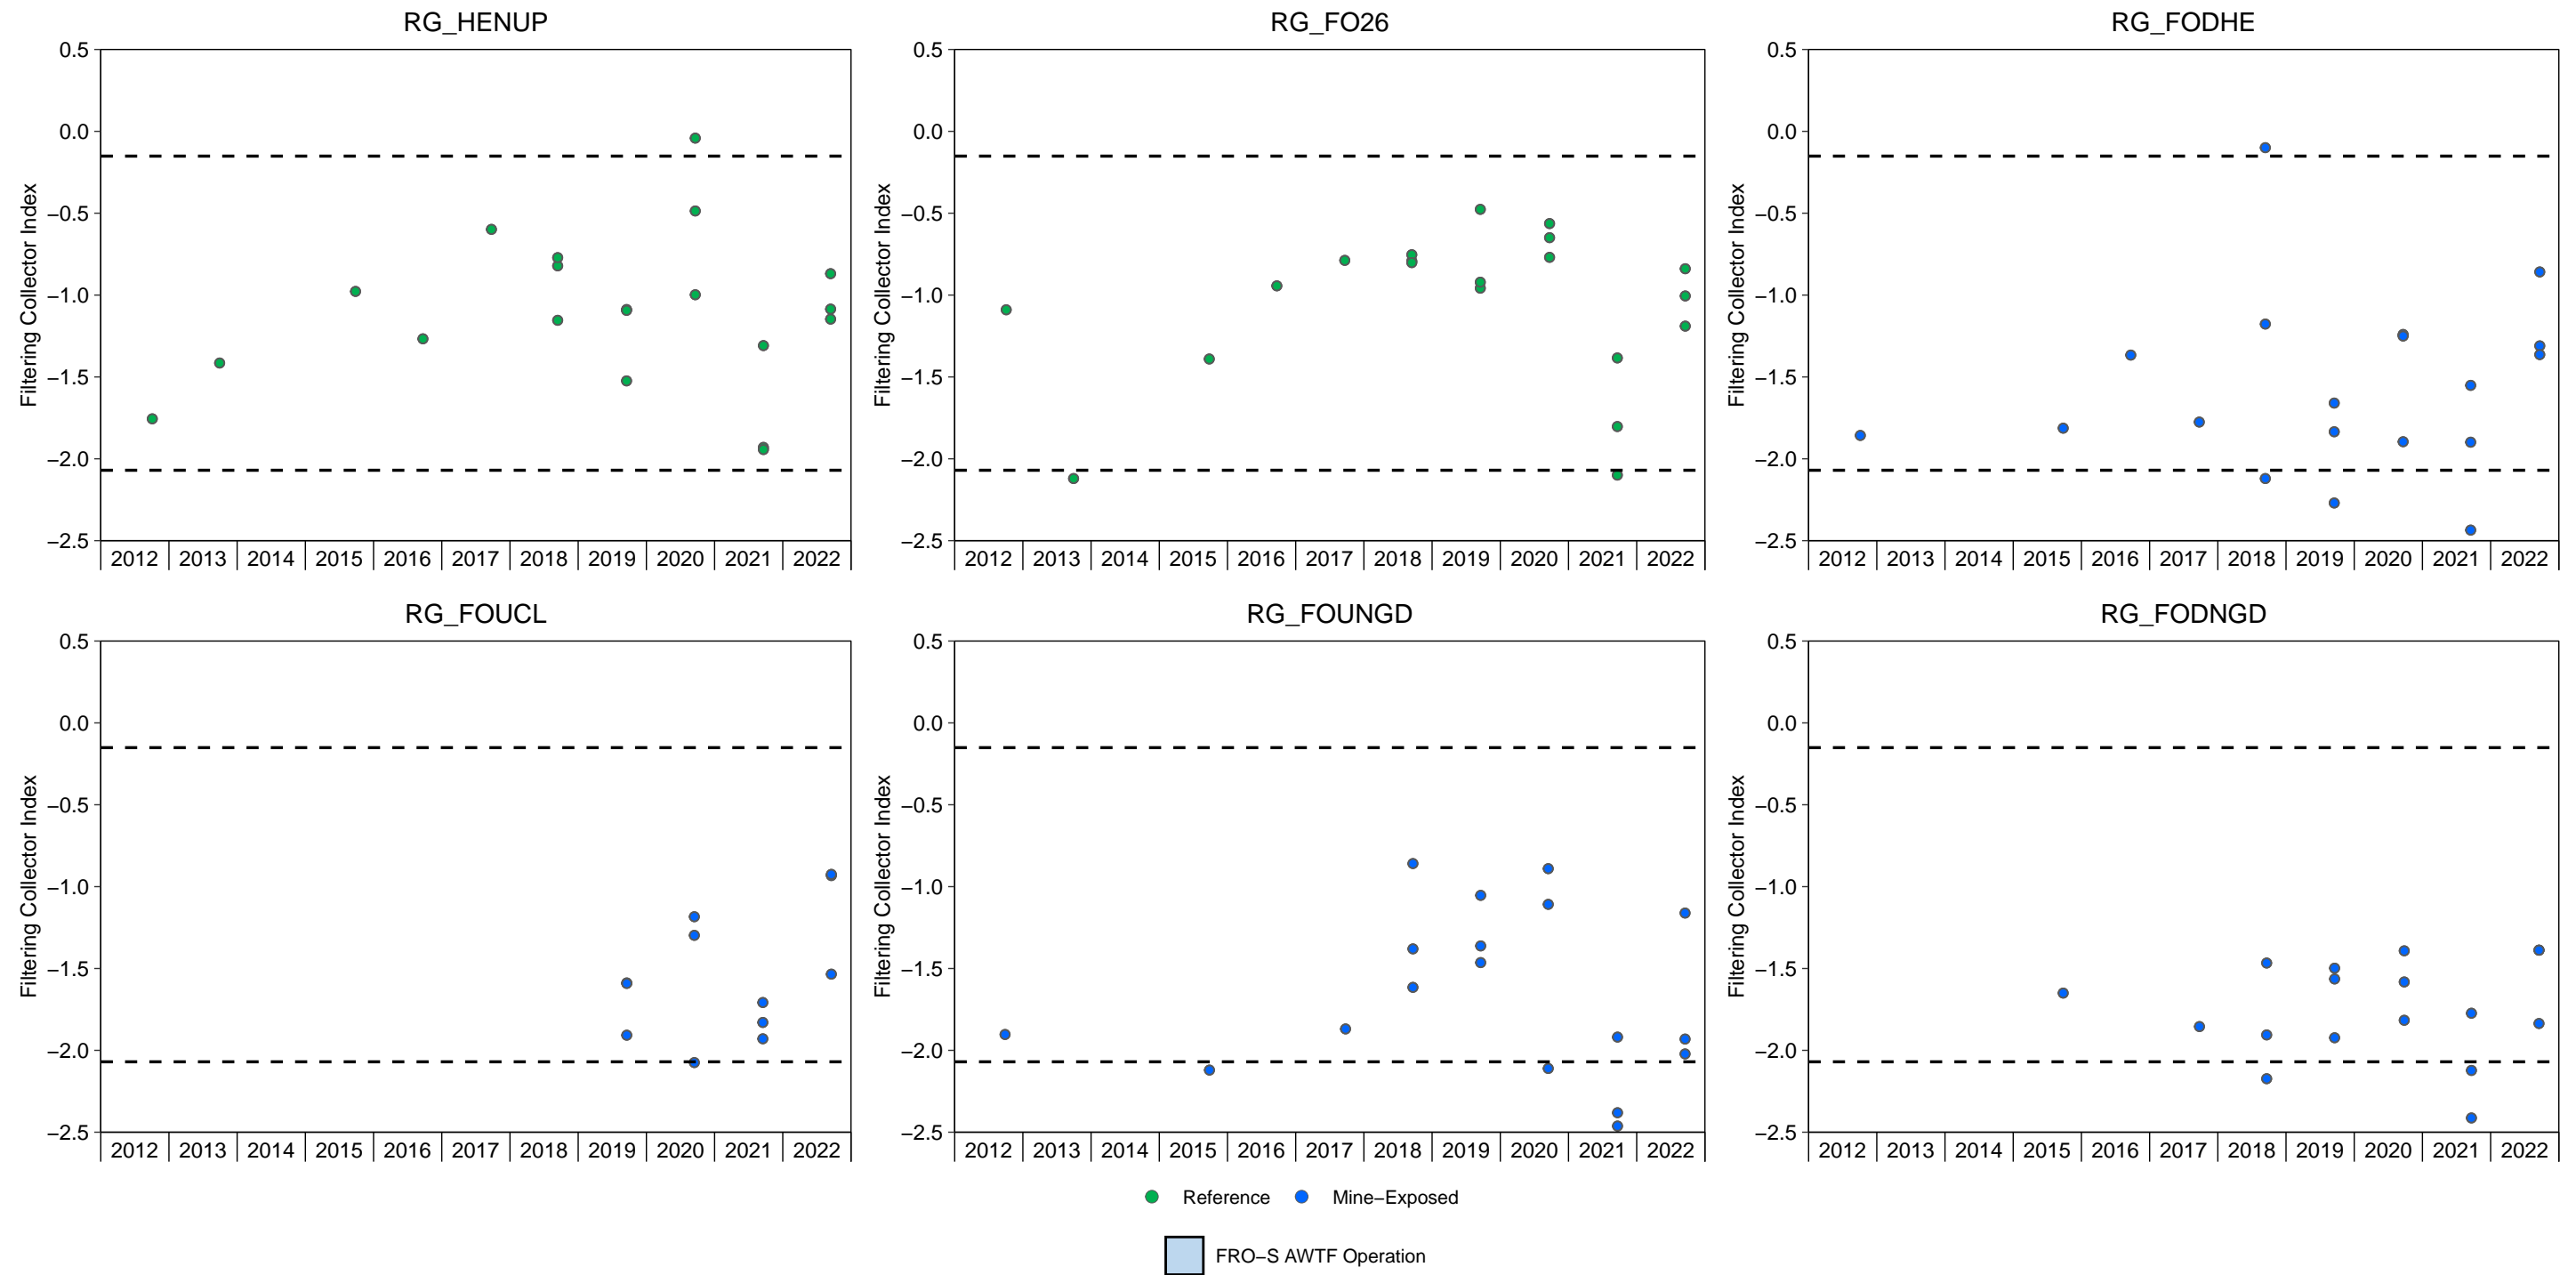

Figure G.27: Benthic Invertebrate Filtering Collector Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

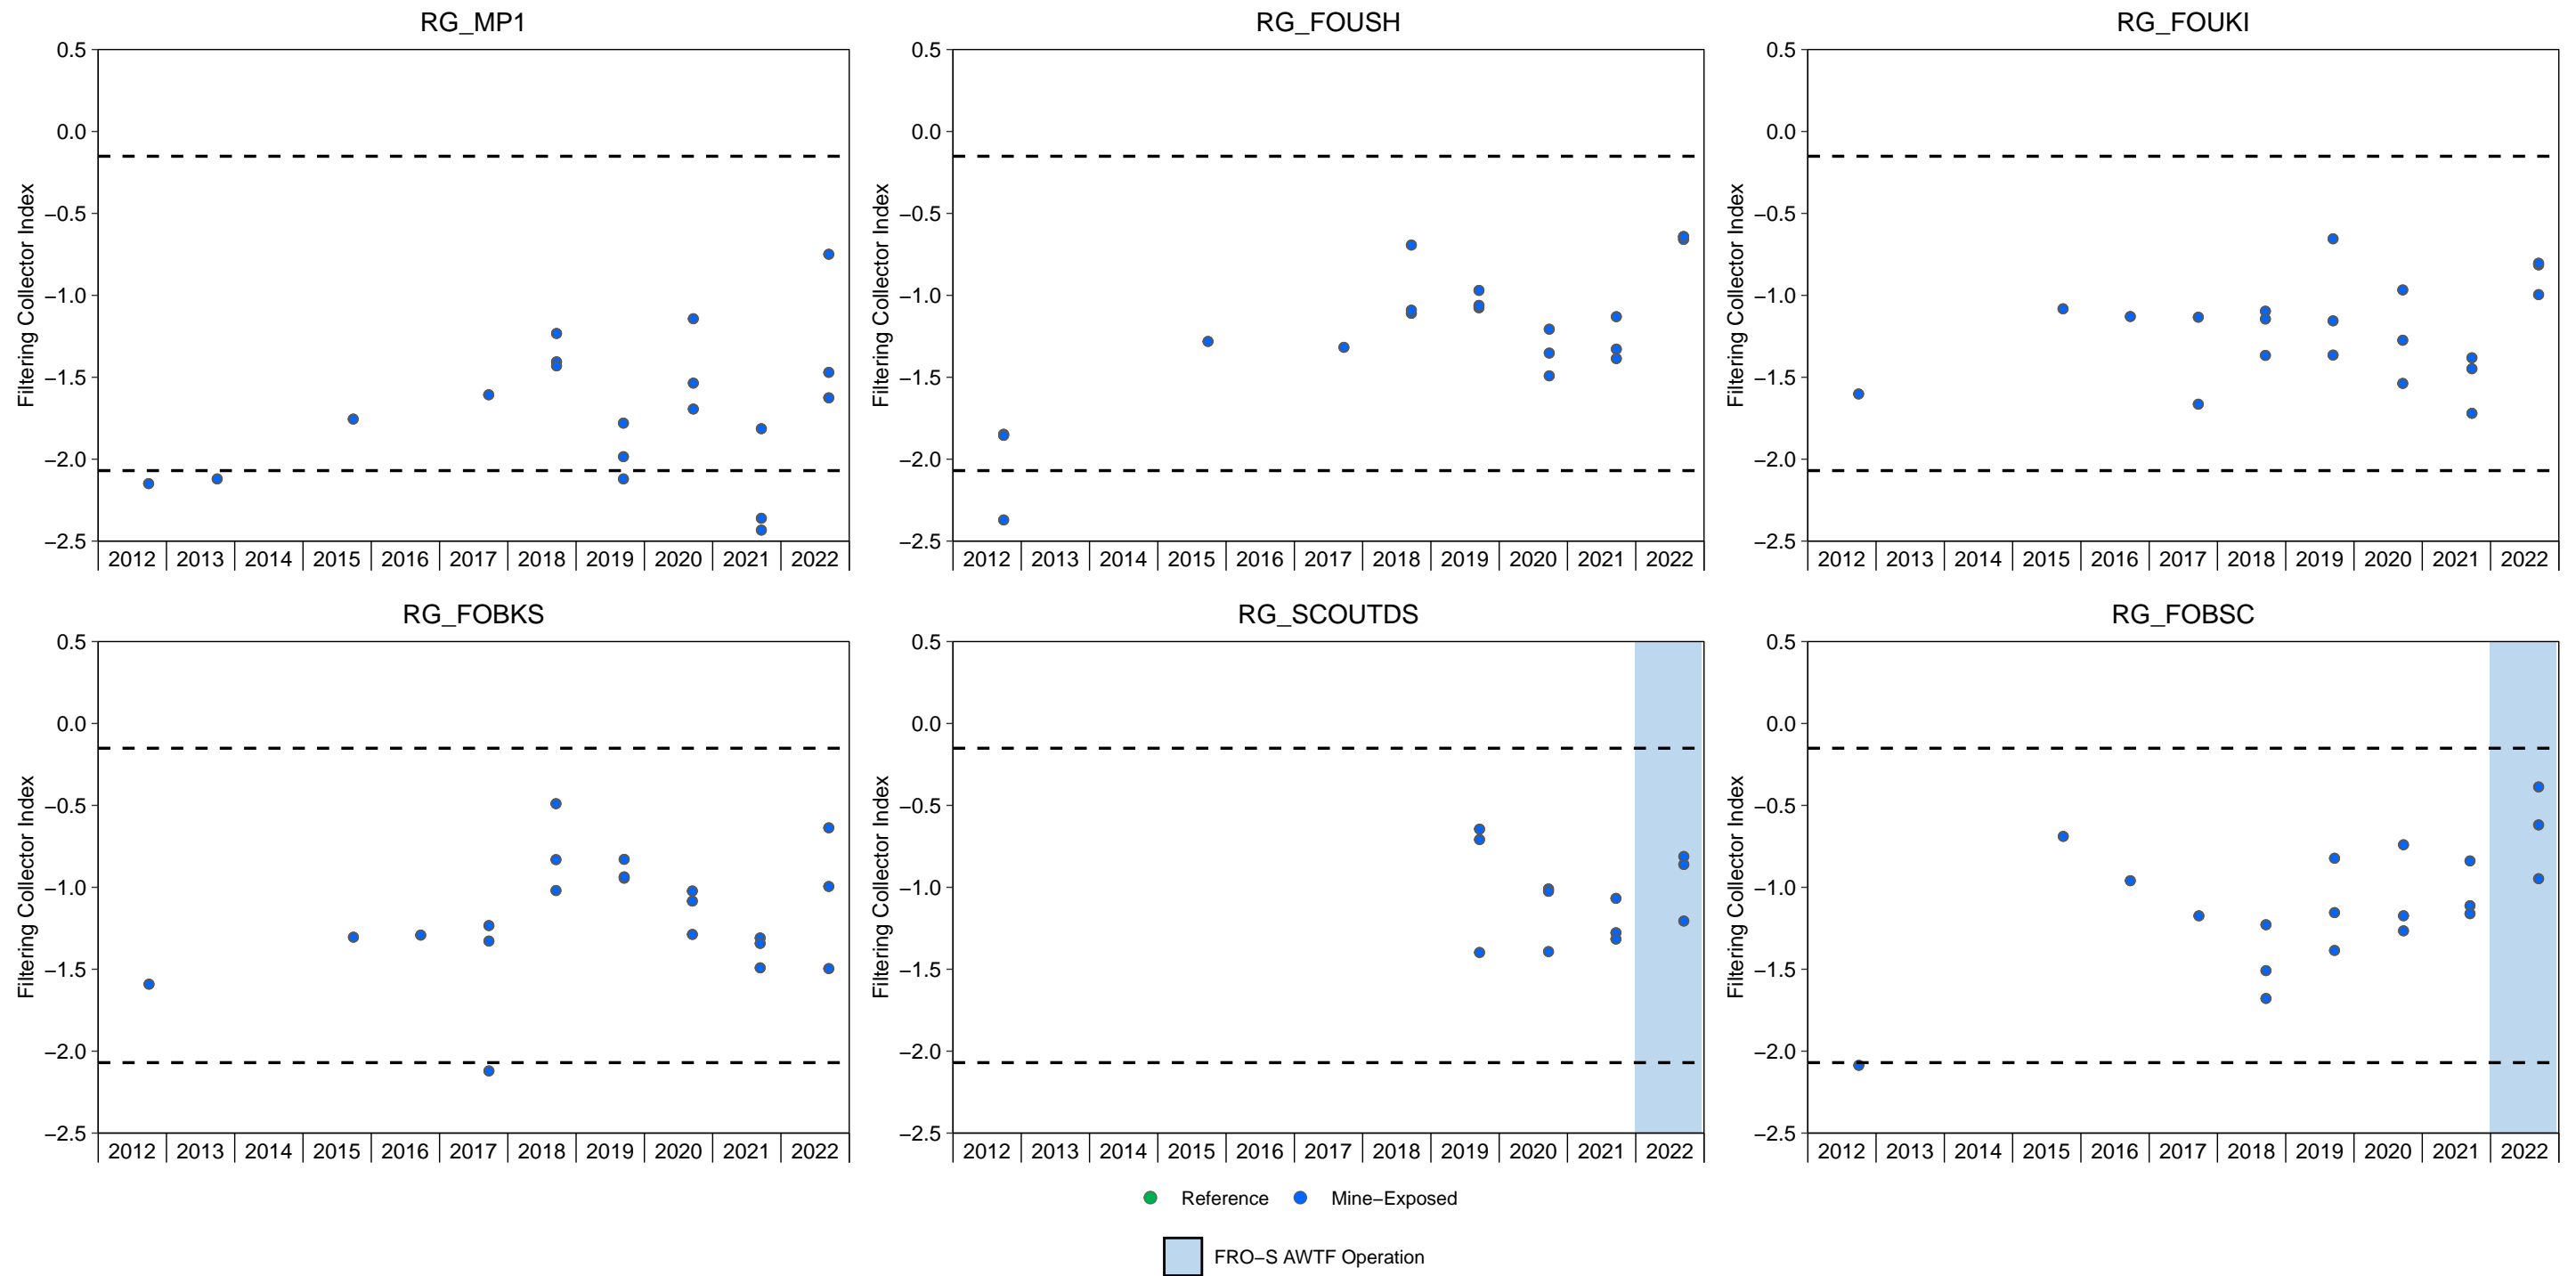

Figure G.27: Benthic Invertebrate Filtering Collector Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.27: Benthic Invertebrate Filtering Collector Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

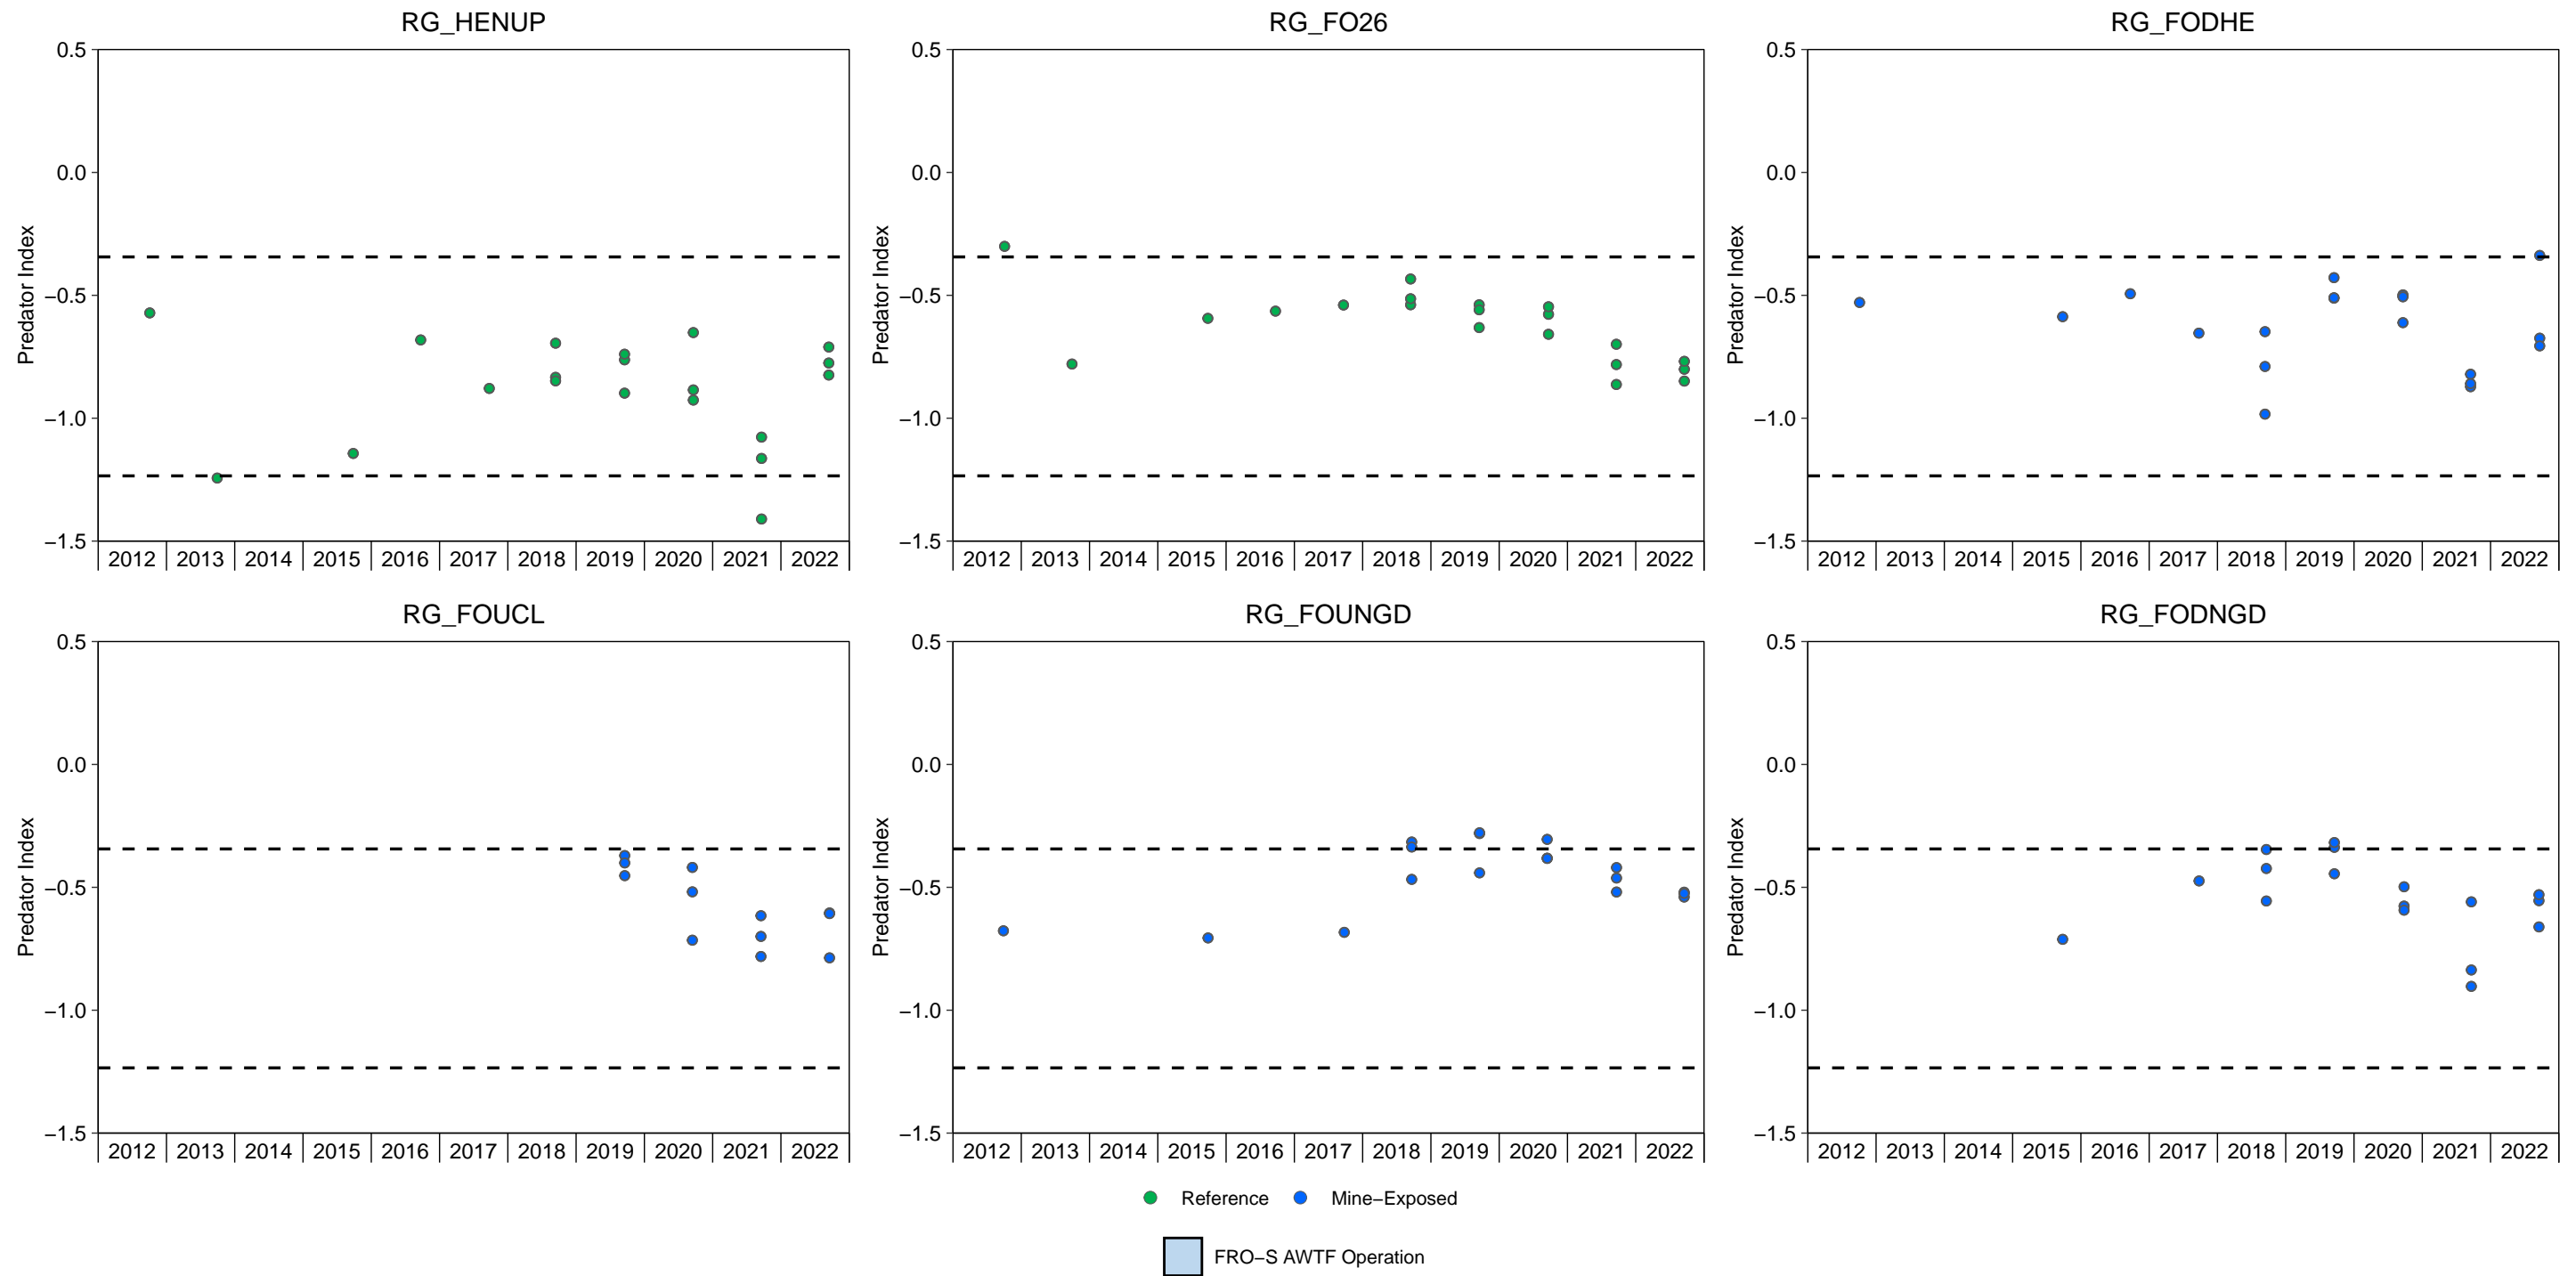

Figure G.28: Benthic Invertebrate Predator Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

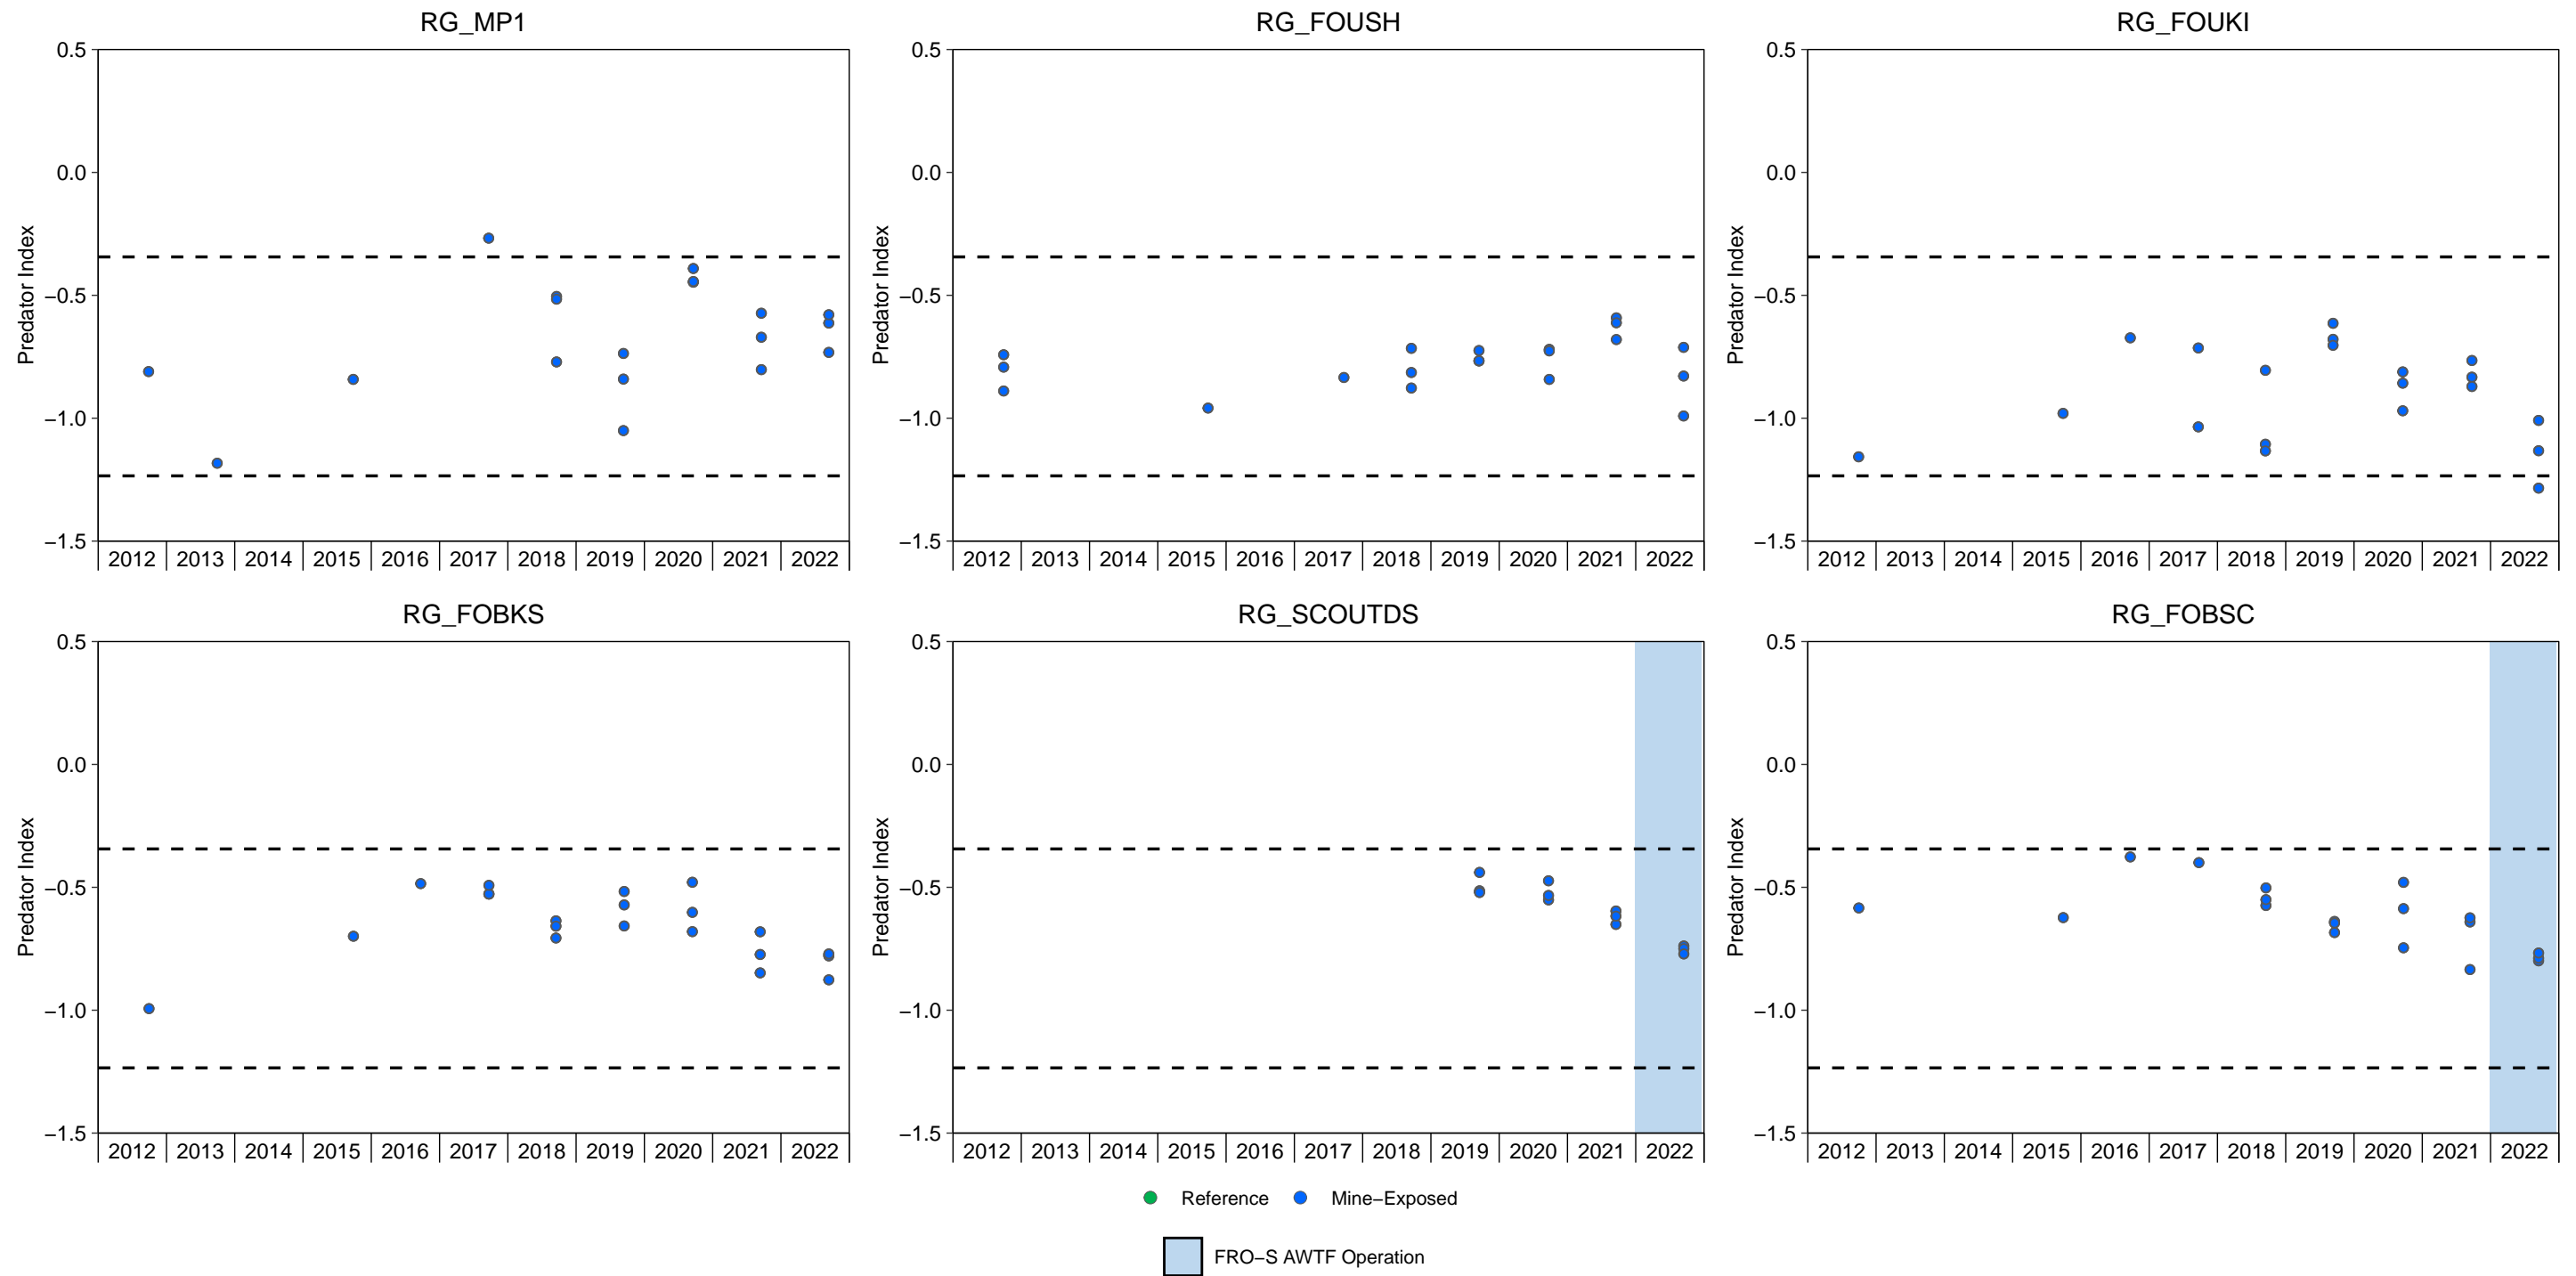

Figure G.28: Benthic Invertebrate Predator Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

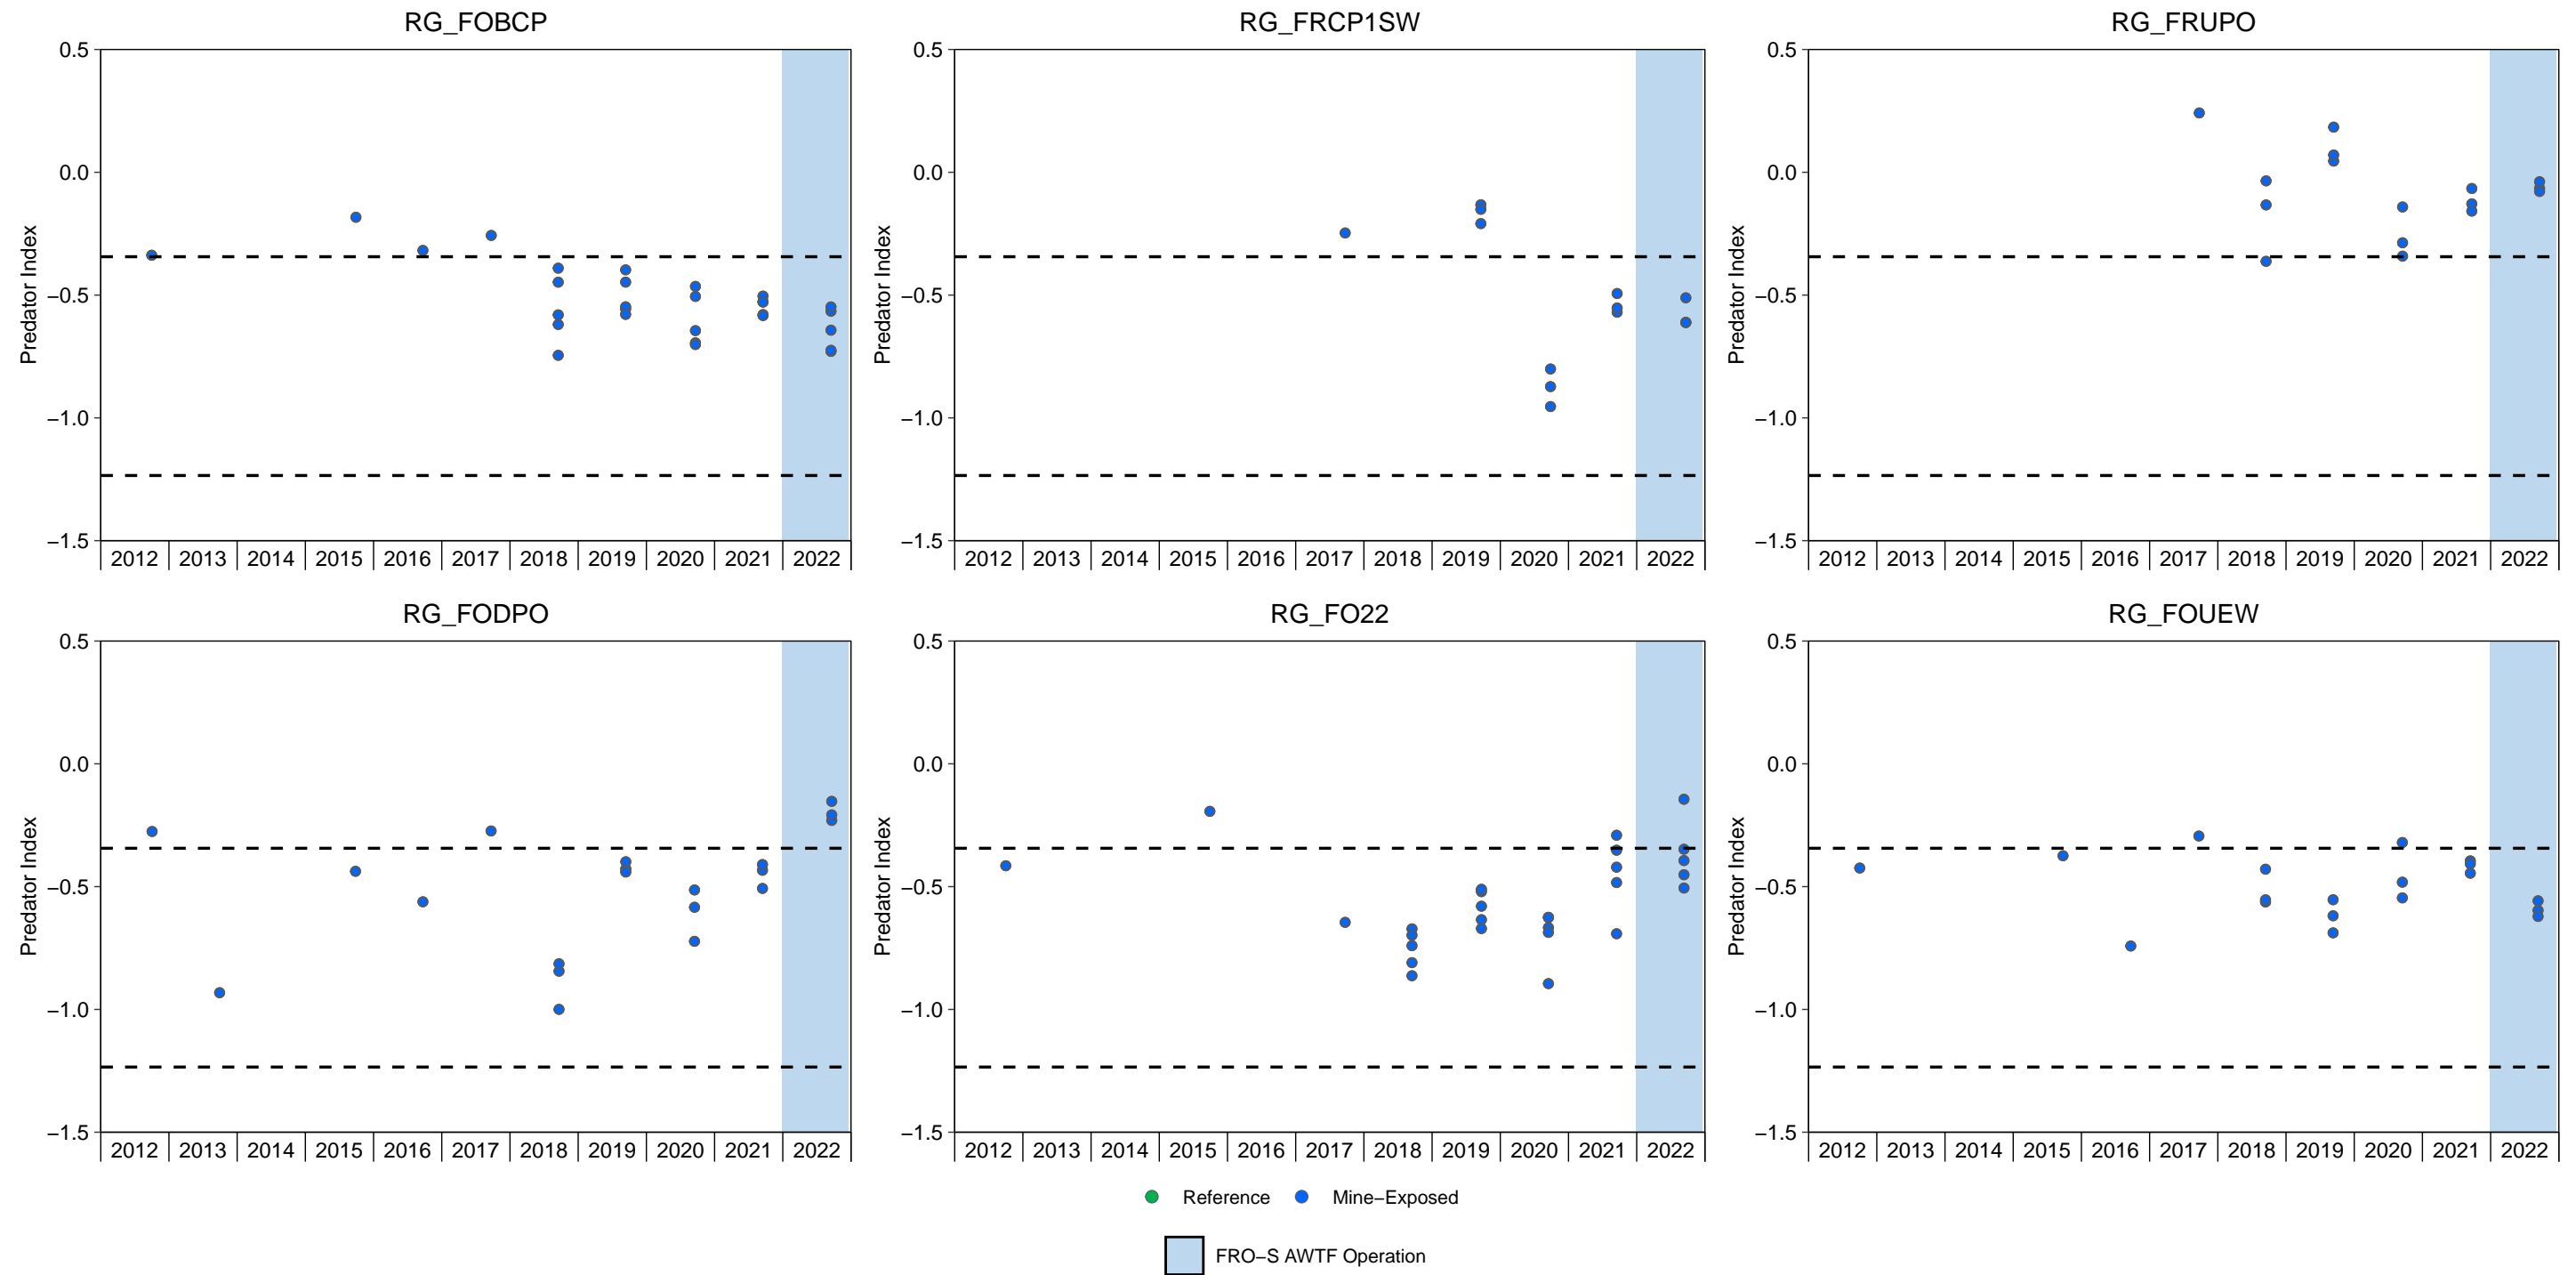

Figure G.28: Benthic Invertebrate Predator Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

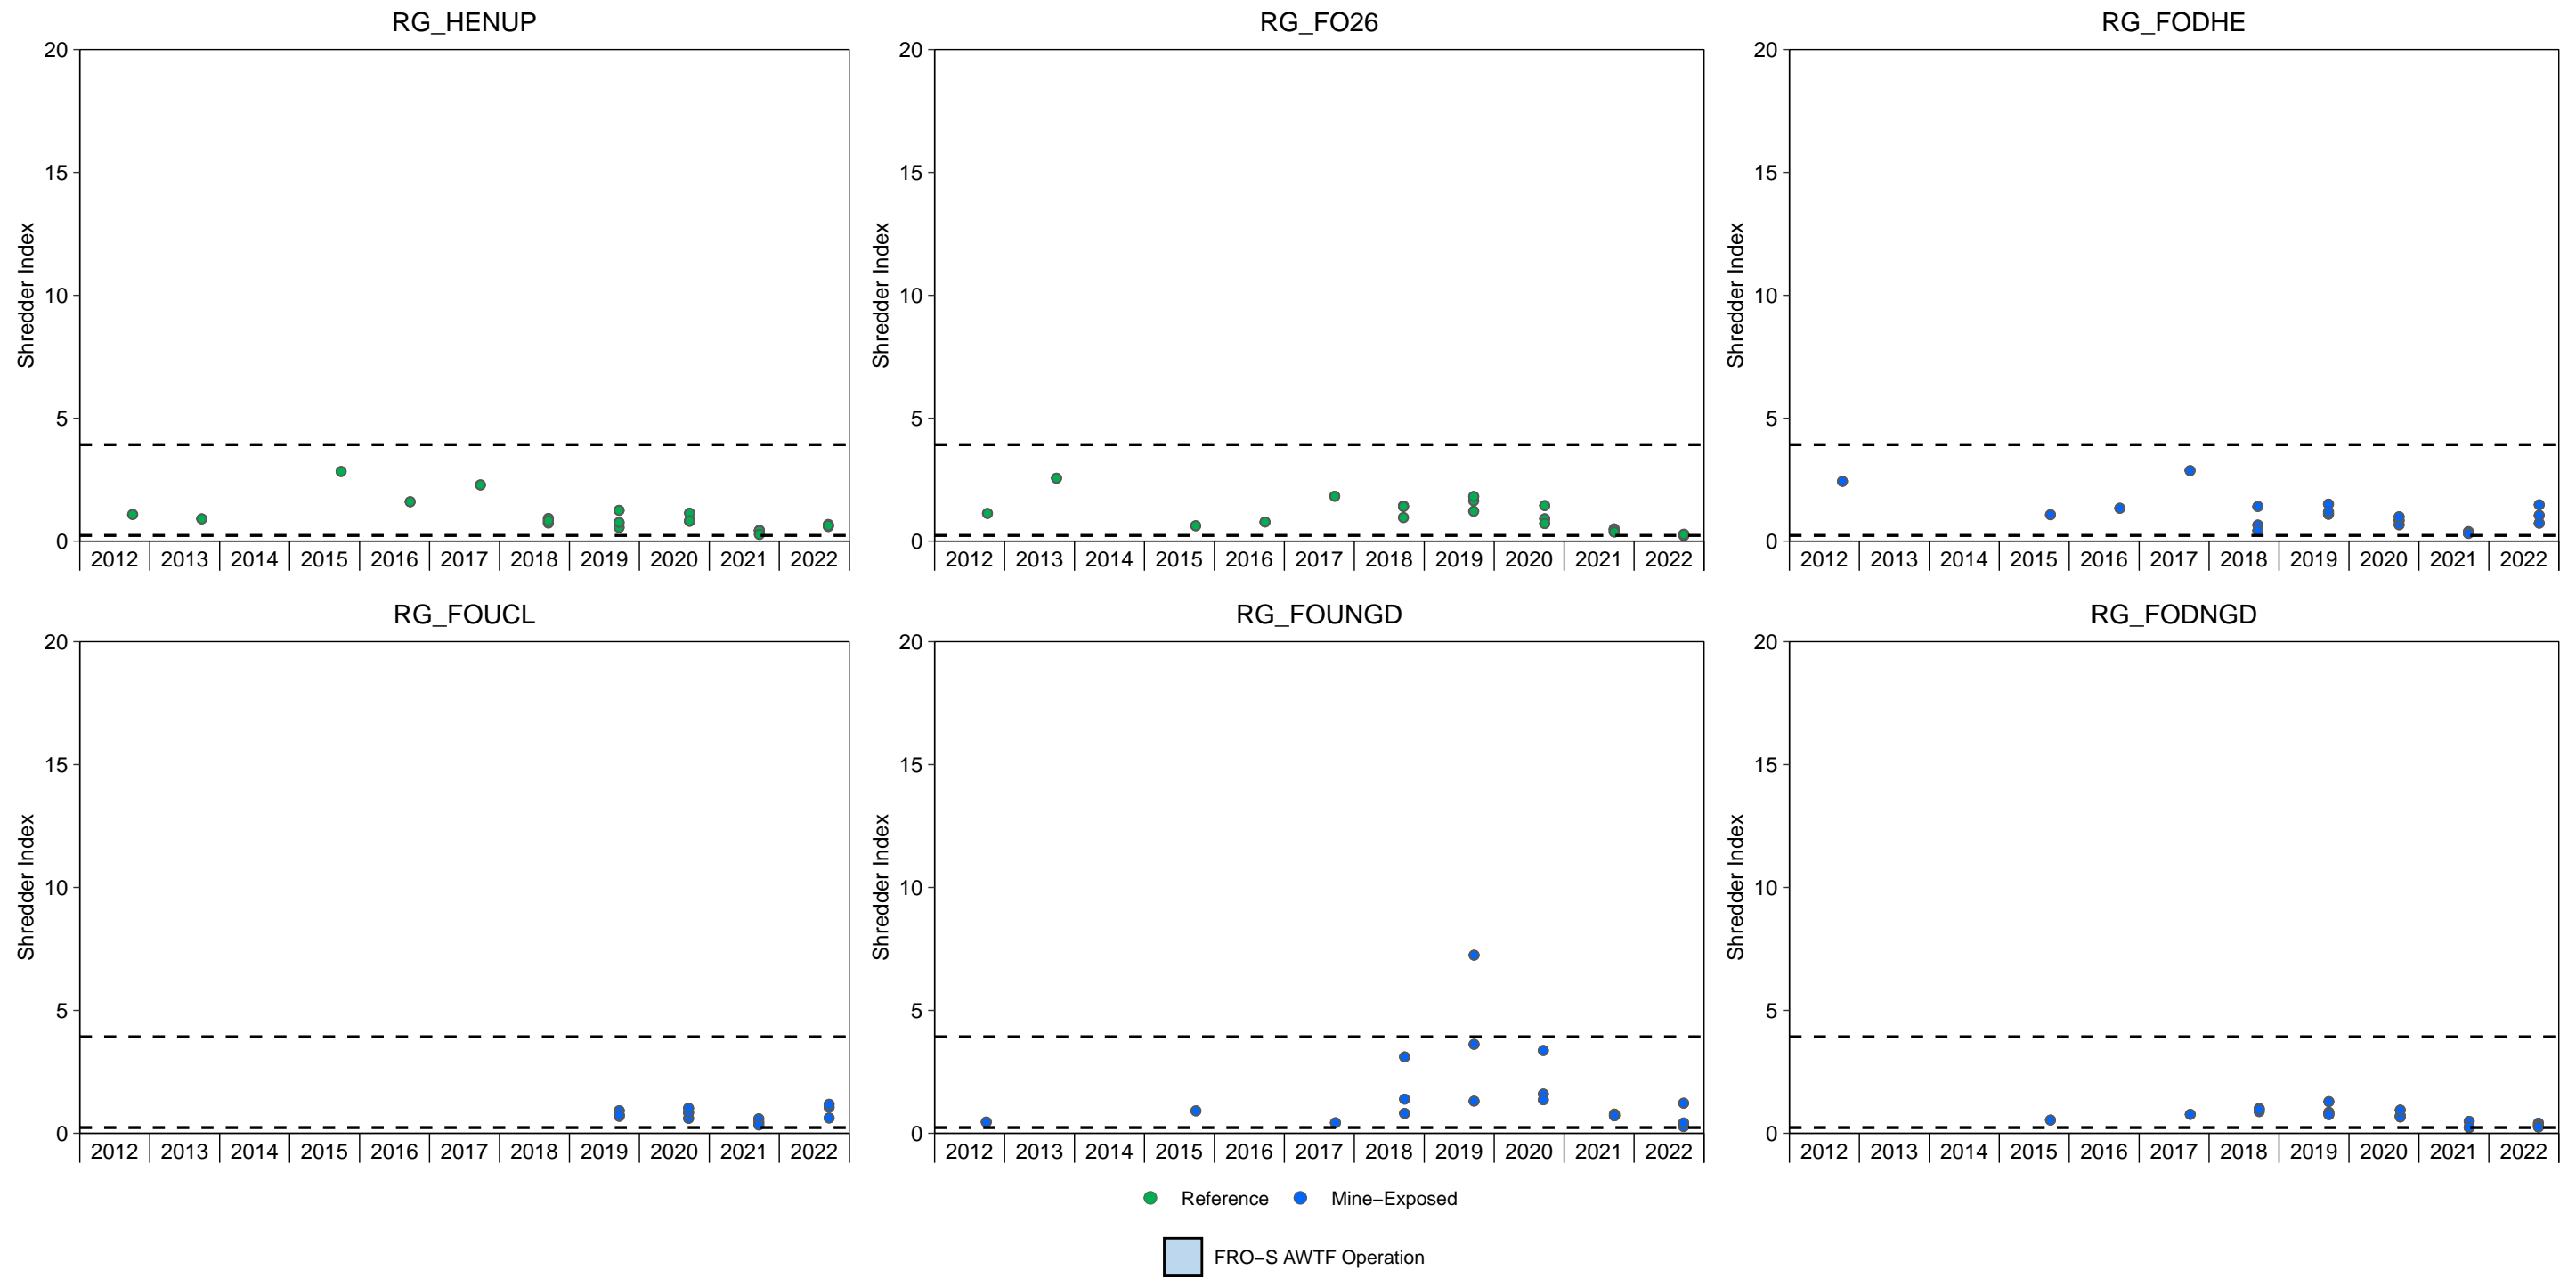

Figure G.29: Benthic Invertebrate Shredder Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

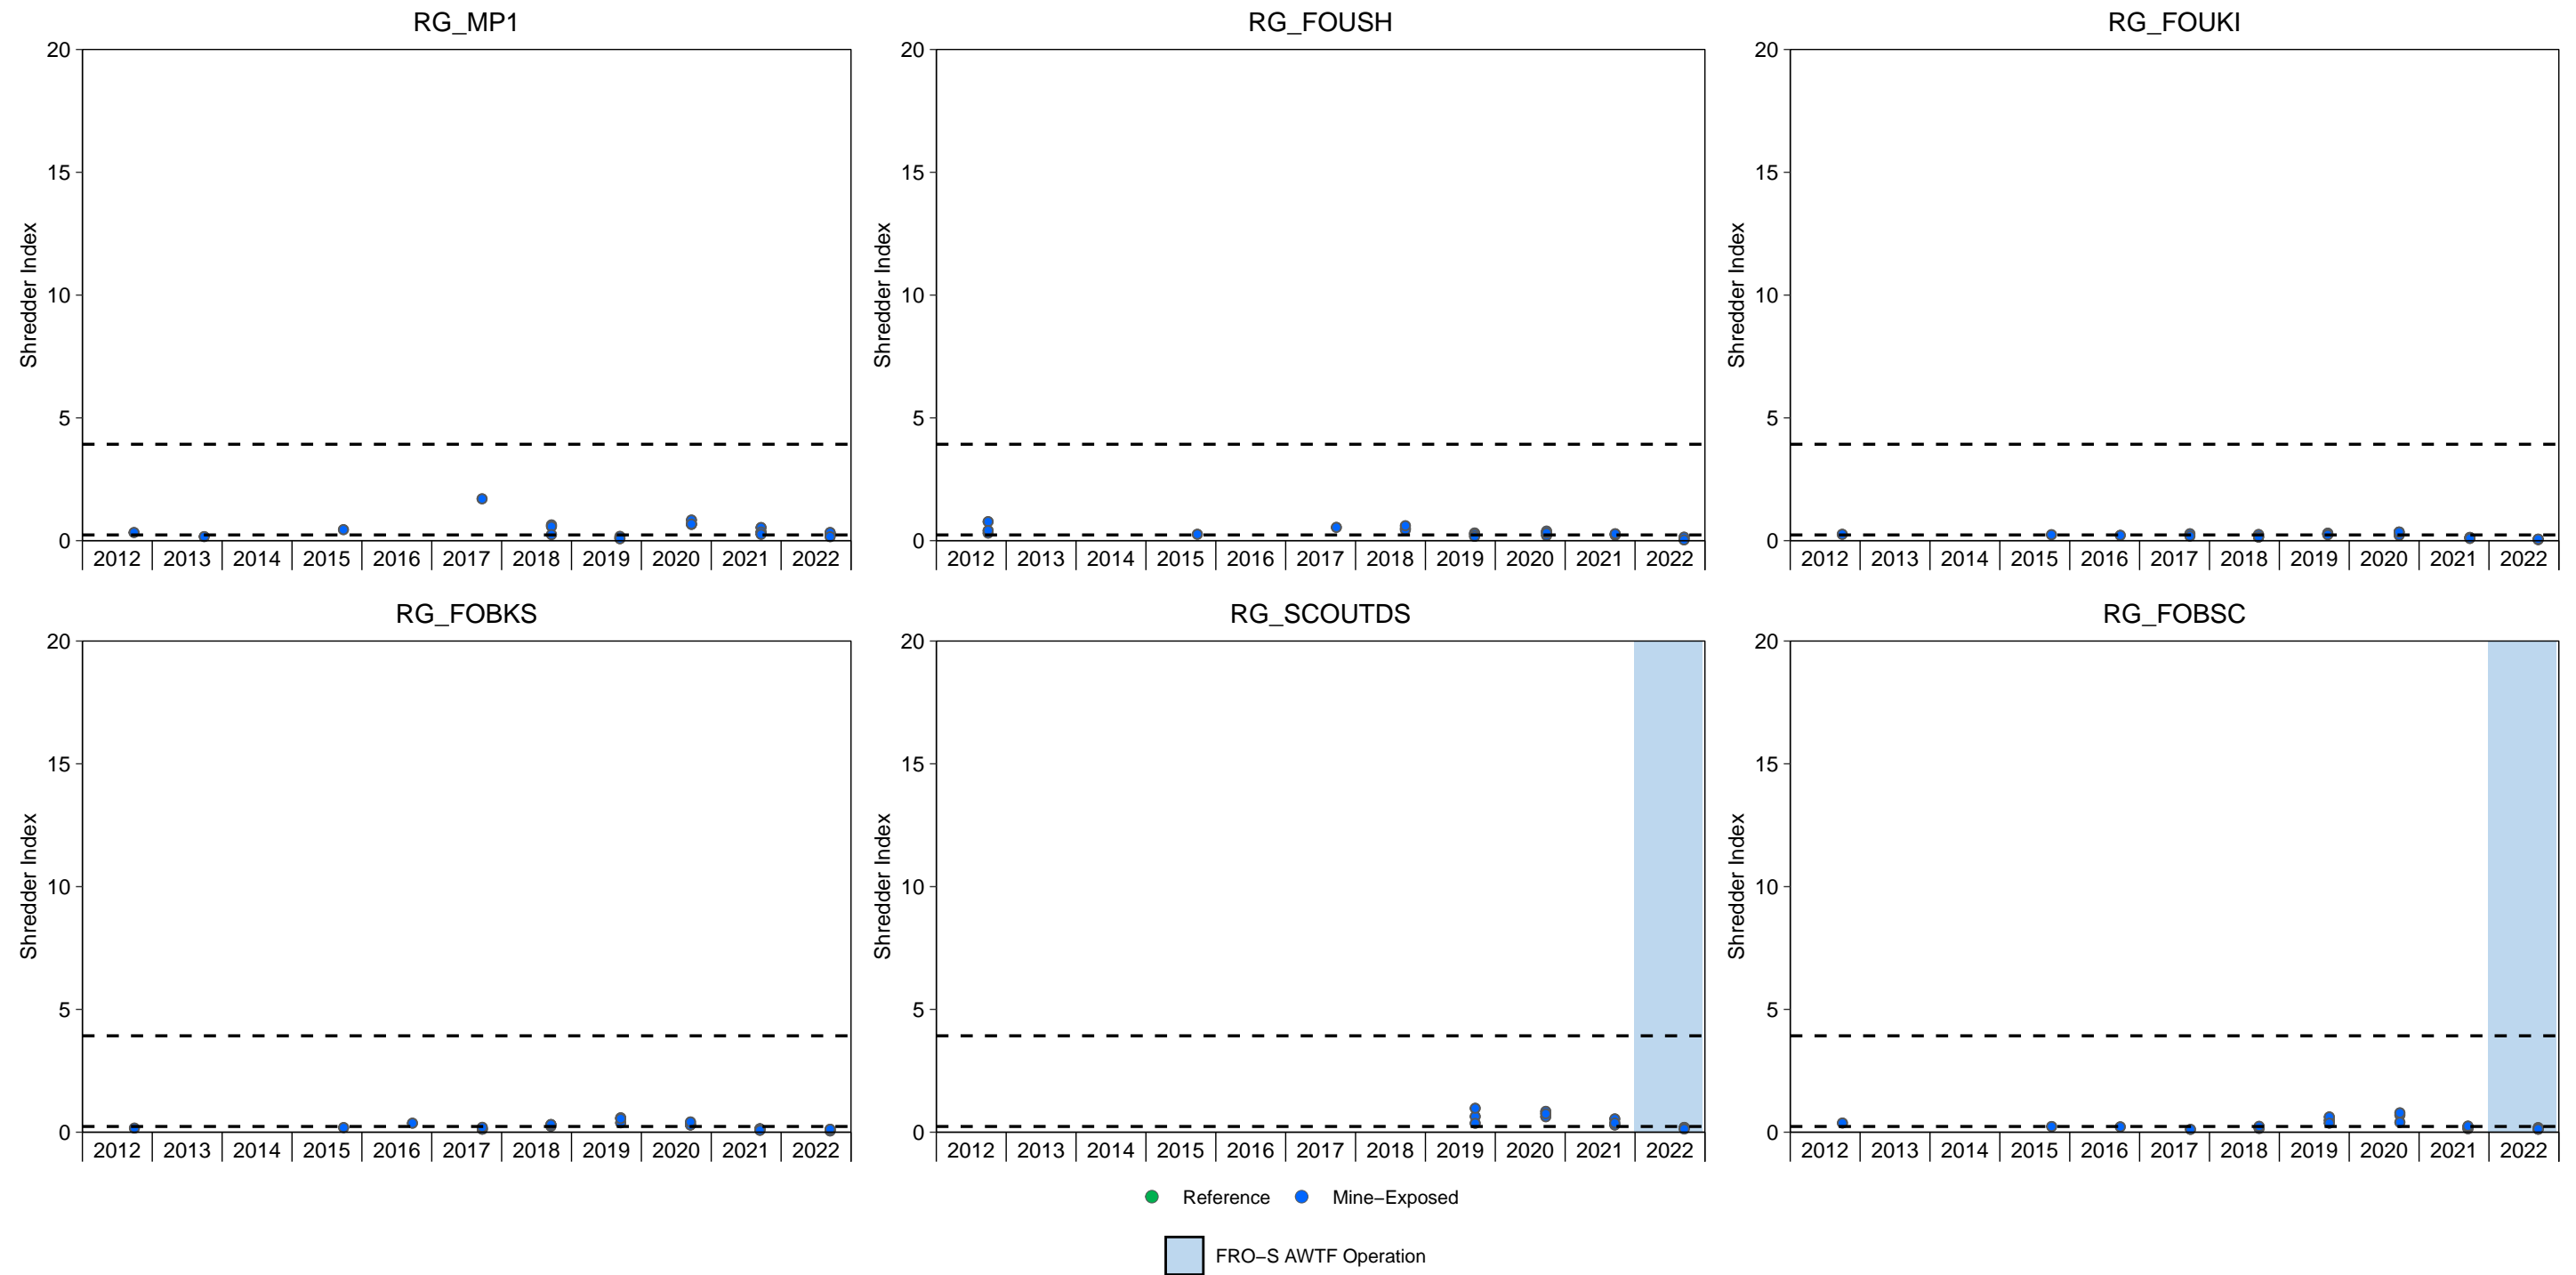

Figure G.29: Benthic Invertebrate Shredder Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

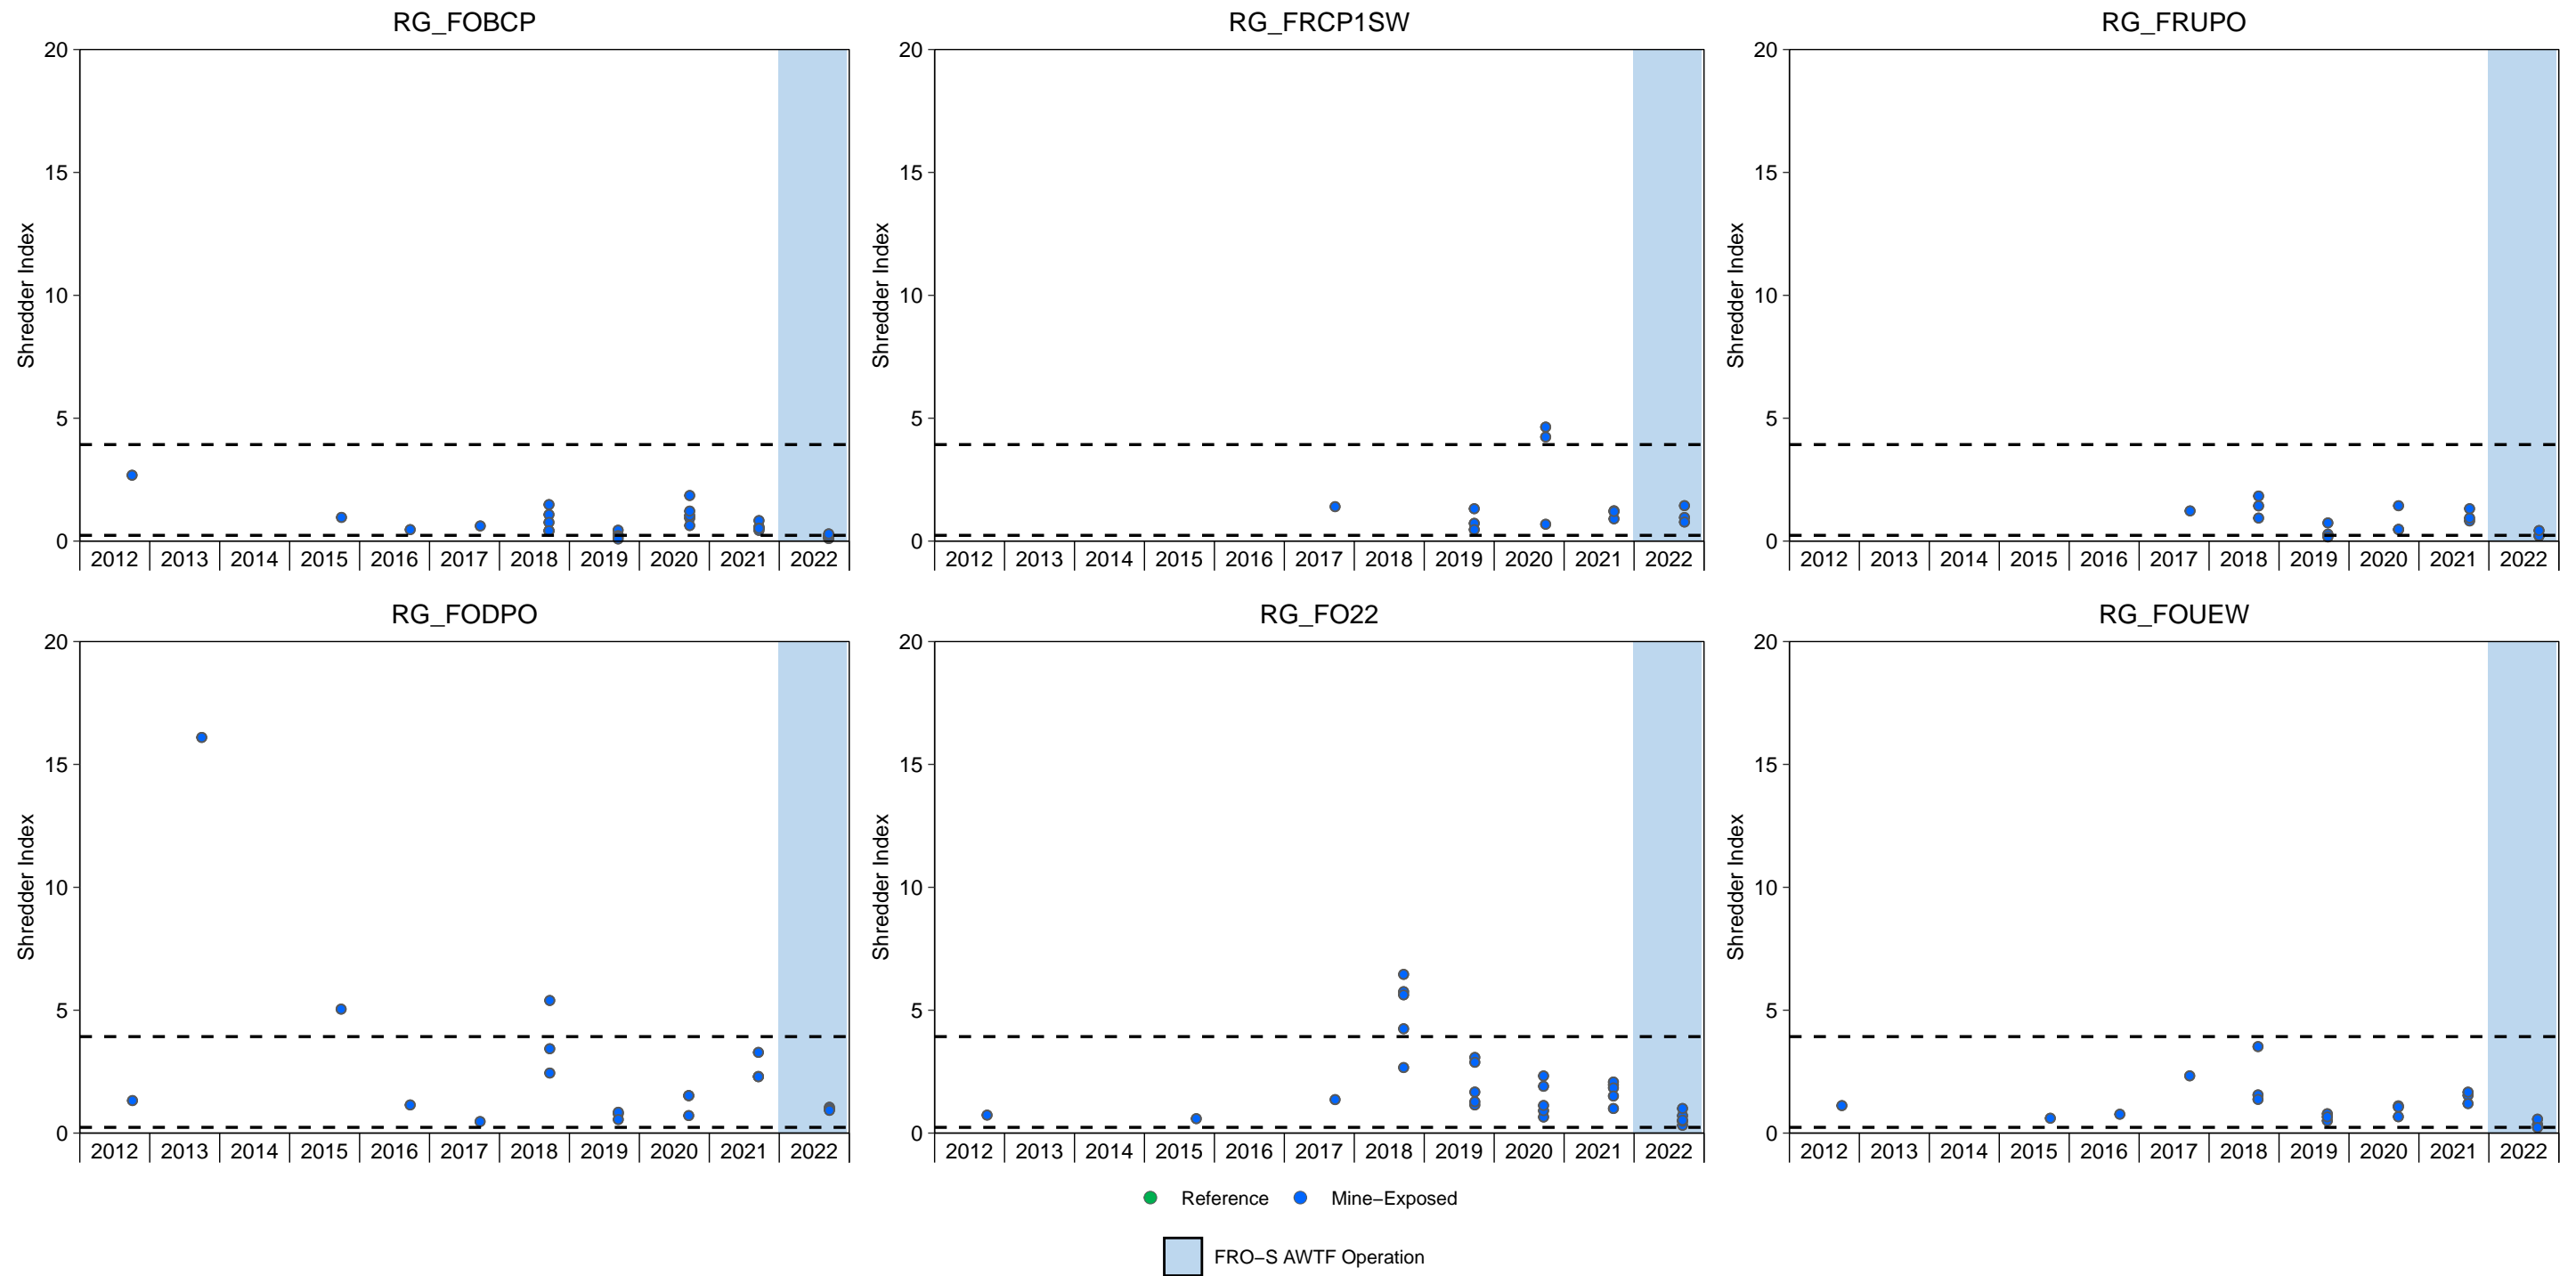

Figure G.29: Benthic Invertebrate Shredder Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

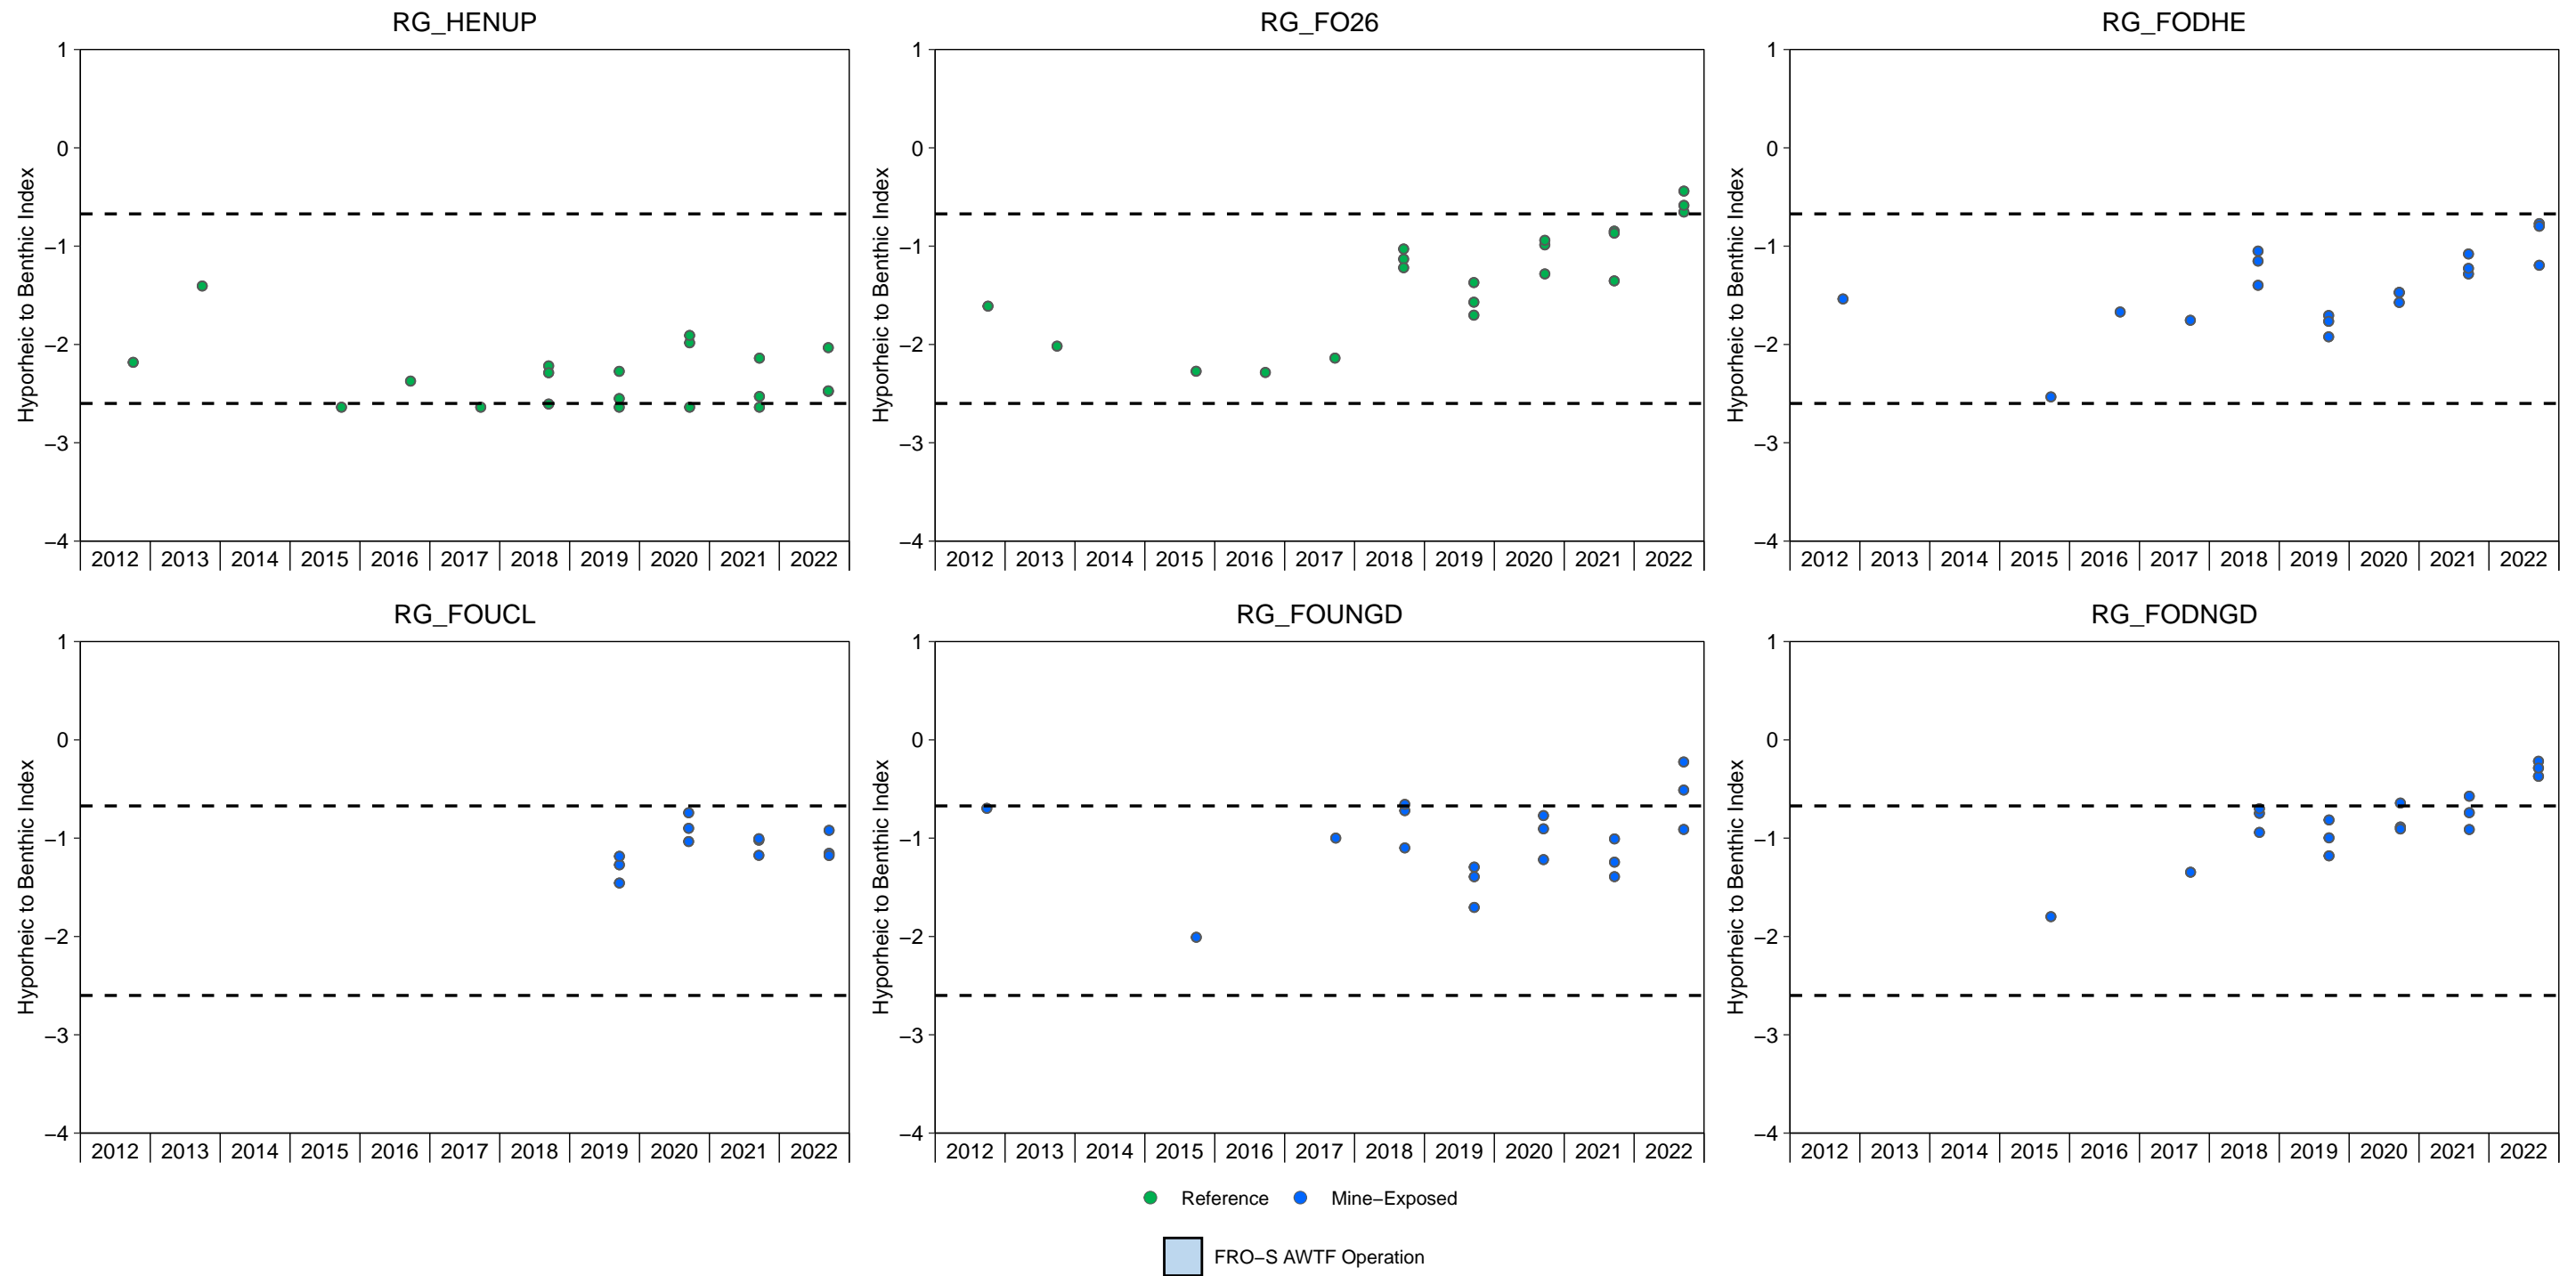

Figure G.30: Benthic Invertebrate Hyporheic to Benthic Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

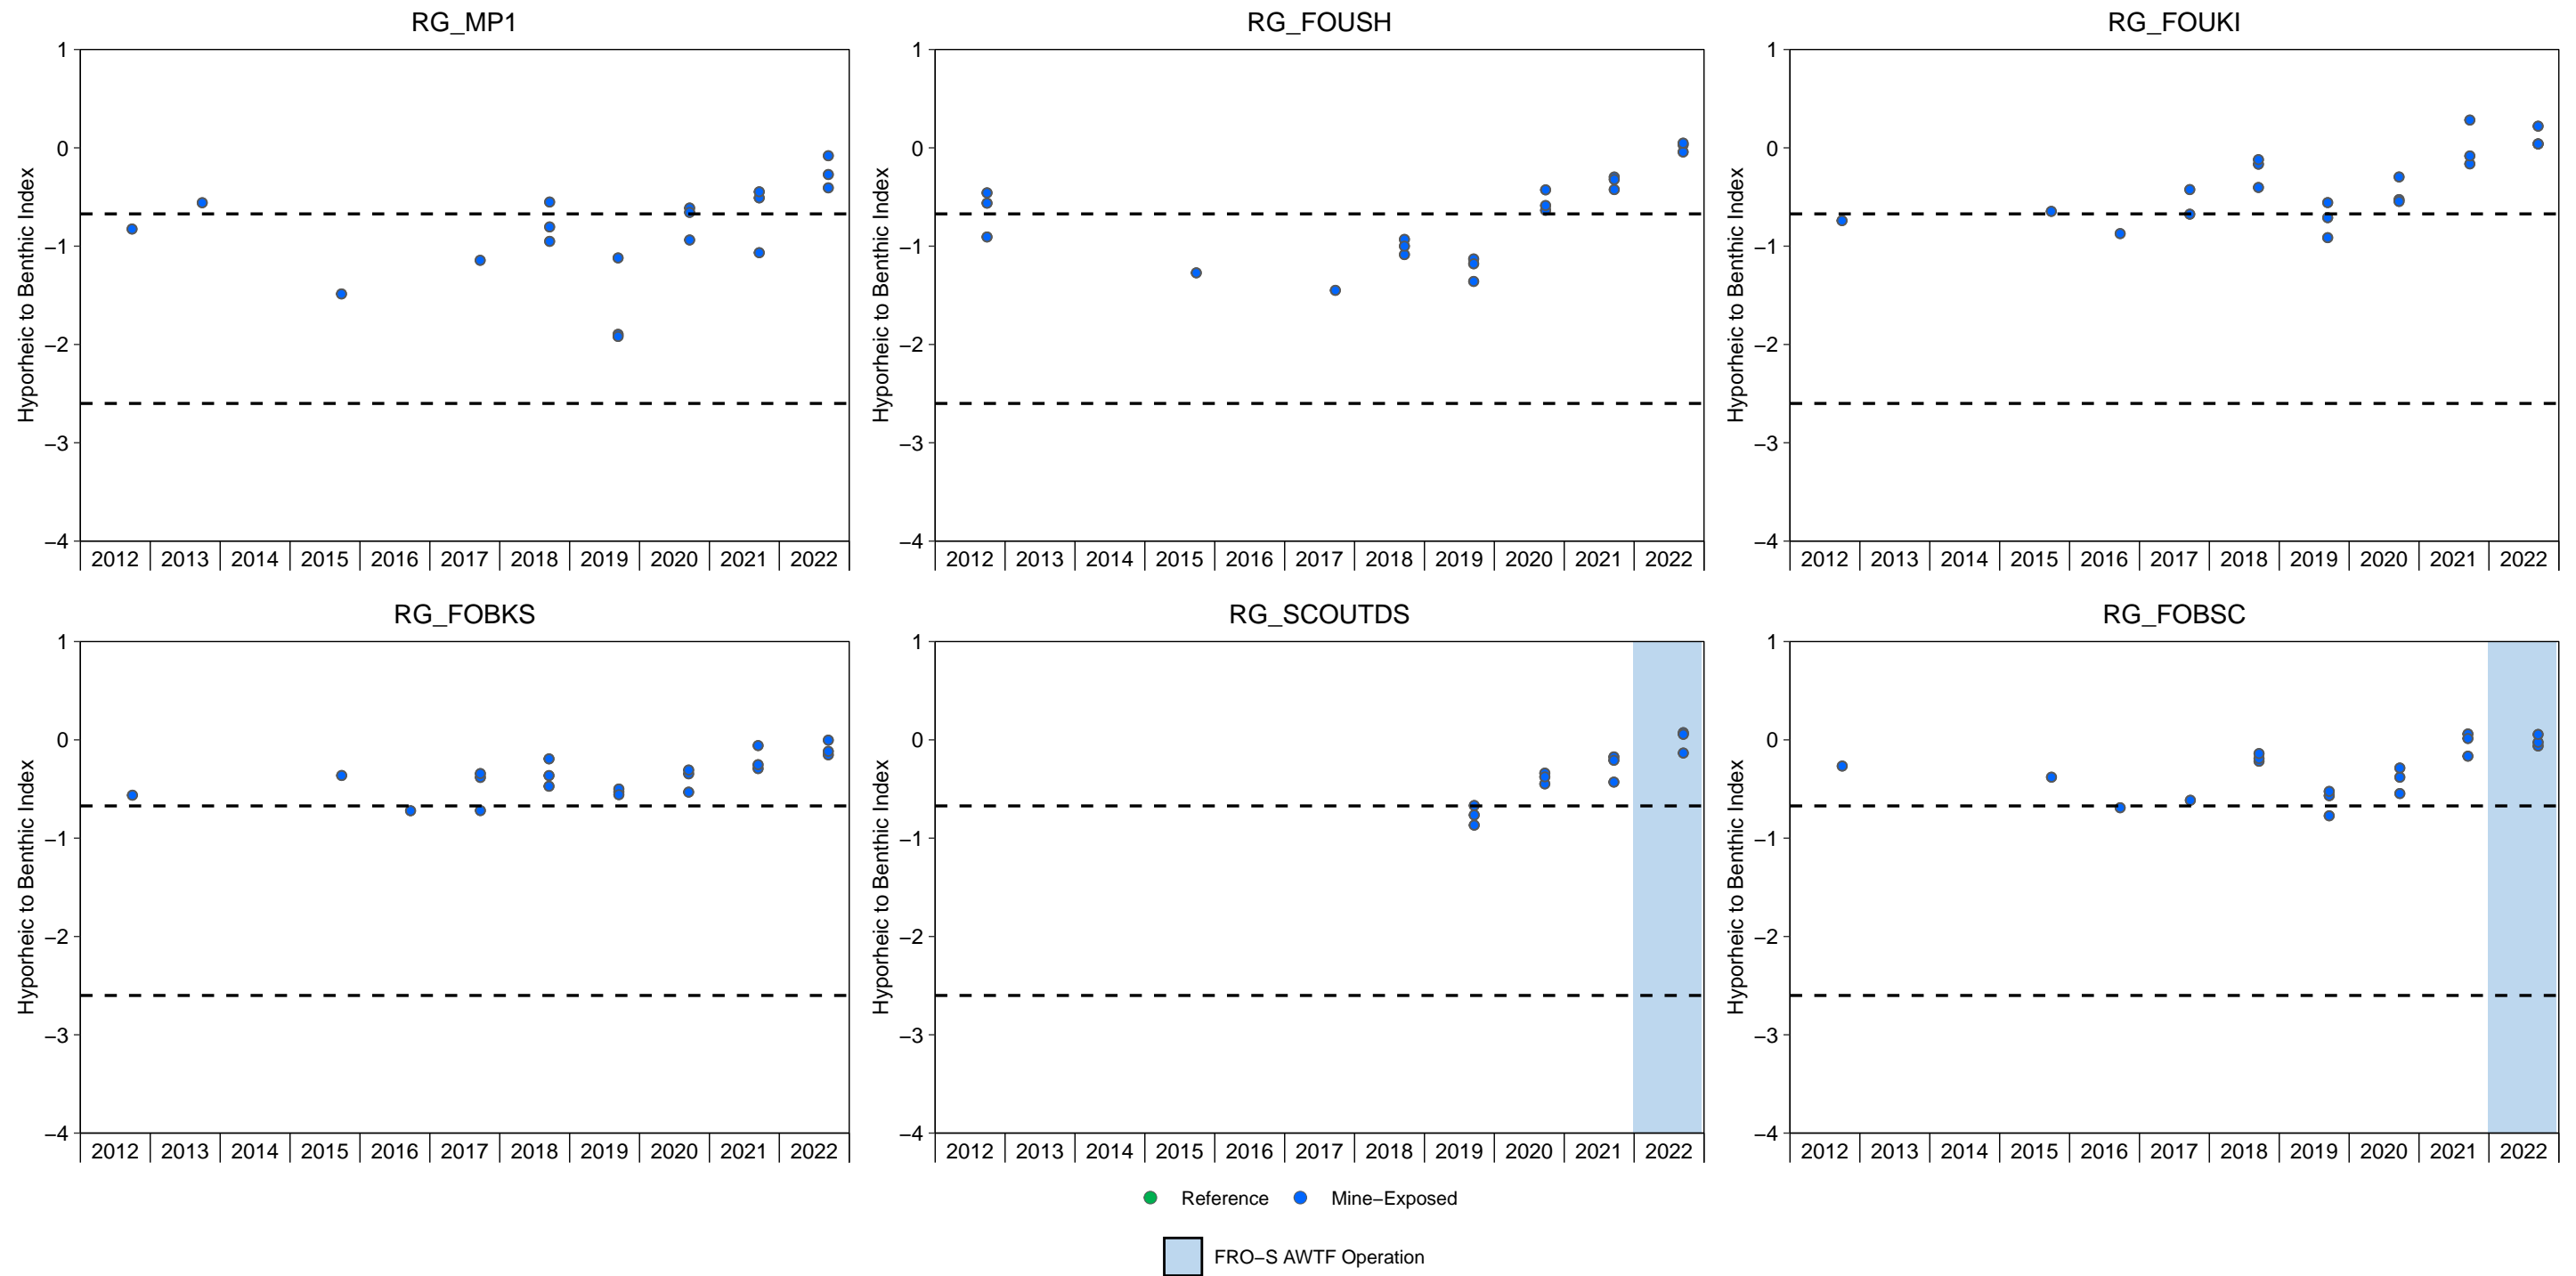

Figure G.30: Benthic Invertebrate Hyporheic to Benthic Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

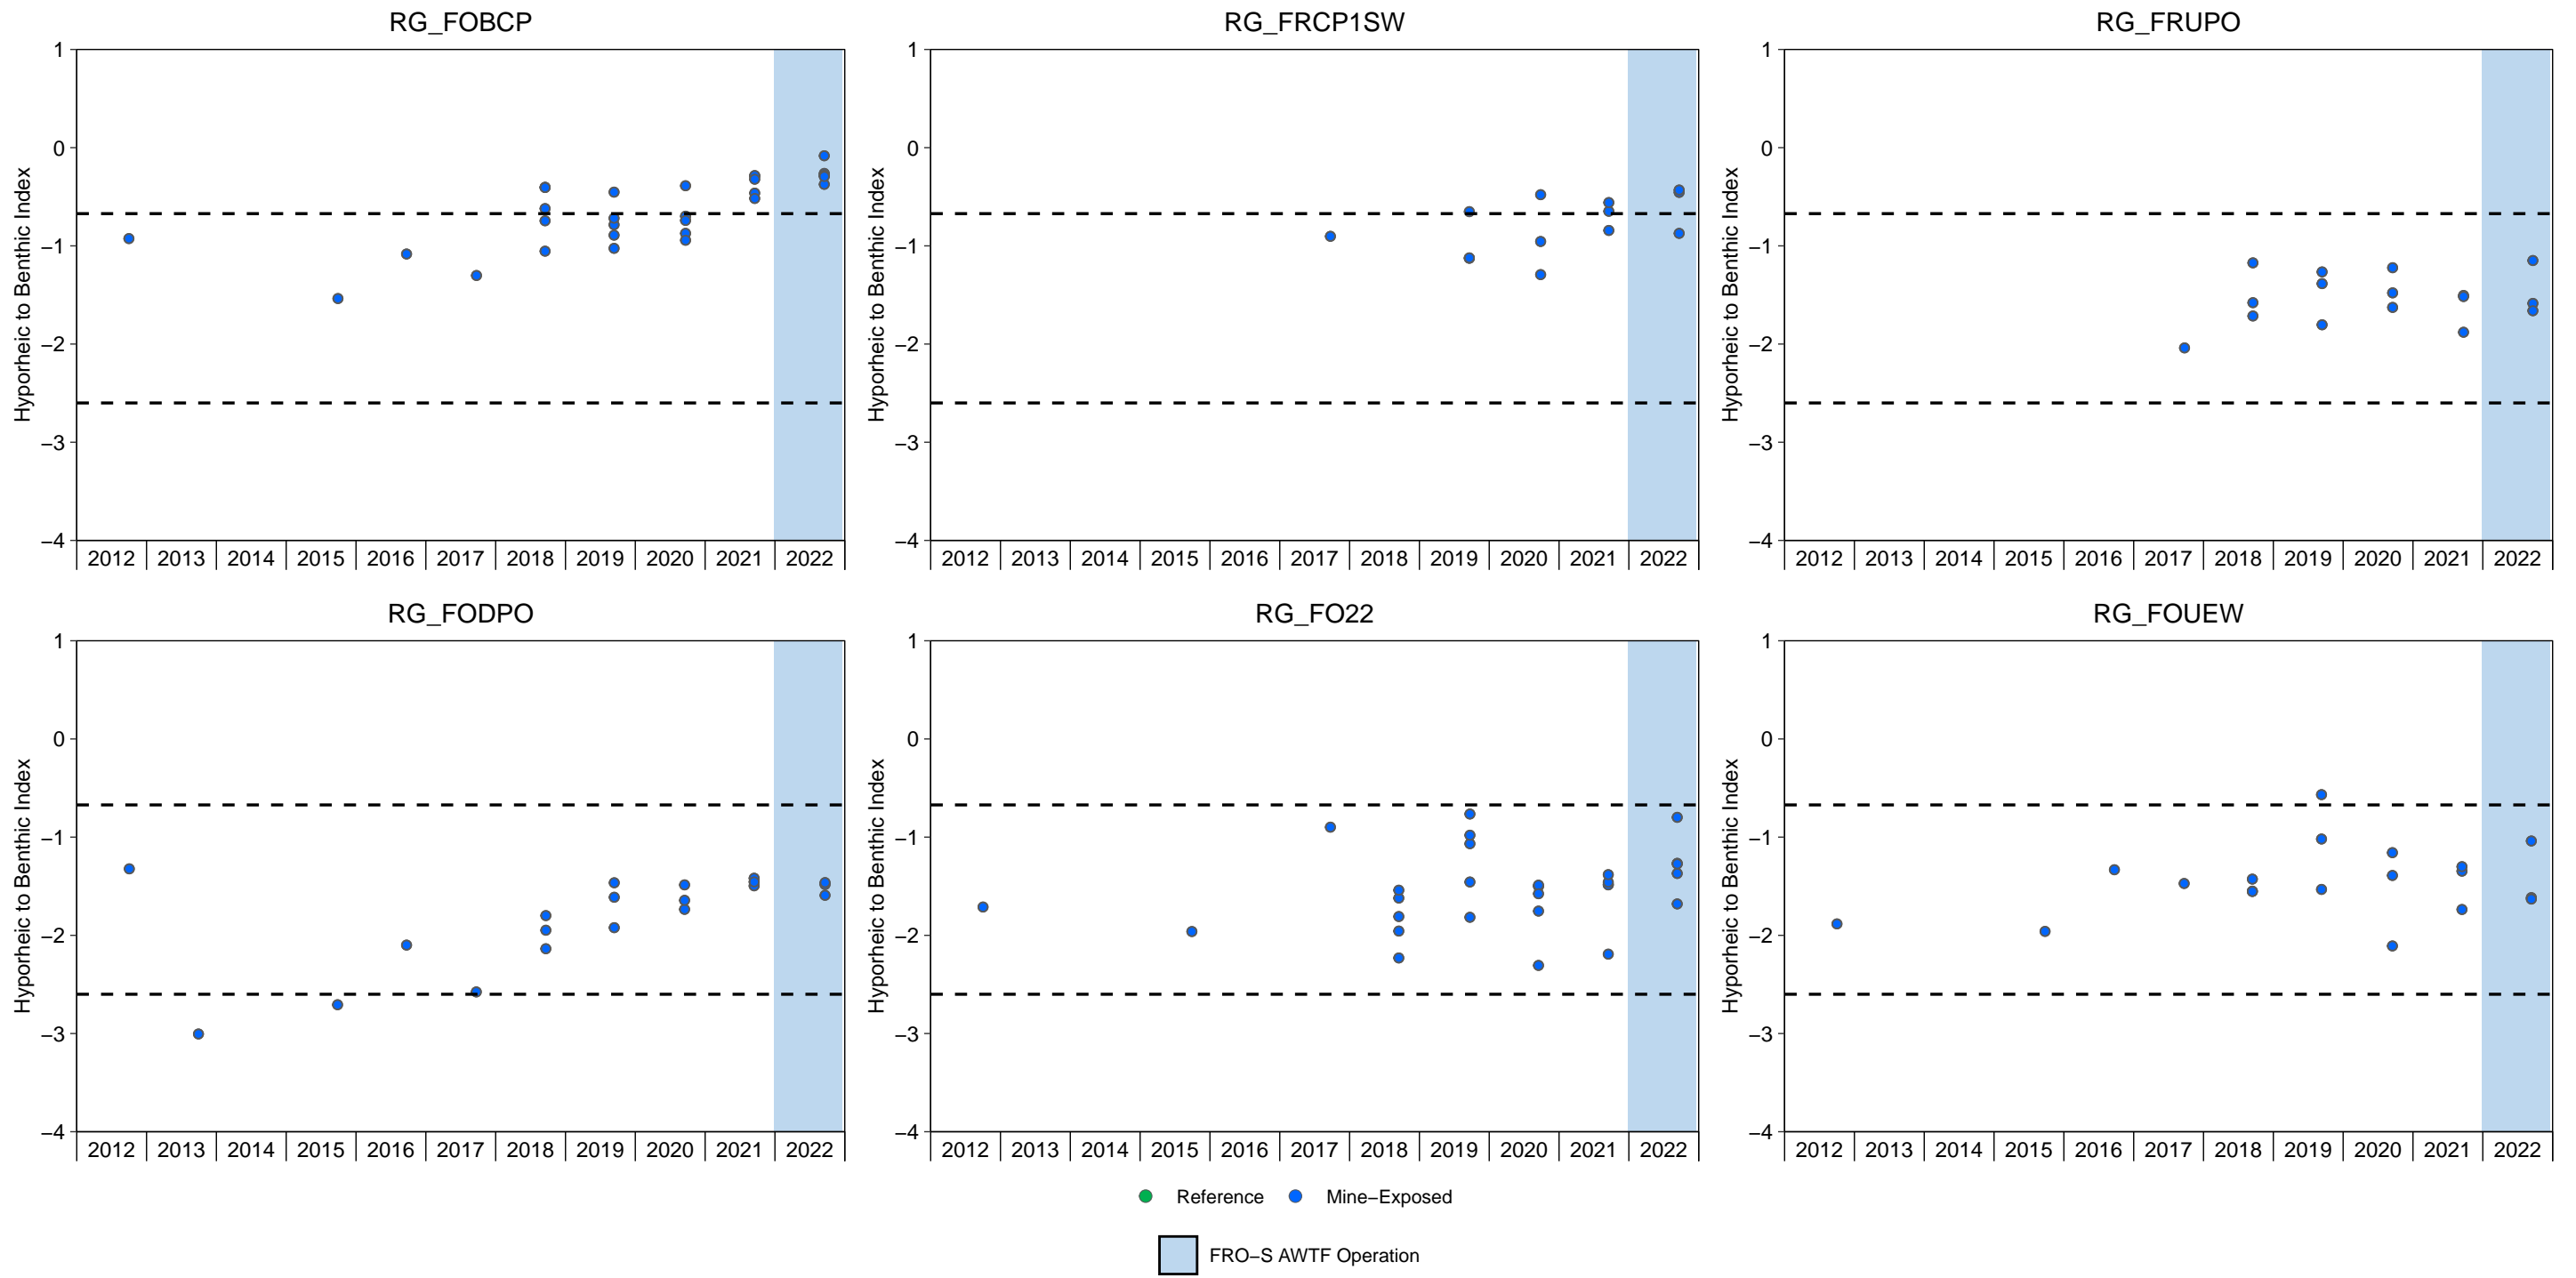

Figure G.30: Benthic Invertebrate Hyporheic to Benthic Index in September, FRO LAEMP, 2012 to 2022

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure G.31: Benthic Invertebrate Community Feeding Groups Percent Composition, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.32: Benthic Invertebrate Community Habitat Groups Percent Composition, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

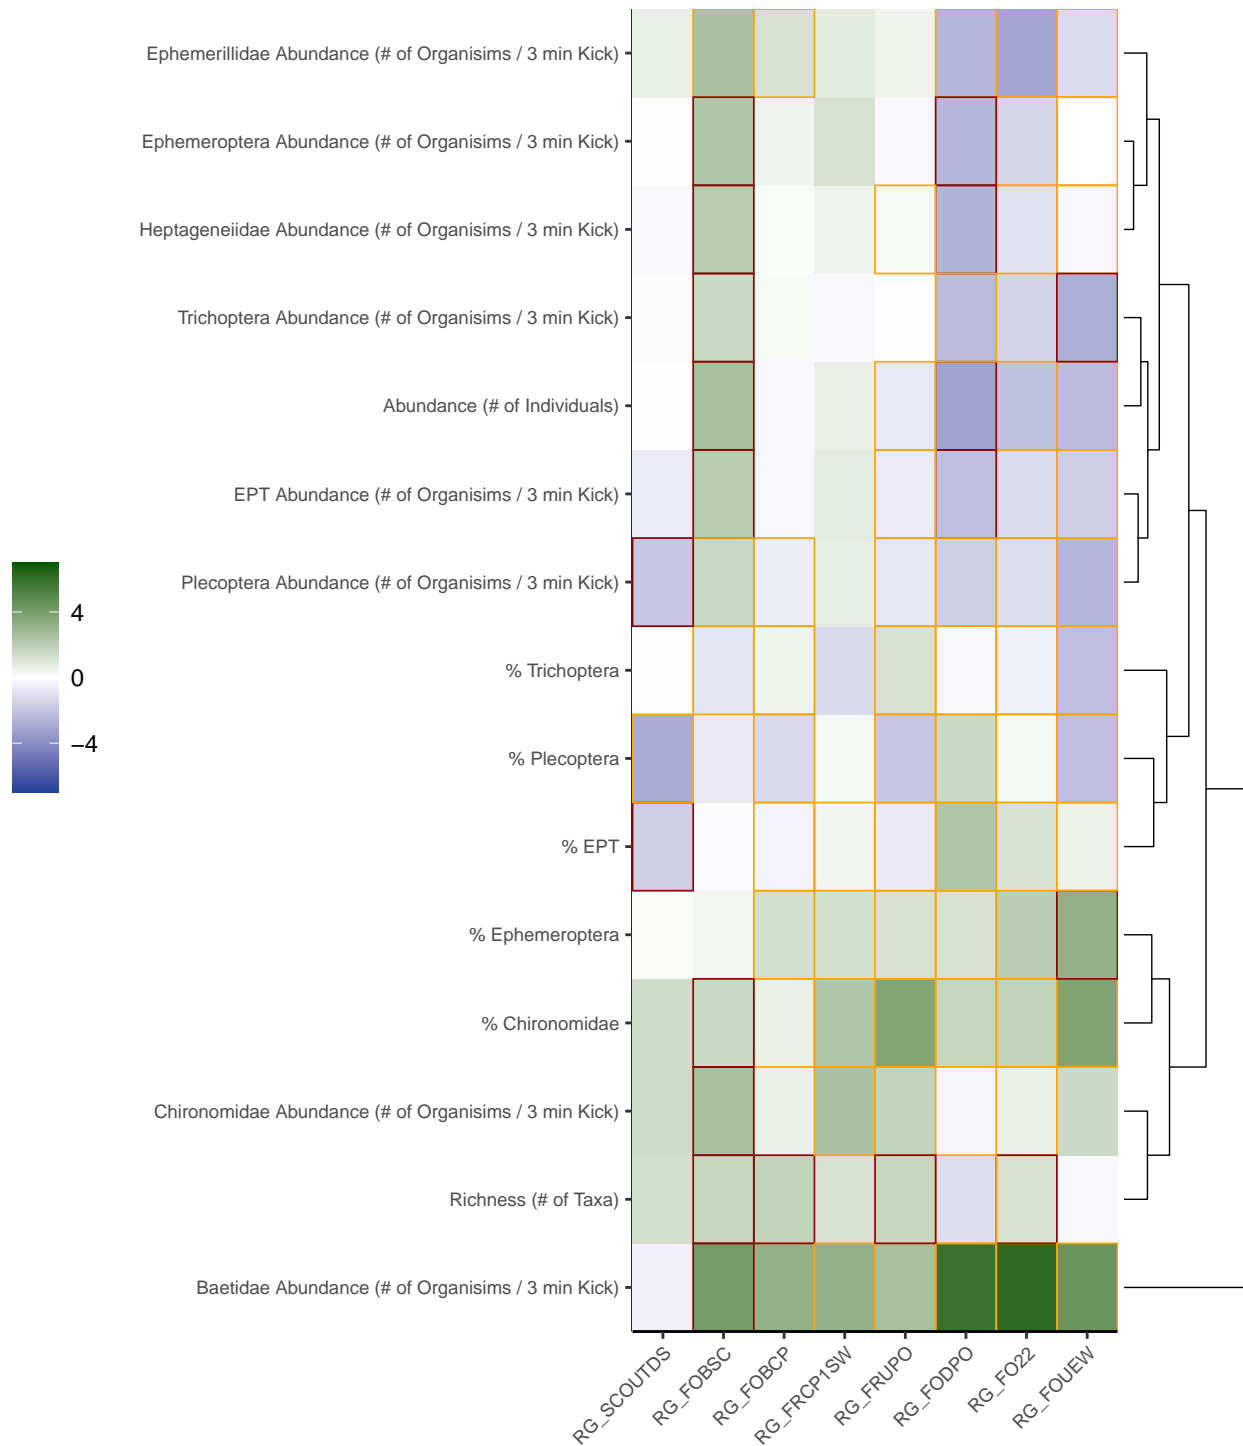

Figure G.33: Heatmap of Magnitude of Differences (MOD) from Statistical Analysis of Benthic Invertebrate Community Upstream and Downstream of Treatment, 2012 to 2022.

Notes: Orange boxes show significant BA (Year) x Treatment effects and red boxes show significant BA x Treatment effects. BA = Before-After term. Magnitude of difference was calculated as described in the table with the statistical analysis presented here.

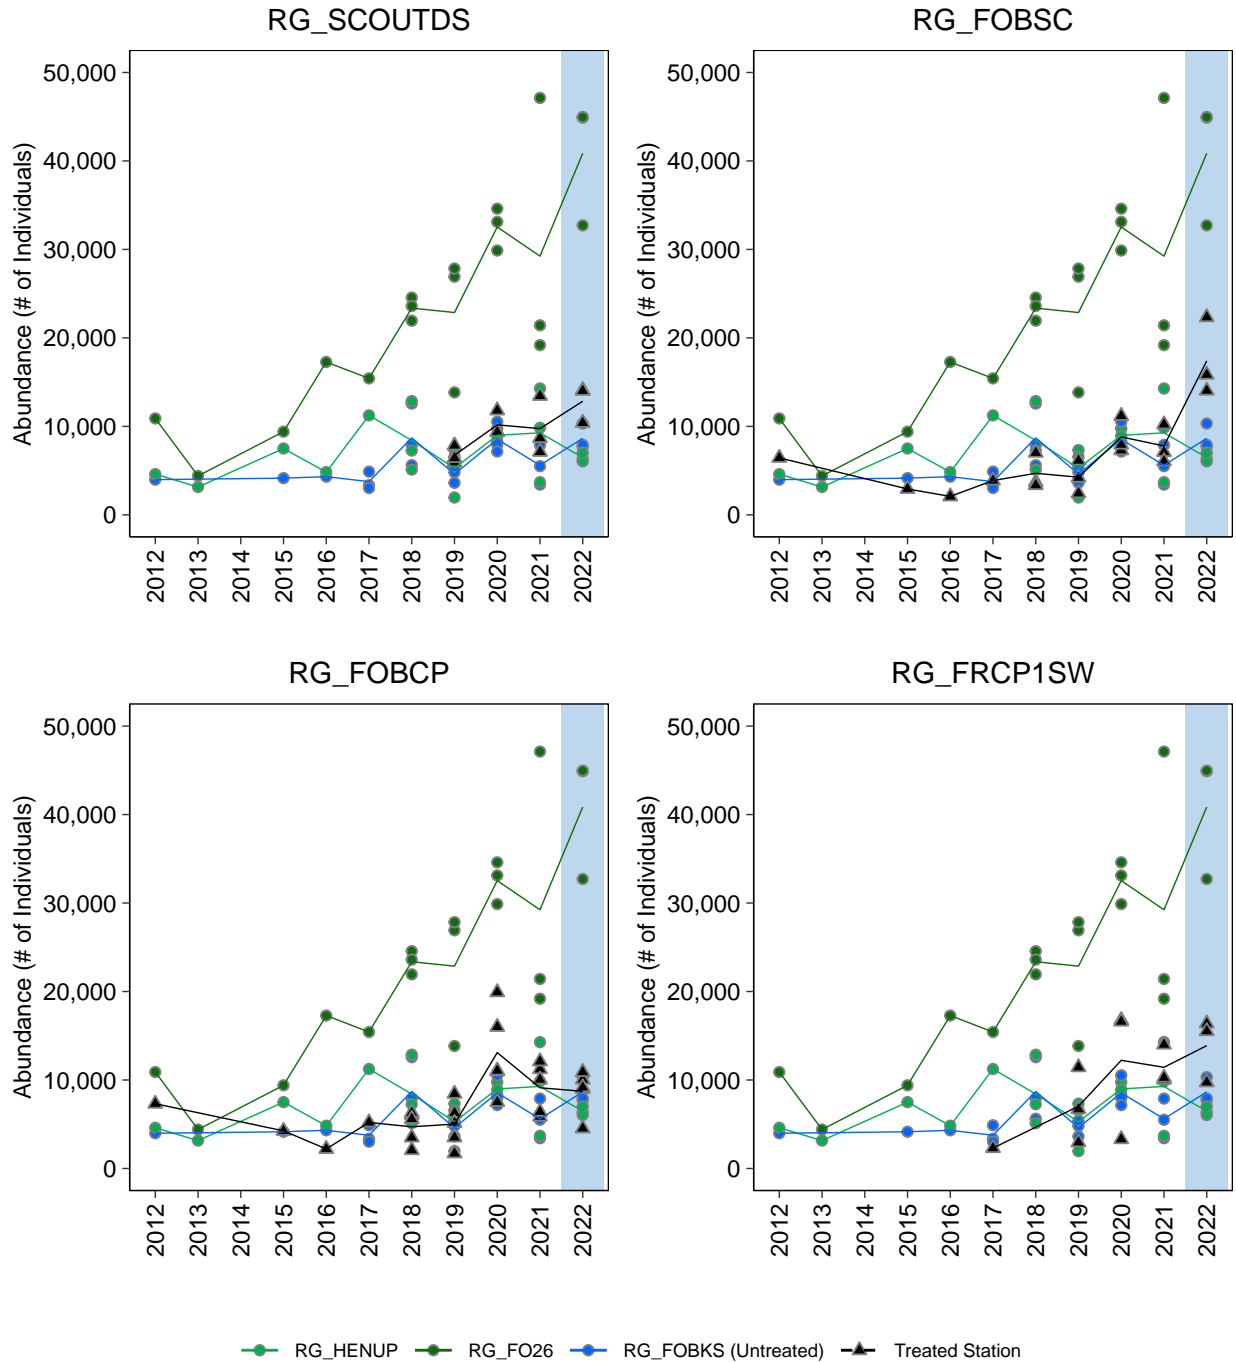

Figure G.34: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

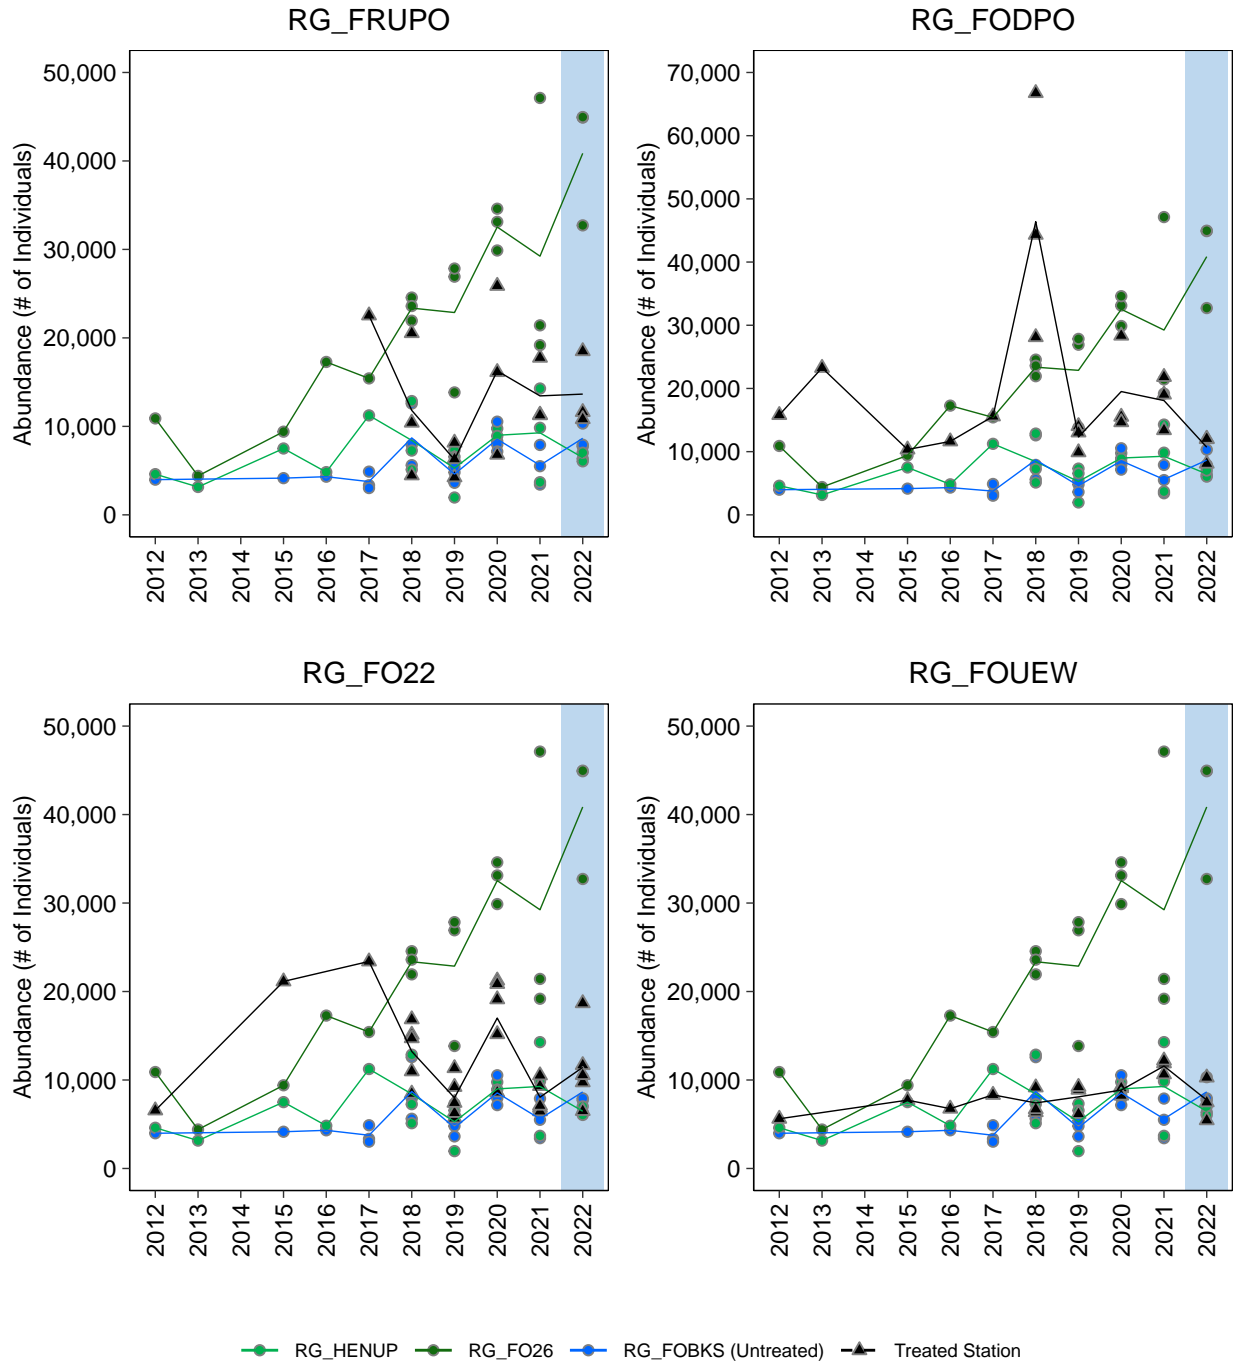

Figure G.34: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

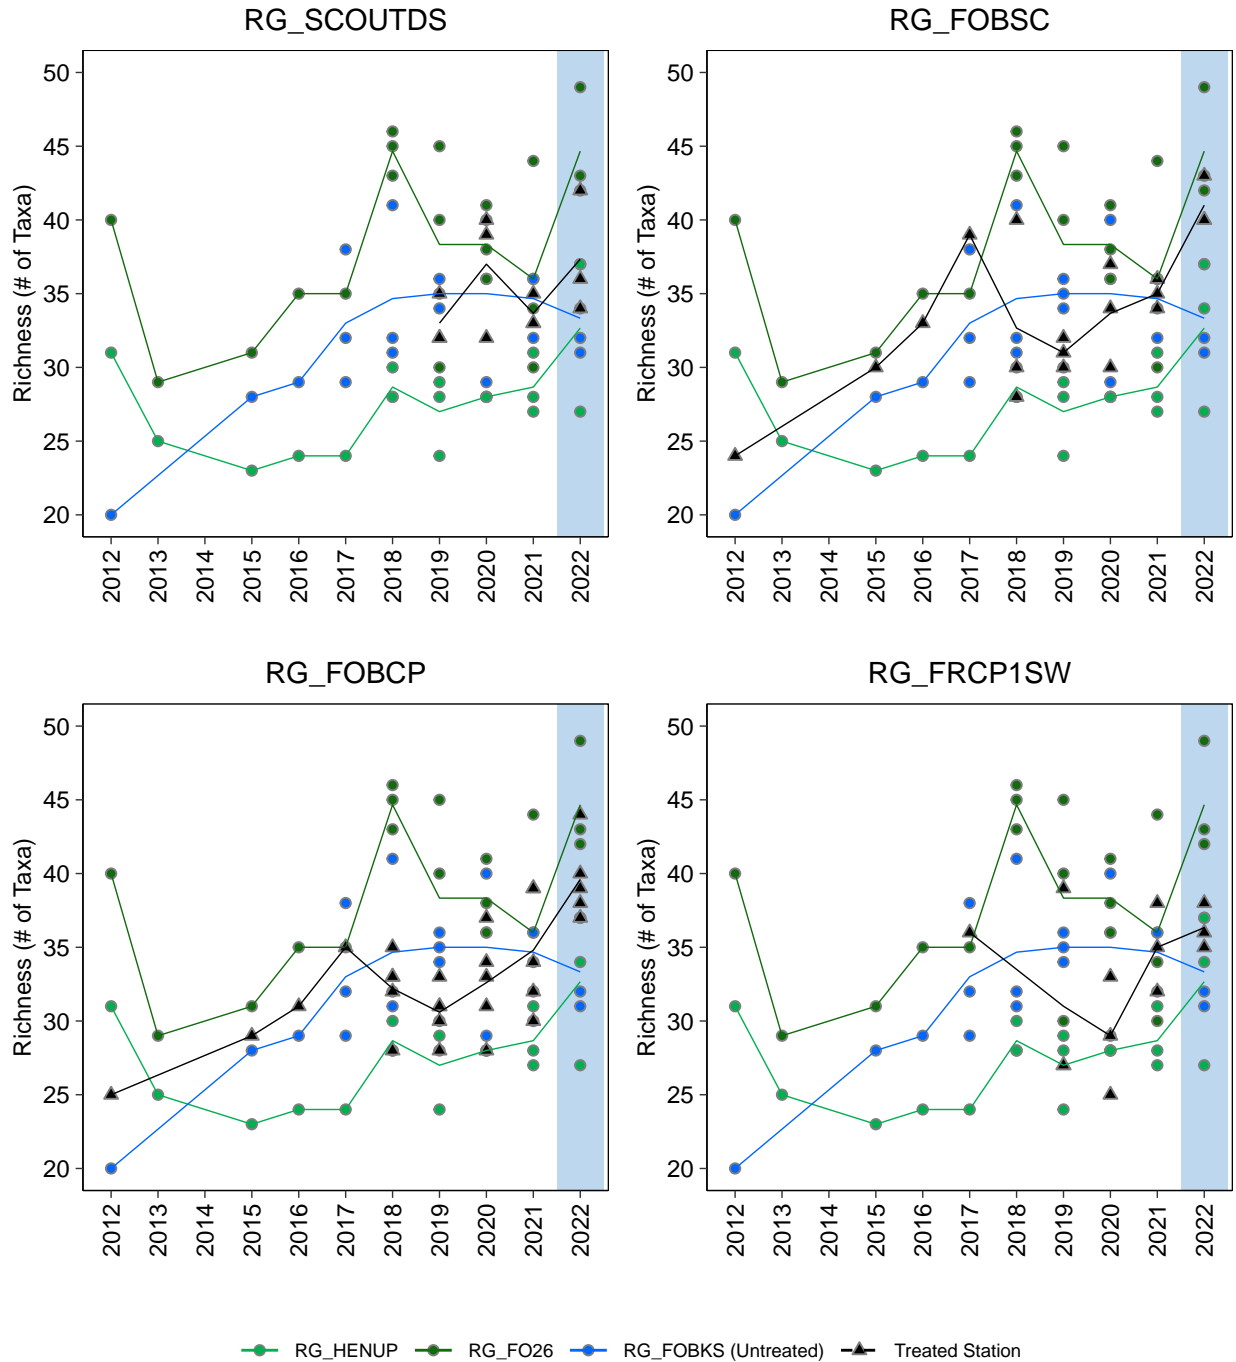

Figure G.35: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

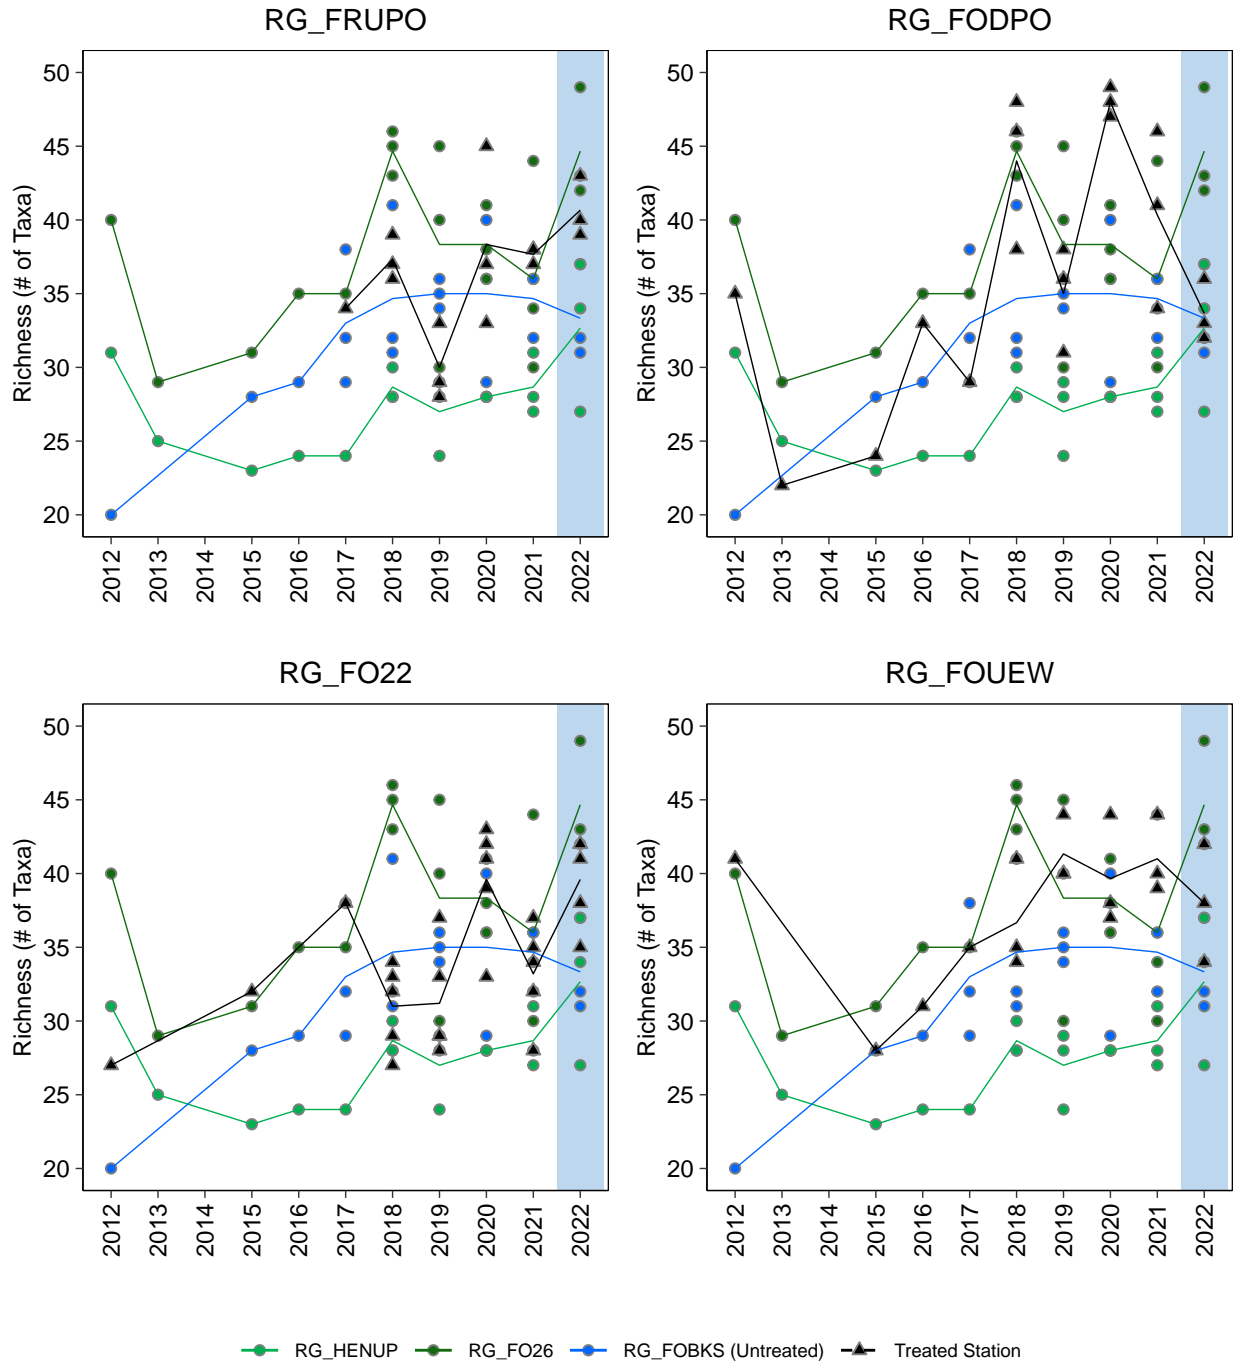

Figure G.35: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

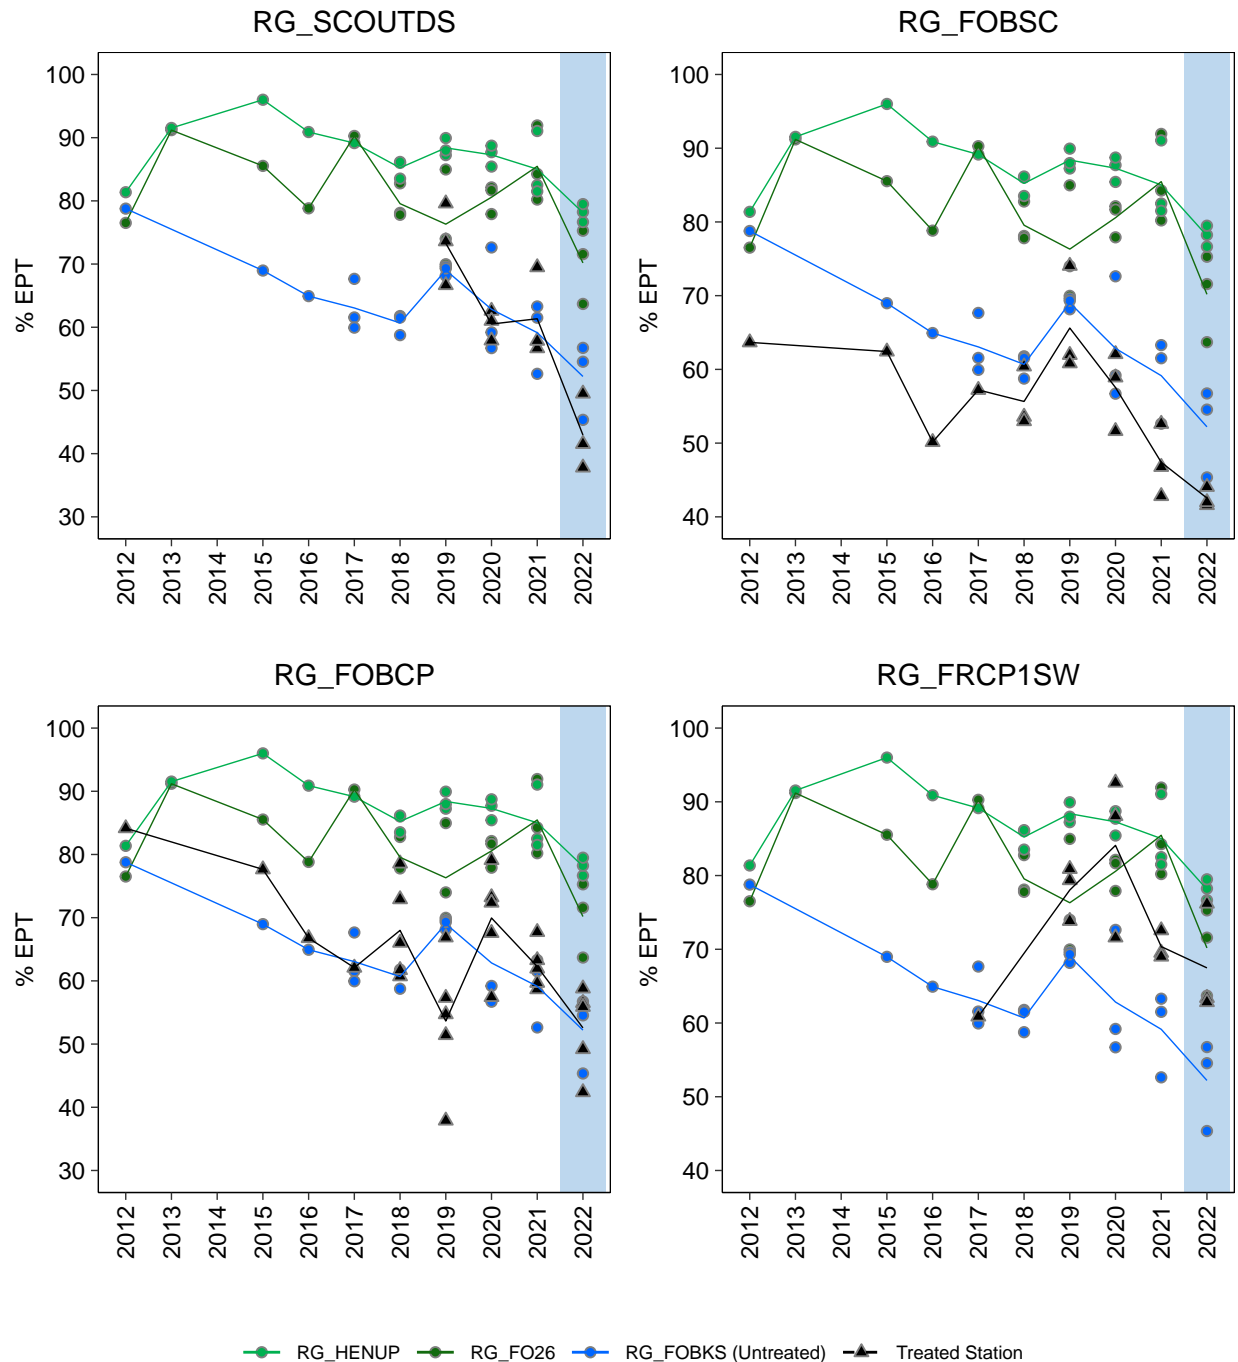

Figure G.36: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

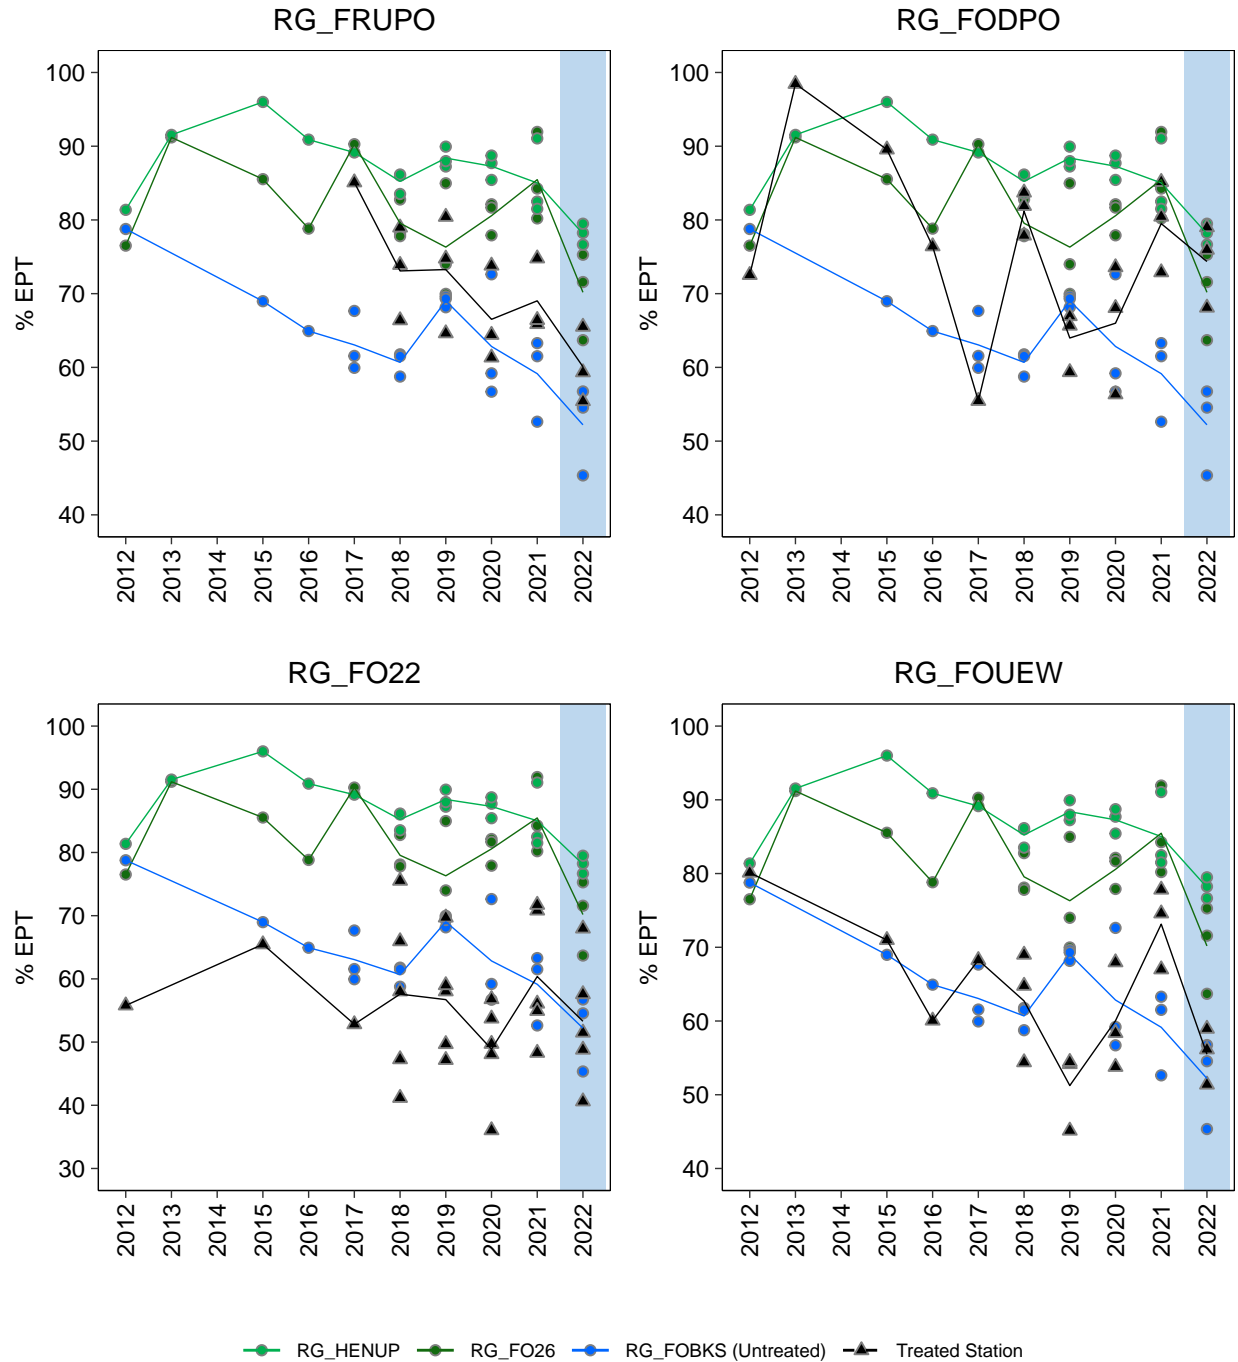

Figure G.36: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

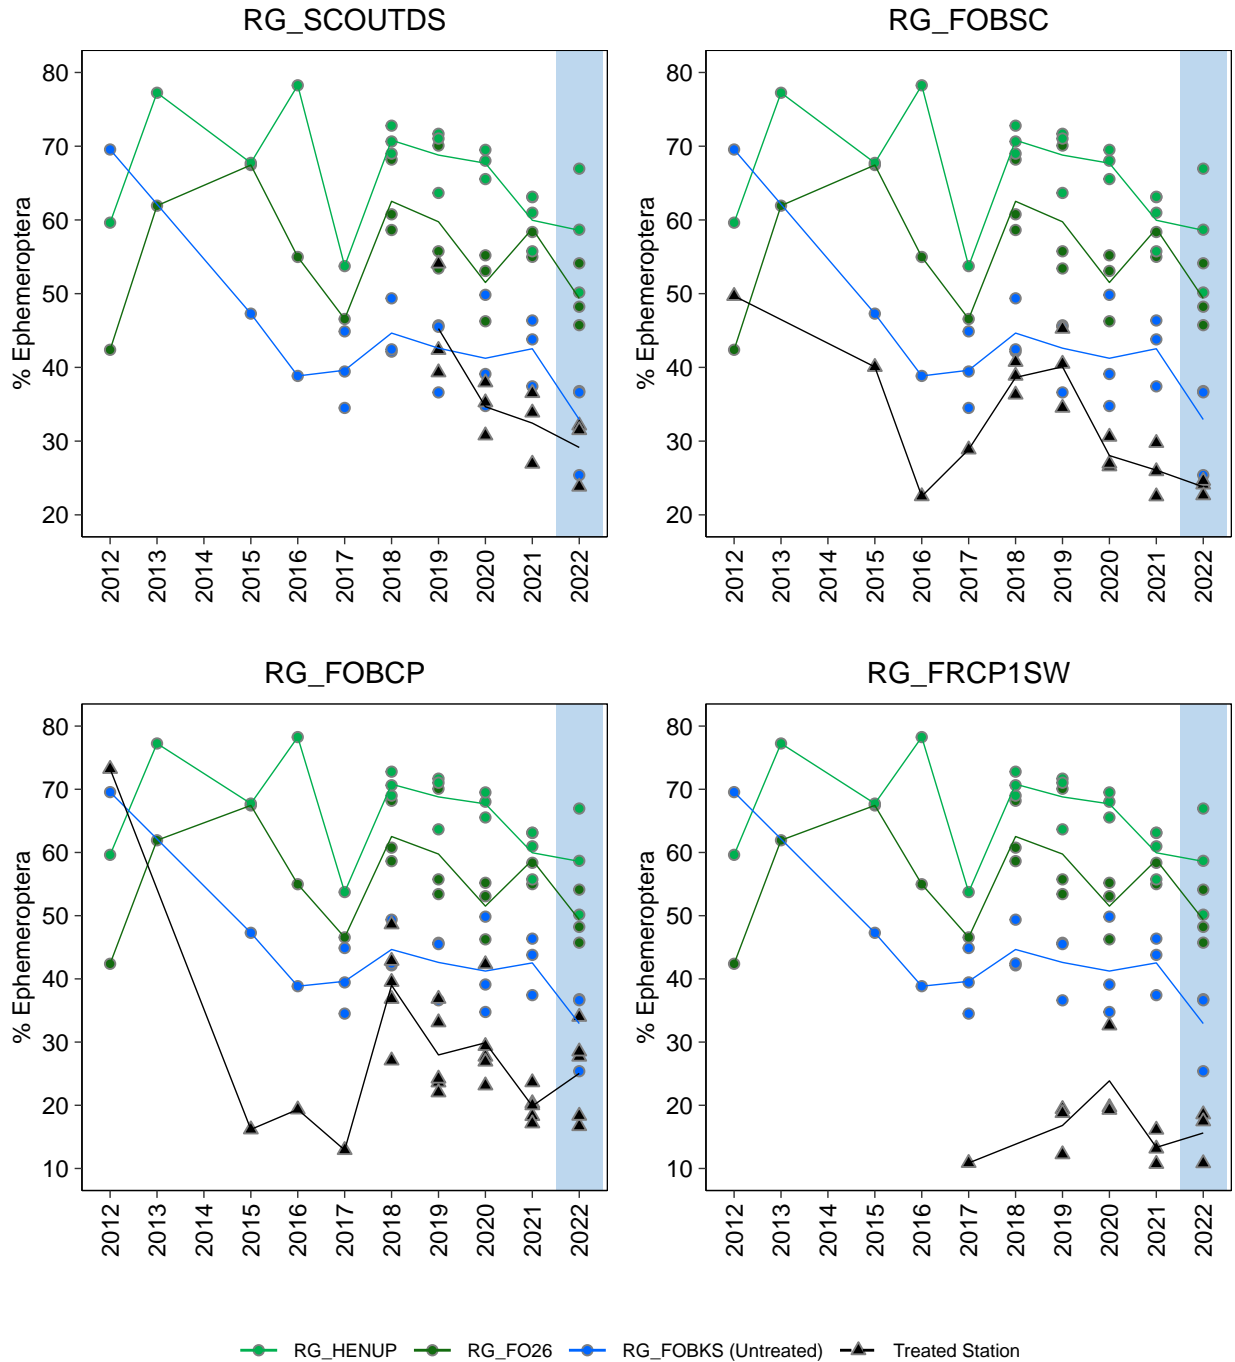

Figure G.37: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

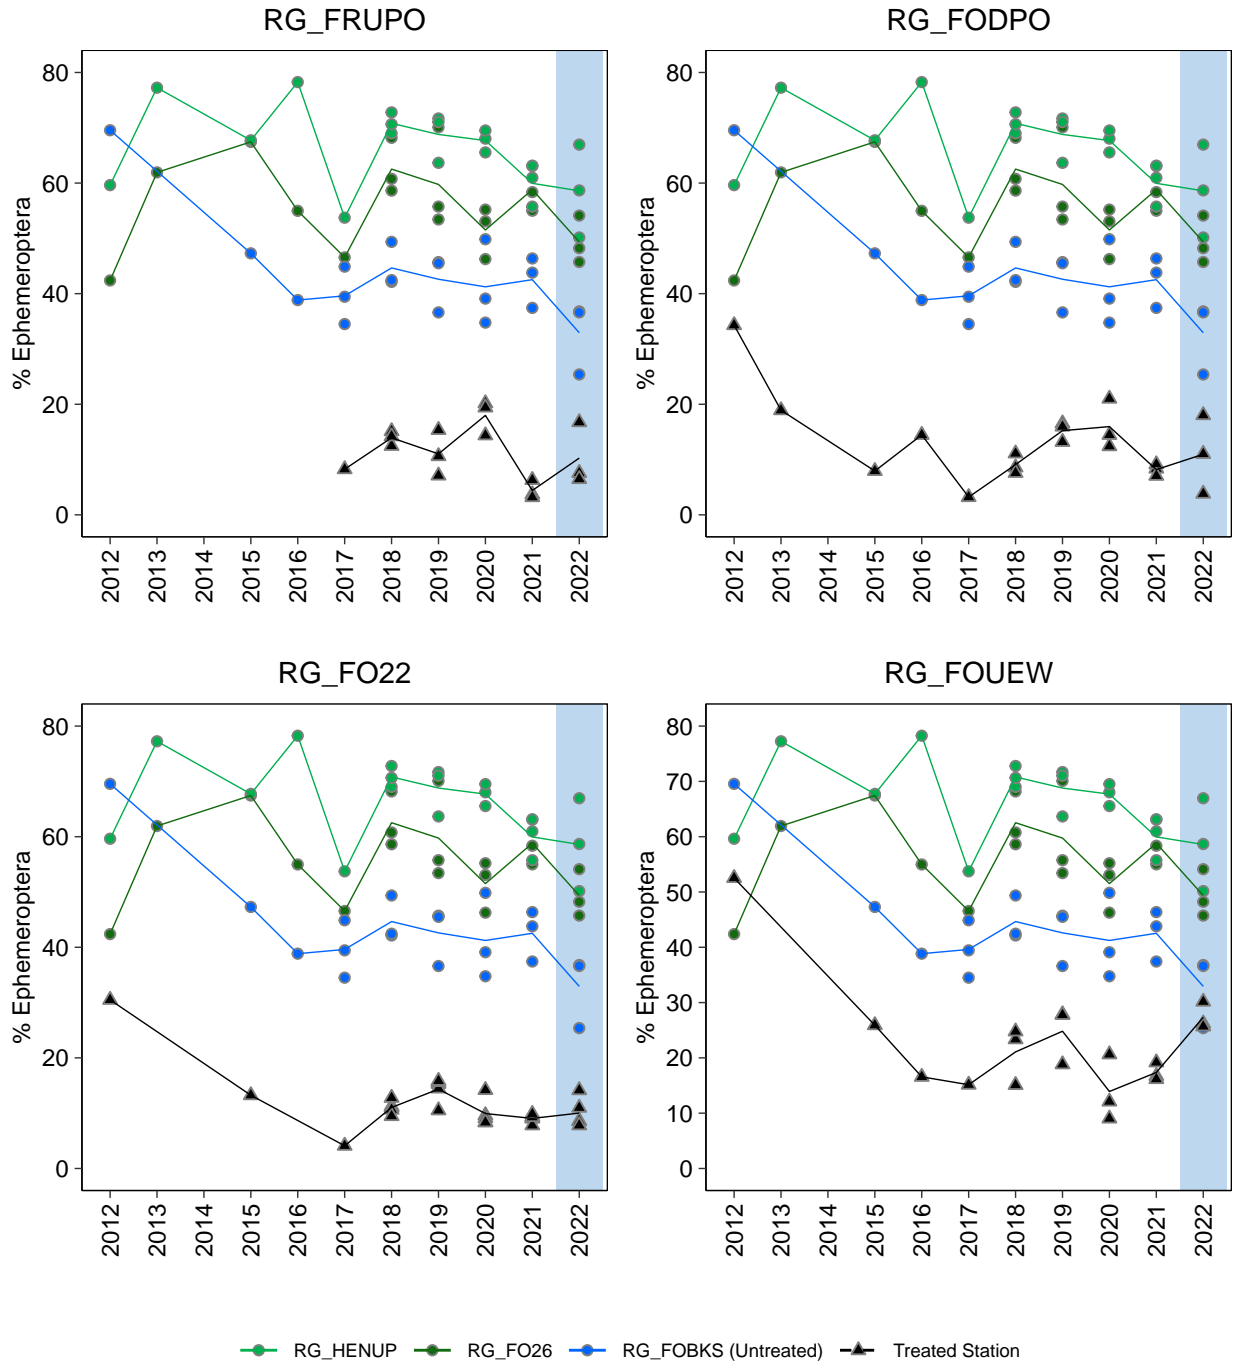

Figure G.37: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

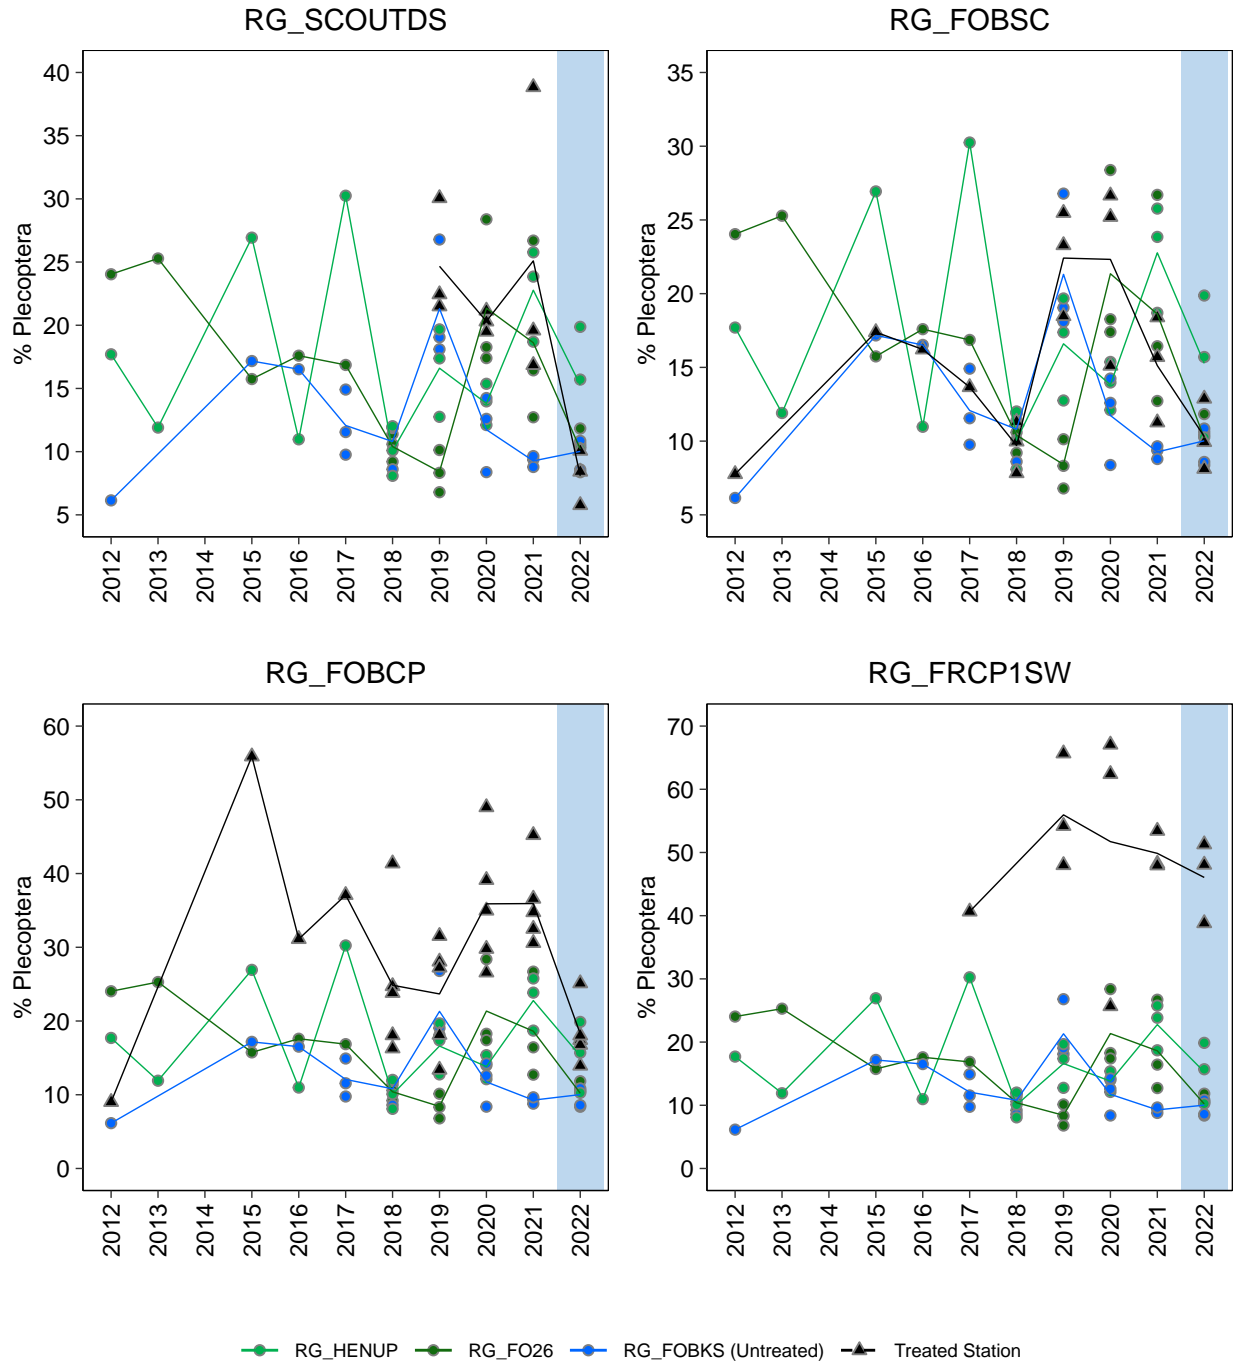

Figure G.38: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

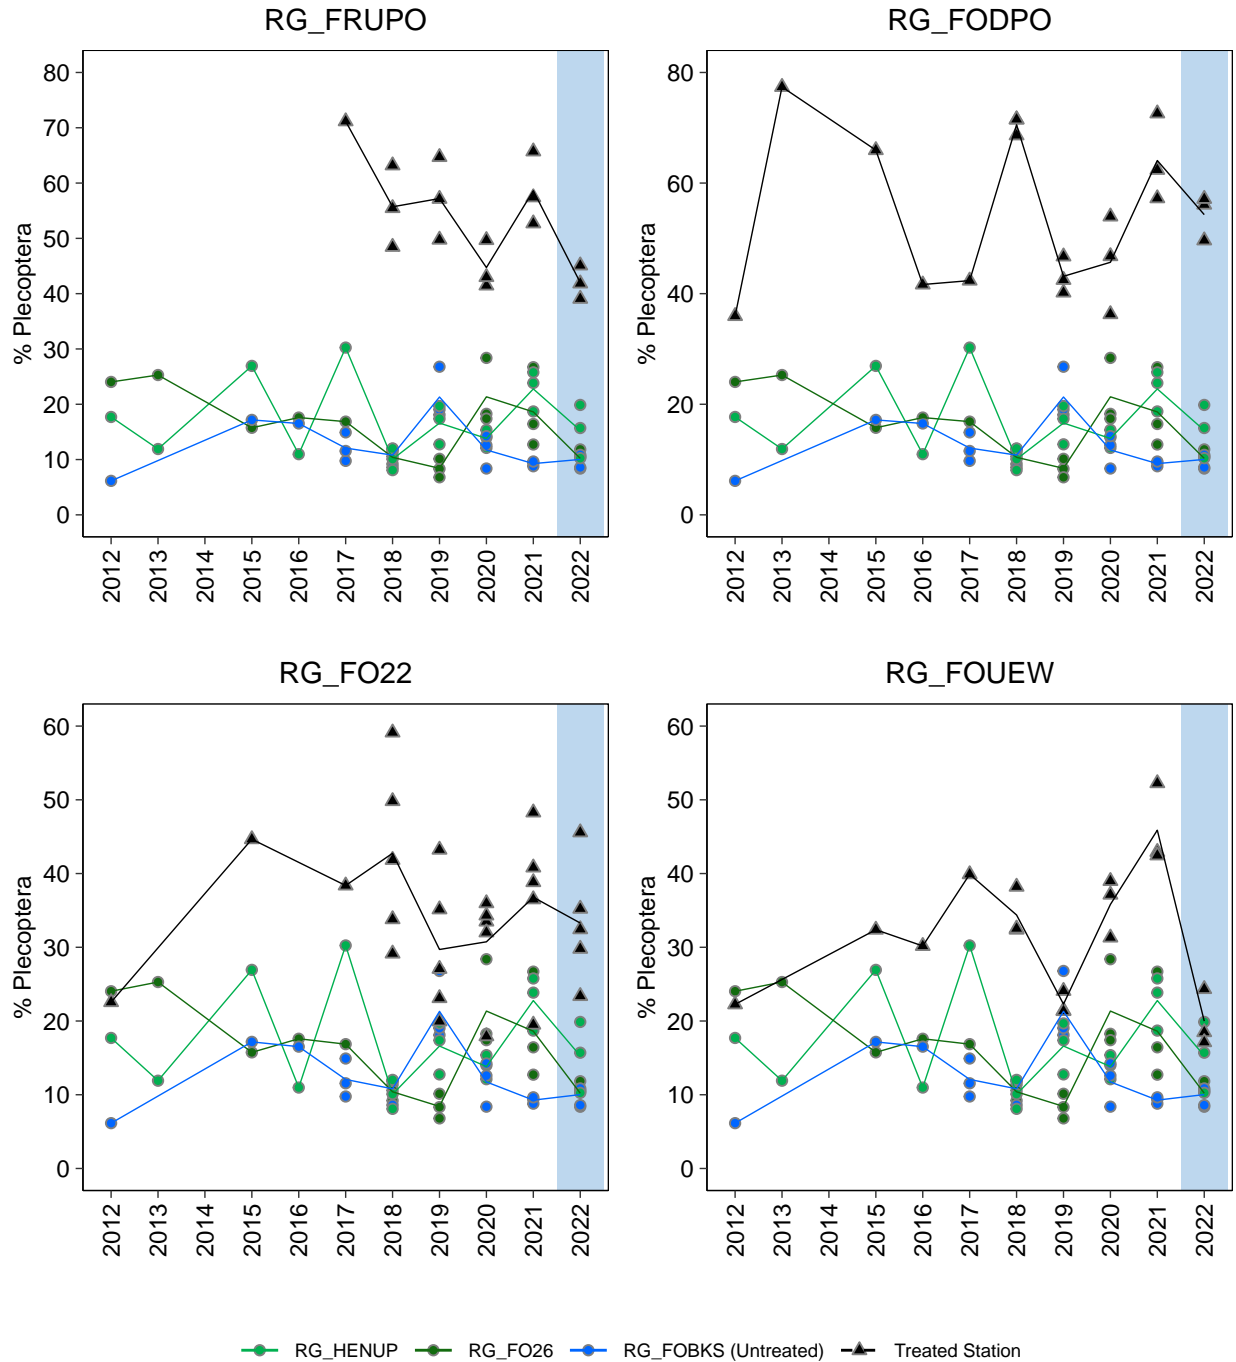

Figure G.38: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

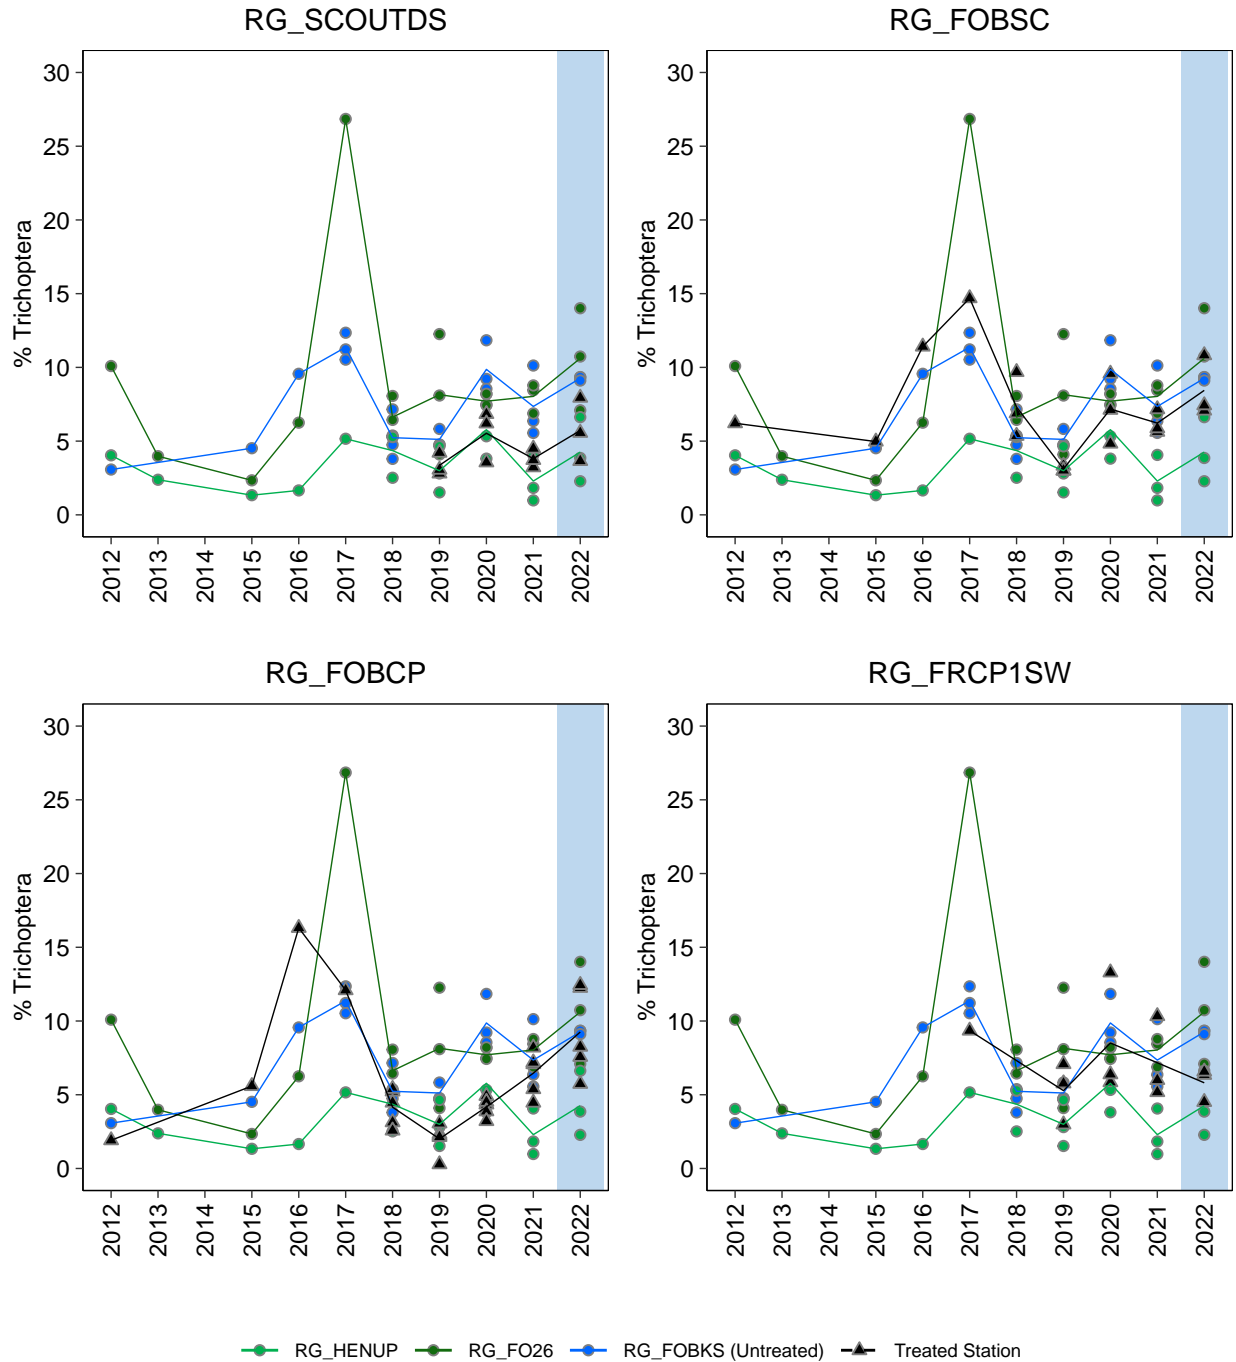

Figure G.39: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

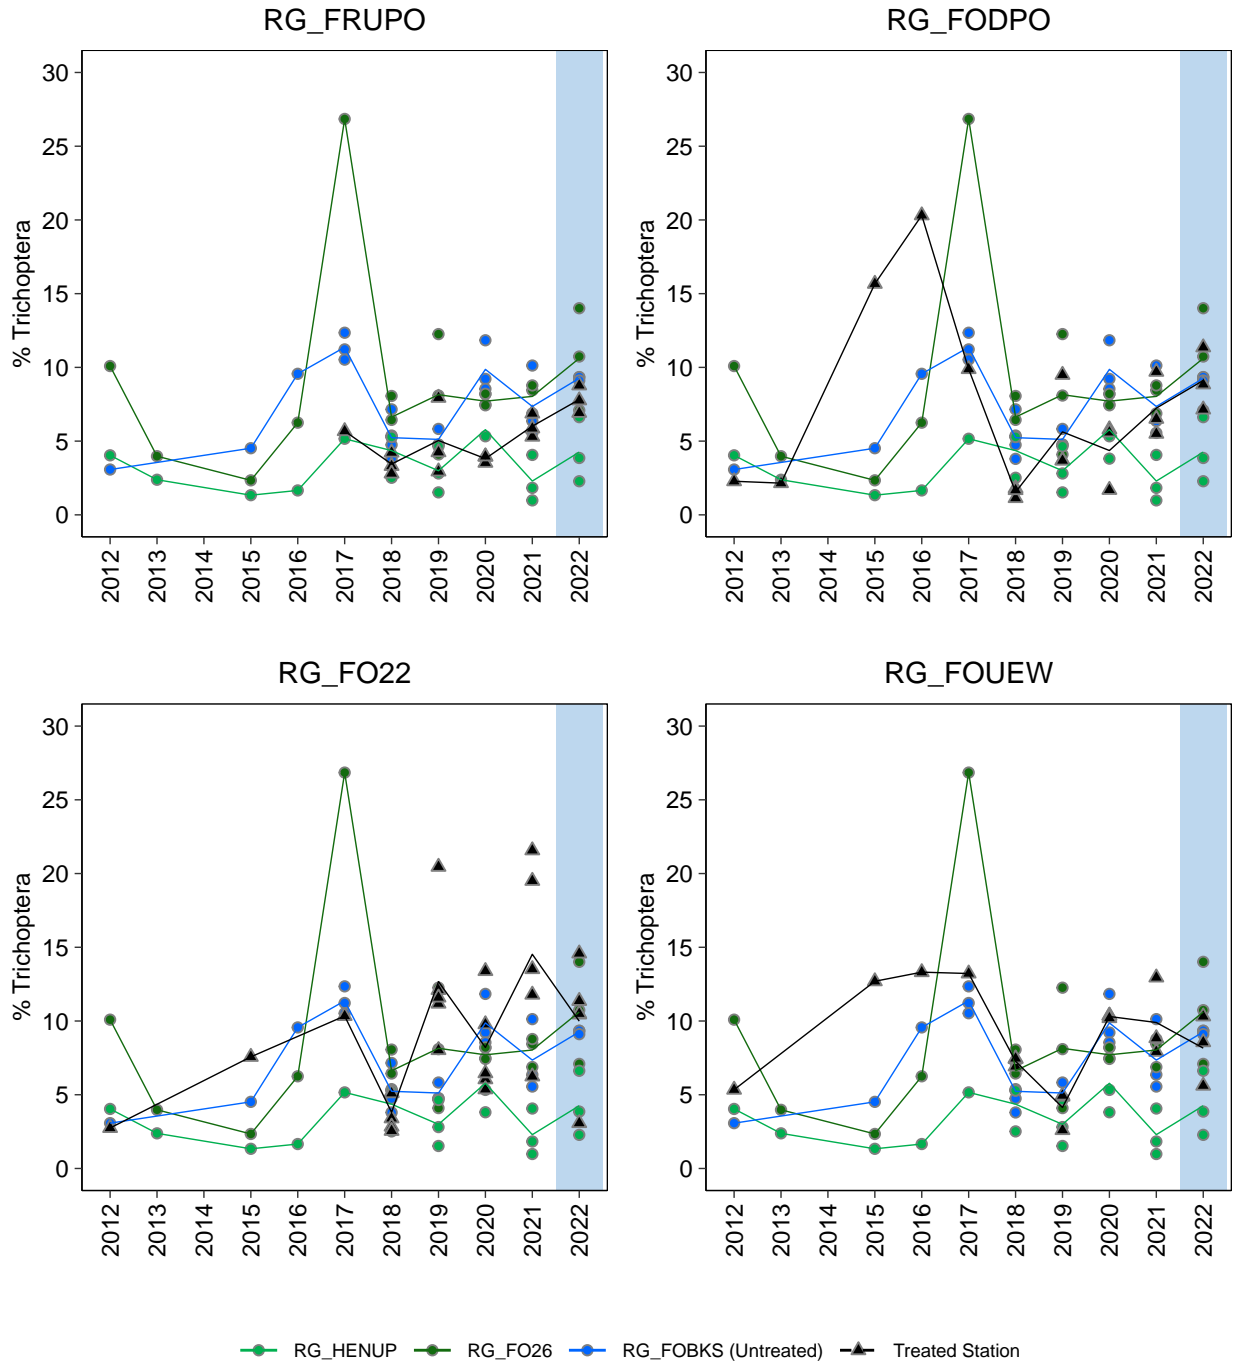

Figure G.39: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

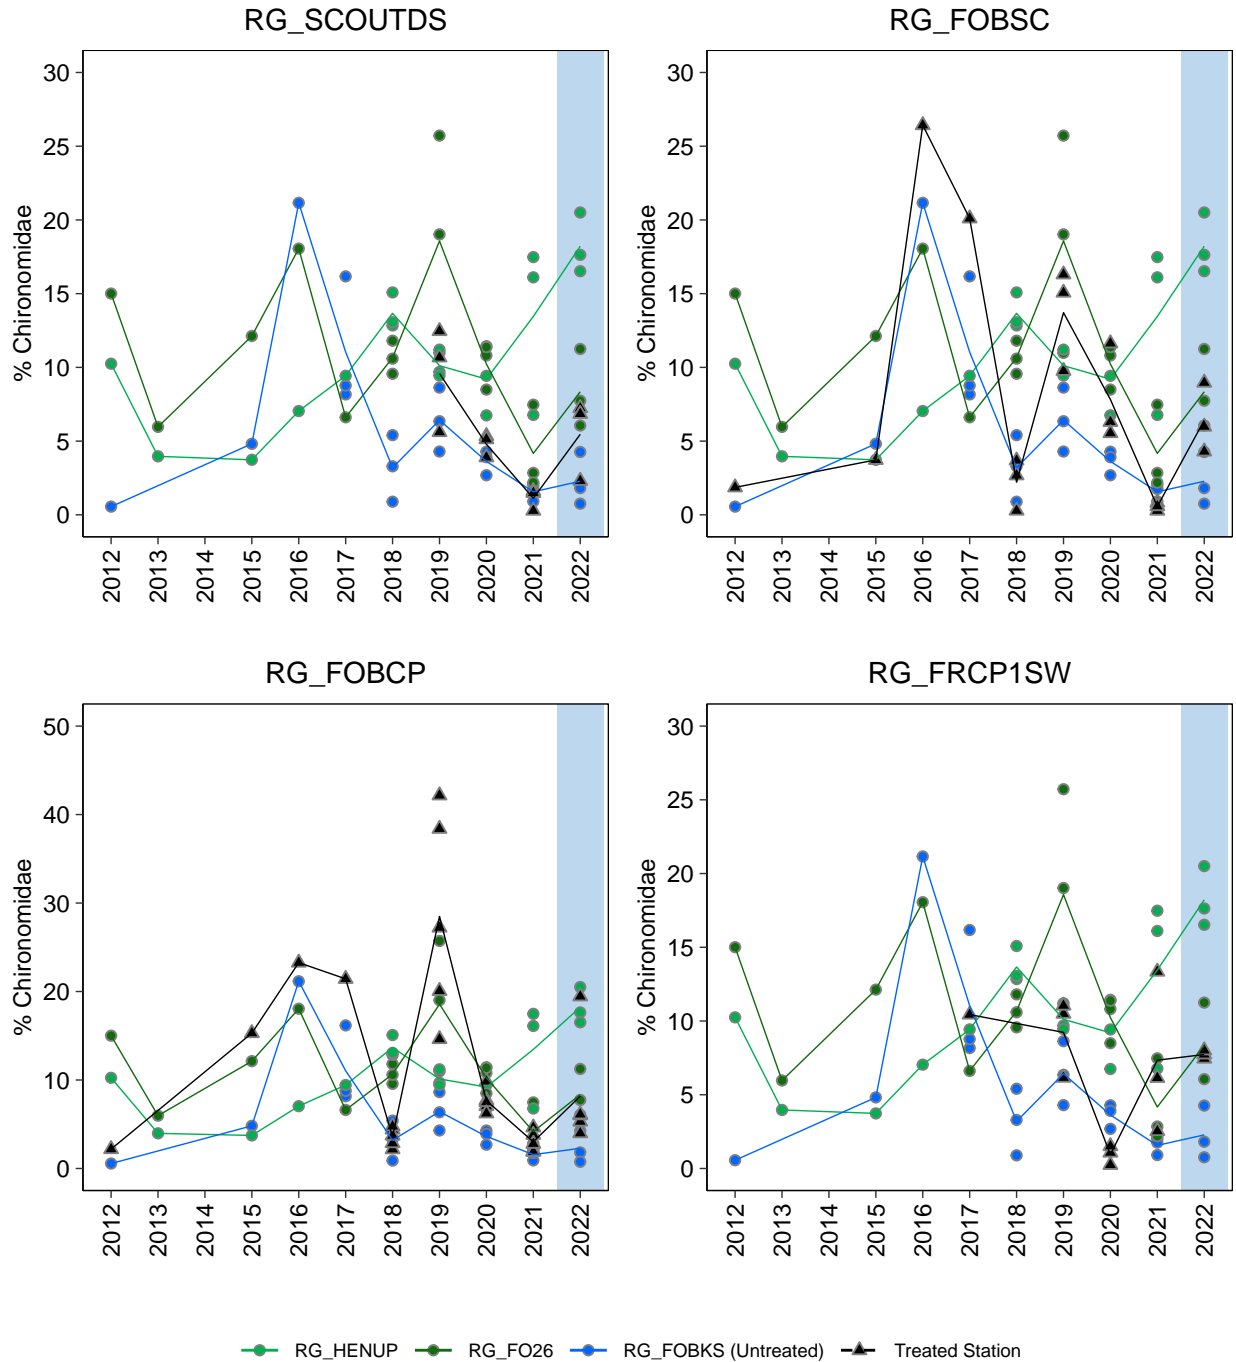

Figure G.40: Benthic Invertebrate Community Endpoints at Reference, Immediately Upstream of Treatment, and at Biological Monitoring Areas Downstream of Treatment, FRO LAEMP, 2012 to 2022

Notes: All data is shown, however only years with the treated station present were used in analysis. RG_FOBKS was the biological monitoring area immediately upstream of the FRO-S AWTF outfall, while RG_SCOUTDS was immediately downstream of the outfall. Green represents reference areas. Blue shading represents FRO-S AWTF operation.

Figure G.54: Composite-taxa Benthic Invertebrate Tissue Selenium Concentrations, FRO LAEMP, 2012 to 2022

Notes: Dashed black lines represent the normal range defined as the 2.5th and 97.5th percentiles of the 2012 to 2019 reference area data from the Regional Aquatic Environmental Monitoring Program (RAEMP). Green represents reference stations and blue represents mine-exposed stations. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line. Samples containing an Oligochaete in September 2022 and after are outlined in purple, samples prior to this date were not necessarily identified as having an Oligochaete. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

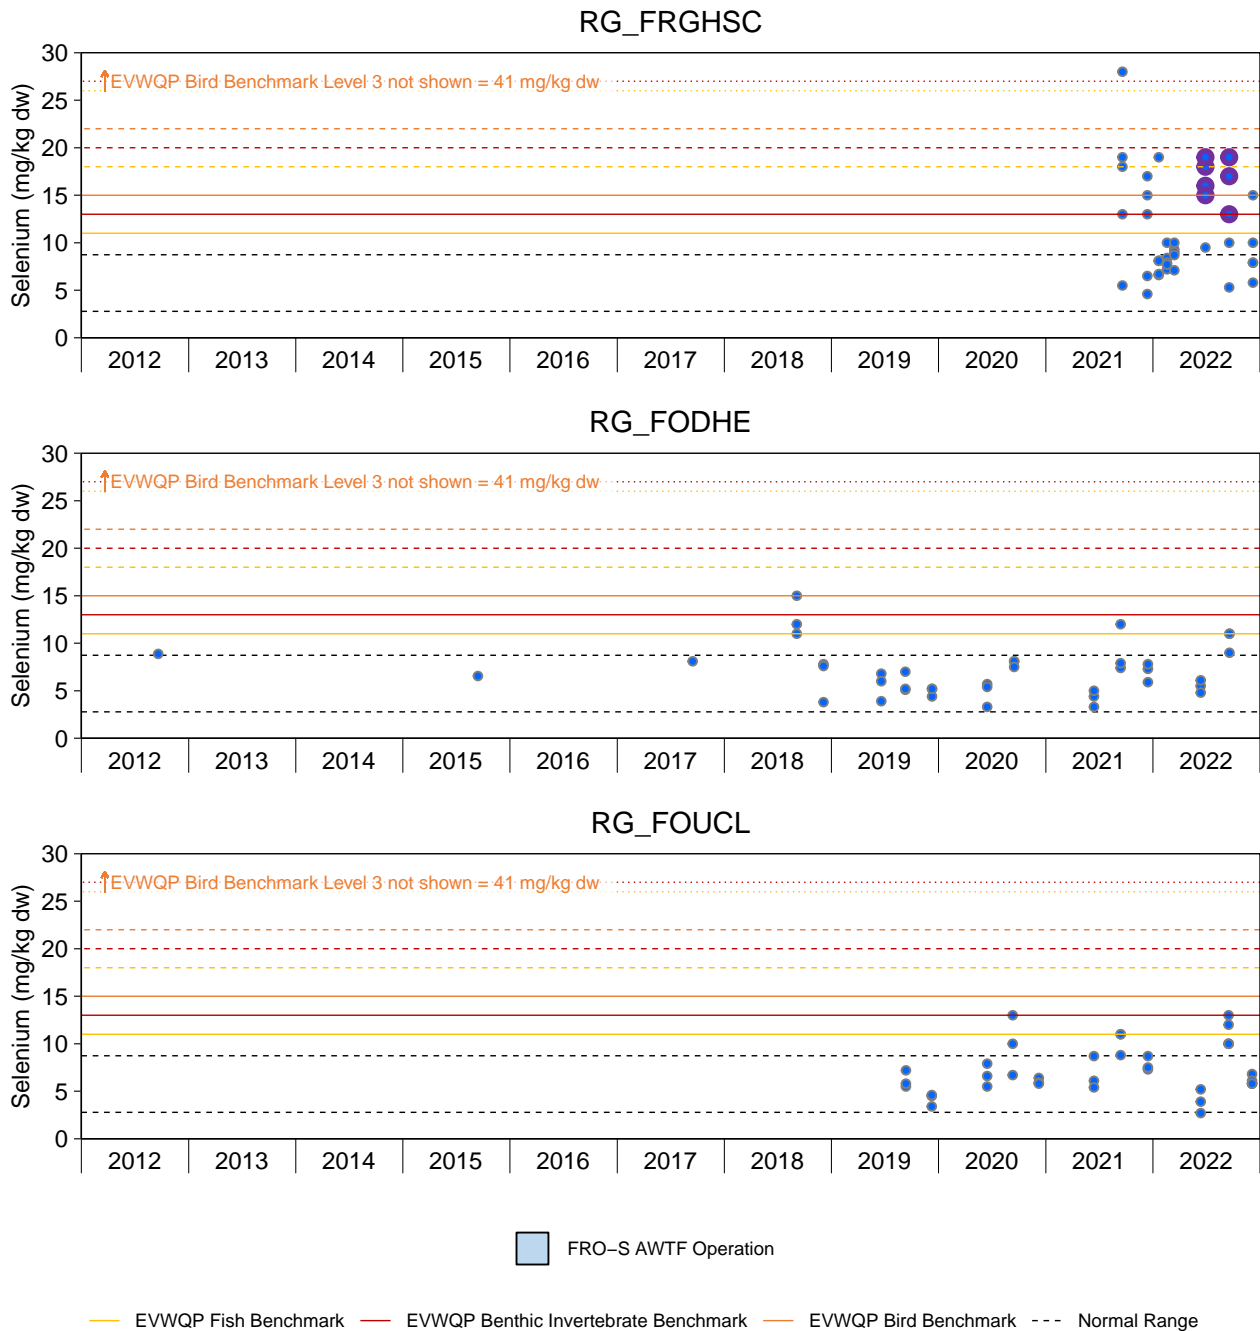

Figure G.54 Composite-taxa Benthic Invertebrate Tissue Selenium Concentrations, FRO LAEMP, 2012 to 2022

Notes: Dashed black lines represent the normal range defined as the 2.5th and 97.5th percentiles of the 2012 to 2019 reference area data from the Regional Aquatic Environmental Monitoring Program (RAEMP). Green represents reference stations and blue represents mine-exposed stations. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

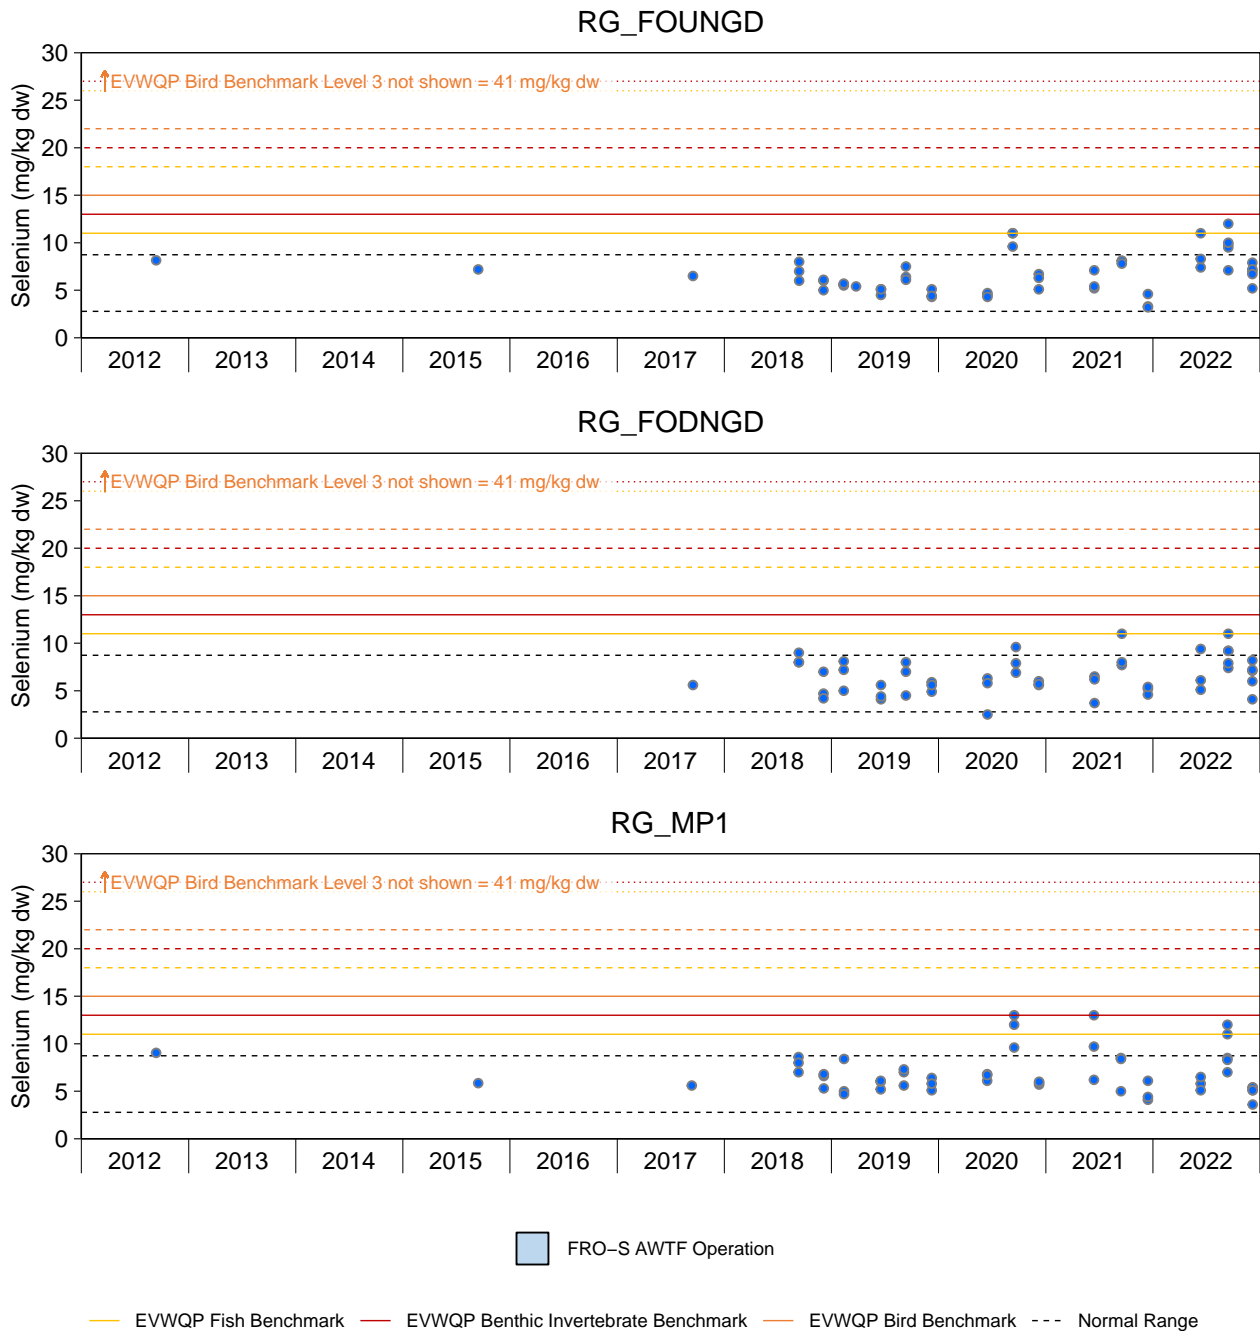

Figure G.54: Composite-taxa Benthic Invertebrate Tissue Selenium Concentrations, FRO LAEMP, 2012 to 2022

Notes: Dashed black lines represent the normal range defined as the 2.5th and 97.5th percentiles of the 2012 to 2019 reference area data from the Regional Aquatic Environmental Monitoring Program (RAEMP). Green represents reference stations and blue represents mine-exposed stations. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line. Samples containing an Oligochaete in September 2022 and after are outlined in purple, samples prior to this date were not necessarily identified as having an Oligochaete. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure G.56: Observed and Modelled Selenium Concentrations in Benthic Invertebrate Composite Samples Relative to Aqueous Selenium Concentrations at Stations Upstream and Downstream of Fording River Operations, FRO LAEMP, 2012 to 2022

Notes: Mean benthic invertebrate selenium concentrations (solid black line) were estimated using a one-step water to benthic invertebrate selenium accumulation model: $\log_{10}[\text{Se}]_{\text{benthic invertebrate}} = 0.717 + 0.072 \times \log_{10}[\text{Se}]_{\text{aq}}$ (Golder 2020). The 95% prediction limits for a single value from the one-step water to benthic invertebrate selenium accumulation model are plotted as dashed red lines. Grey filled symbols are pre-AWTF commissioning data. Coloured filled symbols are post-AWTF commissioning data, in which reference areas are shown in green. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

P-Value < 0.1.
 MOD < -2 SD.
 MOD > 2 SD.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = (MCTTreated After - MCTUntreated After) - (MCTTreated Before - MCTUntreated Before) / SD, where MCT = Measure of Central Tendency, and SD is the residual standard deviation of the model. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (i.e., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

P-Value < 0.1.
 MOD < -2 SD.
 MOD > 2 SD.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = (MCTTreated After - MCTUntreated After) - (MCTTreated Before - MCTUntreated Before) / SD, where MCT = Measure of Central Tendency, and SD is the residual standard deviation of the model. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (i.e., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

P-Value < 0.1.
 MOD < -2 SD.
 MOD > 2 SD.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = (MCTTreated After - MCTUntreated After)-(MCTTreated Before - MCTUntreated Before)/SD, where MCT = Measure of Central Tendency, and SD is the residual standard deviation of the model. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (i.e., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

- Value > EVWQP Level 1 benchmark of 11 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
- Value > EVWQP Level 2 benchmark of 18 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
- Value > EVWQP Level 3 benchmark of 26 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
- Value > EVWQP Level 1 benchmark of 13 mg/kg dw for effects to benthic invertebrates (Teck 2014).
- Value > EVWQP Level 2 benchmark of 20 mg/kg dw for effects to benthic invertebrates (Teck 2014).
- Value > EVWQP Level 3 benchmark of 27 mg/kg dw for effects to benthic invertebrates (Teck 2014).
- Value > EVWQP Level 1 benchmark of 15 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
- Value > EVWQP Level 2 benchmark of 22 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
- Value > EVWQP Level 3 benchmark of 41 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
- Value > upper limit of normal range of (8.74 mg/kg dw; Minnow 2020).

Note: '-' indicates sample that was not taken because it was not a part of the sampling design and/or because of drying and/or ice conditions. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO. Annelids were contained in composite samples collected from RG_FRGHSC (replicates 1, 2, 3, and 5), RG_FRCP1SW (replicate 2), and RG_FODPO (replicates 3, 4, and 5) in June, and RG_FRGHSC (replicates 1, 2, and 4) in September.

^a RG_UFR1 was used as a reference location in December when there was no access to RG_FO26 or RG_HENUP.

- Value > EVWQP Level 1 benchmark of 11 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
- Value > EVWQP Level 2 benchmark of 18 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
- Value > EVWQP Level 3 benchmark of 26 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
- Value > EVWQP Level 1 benchmark of 13 mg/kg dw for effects to benthic invertebrates (Teck 2014).
- Value > EVWQP Level 2 benchmark of 20 mg/kg dw for effects to benthic invertebrates (Teck 2014).
- Value > EVWQP Level 3 benchmark of 27 mg/kg dw for effects to benthic invertebrates (Teck 2014).
- Value > EVWQP Level 1 benchmark of 15 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
- Value > EVWQP Level 2 benchmark of 22 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
- Value > EVWQP Level 3 benchmark of 41 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
- Value > upper limit of normal range of (8.74 mg/kg dw; Minnow 2020).

Note: '-' indicates sample that was not taken because it was not a part of the sampling design and/or because of drying and/or ice conditions. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO. Annelids were contained in composite samples collected from RG_FRGHSC (replicates 1, 2, 3, and 5), RG_FRCP1SW (replicate 2), and RG_FODPO (replicates 3, 4, and 5) in June, and RG_FRGHSC (replicates 1, 2, and 4) in September.

^a RG_UFR1 was used as a reference location in December when there was no access to RG_FO26 or RG_HENUP.

- P-Value for relevant BACI term < 0.1.
- Increase in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25 %.
- Decrease in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25%.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = $(MCT_{Treated, after} - MCT_{Predicted, after}) / MCT_{Predicted, after} * 100\%$, where $MCT_{Predicted, After} = MCT_{Untreated, after} + (MCT_{Treated, Before} - MCT_{Untreated Before})$ and MCT = Measure of Central Tendency. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (i.e., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

- P-Value for relevant BACI term < 0.1.
- Increase in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25 %.
- Decrease in After Treatment Concentration for Downstream Area Relative to Upstream Area of > 25%.

Notes: "-" = P-Value not relevant, ns = non-significant. MOD = $(MCT_{Treated, after} - MCT_{Predicted, after}) / MCT_{Predicted, after} * 100\%$, where $MCT_{Predicted, After} = MCT_{Untreated, after} + (MCT_{Treated, Before} - MCT_{Untreated, Before})$ and MCT = Measure of Central Tendency. Measure of Central Tendency estimated as marginal means from the full interaction model. MODs represent the difference between the observed upstream vs downstream post-treatment (i.e., 2022) contrasts and expected upstream vs. downstream post-treatment contrasts. If the nested BA (Year) x Treatment term is significant, contrasts were calculated separately for each before year, otherwise the average of all before treatment years was used.

Table G.4: Statistical Comparison of Benthic Invertebrate Tissue Chemistry Upstream (RG_FOBKS) and Downstream of the Active Water Treatment Plant, FRO LAEMP 2018 to 2022

Treated Station	ANOVA MODEL					Post-Hoc Comparisons

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUUEW. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPLATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUW. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPLATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUUEW. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FRSC2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUFW. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

2022	08-Dec-22	82.9	08-Dec-22	7.00				
2022	08-Dec-22	82.9	08-Dec-22	6.40				

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPLATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUWE. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FRSC2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPLATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUW. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FRSC2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Table G.5: Paired Benthic Invertebrate Tissue and Water Selenium Concentrations for the FRO LAEMP, 2012 to 2022

Watershed	Exposure Status	Minnow Biological Monitoring Area	Associated Teck Water Monitoring Station Code	Year	Total Selenium in Water		Selenium in Tissue

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPLATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOU EW. Forward flow of the FRO-S AWTF on 23 December 2021. RG_FR SCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Note: "-" = no data. Forward flow of the FRO-S AWTF on 23 December 2021.

^a Values derived from Bruyn and Luoma (2021) using selenium speciation data and sulphate concentrations for each area on each date to predict benthic invertebrate tissue selenium concentrations. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Table G.7: Temporal Changes in Benthic Invertebrate Abundance for Reference and Mine-exposed Areas in the FRO LAEMP, September 2012 to 2022

Status	Area	Year P-value ^a	Q1. Is there a positive or negative change since the base year (b) of monitoring?											Q2. Is the 2022 September mean greater or less than the September historical means (2012 - 2021) and the previous year (2021)?

- P-value < 0.05.
- > 2 SD Increase.
- > 3 SD Increase.
- > 4 SD Increase.
- > 5 SD Increase.
- > 2 SD Decrease.
- > 3 SD Decrease.
- > 4 SD Decrease.
- > 5 SD Decrease.

- bold Significant increase or decrease from base year.
- ↑ Significantly > than all historical years (or 2020).
- ↓ Significantly < than all historical years (or 2020).

Notes: "ns" = not significant; "-" insufficient data for comparison.

^a Year p-value from an ANOVA.

^b Magnitude of Difference (MOD) = $[\text{Mean}_{\text{given year}} - \text{Mean}_{\text{base year}}] / \text{SD}_{\text{base year}}$

^c Significance among year determined using all pairwise comparisons using Tukey's honestly significant differences method. Years that share a letter are not significantly different. Letters assigned such that the mean with highest magnitude is assigned "a".

Table G.22: Selenium Concentrations in Benthic Invertebrate Tissue at RG_SCDSB, 2022

Replicate	Composite-taxa Tissue Selenium ($\mu\text{g/g dw}$)				
	1	2	3	4	5
Distance from outfall (m)	~30	~22	~14	~8	~6
RG_SCDSB	9.6	10	12	7.4	9.6

-  Value > EVWQP Level 1 benchmark of 11 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
-  Value > EVWQP Level 2 benchmark of 18 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
-  Value > EVWQP Level 3 benchmark of 26 mg/kg dw for dietary effects to juvenile fish (Teck 2014).
-  Value > EVWQP Level 1 benchmark of 13 mg/kg dw for effects to benthic invertebrates (Teck 2014).
-  Value > EVWQP Level 2 benchmark of 20 mg/kg dw for effects to benthic invertebrates (Teck 2014).
-  Value > EVWQP Level 3 benchmark of 27 mg/kg dw for effects to benthic invertebrates (Teck 2014).
-  Value > EVWQP Level 1 benchmark of 15 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
-  Value > EVWQP Level 2 benchmark of 22 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
-  Value > EVWQP Level 3 benchmark of 41 mg/kg dw for dietary effects to juvenile birds (Teck 2014).
-  Value > upper limit of normal range of (8.74 mg/kg dw; Minnow 2020).

APPENDIX

**INTEGRATED
ANALYSIS**

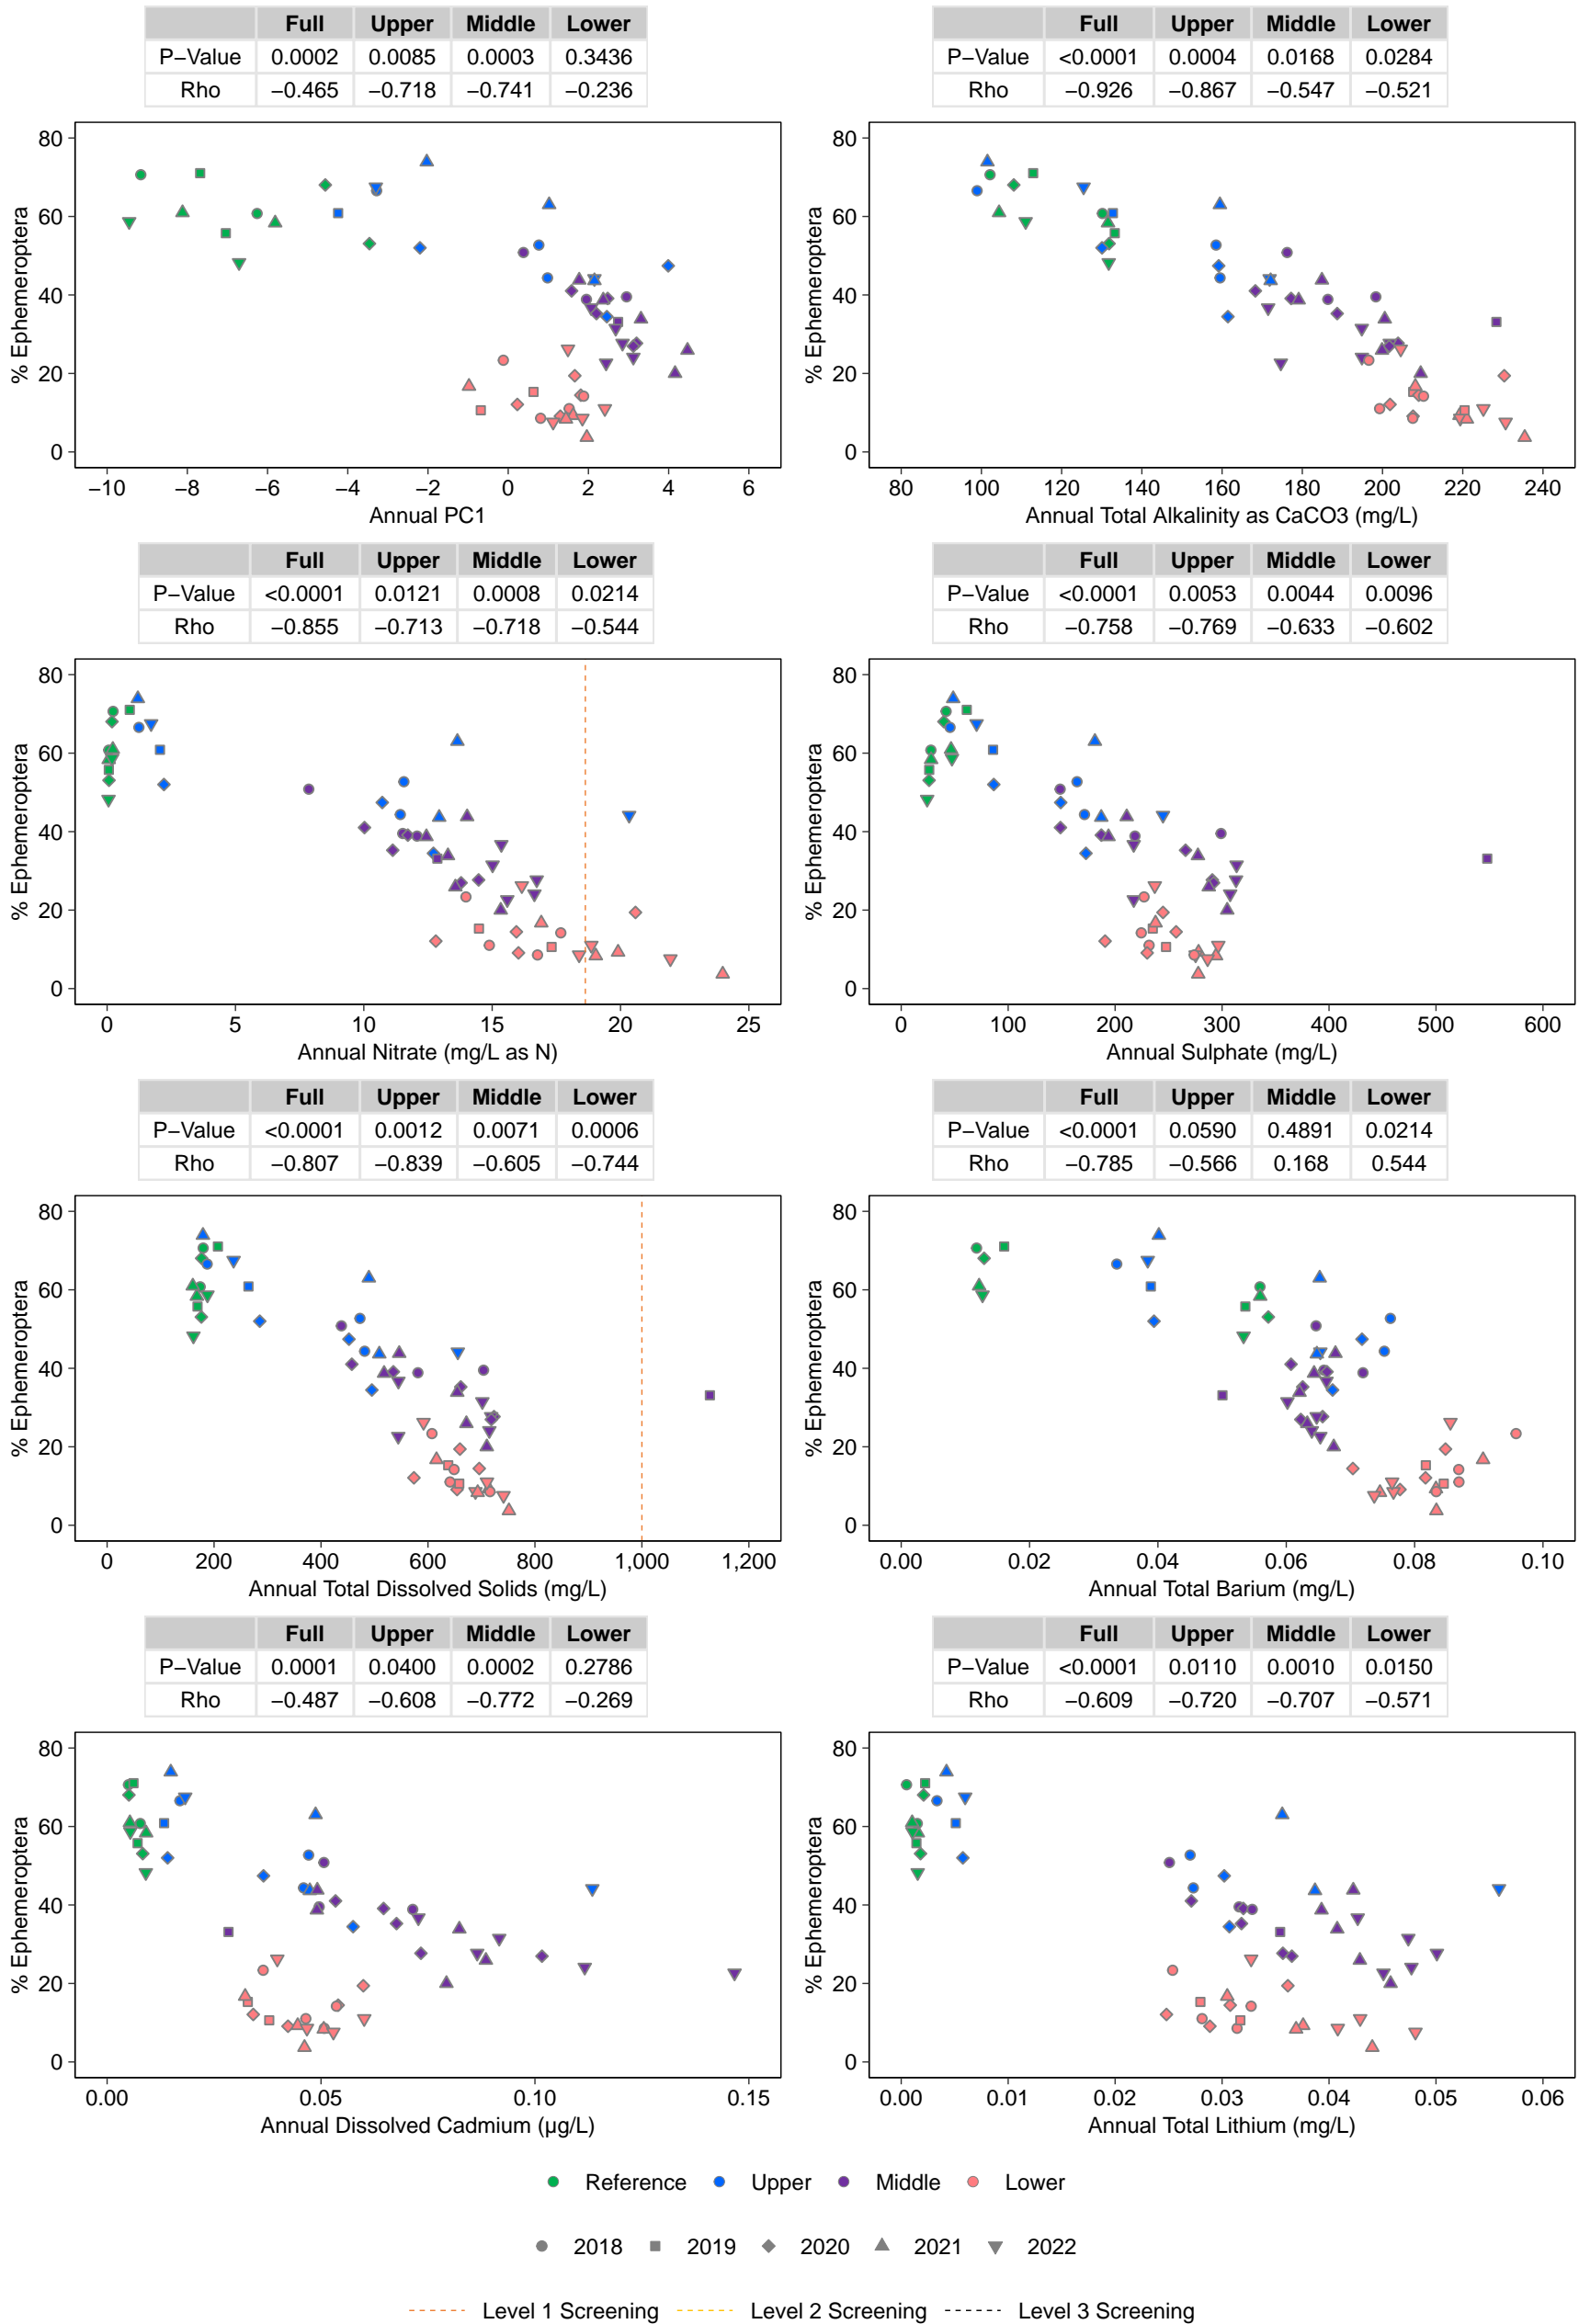

Figure : Scatterplots of Spearman's Correlation Relationships Between Benthic Invertebrate Community Metrics and Physical and Chemical Parameters, Fording River, 2018 to 2022

Notes: Only relationships with at least one relationship with a significant p-value and abs(rho) > 0.6 are displayed. The Full correlations included reference areas as well as the upper, middle, and lower areas. Annual = Averaged mean based on the previous year of water quality sampling (see methods for details). Levels 1, 2, and 3 Screening are Elk Valley Water Quality Plan (EVWQP) benchmarks for Total Dissolved Solid and Cadmium; Updated Effects Concentration for Nitrate and Sulphate; and Proposed benchmarks for Nickel. Screening values were not shown where measured water quality values were below benchmarks or concentrations and for constituents that have no benchmarks. Endpoint residuals represent the residuals of multiple regression models predicting the expected benthic invertebrate community given habitat at mine-exposed sites (RAEMP 2020a). Upper study area is defined as monitoring areas RG_FODHE to RG_FOUSH, middle study area is RG_FOUKI to RG_FRCP1SW, and the lower study area is RG_FRUPO to RG_FOUWEW.

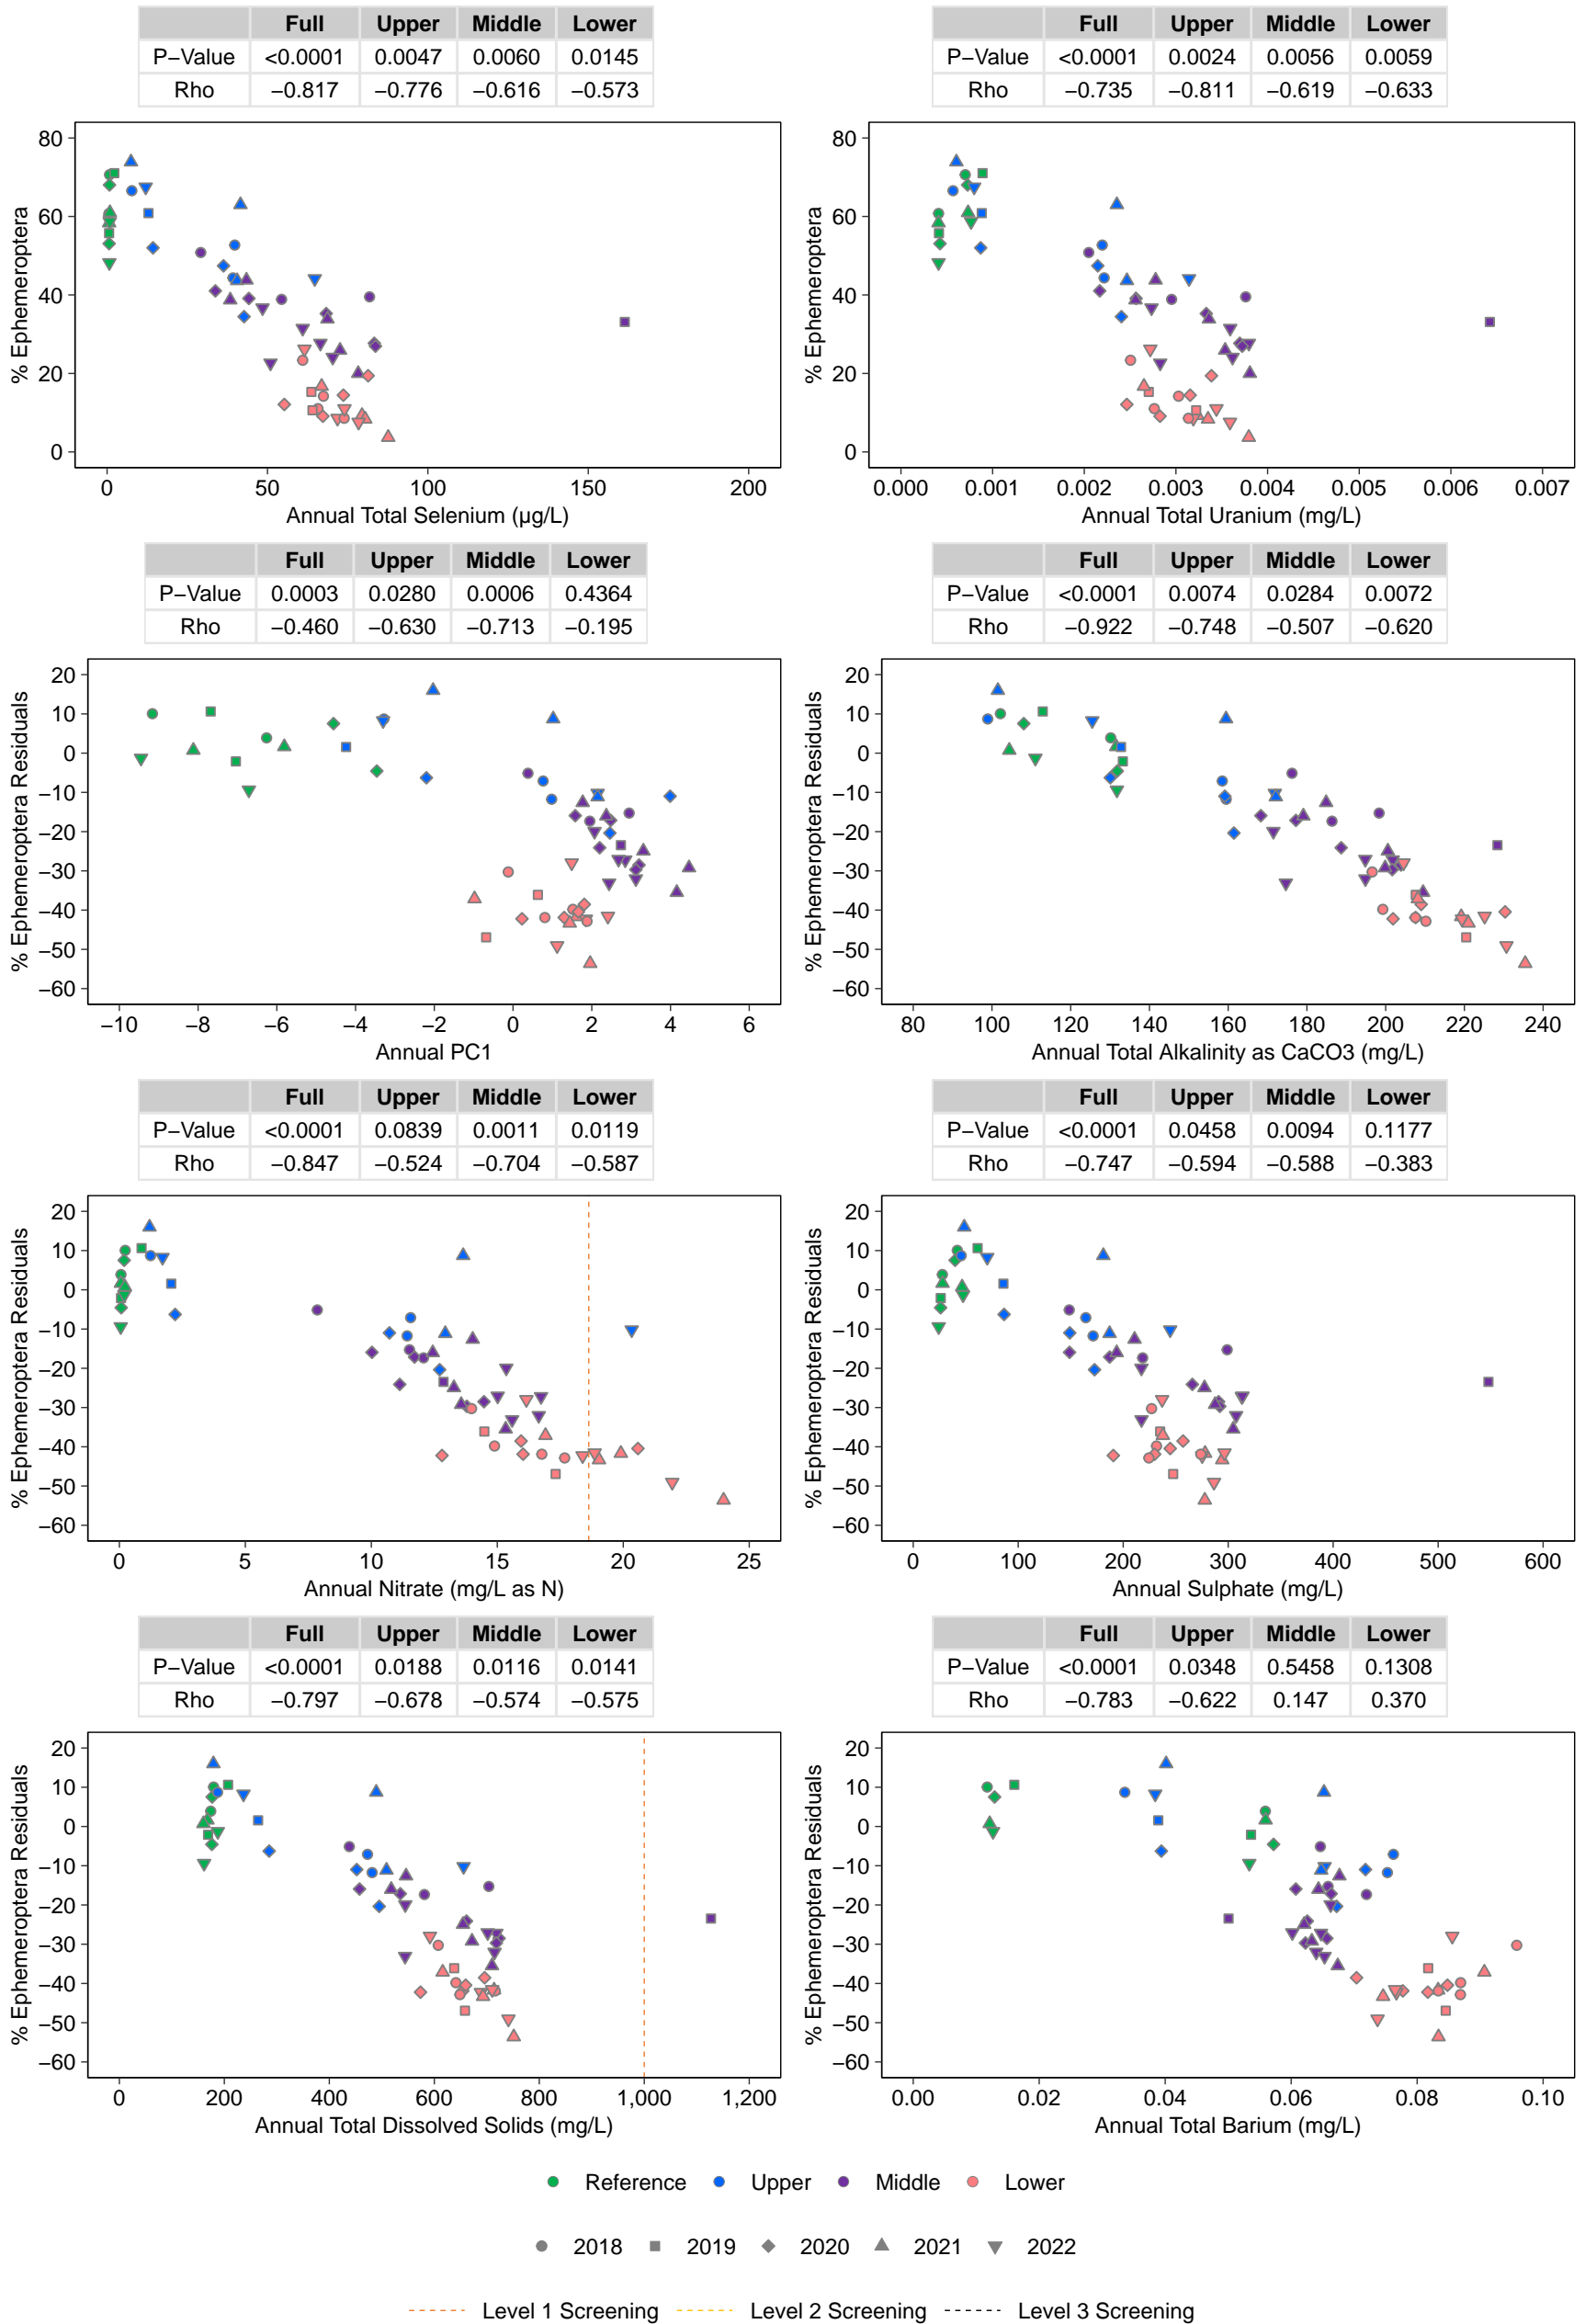

Figure : Scatterplots of Spearman's Correlation Relationships Between Benthic Invertebrate Community Metrics and Physical and Chemical Parameters, Fording River, 2018 to 2022

Notes: Only relationships with at least one relationship with a significant p-value and $abs(rho) > 0.6$ are displayed. The Full correlations included reference areas as well as the upper, middle, and lower areas. Annual = Averaged mean based on the previous year of water quality sampling (see methods for details). Levels 1, 2, and 3 Screening are Elk Valley Water Quality Plan (EWWQP) benchmarks for Total Dissolved Solid and Cadmium; Updated Effects Concentration for Nitrate and Sulphate; and Proposed benchmarks for Nickel. Screening values were not shown where measured water quality values were below benchmarks or concentrations and for constituents that have no benchmarks. Endpoint residuals represent the residuals of multiple regression models predicting the expected benthic invertebrate community given habitat at mine-exposed sites (RAEMP 2020a). Upper study area is defined as monitoring areas RG_FODHE to RG_FOUSH, middle study area is RG_FOUKI to RG_FRCP1SW, and the lower study area is RG_FRUPO to RG_FOU EW.

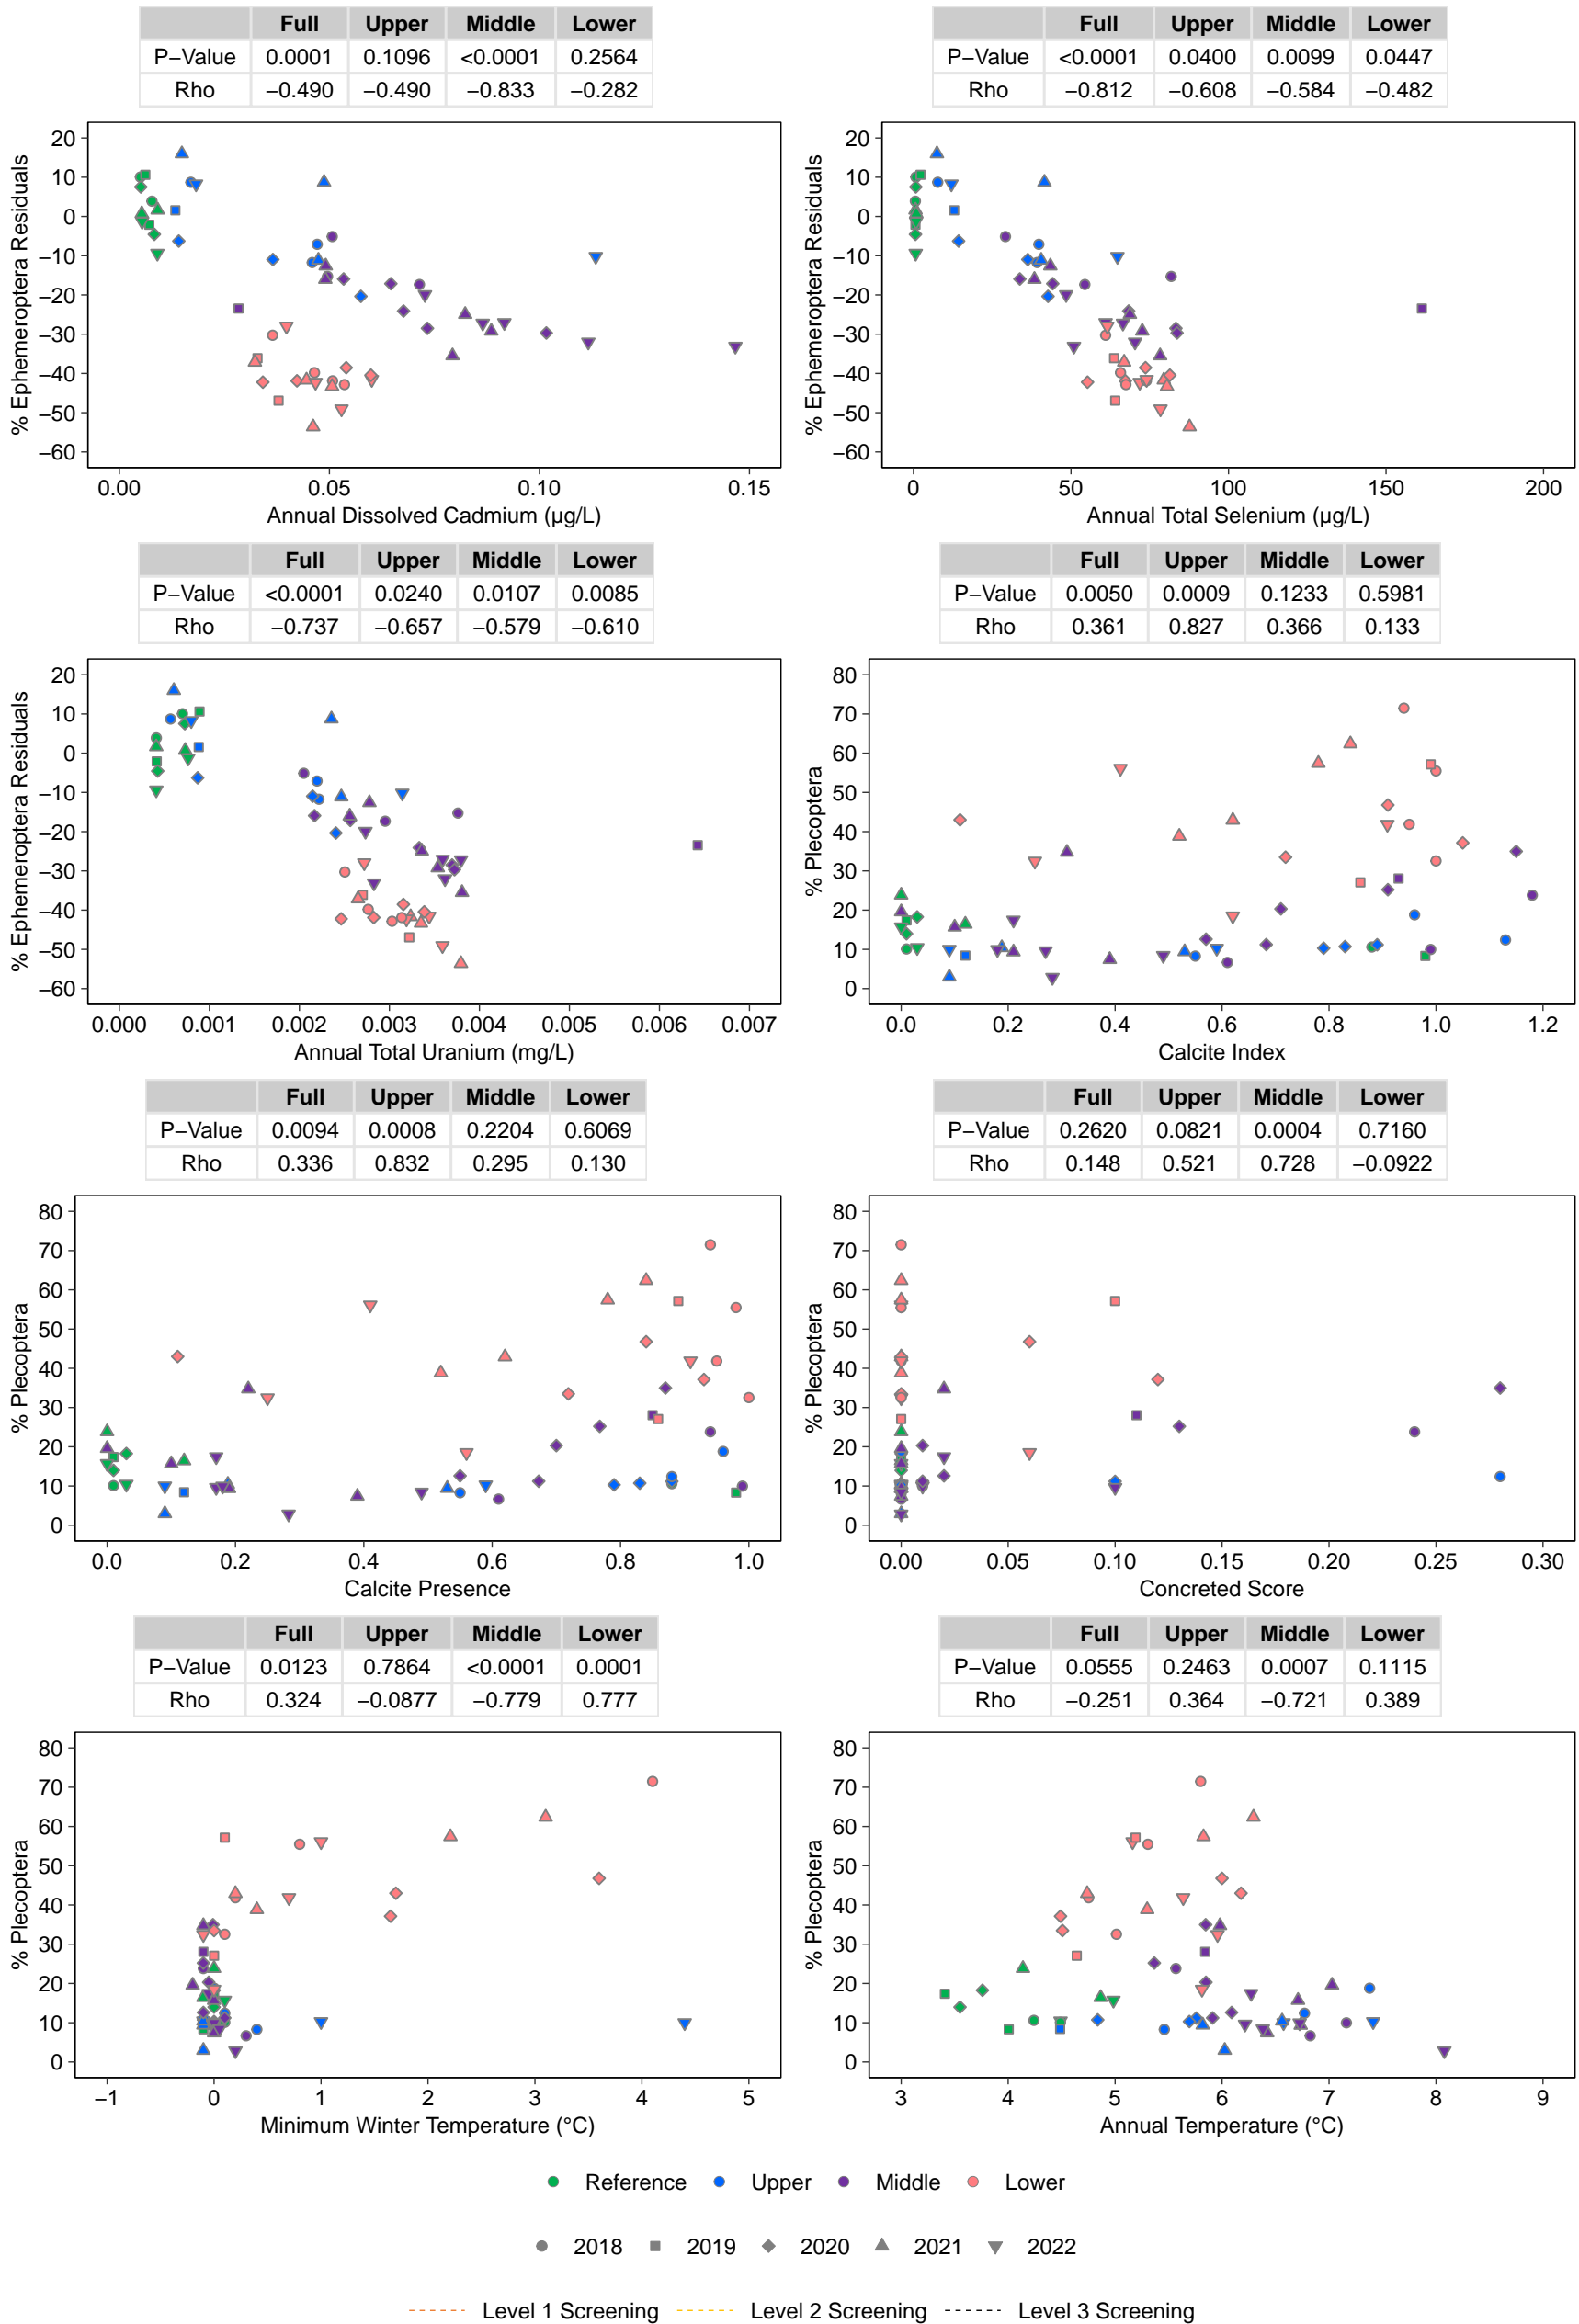

Figure 10 : Scatterplots of Spearman's Correlation Relationships Between Benthic Invertebrate Community Metrics and Physical and Chemical Parameters, Fording River, 2018 to 2022

Notes: Only relationships with at least one relationship with a significant p-value and abs(rho) > 0.6 are displayed. The Full correlations included reference areas as well as the upper, middle, and lower areas. Annual = Averaged mean based on the previous year of water quality sampling (see methods for details). Figure H.2: Heatmap of Spearman Correlation Coefficients of Benthic Invertebrate Community Endpoints against Physical and Chemical Parameters, Full Fording River, 2018 to 2022

Notes: Orange boxes show significant correlations (p -value $< 0.05/38$ for Bonferroni Correction), and red boxes show significant correlations with absolute coefficients > 0.6 . Cluster diagrams on x- and y-axis represent similarities using Euclidean distances clustered according to Ward's minimum variance method.

Figure H.3: Heatmap of Spearman Correlation Coefficients of Benthic Invertebrate Community Endpoints against Physical and Chemical Parameters, Lower Fording River, 2018 to 2022

Notes: Orange boxes show significant correlations (p-value < 0.05/38 for Bonferroni Correction), and red boxes show significant correlations with absolute coefficients > 0.6. Cluster diagrams on x- and y-axis represent similarities using Euclidean distances clustered according to Ward's minimum variance method.

Figure H.4: Heatmap of Spearman Correlation Coefficients of Benthic Invertebrate Community Endpoints against Physical and Chemical Parameters, Middle Fording River, 2018 to 2022

Notes: Orange boxes show significant correlations (p-value < 0.05/38 for Bonferroni Correction), and red boxes show significant correlations with absolute coefficients > 0.6. Cluster diagrams on x- and y-axis represent similarities using Euclidean distances clustered according to Ward's minimum variance method.

Figure H.5: Heatmap of Spearman Correlation Coefficients of Benthic Invertebrate Community Endpoints against Physical and Chemical Parameters, Upper Fording River, 2018 to 2022

Notes: Orange boxes show significant correlations (p-value < 0.05/38 for Bonferroni Correction), and red boxes show significant correlations with absolute coefficients > 0.6. Cluster diagrams on x- and y-axis represent similarities using Euclidean distances clustered according to Ward's minimum variance method.

Figure H.6: Variance Partitioning Between Habitat, Water and Calcite Using Partial Canonical Correspondence Analysis of Benthic Invertebrate Communities in September, FRO LAEMP, 2018 to 2022

Notes: Lowest Practical Level taxon abundances were $\ln(x+1)$ transformed prior to analysis. Taxa that made up less than 1% of total abundance (on the $\ln(x+1)$ scale) and occurred in fewer than 10% of samples were excluded from analysis. Mine-exposed areas included in the FRO LAEMP were divided into three sections from upstream to downstream: Upper Study Area, Middle Study Area, and Lower Study Area.

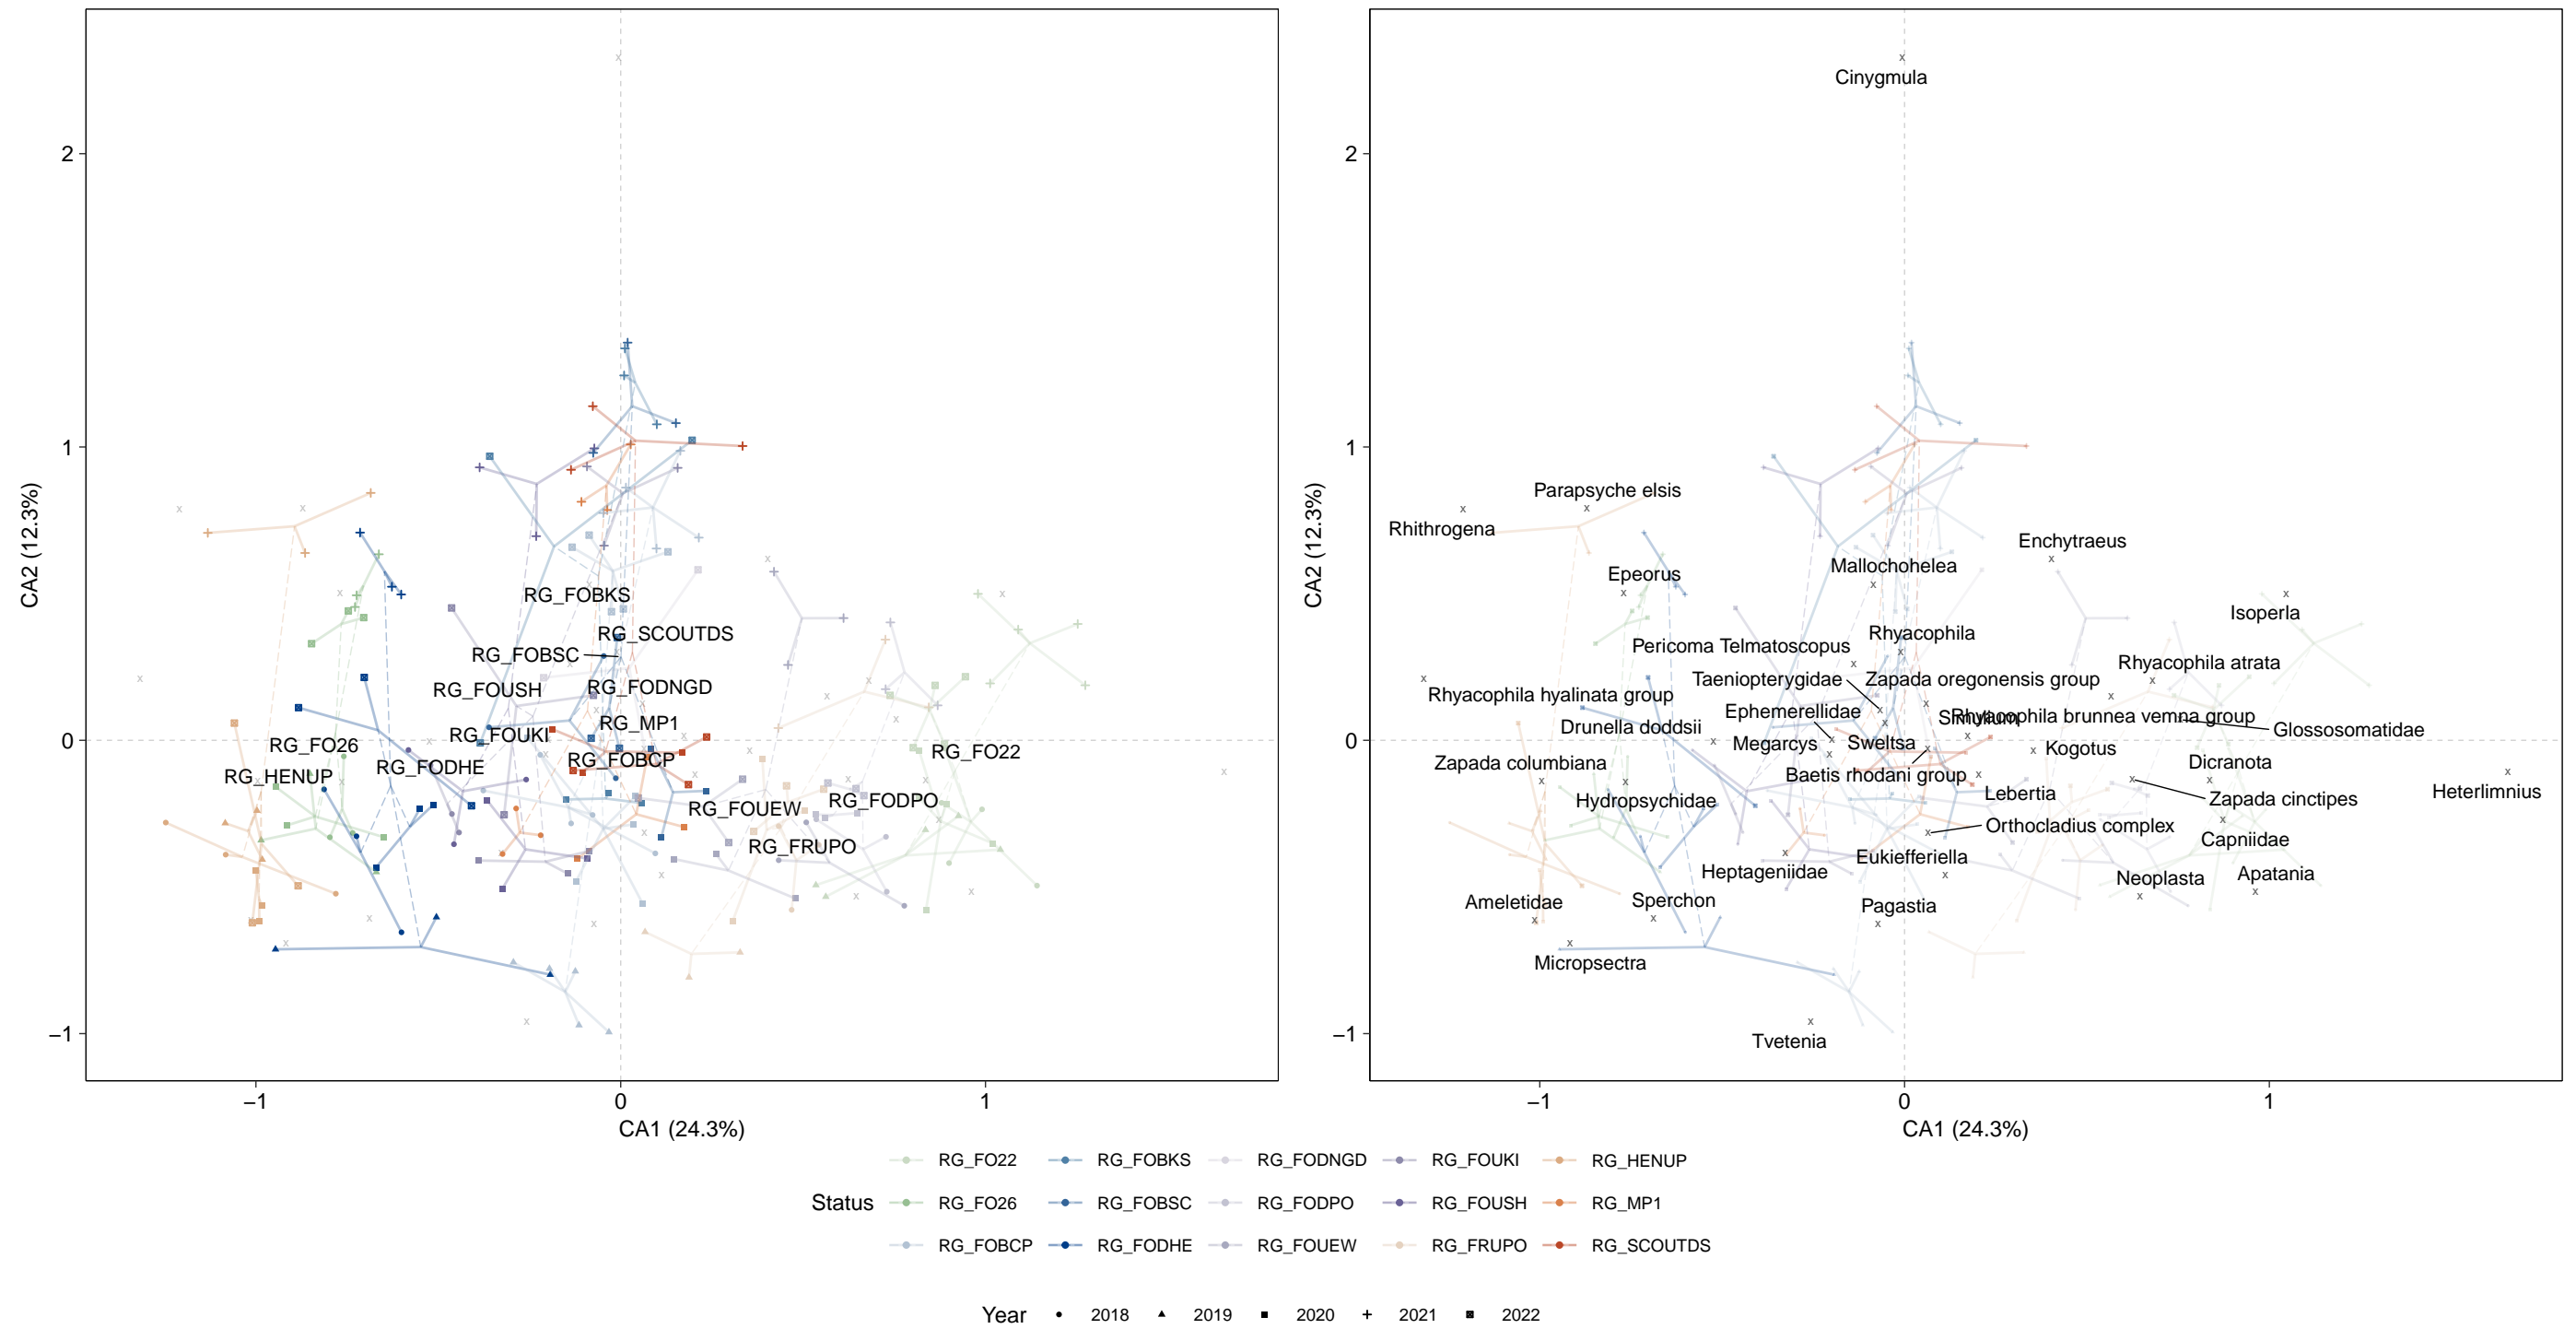

Figure H.7: Correspondence Analysis of Benthic Invertebrate Communities in September, FRO LAEMP, 2018 to 2022

Notes: Lowest Practical Level taxon abundances were $\ln(x+1)$ transformed prior to analysis. Taxa that made up less than 1% of total abundance (on the $\ln(x+1)$ scale) and occurred in fewer than 10% of samples were excluded from analysis. Mine-exposed areas included in the FRO LAEMP were divided into three sections from upstream to downstream: Upper Study Area, Middle Study Area, and Lower Study Area.

Notes: Cells are shaded only if the associated p-value from permutation based ANOVA was < 0.05. Shading is arranged from lightest to darkest according to percentile of F-Statistic distributions within each model to highlight which predictors most strongly influence Benthic Invertebrate Community responses. F-Statistics are shown for each term as Single and Marginal. Single represents the importance of the predictor in isolation of other predictors, while Marginal represents the unique contribution of the predictor to a model containing all other predictors. Predictors were analyzed in one of three Canonical Correspondence Analysis (CCA) models, a Habitat model containing landscape and site specific variables relating to instream and landscape habitat, a Stressor model containing water quality analyte concentrations and calcite variables, and a Stressor after Habitat model, which uses partial Canonical Correspondence Analysis (pCCA) to remove the effects of habitat differences, and explains the remaining variability using variables from the Stressor model. Taxa that made up less than 1% of total abundance (on the ln(x+1) scale) and occurred in fewer than 10% of samples were excluded from analysis. Only water quality analytes which contained fewer than 15% of values below Laboratory Reporting Limits (LRL) were included in the final model. Values below LRL were included at the LRL. All predictors were scaled by subtracting the mean and dividing by the standard deviation prior to analysis.

Proportional Calcite Index (CI')	0.05				

Notes: nm = not measurable, "-" indicates no data. Intermediate axis is the measurement across the intermediate axis of the pebble and presented in centimeters. Cp represents calcite presence score; Cc represents calcite concretion score; CI represents the calcite index determined by calcite presence; CI' represents calcite index determined by fraction of pebble covered in calcite.

Notes: "-" indicates that no calcite monitoring was completed.
 CI represents calcite index determined by presence and CI' represents calcite index determined by fraction of rock having calcite.

APPENDIX

WESTSLOPE CUTTHROAT TROUT (WCT) HEALTH

Figure J.1: Westslope Cutthroat Trout Muscle Selenium Concentrations, FRO LAEMP, 2021 and 2022

Notes: Green represents reference stations and blue represents mine-exposed stations. Muscle samples are plotted with a filled symbol and whole body samples are plotted with an open symbol. Gray shading represents the reference area normal range of lotic/lentic environments defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. M = Mainstream, T = Tributary, L = Lentic.

Notes: '-' denotes no data.

^aRG_FODCH in the present table are the same fish labelled RG_FODGH in Figures 3.21 and 3.23 as the fish were caught in the same general area and these fish move throughout this portion of the watershed. 'I3' is the code associated with anomaly severity assessment table developed in the RAEMP (Minnow 2021).

^b Observation is considered preliminary pending qualified personnel (QP) confirmation for the RAEMP.

K1 INTRODUCTION

K1.1 Background

Biological triggers were developed and implemented to assist with identifying and communicating unexpected and potentially important changes in aquatic ecosystem conditions and are required as part of Teck's Adaptive Management Plan (AMP; Teck 2018). Biological triggers were developed in consultation with the EMC for a subset of the biological monitoring endpoints that are effective indicators of changes at the ecosystem level. The purpose of the biological triggers is to quickly identify biological monitoring areas where unexpected biological conditions may be occurring that may require management action. Additionally, information provided from the analysis of biological triggers may lead to responses under the AMP response framework.

Draft biological triggers were developed in the 2018 AMP (Teck 2018) under Management Question 5, with these were initially reported on in the 2020 and 2021 Local Aquatic Effects Monitoring Program (LAEMP) reports and Regional Aquatic Effects Monitoring Report (RAEMP) data package, and summarized in the 2020 Annual AMP Report (Teck 2021a). When the 2018 AMP was approved, there was an expectation that the 2018 AMP draft/interim biological triggers would be finalized, through engagement with the EMC, prior to December 15, 2021 AMP Update. The biological triggers were finalized in 2021 (Teck 2021b) and the methods applied in this report reflect the finalized biological triggers. It is important to note that the process and/or biological triggers may adjust over time as the purpose of the biological triggers is to be reflective of not only changes in the Elk Valley, but also the current state of knowledge in the area.

The finalized biological triggers (Teck 2021b) include three measurement endpoints:

- Percent EPT (% EPT; Ephemeroptera, Plecoptera, and Trichoptera) – based on travelling kick samples (CABIN protocol), generally three replicates per location per sampling event.
- Benthic invertebrate tissue selenium (BIT Se) – generally several replicates collected per location per sampling event, where each replicate is a composite sample of invertebrates (i.e., composite-taxa sample).

- Westslope cutthroat trout muscle tissue selenium (WCT Se) – generally 8 replicates collected per location per sampling event, where each replicate corresponds to a sample from a single fish¹.

Evaluation of these three biological trigger endpoints is complementary to the fulsome evaluation of biological endpoints that is integrated into the LAEMP and the RAEMP data evaluations. The more fulsome evaluation of biological endpoints is used to support answering the specific LAEMP and RAEMP study questions through the consideration of not only the endpoints used in the biological trigger evaluation, but also a full suite of additional biological, chemical, and physical endpoints. Biological triggers do not provide information on cause and effect, report on trends, or feed directly into decision-making processes. Instead, the biological triggers act to flag areas for further evaluation, which would then take place under existing monitoring programs, through the development of supporting studies or through the response framework, as necessary.

Biological monitoring data are compared to triggers annually, and summaries of the LAEMP and RAEMP trigger evaluations and responses are included in the annual AMP reports.

¹ Fish tissue monitoring was excluded from the 2022 FRO LAEMP monitoring program in an effort to help reduce the potential for sampling stress on westslope cutthroat trout populations in related to FRO LAEMP monitoring activities.

K2 METHODS

K2.1 Overview

As outlined in Section K1.1, analyses for biological triggers are meant to be complementary to other analyses conducted in the LAEMPs and RAEMP. For the 2022 FRO LAEMP, biological trigger analyses only included two of the three measurement endpoints (%EPT and BIT Se) since fish tissue sampling is not part of the FRO LAEMP and is covered under the RAEMP.

For the purpose of application of the biological triggers, expectations for the endpoints evaluated (both the %EPT and BIT Se for the 2022 FRO LAEMP) were based on projected water quality, not on measured water quality. Thus, the triggers should detect biological results that were unexpected, regardless of whether those results are due to unexpected water quality or due to unexpected relationships between water quality and biological endpoints. Biological triggers were therefore only applied at locations where water quality projections were available. Specifically, six of the mine-exposed areas (RG_FODHE, RG_FOUKI, RG_FOBSC, RG_FOBCEP, RG_FODPO, and RG_FO22) and one reference area (RG_FO26) included in the FRO LAEMP were evaluated for biological triggers. Data for other areas studied under the FRO LAEMP (RG_HENUP, RG_UFR1, RG_FRGHSC, RG_FOUCL, RG_FRDSCC1, RG_FOUNGD, RG_FODNGD, RG_MP1, RG_FOUSH, RG_FOBKS, RG_SCOUADS, RG_FRCP1SW, RG_FRSCH2, RG_FRUPO, RG_FOU EW) were assessed elsewhere as part of the main FRO LAEMP report.

Methodological details are discussed for each of the biological trigger metrics below.

K2.2 Percent EPT

Data for percent EPT were compared to:

Normal range: The lower limit of habitat-adjusted normal range (2.5th percentile). Up-to-date limits of normal ranges² are provided in the RAEMP and LAEMPs, where they are recalculated as needed as new data become available (Teck 2019). The derivation of habitat-adjusted normal ranges is described in Appendix J of the 2017 to 2019 RAEMP report, and was based on consideration of more than 30 habitat, substrate, GIS, and land cover variables (Minnow 2020).

Expectations: The lower limit of the range of %EPT corresponds to the predicted aquatic data integration tool (ADIT) score. The predicted ADIT scores correspond to potential effects on

² The normal range will be updated as part of the three-year reporting cycle of the RAEMP (Minnow 2021b).

benthic invertebrate community (BIC) endpoints, based on relationships between water quality projections (for nitrate, sulphate and cadmium)³ and invertebrate toxicity endpoints originally developed for the Elk Valley Water Quality Plan (EVWQP; Teck 2014; Golder 2020a). A predicted ADIT score of 3 corresponds to 50% or greater effects to reproduction of the water flea *Ceriodaphnia dubia*, 2 corresponds to 20 to 50% effects, 1 corresponds to 10 to 20% effects, and 0 corresponds to effect levels of 10% or less. Once %EPT is actually measured, the measured results are converted to a measured ADIT score in relation to the habitat adjusted normal range as follows: An ADIT score of 0 corresponds to expected %EPT \geq the 10th percentile of the habitat-adjusted normal range; an ADIT score of 1 corresponds to expected %EPT between the 10th percentile and the 2.5th percentile of the habitat-adjusted normal range (and is therefore identical in application to the lower limit of normal range); an ADIT score of 2 corresponds to expected %EPT between the 2.5th percentile and half of the 2.5th percentile of the habitat-adjusted normal range; finally, an ADIT score of 3 corresponds to expected %EPT \leq half of the 2.5th percentile and \geq 0. Individual replicate habitat-adjusted normal ranges were used at each location for establishing the %EPT limits associated with each ADIT score. In summary, this component of the biological trigger for %EPT asks whether the measured ADIT score – calculated based on measured %EPT relative to normal ranges – is greater than the ADIT score that was predicted based on water quality projections.

Benthic invertebrate community data for %EPT collected in the fall (September) for the 2022 FRO LAEMP were included in the biological trigger analysis.

K2.3 Benthic Invertebrate Tissue Selenium (BIT Se)

Data for BIT Se were compared to:

Normal range: The upper limit of regional normal range (97.5th percentile) for individual replicates. Up-to-date limits of normal ranges⁴ are provided in the RAEMP and LAEMPs, where they are recalculated as needed as new data become available (Teck 2019).

Expectations: The upper limit of the 95% prediction interval based on the water to BIT bioaccumulation model for lotic environments. The model originally developed in the EVWQP (Golder 2014) was updated (Golder 2020b) and the updated data set was used to calculate prediction intervals for individual replicates. Methodology for estimating the upper limit of the 95% prediction for BIT Se (given any projected value of aqueous selenium) is discussed further

³ Selenium was not included because selenium effects on BIC endpoints are not expected. Projections were based on the highest maximum monthly mean across all flow scenarios (low, average, and high).

⁴ The normal range will be updated as part of the three-year reporting cycle of the RAEMP (Minnow 2021b).

in the Biological Trigger Development for the Elk Valley Adaptive Management Plan (Azimuth 2021 [In Preparation]).

Benthic invertebrate tissue selenium data from sampling events completed throughout 2022 for the FRO LAEMP (June, September, and December) were included in the biological trigger analysis although normal range information is based on fall (September) information. Samples included in biological trigger assessments also included those collected for the FRO-S AWTF commissioning sampling⁵ plan in January February and March and those collected for FRO-S AWTF investigative sampling⁶ in November.

Although effects benchmarks are not part of the trigger, they are relevant for interpreting potential significance and responses. Consequently, the level 1, 2 and 3 benchmarks for the most sensitive receptor (juvenile fish via dietary exposure) are included in plots (11, 18 and 26 mg/kg respectively).

⁵ Included RG_FOUKI, RG_FOBSC, RG_FOBCP, RG_FODPO, and RG_FO22.

⁶ Included RG_FOBSC and RG_FO22.

K3 RESULTS

K3.1 Percent EPT

Individual replicates for % EPT for each of the six mine-exposed areas (RG_FODHE, RG_FOUKI, RG_FOBSC, RG_FOBCP, RG_FODPO, and RG_FO22) as well as one reference area (RG_FO26) were each assessed against their respective biological trigger for the September sampling period (Appendix Table K.1 and Appendix Figure K.1). Except for RG_FODHE (2 of 3 replicates), all replicates from the biological monitoring areas assessed for biological triggers, including the reference area RG_FO26, had %EPT that were lower than the biological trigger (Appendix Table K.1 and Appendix Figure K.1). The biological monitoring area (RG_FOUKI) upstream of the Kilmarnock Creek confluence had the largest deviation from the habitat-adjusted normal range and 2.5th percentile prediction limit in 2022, which was driven by low abundances of both Ephemeroptera and Plecoptera.

K3.2 Benthic Invertebrate Tissue Selenium (BIT Se)

Benthic invertebrate tissue selenium concentrations for each mine-exposed and reference area were assessed against their respective biological trigger for individual replicate samples from each of the six sampling events in 2022 (January, February, March, June, September, November, and December; Appendix Table K.2 and Appendix Figure K.2). No samples at any of the biological monitoring areas exceeded the biological trigger (above the 97.5th percentile of normal range and above the 95% prediction interval) for tissue selenium concentrations, except at RG_FODPO where two samples exceeded the trigger but both of which contained oligochaetes (Appendix Table K.2 and Appendix Figure K.2), which are known to accumulate selenium more than other taxa (Luoma 2021).

Table K.1: Biological Trigger Analysis for %EPT in the Fording River, FRO LAEMP, September 2022

Waterbody		Area	Stream Type	Replicate	Reported Value	ADIT Value ^a	Lower 2.5th Percentile of the Habitat Adjusted Normal Range

			M	4	68.0	85.1	80.9
	M		5	57.6	84.5	79.7	

 Shaded cells signify individual replicates that were associated with a biological trigger (i.e. lower than both the ADIT value [as based on predicted water quality] and the lower 2.5th percentile of habitat-adjusted normal range).

Notes: M= Mainstem and T = Tributary.

^a All areas evaluated had an ADIT score of 0, which corresponds to the 80% lower limit of the expected %EPT (as based on water quality projections).

Figure K.1: Biological Trigger Analysis for % EPT Compared to Predicted Values, Fording LAEMP, September 2022

Notes: Black bars indicate the lower limit of the predicted ADIT score for the location. Blue dots represent values exceeding the trigger (below 2.5th percentile of NR and below lower limit of predicted ADIT score). Gray shading represents the habitat-adjusted normal range for each replicate. T = Tributary, M = Mainstem.

Shaded cells signify those individual replicates that were associated with a biological trigger (i.e. higher than both the upper 95% prediction limit [as based on predicted water quality] and the upper 97.5th percentile of normal range).

Notes: M= Mainstem; T = Tributary; dw = dry weight. Samples containing oligochaetes are highlighted in purple.

^a Denotes samples that contained annelids.

Notes: M= Mainstem; T = Tributary; dw = dry weight. Samples containing oligochaetes are highlighted in purple.

^a Denotes samples that contained annelids.

Figure K.2: Selenium Concentrations in Benthic Invertebrate Composite-Taxa Samples Compared to Predicted Values, Fording LAEMP, 2022

Notes: Black bars indicate the upper 95th prediction interval of the bioaccumulation model. Blue dots represent values exceeding the trigger (above the 97.5th percentile of normal range and above upper 95% prediction interval). Dotted lines indicate EVWQP benchmarks (11, 18, and 26 mg/kg respectively) for juvenile fish. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Samples containing oligochaetes are highlighted with a purple border.

K4 SUMMARY

Except for two of three replicates at RG_FODHE, all samples from both mine-exposed and reference areas exceeded the %EPT biological trigger in 2022. This represented an increase in the number of trigger exceedances compared to previous years (Minnow and Lotic 2021, 2022) and is consistent with other findings in the 2022 FRO LAEMP identifying a greater spatial extent of effects to BIC.

The biological trigger for benthic invertebrate tissue selenium concentrations was not exceeded at any of the biological monitoring areas in 2022, except for two replicates collected at RG_FODPO in June; however, both replicate samples exceeding the biological trigger contained oligochaetes which are known to accumulate selenium more readily than other taxa (Luoma 2021). Overall, results from 2022 were improved compared to 2021, as two replicates at RG_FOBSC in 2021 exceeded the biological trigger for benthic invertebrate tissue selenium concentrations and these exceedances could not be understood from assessment of aqueous selenium concentrations or composite-taxa samples.

As discussed in the main report, biological triggers are consistent with the findings of the FRO LAEMP. Current biological triggers were sufficient to identify monitoring areas where biological responses are occurring, based on the integrated assessment conducted in the LAEMP, and no additional triggers are recommended at this time. Uncertainty, however, remains around the cause of the observed % EPT response at multiple FRO LAEMP monitoring areas, as noted above. In an effort to resolve uncertainty around the combined and individual effects of water quality, habitat, and other mine-related stressors on benthic invertebrate communities in lotic areas in the Elk River watershed, Minnow is developing a predictive model for benthic invertebrate community endpoints, as recently discussed with the EMC in April 2023. Uncertainties are expected to be reduced through this modelling effort, and additional monitoring or potential management responses will continue to be assessed through the adaptive management process.

Figure

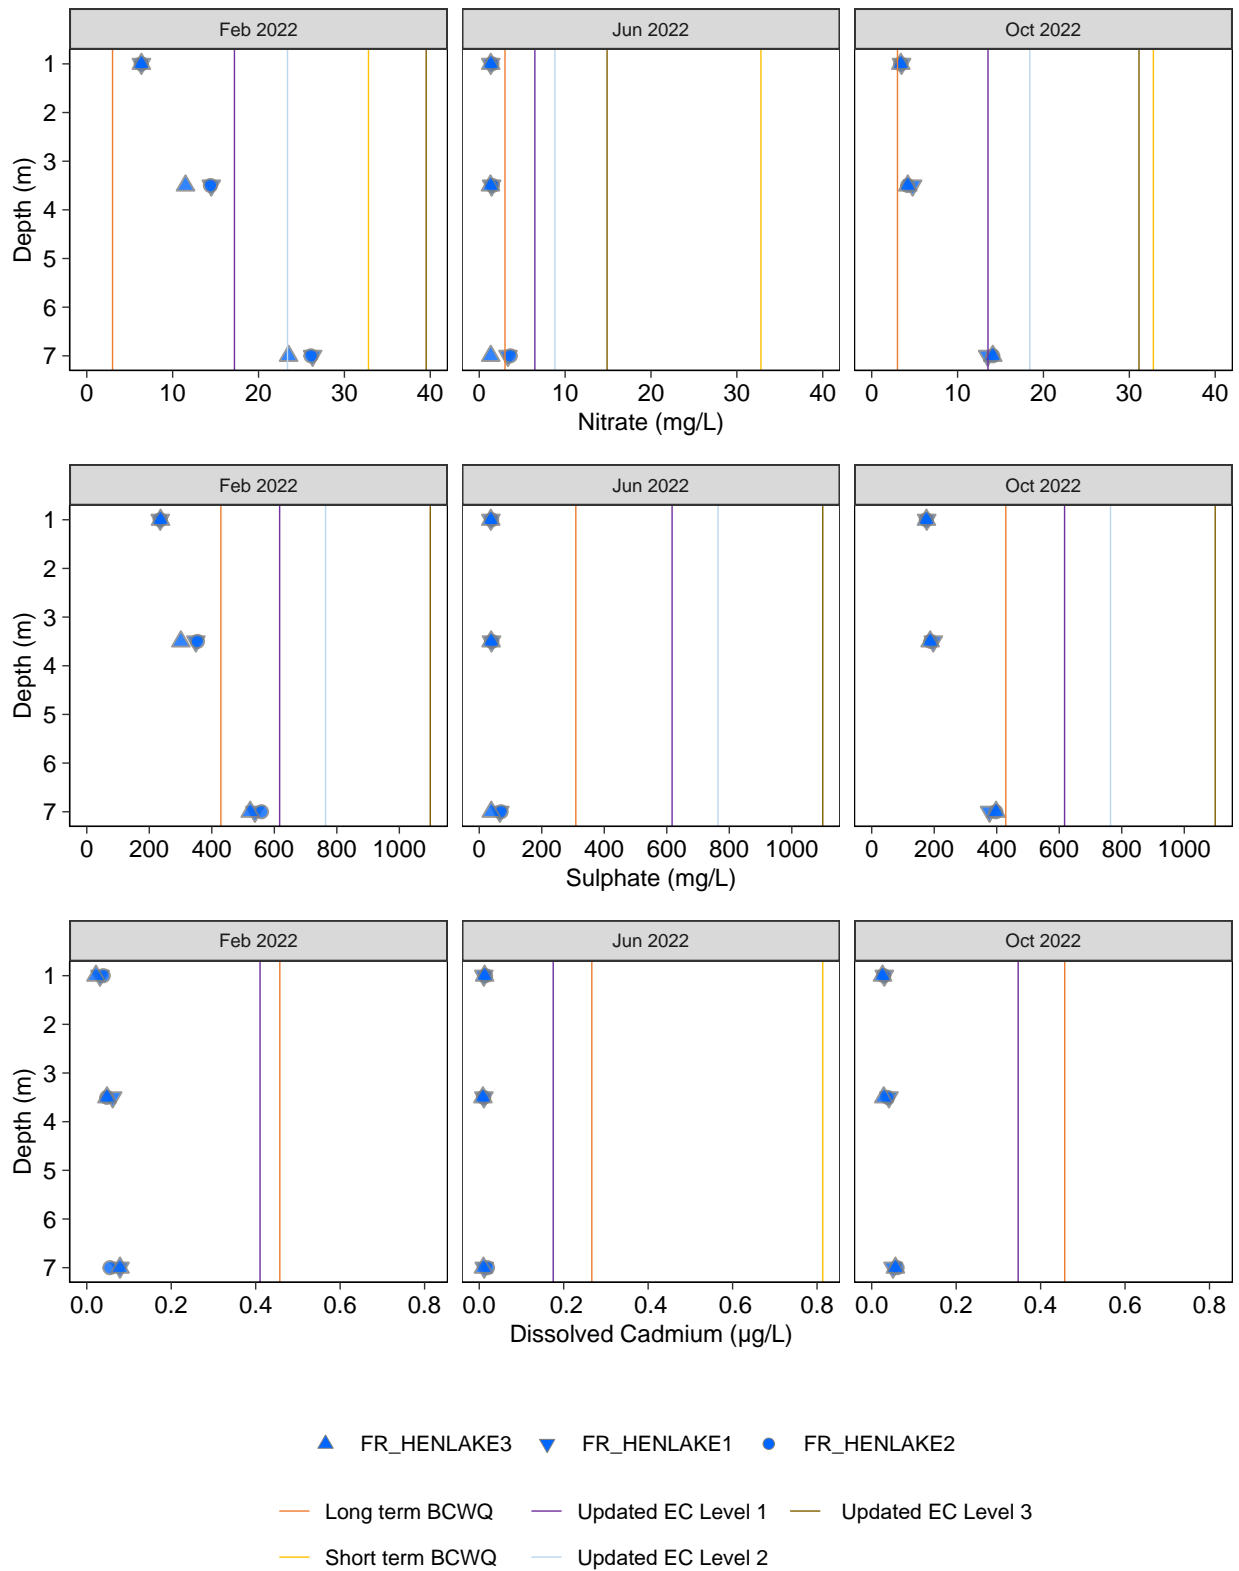

Figure : Selected Water Quality Concentrations in Henretta Lake, 2022

Note: 'EC' = Effects Concentration; Dissolved Cadmium is the only parameter with an EVWQP Benchmark shown instead of a UEC. The proposed benchmark for dissolved nickel was also applied. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Selenium speciation parameters that had 100 % censored data were excluded from the analyses.

Qualifier Legend

DLM Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
FR5 As per applicable reference method(s), soil:water ratio for Fixed Ratio Leach was modified to 1:5 due to high soil organic content

Results Summary CG2213498

Qualifier Legend

DLM Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
DTC Dissolved concentration exceeds total. Results were confirmed by re-analysis.
RRV Reported result verified by repeat analysis.

Qualifier Legend

DLM Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
RRV Reported result verified by repeat analysis.
TKNI TKN result may be biased low due to Nitrate interference. Nitrate-N is > 10x TKN.

Qualifier Legend

DTC Dissolved concentration exceeds total. Results were confirmed by re-analysis.
RRV Reported result verified by repeat analysis.
TKNI TKN result may be biased low due to Nitrate interference. Nitrate-N is > 10x TKN.

Dissolved metals filtration location			Field	Field	Field	Field	Field	Laboratory

Qualifier Legend

DLB Detection Limit Raised. Analyte detected at comparable level in Method Blank.
DLDS Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.
DTC Dissolved concentration exceeds total. Results were confirmed by re-analysis.
RRV Reported result verified by repeat analysis.
TKNI TKN result may be biased low due to Nitrate interference. Nitrate-N is > 10x TKN.

Dissolved metals filtration location			Field	Field	Field	Field	Field	Field	Field

Qualifier Legend

DLDS Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.
 DLM Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
 HTA Analytical holding time was exceeded.
 TKN TKN result may be biased low due to Nitrate interference. Nitrate-N is > 10x TKN.

Results Summary CG2212860

Qualifier Legend

DLDS Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.
DTSE Dissolved Se concentration exceeds total. Positive bias on D-Se suspected due to signal enhancement from volatile selenium species. Contact ALS if an alternative test to address this interference is required.
TKNI TKN result may be biased low due to Nitrate interference. Nitrate-N is > 10x TKN.

Qualifier Legend

DLDS Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.
DLM Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
TKNI TKN result may be biased low due to Nitrate interference. Nitrate-N is > 10x TKN.

Qualifier Legend

DLDS Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.
DTSE Dissolved Se concentration exceeds total. Positive bias on D-Se suspected due to signal enhancement from volatile selenium species. Contact ALS if an alternative test to address this interference is needed.
RRV Reported result verified by repeat analysis.

Qualifier Legend

DLDS Detection Limit Raised: Dilution required due to high Dissolved Solids / Electrical Conductivity.
 DLM Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
 RRV Reported result verified by repeat analysis.
 TKN TKN result may be biased low due to Nitrate interference. Nitrate-N is > 10x TKN.

Results Summary CG2217060

ND designation of a taxa represents a non-distinct taxa. This adjusts where the associated taxa fall in the metrics for this sample because the individuals are likely represented by Genus or Species level identifications.

APPENDIX A 2022 WATER CHEMISTRY DATA

1 INTRODUCTION

1.1 Background

In 2019 an assessment of the population of Westslope Cutthroat Trout (*Oncorhynchus clarkii lewisi*; WCT) within the Upper Fording River (UFR) indicated that a significant decline of sub-adult, adult, and juveniles occurred between 2017 and 2019 (Cope 2020). During this period, the juvenile and sub-adult/adult WCT are predicted to have been reduced by 74% and 93%, respectively (Cope 2020, EOC Team 2021). The limited availability of suitable overwintering habitat was identified as one of the stressors to the UFR WCT population that contributed to the population decline (EOC Team 2021). As long-term options are being developed through a Recovery Action Plan to address overwintering habitat and other issues affecting the population, there is concern that cold temperatures, decreased snowpack, or low flows during the winter could potentially result in further population losses by reducing the concentration of dissolved oxygen (DO) within overwintering habitat. Consequently, we have completed an evaluation of the risk to WCT in Henretta Lake and have identified what data is missing to help determine risk.

1.2 Henretta Lake and Overwintering Habitat

Henretta Lake is an online lentic habitat within Henretta Creek that was built as part of the lower Henretta Valley watershed reclamation during the mid-1990's (Pumphrey 2002) and has been identified as providing important overwintering habitat for WCT in the UFR (Cope et al. 2016). Since its construction, the feature has undergone significant morphological change, most notably the realignment of its inlet channel following the 2013 flood and a suspected reduction in average depth as a result of ongoing sediment deposition. Currently, the feature is an approximately 2.3-hectare lake with an average depth of 4.1 m and a maximum depth of 9.7 m (Teck 2021).

While Henretta Lake does provide good overwintering habitat for the WCT population in the UFR watershed (Cope et al. 2016), there is some risk associated with fish use of lakes in general. Concentrations of DO typically decrease over the winter as ice cover prevents gas exchange with the atmosphere and thus, the reoxygenation of the water column. In a lake system such as Henretta Lake, longer and earlier ice cover (e.g., Flaim et al. 2020, Zdorovenova et al. 2021), delayed ice off (Couture et al. 2015), incomplete overturn prior to ice formation (Wiltse et al. 2020), and/or enhanced biological or chemical oxygen demand (Wetzel 2001), can increase the risk of hypoxic or anoxic conditions at the bottom of the water column during the winter. Although the literature review conducted as part of the Evaluation of Cause found few cases of hypoxia-induced winterkill among trout populations and none to WCT (Ecofish 2021), prolonged hypoxia can result in other metabolic stresses to fish (e.g., reduced growth and food consumption; Rosenfeld 2022).

In addition to the risk posed by low DO concentrations, ice-covered lakes inversely stratify during the winter, with colder temperatures near the lake surface and approximately 4 °C water at the lake bottom. While temperatures below 2 °C are not unsuitable for overwintering adult WCT and are typical during the winter in the mainstem of the UFR, fry and small juveniles can be at risk if they have not grown enough to withstand metabolic deficits at low winter temperatures (Cunjak and Power 1987). The combined influences of low DO near the lake bottom and temperatures below 2 °C near the lake surface can reduce the availability of high-quality winter habitat and may pose additional indirect stressors to the WCT population (such as increased competition for resources; Ficke et al. 2007)

1.3 Objectives

This report provides a review of temperature and dissolved oxygen data collected in Henretta Lake between 2016 and 2022, with the specific focus of characterizing risk to Westslope Cutthroat Trout (WCT). The objectives of this review include:

1. Summarizing the oxythermal conditions in Henretta Lake using available *in situ* water quality data;
2. Identifying if current winter conditions present a risk to the Henretta Lake WCT population based on temperature-oxygen tolerances;
3. Outlining existing data gaps and providing recommendations to address these gaps.

2 FIELD DATA COLLECTION SUMMARY

2.1 Overview

Monitoring of Henretta Lake was conducted in the Winter of 2022 by Lotic Environmental to better characterize overwintering conditions. Continuous monitoring has also taken place within Henretta Lake during the Spring and Summer of 2022¹. Prior to 2022, monitoring of the physical and chemical characteristics of overwintering habitat (e.g., temperature, DO, conductivity) in Henretta Lake was infrequent, with winter field campaigns typically occurring as a snap-shot assessment involving multiple temperature-oxygen profiles collected on a single day.

2.2 Henretta Lake

Data collection varied in Henretta Lake between 2016 and 2022 with respect to the parameters collected, the temporal frequency of *in situ* measures, the depth interval at which data was collected, and the number of locations within Henretta lake that were assessed. The sampling completed in Henretta Lake included:

- 2016 – One temperature-oxygen profile was collected on February 22nd from nine locations within the lake. *In situ* measures of temperature, pressure, DO, conductivity, and pH were also collected at the lake inlet.
- 2020 – One temperature-oxygen profile was collected on February 27th from eight locations within the lake.
- 2021 – Temperature-oxygen profiles were collected on three dates in February. The profiles on February 12th (from three stations) and 14th (from four stations) were conducted to a maximum depth of 4 m. The final profiles were collected on February 17th (from nine station) to a maximum depth of 7 m. One profile was collected at each station, and supporting *in situ* measures of specific conductance, conductivity, pH and ORP were also collected.
- 2022 – *In situ* water quality profiles collected at 11 locations once a month in January, February, and March using a YSI PRODSS sonde (Brooks et al 2022). Measures were recorded at 0.5-m intervals under the ice with sampling areas ranging in depth from 1.0 to 8.5 m. Following ice out, a vertical chain of HOBO data loggers was installed to collect measures of temperature, oxygen, and conductivity at 6 depths in the water column (1.25 m, 2.5 m, 3.75 m, 5.0 m, 6.25 m, and 7.5 m). The loggers were deployed in May 2022 with the first data download occurring at the end of June 2022. Additional data

¹ The preliminary results of the summer sampling program have been incorporated as appropriate.

downloads occurred at end of August, September, and October 2022. On November 4, 2022, a sub-surface vertical chain of *in situ* loggers was deployed for the duration of the winter (i.e., the next time data will be retrieved from the deployment will be after ice-off in 2023). Water chemistry samples were also collected in February, March, June, and October² of 2022 for analysis of metals, nutrients, and major ions from three areas in Henretta Lake and at three depths (1.0 m, 3.5 m, and 7.5 m).

² Water chemistry data collected in October 2022 were not included in this report.

3 TEMPERATURE-OXYGEN DATA REVIEW

Temperature-oxygen profiles collected in February 2016 revealed that the water column was well oxygenated. Concentrations of DO in the top 7 m of the water column were above 7 mg/L in all sampling areas in 2016, and only one DO measure was below the recommended 5 mg/L DO criteria for the protection of aquatic life (recorded at a depth of 8.2 m). In 2020, all DO measures within Henretta Lake were greater than 10 mg/L. Interestingly, in both 2016 and 2020 the lake was not inversely stratified (i.e., warmer temperatures were observed at shallower depths).

During the winter of 2022, the water column of Henretta Lake was inversely stratified with the thermocline occurring at a depth of approximately 3 m in January and February. The top 3 m of the water column were well oxygenated during all sampling events (ranging between 8 and 10 mg/L); however, DO decreased abruptly below this depth to near anoxic conditions at the lake bottom. In January, DO concentrations decreased to below the critical threshold of 5 mg/L for the protection of aquatic life (BC MOE 1997) at depths below 3.5 m and decreased to < 2 mg/L at depth below than 5 m. In February and March, DO concentrations were typically < 1 mg/L below a depth of 5.5 m. The 2022 winter monitoring results are consistent with water quality profiles that were collected in February of 2021. Concentrations of DO from three site visits in 2021 documented near anoxic conditions typically below a depth of 4 m (Teck 2021). These data suggest there was a reduction in the amount of oxygenated WCT overwintering habitat in both 2021 and 2022 relative to 2016 and 2020; however, the amount (i.e., volume) of optimal WCT habitat within Henretta will be more accurately estimated following the detailed bathymetric survey that was conducted in November 2022.

The data-logger deployment in Henretta Lake in May 2022 presented unusual temporal and vertical trends in temperature and oxygen within the lake (Brooks et al. 2022), that were atypical of expected conditions following ice-out (Wetzel 2001). Specifically, the warmest temperatures, highest DO concentrations, and highest measures of conductivity were present at the bottom of Henretta Lake (at a depth of 7.5). In addition, measures of temperature and concentrations of DO increased over the month of May below a depth of 6.25 m, whereas the overlying water remained relatively well mixed. These unusual oxythermal dynamics may be indicative of a high-density water source, such as a groundwater intrusion, that would sink under the well-mixed epilimnion and result in isolated effects to hypolimnetic water quality. The atypical oxythermal regime was somewhat transient during early spring as an incomplete mixing effect occurred in the top 6 m of the water column between May 27th and 29th, 2022, and a full mixing event occurred between June 5th and 6th, 2022. The complete water column presented with uniform measures of temperature, oxygen, and conductivity following the June mixing event.

Large diel oscillations in oxygen concentrations were also recorded in Henretta Lake during May and June of 2022, which may be the result of diurnal fluctuations in photosynthesis and respiration, sediment oxygen demand, and/or variability in DO concentrations from groundwater sources. Throughout the logger deployment, DO concentrations only decreased to below 5 mg/L on 6 days out of the 55-day monitoring period, and only at a depth of 6.25 m. This suggests that hypoxia is not a concern for WCT populations following ice-out. In addition, the unique observation of warmer more oxygen-rich water near the lake bottom that occurred over the month of May had the potential to provide deep-water refuge for WCT in the spring immediately following ice off.

The temperature, oxygen, and conductivity data from July to October (summarized below) are presented in Brooks et al. 2022b, Brooks and Gordon 2022, and Brooks and Gordon 2022b. During July and August, temperatures at all logger depths warmed in Henretta Lake following the June mixing event (data presented in Brooks et al. 2022b). By early August, distinctly warmer temperatures were typically observed at a depth of 6.25 m relative to shallower loggers (temperatures logged at 1.25-m depth were only periodically above those observed at 6.25-m depth). Moving into September, temperatures at 6.25-m and 7.5-m depth were higher than rest of the water column above, with temperatures at 6.25-m depth slightly warmer than those measured at 7.5-m depth (data presented in Brooks and Gordon 2022). This phenomenon persisted until the last data download, at the end of October, despite cooling water temperatures measured at the lakes surface to a depth of 5 m (data presented in Brooks and Gordon 2022b).

The DO concentration data collected during July and August had increasingly large diel ranges which may have been the result of biofouling of the DO sensor. Following this result, copper cages were installed around the sensor to minimize algal growth and interference with the DO measures. Interestingly, September concentrations of DO were highest (and appear to be supersaturated) at a depth of 6.25 m. Warmer, more-oxygenated water at depth persisted into October, with DO concentrations eventually decreasing at a depth of 6.25-m to become more similar to the rest of the water column. During this period, the DO logger at a depth of 7.5 m was buried in the sediment and thus data associated with this logger was not interpreted.

Similar to conditions observed in early May, conductivity was highest at 6.25-m and 7.5-m depth. Conductivity progressively increased at the two bottom-most depth starting in mid-July and persisted until the final data download at the end of October. Collectively, warmer, more-oxygenated, and high-conductivity water observed in the bottom strata of Henretta Lake is suggestive of continued influence throughout the growing season. Logger data from the winter of 2023 will help to inform the dynamics of this water layer under ice.

Water chemistry samples were collected in Henretta Lake from three locations and at three depths (1 m, 3.5 m, and 7 m) in June 2022 (Appendix Table A.1). The average concentration of total phosphorus was 5.0 µg/L and the average concentration of nitrate was 1.86 mg/L with only subtle differences in concentrations observed between depths. These data suggest Henretta Lake is phosphorus limited and was well mixed during the June sampling event. Water chemistry was also collected during the winter of 2022 (four locations in February and 1 location in March) at the same three discrete depths in the water column. Total phosphorus concentrations were often below the 2 µg/L analytical detection limit during this period, and when detected, concentrations ranged from 2.2 to 26.8 µg/L. The highest total phosphorus concentration (26.8 µg/L) was detected in one sample at a depth of 7 m; however, concentrations in other areas of the lake at the same depth were much lower (ranging from below the analytical detection limit of 2 µg/L and 5.3 µg/L). Nitrate concentrations during the winter were elevated relative to summer conditions with an average surface concentration of 6.5 mg/L and an average bottom concentration of 26.6 mg/L in February.

In addition to nutrients, the concentrations of other water quality constituents also increased with depth in February 2022. Among constituents of interest (i.e., Order constituents and nickel), concentrations of nitrate, sulphate, total and dissolved cadmium, nickel, and selenium were highest in the water sample collected from 7-m depth (Appendix Figure A.1). Concentrations of sulphate and nickel also exceeded the Elk Valley Water Quality Plan (EVQWP) level 1 benchmark and level 1 interim screening value, respectively, at 7-m depth, and concentrations of nitrate exceeded the EVQWP level 1 benchmark at a depth of 4 m and the level 2 benchmark at a depth of 7 m. It is atypical to observe relatively higher concentrations of nitrate and sulphate under anoxic conditions (relative to the oxic surface waters) as nitrate should be reduced to ammonia and sulphate should be reduced to sulphide (Wetzel 2001). Concentrations of ammonia also increase with depth in February 2022 (Appendix Table A.1) and confirm anoxic conditions at depth in Henretta Lake. The water chemistry data, particularly nitrate and sulphate results, are further evidence of another input at depth in Henretta Lake.

The June water chemistry data had relatively consistent constituent concentrations with depth and were indicative of a well-mixed water column (Appendix Table A.2). These water chemistry data support the *in-situ* logger data which suggest a homogeneous water column following the early-June mixing event.

4 PRELIMINARY RISK ASSESSMENT

The preliminary data suggests that there is some risk to overwintering WCT in terms of the availability of suitable oxythermal habitat within Henretta Lake. Although concentrations of dissolved oxygen were lower at depth within Henretta Lake in 2021 and 2022 relative to observations in 2020 and 2016, there is still considerable area within the lake that has well oxygenated habitat at temperatures that are appropriate for overwintering WCT. Much of the appropriate habitat is found at the margins of the lake which is not of sufficient depth to stratify, and where fish can hold at the bed rather than being suspended in the upper water column.

Given the status of the population, there is value in continuing to sample in Henretta Lake to better understand risk to WCT as a result of potential seasonal decreases in well-oxygenated habitat. However, sampling should be tailored both in terms of the timing of surveys and the data that is collected to ensure that the highest risk to WCT is being characterized (i.e., sampling right before ice out), that the information is tailored to inform management decisions, and resources are being well allocated.

5 DATA GAPS AND RECOMMENDATIONS

5.1 Identified Data Gaps

Winter limnology is an area of emerging science that has traditionally been understudied as winter was often viewed as a “dormant” period of biological activity. As such, the complex interactions of abiotic and biotic factors that influence oxygen depletion during the winter are not well understood despite the known role under-ice processes play in shaping the physical and biological limnology during the ice-free season (Jansen et al. 2021).

In particular, primary production is poorly characterized in Henretta Lake, which prevents linkages being made between DO depletion and chemical/biological drivers. Algal growth is traditionally thought to be limited during winter months due to decreased light and external nutrient sources; however, anoxic conditions can enhance the release of bioavailable phosphorus (Nürnberg et al. 2019), which in turn, can promote growth of the under-ice phytoplankton community (Joung et al. 2017). High under-ice algal biomass has been documented even in areas where snow cover limits light penetration in the water column (Hampton et al. 2015). In a survey of temperate lakes, winter metrics of primary production were on average 43% of the values observed in summer (Hampton et al. 2017), suggesting that winter biomass may also drive hypolimnetic oxygen depletion under ice. Carry-over effects from the growing season may also have implications of winter DO depletion rates. Collectively, changes in primary production throughout the year may have profound consequences for lake oxygen dynamics and thus, habitat availability for fish (Ficke et al. 2007; Arend et al. 2011). Developing a better understanding of primary production in Henretta Lake also has broader implications for ecosystem health, and specifically the risk of selenium bioaccumulation for biota.

Understanding how temperature-oxygen dynamics is influenced by regional climate drivers is poorly understood in Henretta Lake. The concentration of DO in the hypolimnion at the onset of stratification is dependent on a variety of complex, and often interacting, physical and meteorological variables that include temperature, wind, fetch, and lake morphometry (Wetzel 2001, Smits et al. 2021). Regional air temperatures can indirectly influence hypolimnetic DO concentrations during the winter and summer when lakes are thermally stratified (Fang and Stefan 2009). Warmer air temperatures can result in reduced ice-cover (Preston et al. 2016, Sharma et al. 2021), promote earlier and longer stratification (Li et al. 2018, Richardson et al. 2017), and alter mixing regimes (Dugan et al. 2021), all of which can lead to longer or more severe periods of hypolimnetic DO depletion. Henretta Lake is typically well mixed during the summer; however, brief periods of stratification in shallow lakes can influence DO dynamics and result in temporary periods of anoxia or hypoxia (e.g., James 2017). Therefore, continued air

temperature increases and subsequent changes in ice phenology threaten to reduce the availability of optimal WCT habitat when the lake is stratified (particularly in the summer). Conducting an annual data review that pairs climate variables (i.e., air temperatures, wind speed, ice phenology) will aid in the interpretation of within lake temperature-oxygen profiles.

5.2 Recommendations

There are knowledge gaps identified through this temperature-oxygen data review that limit the development of strong conclusions with respect to WCT overwintering risk in Henretta Lake. While the goals of each specific data collection campaign may vary, it is important to determine if current monitoring can adequately detect change, identify potential stressors, and adapt to emerging issues. The following recommendations are provided to give direction on how to best improve routine monitoring and data analysis (with specific focus on risk to WCT):

1. There is uncertainty in the depth and spatial heterogeneity of DO and conductivity in Henretta Lake. We recommend continued use of the vertical data logger deployment within Henretta Lake to collect high-frequency *in situ* water quality data (for at least one calendar year upon which, sampling efforts should be reassessed). To improve understanding of the vertical and temporal extent of stratification conditions additional data loggers can be implemented (data loggers are currently at 1.25-m intervals throughout the water column). This would provide a high-frequency data set that could better characterize temperature-oxygen dynamics and vertical mixing patterns within the lake during both winter and summer. Henretta lake is ~8 m and thus it may be more susceptible to mid-summer mixing events; however, more summer data is needed to understand the mixing regime in this system. Due to the atypical hypolimnetic temperature-oxygen water mass observed in 2022, continued assessment of the data loggers from below 5 m depth would help to characterize the physical and chemical effects in Henretta Lake. To address any spatial variability in the lake we suggest continued collection of lake profiles using lowered probes consistent with data presented here-in. An evaluation of this spatial distributed data will help address any uncertainty.
2. To aid in identifying the drivers of oxygen demand in Henretta Lake (i.e., primary production, internal nutrient loading, etc.), we recommend sampling for nutrients and chlorophyll-a at key times throughout the year. Water samples should also be collected at multiple depths within the water column to evaluate the potential for internal nutrient loading during periods of anoxia. Understanding the influence of algal growth (in both the summer and winter) on oxygen depletion rates will help determine if biological factors may have contributed to the hypolimnetic winter anoxia observed in 2021

and 2022. In addition, characterizing aquatic primary production in Henretta Lake may provide further insights on the risk of selenium bioaccumulation in WCT.

3. To better characterize the influence of climate variables on temperature-oxygen dynamics in Henretta lake, we suggest conducting an annual climate data review. This would involve pairing air temperature and available ice records with the *in situ* temperature-oxygen data collected in Henretta Lake to better understand the influences of climate on WCT habitat quality. This would primarily be a desktop exercise but would enable a more complete interpretation of the data set (e.g., it would be possible to detect carry-over effects from year to year and identify if atypical results were correlated with climate anomalies). Further, we suggest continuing to log the ice-on and ice-off dates for the lake each year.
4. We recommend an annual assessment of WCT habitat quantity and quality. Potential metrics include oxythermal habitat volume, volume-weighted hypolimnetic oxygen concentrations, and/or anoxic factor (Nürnberg et al. 2019). Annually assessing these types of metrics integrates large amount of data into a single value, which can be tracked over time.
5. It is currently difficult to determine whether the stratification of Henretta Lake is a consequence of climatic and instream conditions, or if this process may be influenced by mining. If a lake could be identified that has similar characteristics (morphology, valley alignment, elevation, climate, biotic community, etc.), collecting data in this environment could inform our understanding of the mine's effect on Henretta Lake. Given the challenges associated with resource allocation and safety with collecting data at a reference site we would not suggest for it to be a frequent sampling location.

6 CONCLUSIONS

The recent monitoring of Henretta Lake in 2021 and 2022 suggests sub-optimal water temperature (near the lake surface) and DO conditions (near the lake bottom) are present during the winter, but the data does not suggest there is an acute risk to WCT. Conditions observed in 2021 and 2022 were inconsistent with previous winter monitoring conducted in 2020 and 2016, where the water column did not stratify and was well oxygenated. Key data gaps exist particularly with respect to what factors may have resulted in hypolimnetic anoxia observed in 2021 and 2022 (i.e., longer period of ice cover, incomplete fall mixing, enhanced primary production). To address this, we recommend expanding the sampling to include continuous *in situ* water quality data, the development of a sampling protocol to document primary production, the integration of climate variables in annual data review, the quantification of available oxythermal habitat, and the collection of data at a reference site.

1 Introduction

Henretta Creek is a third order tributary to the Fording River. It was historically diverted into culverts to allow for mining of the Henretta Pit. Once mining was complete, new channels were constructed and water was allowed to flow into the pit creating Henretta Lake. A reclaimed channel flow-through lake system. Henretta Lake has a maximum depth of 9.4m, surface area of 23,300m² and a volume of approximately 95,300m³ as determined by a bathymetric survey (Figure 13) completed by Lotic Environmental Ltd. in 2018 (Roulston, B. and M.D. Robinson. 2018). Henretta Lake has been documented as popular overwintering and is important rearing habitat for Westslope Cutthroat Trout (*Oncorhynchus clarkii lewisi*; WCT) in the Upper Fording River (Cope et al. 2016). Lotic Environmental Ltd. was retained by Teck Coal to complete in-situ water quality profiles in Henretta Lake during the winter of 2020, 2021, and 2022 under ice cover conditions at several locations. Profiles in 2020 showed consistent dissolved oxygen throughout the water column above recommended guidelines and showed no concern for overwintering WCT. The results of the profiles collected in 2021 and 2022 showed Henretta Lake stratifying and the portion of the lake below the thermocline turning hypoxic during the winter months. In the spring of 2022 Lotic Environmental Ltd. deployed a vertical string of loggers through the water profile of Henretta Lake to improve the understanding of water quality before and after spring turnover. The objective of this report is to summarise and interpret the logger data, and to recommend further discussion and data requirements.

2 Overview of the methods

Hobo U24-001 Conductivity and a Hobo U26-001 Dissolved Oxygen loggers were deployed along a vertical chain at depths of 1.25 m, 2.5 m, 3.75 m, 5.0 m, 6.25 m, and 7.5 m beneath the surface of Henretta Lake at site FR_HENLAKE3 (11U 652534 5566398) on May 4, 2022. Location FR_HENLAKE3 was chosen as it is a central location on Henretta Lake with sufficient depth and coincides with previous water quality collection completed on Henretta Lake. The loggers were downloaded and reinstalled on June 29, 2022. A future site visit is planned for October 2022, when loggers will be downloaded, caps replaced on dissolved oxygen loggers and cleaning of any loggers with scour or algae buildup. Water temperature (°C), dissolved oxygen (DO; mg/L), and conductivity (µS/cm) were collected at 15-minute intervals. Additional water quality profiles were completed during installation and when the loggers were downloaded. These profiles were used to correct and check the loggers for accuracy. HOBOWare Software (version 3.7.23) was used to correct logger records and develop a specific conductance record (µS/cm). Discharge was collected at the inlet and outlet of Henretta Lake using a Hach EM950 velocity meter following the Manual of British Columbia Hydrometric Standards (RISC 2009) on a biweekly basis between March and April 2021, and monthly between January and May in 2022.

3 Results

The water quality data from the vertical chain of loggers showed interesting temporal and vertical trends in temperature, dissolved oxygen, and conductivity throughout the 55-day monitoring record. Water temperatures ranged between 1.36 °C and 8.62 °C, with a mean of 4.22 °C. Dissolved oxygen ranged between 3.78 mg/L and 21.18 mg/L, and averaged 10.15 mg/L and conductivity ranged between 241.6 and 2102.6 µS/cm.

Henretta Lake appeared to experience a small turnover event in the top 6 m of the water column between May 27- 29, 2022, and a full turnover event between June 5-6, 2022 (Figure 1). The deepest loggers at 6.25 m and 7.5 m recorded a steady increase in temperature over the first 3 weeks of deployment at a faster rate than the rest of the water column. The logger at 6.25 m documented a rapid decline on May 28, 2022, illustrating the smaller turnover event, and the deepest logger (7.5m) documented a rapid decline on June 5, 2022, illustrating the full turnover event. After the event on June 5, 2022, all loggers recorded similar water temperatures throughout the water column for the rest of the study period, indicating full mixing of the lake. Dissolved oxygen trends are complicated, as the deepest logger is detecting the highest values of DO (not typical of a dimictic lake). Dissolved oxygen below 5 m is observed to gradually increase from hypoxic levels before a turnover event takes place. Dissolved oxygen below 6.5 m shows declines consistent with the first small turnover event around May 27, 2022, and the full turnover on June 6, 2022 (Figure 2). A second drastic decrease in dissolved oxygen is observed after full turnover on June 11, 2022, below a depth of 5 m potentially caused by an increased turbidity event (Figure 8). After the small turnover event on May 27, 2022, conductivity in the upper 5 m of Henretta Lake were consistent. The 6.25 m logger rapidly decreased from ~1200 $\mu\text{S}/\text{cm}$ to ~400 $\mu\text{S}/\text{cm}$ and only a small gradual decrease in conductivity was observed at 7.5 m, indicating poor mixing at the bottom during the small turnover event. A second large drop in conductivity was seen between June 3-6, 2022, at 6.25 m and 7.5 m during the full turnover event, whereas afterwards Henretta Lakes conductivity was consistent throughout the profile (Figure 3). A detailed look at the water quality parameters around the full turnover event can be found in Figure 4, Figure 5, and Figure 6. Trail camera images of June 4th, 5th, and 6th illustrate a potential increase in turbidity as a result of the full turnover on June 6, 2022 (Figure 7).

Dissolved oxygen rarely dropped below 5 mg/L between May 4, 2022, and June 29, 2022, the recommended criteria for the protection of aquatic life (BC Provincial Guidelines, 1997). Compared to in-situ profiles collected in January to March, 2022 where dissolved oxygen dropped below 5mg/L below 4m in depth (Lotic, 2022). Only 6 out of 55 days had a mean DO value less than 5 mg/L, and at only one depth (6.25 m) (Table 1). Hypoxia does not appear to be a concern for Westslope Cutthroat Trout during the period recorded.

Diel oscillations in temperature and DO occur throughout the logger record, as expected in such a shallow system, however the daily range in DO values were of interest (Figure 10 and Figure 11). Due to the limited logger record at one location in Henretta Lake the cause of the Diel oscillations is currently unknown. Diel variability in DO can be due a variety of things, including biological activity, i.e., photosynthesis occurring during only daylight hours, and respiration occurring throughout the 24-hour period; wind-driven internal seiches of a stratified waterbody (Flood et al. 2021, Brooks et al. 2022); sediment oxygen demand, or diel variability in the inflow. Diel variability as a result of biological activity has been documented to fluctuate in streams by a range of 2- 3 mg/L (Null et al. 2017); in surface waters of a shallow (0.6 m) and densely vegetated lake during summer by a range of 12% to 235% saturation (Andersen et al. 2017); and around 7 mg/L in a dystrophic lake (Staeher et al. 2010). It is unlikely, however, that photosynthesis of vegetation or algae at 7.5 m deep in Henretta Lake in May would be able to change DO concentrations by such a large amount. Wind-driven internal seiches occur when a sustained wind blows over a stratified waterbody, surface water accumulates at the downwind area, depressing the thermocline, and allows upwelling of the hypolimnion up to the surface at the upwind region, and then when wind relaxes, the thermocline 'rocks' back and allows downwelling of surface waters, and can also influence how fish use the water column (Helveca et al. 2015; Brooks et al. 2022). Wind-driven seiche events are common in lentic environments, however without a second vertical chain of temperature and DO data, we don't know if this 'rocking' is

occurring in Henretta Lake. The oxygen regime of small eutrophic waters can be affected by respiration in the organic sediment (Baxa et al. 2021), in addition to the water column as discussed previously. Sediment oxygen demand can account for over 50% of total oxygen demand and is a major factor of DO deficits in aquatic ecosystems (Matlock et al. 2003). And finally, if there is extreme diel variability in the incoming water source(s), it will likely be reflected in the water column.

Discharge measurements were compared between the inflow and the outflow of Henretta Lake during late winter and early spring of 2021 and 2022. All but one sampling point showed a positive difference between the discharge rates, i.e., more flow leaving Henretta Lake than entering (Figure 12). One anomaly in April 2021 shows a negative difference and this may be because of measurement error or ice effects.

The increased water temperatures, high levels of conductivity and DO at 6.25 m and 7.5 m depth until turnover, and a positive difference between the outflow and inflow discharge rates could indicate a secondary water source at the bottom of the lake, potentially groundwater seepage. Water temperature at the deepest part of a lake tends to be the coolest and highest density (typically 4 °C), however data shows the logger at the bottom of the lake is measuring the highest temperature in the water column until turnover occurs on June 6, 2022. The bottom of the lake also experienced the highest daily fluctuations in DO (Figure 2) which is not typically the photic zone and therefore likely not as a result of photosynthesis, and perhaps indicative of other mechanisms involving either sediment demand or groundwater infusions.

4 Conclusions

The data show some interesting and complex trends, including the presence of two turnover events, some unexpected warmer temperatures and high DO values at the bottom of the lake not typical for spring post ice-off conditions, and some extreme daily fluctuations in DO. Further profile data collection is required in Henretta Lake to determine the cause of these trends. We recommend continuing the recording of temperature, dissolved oxygen, and conductivity over the winter of 2022/2023. This will allow for further analysis of thermal stratification during the summer and if the hypolimnion in Henretta Lake turns hypoxic during these times. As well as to closely monitor the stratification in Henretta Lake that occurs under ice over the winter months.

Future recommendations for Henretta Lake monitoring are to continue collecting water quality profiles and discharges at the inlet/outlet over the winter months to monitor the development and potential movement of the hypoxic zone and useable overwintering habitat in Henretta Lake. Continuous temperature, dissolved oxygen, conductivity logger records and daily photo points of Henretta Lake will assist with detailed monitoring and help identify potential influencing factors and environmental variability. We recommend investigating the source of these diel oscillations and the source of the warmer, oxygenated, and high conductivity water at the bottom of the lake. Finally, we recommend completing a literature review and conducting water quality profiles of other high elevation lakes for comparison of trends in stratification and turnover.

Figure 5. Dissolved oxygen measurements at each of the 6 depths over a 4-day period of the full turnover event on 6 June 2022. X axis represents (yyyy-mm-dd hh)

Figure 6. Conductivity measurements at each of the 6 depths over a 4-day period of the full turnover event on 6 June 2022. X axis represents (yyyy-mm-dd hh)

Figure 7. Trail camera photos obtained on the 4, 5, and 6 June 2022, prior, during and post full turnover.

Figure 8. An apparent increase in turbidity observed on June 11, 2022 when there was a decrease in DO below 5m in depth.

Figure 9. Trail camera photos before, during, and after the sudden decrease in water temperature experienced throughout the whole water column on June 14, 2022.

Figure 10. Diel range in temperatures experienced at each depth, per day of the study period between May 4, 2022, and June 29, 2022.

Figure 11. Diel range of dissolved oxygen experienced at each depth, per day of the study period between May 4, 2022, and June 29, 2022.

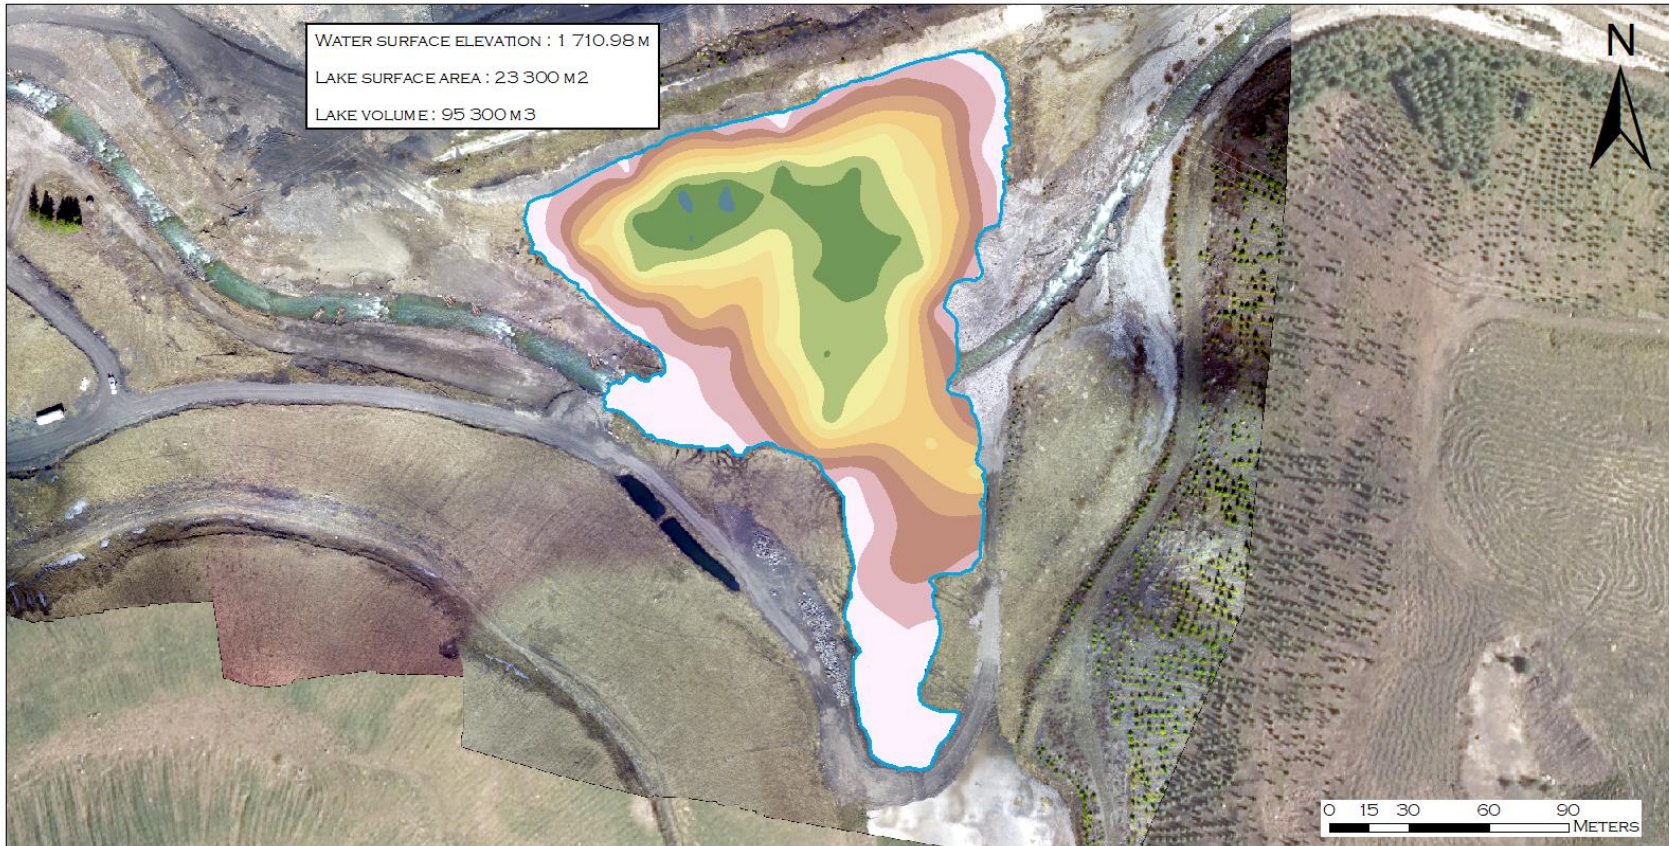

Figure 12. The difference between the discharge measurements of the outflow and inflow of Henretta Lake. Positive values indicate a secondary source of water into the lake.

List of Figures

Figure 1. Water temperature obtained from six loggers at various depths in Henretta Lake (site 3) between June 29 and September 01, 2022. Dates along the x-axis in yyyy-mm-dd format. 5

Figure 2. Dissolved Oxygen data obtained from six loggers at various depths in Henretta Lake (site 3) between June 29 and September 01, 2022. Dates along the x-axis in yyyy-mm-dd format. Of particular interest is the increasing diel ranges, potentially a signature of increasing algae growth, either in the water column or in the sensor cavity. Copper cages around the sensor have now been installed to minimize growth. The DO level only drops below 5 mg/L (the dashed horizontal line) once on August 27. 6

Figure 3. Conductivity ($\mu\text{S}/\text{cm}$) data obtained from six loggers at various depths in Henretta Lake (site 3) between June 29 and September 01, 2022. Dates along the x-axis in yyyy-mm-dd format. The lowest two loggers detecting higher conductivity than other water depths, as observed in the Spring 2022. 7

Figure 4. A heat map of water temperature throughout the water column at site 3. As seen previously, the lower part of the water column appears to be warmer. Diel variation in water temperature is likely a result of solar radiation. Potentially some stratification, especially around early and late August, however cooler water is sitting above warmer water- the inverse of a typical dimictic lake. 8

Figure 5. A heat map of water Dissolved Oxygen throughout the water column at site 3. The lower part of the water column appears to have increased DO values when compared to the surface. Diel variation in water DO is likely a result of algae photosynthesis and respiration. Loggers have now been fitted with copper cages to minimize growth of algae around the sensor. Potentially some stratification, especially around late August, however higher DO water is sitting above lower DO water- the inverse of a typical dimictic lake. 9

Figure 6. A heat map of water conductivity ($\mu\text{S}/\text{cm}$) throughout the water column at site 3. 9

List of Figures

Figure 1. Water temperature obtained from six loggers at various depths in Henretta Lake (site 3) between September 02 and September 30, 2022. Dates along the x-axis in yyyy-mm-dd format. 5

Figure 2. Dissolved Oxygen data obtained from six loggers at various depths in Henretta Lake (site 3) between September 02 and September 30, 2022. Dates along the x-axis in yyyy-mm-dd format. The deepest logger at 7.5 m was buried in the sediment. 6

Figure 3. Conductivity ($\mu\text{S}/\text{cm}$) data obtained from six loggers at various depths in Henretta Lake (site 3) between September 02 and September 30, 2022. Dates along the x-axis in yyyy-mm-dd format. The deepest two loggers detecting higher conductivity than other water depths, as observed in the Spring and Summer of 2022. 6

Figure 4. A heat map of water temperature throughout the water column at site 3. As seen previously, the lower part of the water column appears to be warmer. Diel variation in water temperature is likely a result of solar radiation or wind-driven water movement. 8

Figure 5. A heat map of water Dissolved Oxygen throughout the water column at site 3. The lower part of the water column appears to have increased DO values when compared to the surface. Diel variation in water DO is likely a result of algae photosynthesis and respiration. Loggers have now been fitted with copper cages to minimize growth of algae around the sensor. 9

Figure 6. A heat map of water conductivity ($\mu\text{S}/\text{cm}$) throughout the water column at site 3. 10

List of Tables

Table 1. Summary statistics of the temperature, DO, and conductivity data (minimum, maximum, mean, and variance) per depth for each day of the study. 21

1 Summary

Henretta Lake appears to be relatively stable for the month of September, with water temperatures throughout the water column ranging between 6 – 9.5 °C, Dissolved Oxygen (DO) ranging between 6 – 16 mg/L, and conductivity between 313 – 766 µS/cm. There was little evidence of thermal stratification during September. DO remained above the limit for Westslope Cutthroat Trout (*Oncorhynchus clarkii lewisi*; 5 mg/L), and the loggers recorded less diel variability than previous months- likely as a result of the new copper cages reducing algal growth and minimizing the immediate effects of photosynthesizing algae near the sensors. There were some instances of rapid drops in DO, for example at 1.25 m on September 13, and 3.75 m on the 15th of September, however none fall below the critical level for WCT, and DO levels increase back to 'normal' relatively quickly. Water levels appear to be lower than during the summer and the deepest logger positioned at 7.5 m was subsequently buried in the sediment for the month of September. Data from this logger was removed from the summary data table and heat map plots. As previously documented, the deepest section of Henretta was typically warmer than the surface and had higher levels of oxygen and conductivity.

2 Appendices

Figure 1. Water temperature obtained from six loggers at various depths in Henretta Lake (site 3) between September 02 and September 30, 2022. Dates along the x-axis in yyyy-mm-dd format.

Figure 2. Dissolved Oxygen data obtained from six loggers at various depths in Henretta Lake (site 3) between September 02 and September 30, 2022. Dates along the x-axis in yyyy-mm-dd format. The deepest logger at 7.5 m was buried in the sediment.

Figure 3. Conductivity ($\mu\text{S}/\text{cm}$) data obtained from six loggers at various depths in Henretta Lake (site 3) between September 02 and September 30, 2022. Dates along the x-axis in

yyyy-mm-dd format. The deepest two loggers detecting higher conductivity than other water depths, as observed in the Spring and Summer of 2022.

Figure 4. A heat map of water temperature throughout the water column at site 3. As seen previously, the lower part of the water column appears to be warmer. Diel variation in water temperature is likely a result of solar radiation or wind-driven water movement.

Figure 5. A heat map of water Dissolved Oxygen throughout the water column at site 3. The lower part of the water column appears to have increased DO values when compared to the surface. Diel variation in water DO is likely a result of algae photosynthesis and respiration. Loggers have now been fitted with copper cages to minimize growth of algae around the sensor.

Figure 6. A heat map of water conductivity ($\mu\text{S}/\text{cm}$) throughout the water column at site 3.

Figure 7. Water temperature ($^{\circ}\text{C}$) profiles for 01, 15, and 29 September 2022 at site 3.

Figure 8. Dissolved Oxygen (mg/L) profiles for 01, 15, and 29 September 2022 at site 3.

Figure 9. Water conductivity (µS/cm) profile for 01, 15, and 29 September 2022 at site 3.

List of Figures

Figure 1. Water temperature obtained from six loggers at various depths in Henretta Lake (site 3) between September 30 and October 28, 2022. Dates along the x-axis in yyyy-mm-dd format. .. 5

Figure 2. Dissolved Oxygen data obtained from six loggers at various depths in Henretta Lake (site 3) between September 30 and October 28, 2022. Dates along the x-axis in yyyy-mm-dd format. The deepest logger at 7.5 m was buried in the sediment. 6

Figure 3. Conductivity ($\mu\text{S}/\text{cm}$) data obtained from six loggers at various depths in Henretta Lake (site 3) between September 30 and October 28, 2022. Dates along the x-axis in yyyy-mm-dd format. The deepest two loggers detecting higher conductivity than other water depths, as observed throughout all monitoring conducted in 2022. 6

Figure 4. A heat map of water temperature throughout the water column at site 3. As seen previously, the lower part of the water column appears to be warmer. Diel variation in water temperature is likely a result of solar radiation or wind-driven water movement. 7

Figure 5. A heat map of water Dissolved Oxygen throughout the water column at site 3. The lower part of the water column appears to have increased DO values when compared to the surface (particularly at 6.25 m below surface). Diel variation in water DO is likely a result of algae photosynthesis and respiration in the water column. 7

Figure 6. A heat map of water conductivity ($\mu\text{S}/\text{cm}$) throughout the water column at site 3. As per all sampling in 2022, the bottom 2 m have a higher conductivity than the rest of the water column. 8

Figure 7. Water temperature ($^{\circ}\text{C}$) profiles for 01, 15, and 27 October 2022 at site 3. 8

Figure 8. Dissolved Oxygen (mg/L) profiles for 01, 15, and 27 October 2022 at site 3. 9

List of Tables

Table 1. Summary statistics of the temperature, DO, and conductivity data (minimum, maximum, mean, variance, and range) per depth for each day of the study. 19

1 Summary

Henretta Lake appears to be relatively stable for the first two weeks of October followed by two weeks of cooling, particularly at the surface, with water temperatures throughout the water column ranging between 3.3 – 8.9 °C, Dissolved Oxygen (DO) ranging between 5.8 – 14.3 mg/L, and conductivity between 580 – 1157 µS/cm. There was little evidence of thermal stratification during the first half of October, however the last two weeks showed evidence of gradual stratification as the surface cooled. The lower two loggers were the warmest in the water column. DO remained above the limit for Westslope Cutthroat Trout (*Oncorhynchus clarkii lewisi*; 5 mg/L), and the loggers recorded less diel variability than previous months- likely as a result of the new copper cages reducing algal growth and minimizing the immediate effects of photosynthesizing algae near the sensors. There were some instances of rapid drops in DO, for example at 5.0 m on the 18 October, however none fall below the critical level for WCT, and DO levels increase back to ‘normal’ relatively quickly. As previously documented, the deepest section of Henretta was typically warmer than the surface and had higher levels of oxygen and conductivity.

2 Appendices

Figure 1. Water temperature obtained from six loggers at various depths in Henretta Lake (site 3) between September 30 and October 28, 2022. Dates along the x-axis in yyyy-mm-dd format.

Figure 2. Dissolved Oxygen data obtained from six loggers at various depths in Henretta Lake (site 3) between September 30 and October 28, 2022. Dates along the x-axis in yyyy-mm-dd format. The deepest logger at 7.5 m was buried in the sediment.

Figure 3. Conductivity ($\mu\text{S}/\text{cm}$) data obtained from six loggers at various depths in Henretta Lake (site 3) between September 30 and October 28, 2022. Dates along the x-axis in yyyy-mm-dd format. The deepest two loggers detecting higher conductivity than other water depths, as observed throughout all monitoring conducted in 2022.

Figure 4. A heat map of water temperature throughout the water column at site 3. As seen previously, the lower part of the water column appears to be warmer. Diel variation in water temperature is likely a result of solar radiation or wind-driven water movement.

Figure 5. A heat map of water Dissolved Oxygen throughout the water column at site 3. The lower part of the water column appears to have increased DO values when compared to the surface (particularly at 6.25 m below surface). Diel variation in water DO is likely a result of algae photosynthesis and respiration in the water column.

Figure 6. A heat map of water conductivity ($\mu\text{S}/\text{cm}$) throughout the water column at site 3. As per all sampling in 2022, the bottom 2 m have a higher conductivity than the rest of the water column.

Figure 7. Water temperature ($^{\circ}\text{C}$) profiles for 01, 15, and 27 October 2022 at site 3.

Figure 8. Dissolved Oxygen (mg/L) profiles for 01, 15, and 27 October 2022 at site 3.

Figure 9. Water conductivity (µS/cm) profile for 01, 15, and 27 October 2022 at site 3.

1 Introduction

Henretta Lake is located on Teck Coal Ltd. (Teck) – Fording River Operations’ (FRO) mine site, 29 km northeast of Elkford, BC. The Henretta Creek system is a third order tributary to the Fording River. Historically Henretta Creek was diverted into culverts to allow for mining of the Henretta Pit. Once mining was completed new channels were constructed and Henretta Creek was diverted into the pit creating Henretta Lake and a reclaimed flow through lake system. Effectiveness monitoring was completed for seven years after Henretta Lake was created fulfilling permit requirements in 2006.

Henretta Lake provides one of the highest used overwintering habitats for Westslope Cutthroat Trout (*Oncorhynchus clarkii lewisi*) (WCT) in the upper Fording River (Cope *et al.* 2016). However, recent capture, snorkel, and Passive Integrated Telemetry data have also shown movement into and use of the lake during the summer months and early fall (Bransfield 2020; Penman *et al.* 2022). Therefore, it is believed that Henretta Lake provides high-value, year-round habitat for adult WCT, and potentially earlier life stages as well.

The importance of Henretta Lake as valuable fish habitat has consequently resulted in the completion of multiple Henretta Lake monitoring programs. Since Henretta Lake is a reclaimed flow through lake system there is interest in whether selenium bioaccumulation is occurring or not, and whether the lake is connected to groundwater sources in the area, and how groundwater may affect fish habitat and water quality. Furthermore, previously recorded overwintering temperatures and dissolved oxygen concentrations in Henretta Lake were lower than recommended fish guidelines (BCMoE 2021). This resulted in hypoxic conditions occurring at the bottom of Henretta Lake during the winter. Therefore, the combined low dissolved oxygen concentrations and temperatures may reduce the overwintering habitat available for WCT. Consequently, this Henretta Lake water quality profiling program occurred in conjunction with an existing *in-situ* profile monitoring program on Henretta Lake, as part of the FRO dewatering surveys program, which used continuous loggers at 11 sites. This Henretta Lake program involved collecting water quality grab samples and *in-situ* profiles at three sites: HEN1, HEN2 and HEN3 (Figure 1). *In-situ* profiles using a YSI ProDSS, and water samples were collected in the winter, summer, and fall of 2022 to monitor water quality in Henretta Lake.

1.1 Objectives

The purpose of this Henretta Lake water quality profiling program was to collect data to support ongoing studies on Henretta Lake and to understand the potential of stratification of constituents of interest within Henretta Lake. Key objectives for profiling the water quality in Henretta Lake were:

1. To determine if thermal and/or chemical stratification was evident in the lake.
2. To define temporal and spatial trends in the water quality parameters.
3. To determine selenium speciation found within the lake.
4. To compare water quality results to the BC ambient water quality guidelines for the protection of freshwater aquatic life, in regards of whether any exceedances occurred.
5. To compare water quality results to Teck’s specific water quality limits for total selenium, nitrate and sulphate from Permit 107517 (the Permit) for the FRO compliance point (FR_FRABCH) closest to Henretta Lake.

Figure 1. HEN1, HEN2, and HEN3 Henretta Lake water quality profile locations which overlap with sites from the FRO dewatering surveys.

2 Methods

Water samples were collected at three locations within Henretta Lake (Table 1) in the winter (February 17, 2022), summer (June 29, 2022), and fall (October 21, 2022). *In-situ* profiles were collected at each location with a YSI ProDSS (hand-held digital sampling system) at depth intervals of 0.5 m throughout the water column. *In-situ* parameters included temperature, dissolved oxygen (DO), specific conductivity (SPC), pH, and oxidation reduction potential (ORP).

Water samples were collected with a Kemmerer sampler at depths of 1 m, 3.5 m and 7m and shipped to and analyzed by ALS Environmental (ALS), Calgary, AB. All samples were analyzed for Teck’s routine parameters, total and dissolved organic carbon (TOC and DOC), total Kjeldahl nitrogen (TKN), total and dissolved metals, and total and dissolved mercury. Additional water samples were collected at HEN3 to determine selenium speciation at each depth. Selenium speciation samples were shipped to and analyzed by Brooks Applied Labs (Brooks), Bothell, WA, USA.

Table 1. Henretta Lake water quality sampling and profiling locations.

Site	UTM location	Maximum Lake Depth (m)		
		February	June	October
HEN1	11U 652482 5566421	6.2	7.5	7.7
HEN2	11U 652540 5566449	6.9	7.5	7.0
HEN3	11U 652534 5566398	7.5	8.5	7.7

To determine stratification, as well as spatial and temporal trends within Henretta Lake, water quality results were plotted by depth and by date using either Excel or R software (R Core Team 2022). Total selenium, nitrate, and sulphate were water quality parameters of interest for Teck. Therefore, those three parameters were exclusively analyzed for stratification and trends observed in Henretta Lake. Water quality parameters were manually compared to the BC ambient water quality guidelines (BCMoE 2021) and Teck’s specific limits with exceedances reported. If reoccurring exceedances were observed for any water quality parameter, then that parameter was analyzed for chemical stratification as well. As stated in the permit, Teck specific limits were compared to water quality results as follows: “for months where only one result is collected, that result shall be compared to both the monthly average and daily maximum limits. Daily maximums are defined as any single grab sample.”.

To maintain quality assurance and quality control (QA/QC) of the water samples, trip blanks, field blanks and duplicate samples were collected once per sampling event (i.e., one of each QA/QC sample during winter, summer and fall sampling events). The QA/QC methods and results are presented in Appendix 3. Quality assurance analyses indicated that field sampling and lab analysis procedures were accurate and precise There were no flagged results of concern from the QA/QC review process.

Results

All water quality *in-situ* field data and lab results of grab samples are listed in Appendix 1. Any exceedances of BC ambient water quality guidelines for the protection of freshwater aquatic life were bolded in the appended table.

2.1 *In-situ* water quality profiles

2.1.1 Temperature

Temperature profiles of Henretta Lake (Figure 2) indicated thermal stratification on February 17 and October 21, 2022. No thermal stratification was evident on June 29, 2022. This was indicative of ice free, high flow conditions post-freshet, resulting in isothermal conditions from spring turnover.

Figure 2. Temperature profiles of three Henretta Lake sites comparing seasonal data.

February 17, 2022 showed gradual thermal stratification of increasing temperatures moving from below the water surface to the bottom of the lake, but without distinct stratified layers. Increased temperature moving down through the water column occurred due to ice cover and cold winter conditions cooling the first 4 m of lake water to temperatures below 4 °C, which was less dense than water below 4 m deep. Therefore, the colder, less dense surface water floated on top of the more dense, deeper water with higher temperatures close to 4 °C. Freshwater is at its greatest density at 4 °C.

Temperature profiles from October showed distinct thermal stratification of increasing temperatures from the surface of the lake to the bottom. In October, all three sites' epilimnion extended from the water surface down to approximately 3 m as indicated by low temperature variability. The thermocline extended from approximately 3 m below the water surface to 6 m as indicated by the variability in increasing temperatures, and the hypolimnion extended from approximately 6 m to the bottom, 7 – 7.5 m depth, as shown by low water temperature variability at those depths. The increasing warmer temperatures with depth in October was unexpected, as more dense water (4.9 – 5.0 °C) was observed above less dense water (5.1 – 8.4 °C). It was suspected that groundwater influences may have caused the increased temperatures at lower lake depths. However, groundwater influences have not been verified. The same thermal stratification was found in October 2022 during the Henretta Lake profiling monitoring program using continuous loggers (Brooks and Gordon 2022). Brooks and Gordon (2022) also proposed groundwater influences as a potential explanation for the increasing temperature gradient moving down through the water column.

There were differences in total lake depth at each site (Table 1) due to site location and flow conditions. The start depth of each layer of stratification slightly varied between sites as HEN1 was the shallowest site, except for in October when HEN2 was shallowest, while HEN3 was the deepest site in all months. This resulted in an approximately 0.5 m maximum difference between the depths of each stratified layer amongst the three sites sampled.

There was little variability observed in temperature across all three sites of Henretta Lake (Figure 3). All three sites showed similar temperatures at each 0.5 m interval depth. Therefore, all three sites were representative of water temperatures observed in Henretta Lake at any given depth or location.

Figure 3. Seasonal temperature profiles comparing three Henretta Lake sites.

2.1.2 Dissolved Oxygen

Dissolved oxygen profiles at all three Henretta Lake sites (Figure 4) showed similar results as temperature profiles, in that both February and October showed lake stratification, whereas June did not. February had well oxygenated water in the epilimnion down to 2.5 – 3 m below surface. The thermocline observed in February extended from 2.5 – 3 m below surface to 5 – 5.5 m with dissolved oxygen rapidly decreasing to hypoxia owing to ice cover reducing light and blocking atmospheric oxygen and aeration by wind. The hypolimnion was hypoxic with DO ranging from 0.30 – 1.19 mg/L from approximately 5.5 m to the bottom of the lake.

Figure 4. Dissolved oxygen profiles of three Henretta Lake sites comparing seasonal data.

June 29, 2022, had high DO concentrations ranging from 9.77 – 10.39 mg/L. DO stratification did not occur due to isothermal conditions from spring turnover. This resulted in optimal DO concentrations at all lake depths for rearing WCT life stages. BC water quality guidelines state that DO must be ≥ 5 mg/L for the protection of all rearing stages of freshwater aquatic life.

DO measurements from October showed high DO concentrations throughout the water column and similar lake stratification as indicated by temperature profiles. The epilimnion extended down to 3 m, the thermocline extended from 3 m in depth to 6 m in depth where DO decreased from 3 – 4.5 m and then increased from 4.5 – 6 m. The hypolimnion extended from 6 m to the bottom where the highest DO concentrations were recorded. The bottom 0.5 – 1 m layer of water in October had decreased DO (~ 1 – 3 mg/L) compared to the concentrations observed in the top layers of the hypolimnion, potentially as a result of Sediment Oxygen Demand. The increased DO in the hypolimnion showed similar trends to the increase in temperature observed in October. Higher DO concentrations measured in the hypolimnion were speculated to be caused by phytoplankton photosynthesizing and/or groundwater influences, as was proposed during the 2022 Henretta Lake profiling monitoring program using continuous loggers (Brooks and Gordon 2022).

As observed in the temperature data, there was minimal spatial variability observed in DO between all three sites of Henretta Lake (Figure 5). Similar DO concentrations were found at each 0.5 m interval depth at all three sites. Therefore, all three sites were representative of DO concentrations found in Henretta Lake at any give depth or location.

Figure 5. Seasonal dissolved oxygen profiles comparing three Henretta Lake sites.

2.1.3 pH

Henretta Lake pH profiles of all three sites (Figure 6) showed similar trends to as mentioned above. February and October showed lake stratification, while June did not. Both February's and October's epilimnion extended down to 2.5 m, the thermocline ranged from 2.5 – 3.5 m and the hypolimnion ranged from 3.5 m to the bottom. Throughout the thermocline and hypolimnion pH gradually decreased. All pH values recorded were neutral to slightly alkaline, ranging from 7.13 – 8.06, well within the BC water quality guidelines of 6.5 – 9.0 pH for the protection of freshwater aquatic life.

Figure 6. pH profiles of three Henretta Lake sites comparing seasonal data.

There was slight spatial variation observed in pH within the epilimnion and thermocline of HEN1 on February 17, 2022 compared to HEN2 and HEN3 (Figure 7). Both HEN2 and HEN3 had similar pH values in February. The largest difference observed was at the 0.5 m depth measurement where HEN1 pH was equal to 7.62, less alkaline than HEN2 = 7.86 and HEN3 = 7.84. On June 29, 2022 there was slight spatial variation between HEN3 and HEN1 and HEN2, where HEN3 was less alkaline than the other two sites down to a depth of 7 m. From 7 – 8.5 m, pH at HEN3 was similar to HEN1 and HEN2. Again, the largest difference observed was near the surface at 0.5 m where HEN1 was equal to 8.06, HEN2 = 7.96 and HEN3 = 7.59. October had minimal variation in pH values between the three sites at each 0.5 m interval depth. Overall, the spatial differences observed in February and June in pH did not indicate high spatial variability amongst the sites. Therefore, each of the three sites were representative of pH values recorded in Henretta Lake individually. All data ranged between 7.13 – 8.06 pH indicating slightly alkaline conditions throughout the whole lake.

Figure 7. Seasonal pH profiles comparing three Henretta Lake sites.

2.1.4 Specific conductivity

Specific conductivity (SPC) showed the same trends as seen in the previously discussed *in-situ* water quality parameters. February and October experienced lake stratification while June did not (Figure 8). February had the highest SPC values recorded, followed by October, while June had the lowest SPC values recorded at all three sites. February had the most obvious stratification with the epilimnion extending down to 2.5 m. The thermocline extended from 2.5 – 4.5 m for HEN1, 2.5 - 5 m for HEN2, and 2.5 – 5.5 m for HEN3. The epilimnion had slight increases in SPC moving down through the water column. June had no stratification evident in SPC. October showed subtle SPC stratification where the epilimnion extended down to 3 m. The range in depth of the thermocline and epilimnion in October was dependent on site, where: HEN1 thermocline ranged from 3 – 6.5 m, HEN2 thermocline from 3 – 5.5 m and HEN3 thermocline from 3 – 6 m. The hypolimnion began in the range of 5.5 – 6.5 m. Lower SPC values observed in June were associated with lake turnover and high flow conditions, whereas higher SPC values recorded in February and October were associated with absence of mixing and low flow conditions.

Figure 8. Specific conductivity profiles of three Henretta Lake sites comparing seasonal data.

There were no spatial differences observed in SPC between all three sites (Figure 9). The three sites showed similar SPC concentrations at each 0.5 m interval depth. Therefore, all three sites were representative of SPC concentrations found in Henretta Lake at any given depth or location.

Figure 9. Seasonal specific conductivity profiles comparing three Henretta Lake sites.

2.1.5 Oxidation reduction potential

Oxidation reduction potential (ORP) profiles of Henretta Lake indicated minimal variability throughout most of the water column within any of the months sampled (Figure 10). As opposed to other *in-situ* water quality parameters, ORP showed the most variability in June, increasing at a mean rate of 4.2 mV moving down through the water column. However, no stratification was evident in June. HEN2 was the only site where ORP sharply decreased at the bottom 0.5 – 1 m of the lake. At HEN2 in February, ORP decreased from 219.4 mV to 193.7 mV from the 6 m to 6.5 m depth, in June from 277.1 mV to 225.1 mV from the 6.5 m to 7.5 m depth, and in October from 195.1 mV to 180.5 mV from the 6.5 m to 7 m depth. HEN2 was the only site where a sudden change in ORP was observed, and ORP was the only *in-situ* parameter that exhibited this.

Figure 10. Oxidation reduction potential profiles of three Henretta Lake sites comparing seasonal data.

There were minimal spatial differences observed in ORP between all three sites of Henretta Lake (Figure 11). In February and October, similar SPC concentrations at each 0.5 m interval depth were observed at all three sites. June ORP showed slight spatial variability between the three sites where HEN1 had the lowest ORP values, and HEN2 had the highest ORP values. Except for the bottom two ORP records of HEN2 which were the lowest ORP values recorded in June. ORP had the largest range in June from 198.6 – 277.4 mV between the three sites. Regardless, ORP indicated that all three sites were oxidizing environments. Therefore, all three sites were considered representative of ORP measured at any given depth or location within Henretta Lake.

Figure 11. Seasonal oxidation reduction potential profiles comparing three Henretta Lake sites.

2.2 Water quality grab sample profiles

Total selenium, nitrate and sulphate were compared to Teck specific limits and BC water quality guidelines for both short- term acute (maximum) and long-term chronic (30-day average) limits (Table 2). The remaining water quality parameters were compared to the BC water quality guidelines for the protection of freshwater aquatic life (Appendix 1). All water quality results presented herein were analyzed by ALS unless otherwise stated. Site HEN3 selenium concentrations had both Brooks and ALS lab results presented.

Table 2. Teck specific water quality limits and BC water quality limits for the protection of freshwater aquatic life for total selenium, nitrate and sulphate.

Parameter	Teck Daily Maximum	Teck Monthly Average	BC Acute	BC Chronic
Total Selenium (µg/L)	100	85	-	2
Nitrate as N (mg/L)	21	18	32.8	3
Sulphate (mg/L)	-	577	-	429

Minimal spatial variation in water quality was observed amongst the three sites. Total selenium collected within the same month resulted in similar concentrations measured at each site (Figure 12). Slight spatial differences occurred at the 7 m depth only, in February and June. All sites measured the highest total selenium in February, followed by October and lowest concentrations measured in June. Dissolved selenium, nitrate and sulphate all showed the same seasonal trends and lack of spatial differences between sites. Therefore, for the sake of brevity, as HEN3 plots

were representative of all three water quality profiles, we have only included plots and discussions for HEN3 in the body of this report. Individual plots for HEN1 and HEN2 for total and dissolved selenium, nitrate and sulphate are found in Appendix 2.

Figure 12. Seasonal total selenium profiles comparing three Henretta Lake sites.

2.2.1 Total and dissolved selenium

Higher dissolved selenium than total selenium concentrations were identified in October at all three sites, and at HEN3 in June from ALS results (Figure 13 and Appendix 2). The Brooks results for HEN3 also showed higher dissolved selenium than total selenium concentrations at varying depths in all months (Figure 14). Brooks dissolved selenium results had higher concentrations than total selenium at 7 m deep in February, at 3.5 m and 7 m deep in June, and at 1 m and 3.5 m deep in October. Brooks lab reports indicated that sample container labels were checked, and no mislabelling occurred, re-analysis of samples confirmed that dissolved selenium was greater than the corresponding total selenium, ultimately suggesting sample heterogeneity. Since both labs produced different results with higher dissolved selenium than total selenium concentrations, sampler error was ruled out.

It was unclear why dissolved selenium was higher than total selenium. The heterogeneity of the sampling environment may be the cause. However, Brooks confirmed the results were representative of the submitted samples.

Figure 13. ALS total (Tot. Se) and dissolved selenium (Diss. Se) concentrations at site HEN3.

Chemical stratification of total and dissolved selenium was difficult to define with only three sample points (Figure 13 and Figure 14). ALS results indicated that February was the only month with chemical stratification in both total and dissolved selenium with increasing concentrations moving down through the water column at HEN3 (Figure 13). June and October had similar selenium concentrations at all three depths sampled with no chemical stratification evident. However, Brooks results indicated stratification in both February and October with increased selenium within the thermocline, which then decreased at 7 m deep back to concentrations similar to the 1 m depth (Figure 14).

One difference noted in stratification between sites was at HEN1, where selenium continued to increase at 7 m deep, ~ 10 µg/L more than concentrations at 3 m deep in HEN 2 and HEN3 (Appendix 2). The second stratification difference noted between sites was that HEN1 (12.8 µg/L total selenium) and HEN2 (13.5 µg/L total selenium) had two times higher total and dissolved selenium concentrations at 7 m deep in June than HEN 3 (6.7 µg/L total selenium) (Appendix 2). Although spatial differences amongst sites were noted, selenium concentrations exhibited similar stratification and seasonal trends at all sites.

Both ALS and Brooks total selenium concentrations measured at HEN3 exceeded the BC long-term chronic guideline for the protection of freshwater aquatic life for total selenium (2 µg/L). As well, both ALS and Brooks HEN3 total selenium concentrations were less than the Teck daily maximum (100 µg/L) and monthly average (85 µg/L) total selenium limits. The same results were observed at both HEN1 and HEN2 where total selenium exceeded the BC long-term chronic guideline for the protection of freshwater aquatic life and were less than the Teck specific total selenium limits.

Figure 14. Brooks total (Tot. Se) and dissolved selenium (Diss. Se) concentrations at site HEN3.

The same seasonal variability was observed in total and dissolved selenium from both ALS and Brooks lab results (Figure 15). February had the highest selenium concentrations recorded likely owing to base flow conditions and ice cover, both of which prevent mixing and promote selenium accumulation. June had the lowest selenium concentrations recorded likely owing to spring turnover and high flow conditions reducing retention time of Henretta Lake and diluting concentrations with increased lake volume. October selenium increased from June owing to the onset of low flow conditions decreasing water volume and likely increasing retention time.

In-situ data indicated lake stratification in both February and October, but not in June. Lake stratification was indicative of separate layers of water that were not mixing, which supports the higher selenium concentrations measured in February and October than those measured in June. No lake stratification was evident from June *in-situ* data, which was indicative of a well-mixed homogenous environment that promoted lower selenium concentrations.

When comparing ALS and Brooks total and dissolved selenium results, ALS continuously had higher measured concentrations than Brooks. Minimal differences between February results from the two labs were observed. However, both total and dissolved selenium in June and October was noticeably higher in the ALS results than in the Brooks results.

Figure 15. Seasonal variability of total and dissolved selenium measured at HEN3 by Brooks and ALS.

2.2.2 Selenium speciation

Selenium speciation analysis was performed by Brooks lab for site HEN3 only, which included dissolved forms of:

1. selenite [Se(IV)]
2. selenate [Se(VI)]
3. selenocyanate [SeCN]
4. methylseleninic acid [MeSe(IV)]
5. methaneselenonic acid [MeSe(VI)]
6. selenomethionine [SeMet]
7. selenosulfate [SeSO₃]
8. dimethylselenoxide [DMSeO]
9. unknown selenium species

Selenium speciation analyses resulted in four selenium species detected: two inorganic forms, 1) selenite, and 2) selenate, and two organic forms, 1) methylseleninic acid and 2) dimethylselenoxide. No unknown selenium species were detected.

The selenite profiles (Figure 16) indicated chemical stratification in February and October. June showed no chemical stratification for selenite with similar concentrations detected at each depth. February had more obvious selenite stratification than October with increasing concentrations moving down through the water column. October indicated selenite stratification below 3.5 m. February had the highest and most variable selenite concentrations, followed by October with June having the lowest concentrations (Figure 17). These were the same results reported for total and dissolved selenium.

Figure 16. Selenite profiles measured at site HEN3.

Figure 17. Seasonal variability of selenite measured at HEN3.

Selenate profiles indicated chemical stratification at the 3.5 m depth in February, where it increased by 5.2 µg/L from the surface, then decreased closer to surface concentrations at 7 m deep (Figure 18). June and October had no selenate stratification observed. Selenate concentrations were highest in February, followed by October and lowest in June (Figure 19), as was observed with selenite.

Figure 18. Selenate profiles measured at site HEN3.

Figure 19. Seasonal variability of selenate measured at HEN3.

Methylselenenic acid profiles indicated stratification within all months sampled (Figure 20). However, each month had different stratification trends. February measured no methylselenenic acid at 1 m and 3.5 m deep. However, at 7 m deep methylselenenic acid measured 0.013 $\mu\text{g/L}$. June profiling indicated an increase in methylselenenic acid from 1 – 3.5 m deep, then decreased to zero at 7 m deep. October methylselenenic acid decreased from 1 – 3.5 m and increased to the highest concentration measured, 0.016 $\mu\text{g/L}$, at 7 m.

Figure 20. Methylselenenic acid profiles measured at site HEN3.

Methylselenenic acid seasonal variability was different from other water quality parameters measured. October had the highest concentrations recorded (Figure 21). Although June had methylselenenic acid concentrations detected at two depths out of three, and February only at one depth interval out of three, February’s variability in concentrations indicated it had higher overall concentrations than in June.

Figure 21. Seasonal variability of methylseleninic acid measured at HEN3.

Dimethylselenoxide profiles indicated stratification in February and October below 3.5 m from the surface (Figure 22). Dimethylselenoxide was not detected at any depth in June. No dimethylselenoxide was measured at 1 m in February. However, dimethylselenoxide increased moving down through the water column in February, with the highest concentrations measured at the 3.5 m and 7 m depths. October grab samples detected dimethylselenoxide at the bottom of the lake at 7 m deep only.

Figure 22. Dimethylselenoxide profiles measured at site HEN3.

The same seasonal variation found in total and dissolved selenium, selenite and selenate was also observed in dimethylselenoxide concentrations. February had the highest dimethylselenoxide concentrations measured, followed by October, with none detected in June (Figure 23).

Figure 23. Seasonal variability of dimethylselenoxide measured at HEN3.

The dominant selenium species detected in Henretta Lake at all depths and within each season was selenate (Figure 24). Selenate concentrations in February were higher than dissolved selenium and were higher than total selenium at 1 m and 7 m deep. At 3.5 m deep in February total selenium was higher than selenate. In June and October, selenate concentrations were higher than both total and dissolved selenium.

Selenate concentrations ranged from 5.36 - 45 µg/L, whereas selenite ranged from 0.042 – 0.930 µg/L, methylseleninic acid from 0 – 0.016 µg/L, and dimethylselenoxide from 0 – 0.022 µg/L. Selenate and selenite were detected at all lake depths and in all months sampled. Methylseleninic acid was detected in six out of nine samples collected, at varying depths and within each month sampled. No trend in methylseleninic acid concentrations was observed. Dimethylselenoxide was identified in three out of nine samples in February and October at or below 3.5 m depth.

Figure 24. Comparison of total and dissolved selenium (Tot. Se and Diss. Se) profiles to selenate profiles at site HEN3.

2.2.3 Nitrate

Nitrate stratification was observed in February and October and was absent in June at all three sites in Henretta Lake (Figure 25 and Appendix 2). Nitrate stratification was more defined in February than in October with increasing concentrations moving down through the water column. The 7 m depth nitrate concentrations measured in February at all sites exceeded both Teck’s daily maximum (21 mg/L) and monthly average (18 mg/L) limits, as well as the BC long-term chronic guideline (3 mg/L). February nitrate concentrations at 1 m and 3.5 m deep exceeded the BC long-term chronic exposure guideline but fell below both Teck limits and the BC short-term acute exposure guideline. June nitrate concentrations fell below all BC and Teck limits, except at the 7 m depth at sites HEN1 (3.34 mg/L) and HEN2 (3.62 mg/L), where nitrate was slightly elevated above the BC chronic limit of 3 mg/L. October nitrate stratified below 3.5 m, where it increased by approximately 3.5 times at 7 m deep (14.1 mg/L). October nitrate concentrations exceeded the BC long-term chronic guideline but were less than both Teck limits and the BC short-term acute guideline.

Figure 25. Nitrate profiles measured at site HEN3.

No spatial differences in nitrate concentrations occurred amongst the three sites. Temporal differences were observed in all seasons, with February having the highest nitrate concentrations detected, followed by October and June having the lowest concentrations (Figure 26).

Figure 26. Seasonal variability of nitrate at HEN3.

2.2.4 Sulphate

Sulphate stratification was evident in February and October but absent in June at all sites (Figure 27 and Appendix 2). Sulphate levels increased with increasing depth in both February and October with defined stratification occurring between 3.5 – 7 m deep. February had one sulphate exceedance of the BC chronic limit (429 mg/L) at 7 m but was below the Teck monthly average limit (577 mg/L) for all sites. The 1 m and 3.5 m sulphate concentrations in February for all sites were both below the BC chronic and Teck monthly average limits. Sulphate measured in June and October were less than both the BC chronic and Teck monthly average limits at all three Henretta Lake sites. Seasonal variability detected the highest sulphate concentrations in February, followed by October, and the lowest concentrations in June (Figure 28). There were no spatial differences measured in sulphate amongst the three sites.

Figure 27. Sulphate profiles measured at site HEN3.

Figure 28. Seasonal variability of sulphate at site HEN3.

2.3 BC ambient water quality guideline exceedances

Five water quality parameters: temperature, DO, nitrate, sulphate, and total selenium had exceedances of the BC ambient water quality guidelines for the protection of freshwater aquatic life (Appendix 1). Temperature, nitrate, and total selenium had multiple exceedances within all sites and months sampled. DO and sulphate had exceedances only in February at 7 m deep in all three sites.

The most relevant temperature guideline, +/- 1 °C from 7.0 ° - 16.0°C, for the protection of rearing WCT was chosen for comparison to Henretta Lake temperatures. All lake temperatures recorded in February and June were < 6.0 °C and therefore did not meet the BC water quality guideline. All sites' temperatures recorded in October, at the 1 m and 3.5 m depths, were < 6.0 °C and therefore did not meet the BC water quality guideline. Only the 7 m temperatures in October fell within the temperature range for the protection of rearing WCT. Temperature in Henretta Lake was outside of the recommended range for rearing WCT in 89% of the readings collected. Since adult WCT are known to reside in Henretta Lake, the effects of those temperature exceedances of the BC water quality guideline were negligible. However, the lower than recommended temperatures may affect WCT fry and juvenile rearing in Henretta Lake.

Nitrate exceeded the BC long-term chronic water quality guideline (≤ 3 mg/L) in 74% of the samples collected. Nitrate exceeded the BC chronic guideline in all February and October samples, and at 7 m deep in June at HEN1 and HEN2. All nitrate concentrations collected in Henretta lake met the BC short-term acute water quality guideline for nitrate (≤ 32.8 mg/L).

Total selenium concentrations measured in Henretta Lake exceeded the BC long-term chronic exposure guideline ($\leq 2 \mu\text{g/L}$) in 100% of the samples collected. The mean total selenium for February was $46.0 \mu\text{g/L}$, for June = $8.2 \mu\text{g/L}$, and October = $30.1 \mu\text{g/L}$. The mean of all three Henretta Lake sites' total selenium concentrations was $28.1 \mu\text{g/L}$. All means exceeded the BC chronic guideline for total selenium. All total selenium concentrations and means met the Teck specific limits.

DO did not meet the BC water quality guideline ($\geq 5 \text{ mg/L DO}$) in 11% of the samples collected. The BC criteria for DO was not met in February at the lowest depth sampled at all sites, where hypoxic conditions persisted at $\text{DO} < 1 \text{ mg/L}$. Same as DO, sulphate exceeded the BC water quality guideline ($\leq 429 \text{ mg/L}$) in 11% of the samples collected, and only in February at the lowest depth sampled at all sites.

3 Conclusions

Objective 1: To determine if thermal and/or chemical stratification was evident in the lake.

Stratification occurred in Henretta Lake in February and October 2022. Isothermal conditions attributable to spring turnover produced no thermal or chemical stratification in June. *In-situ* parameters indicated that the epilimnion was approximately 2.5 – 3 m deep, the thermocline ranged from 1 – 3 m deep and the hypolimnion ranged from 1 – 2.5 m deep. ORP was the only water quality parameter that exhibited no stratification in any month sampled.

Water sample concentrations generally increased with lake depth when chemical stratification was observed. Total and dissolved selenium, and selenate had the highest concentrations recorded in the thermocline. Whereas, selenite, dimethylselenoxide, nitrate and sulphate had the highest concentrations measured near the bottom of the lake.

Methylseleninic acid, an organic species of selenium, was the single water quality parameter that exhibited stratification in June. Methylseleninic acid was detected in the upper layers of the lake and absent from the bottom in June. Highest concentrations were detected in October, followed by February which is opposite from all other water samples.

Objective 2: To define temporal and spatial trends in the water quality parameters.

February had the highest concentrations of any water quality parameter detected, likely as a result of base flow conditions and ice cover preventing mixing and concentrating water quality parameters. June had the lowest concentrations of any water quality parameter recorded, likely owing to mixing of the lake from spring turnover, and high flow conditions reducing retention time of Henretta Lake and diluting concentrations with increased lake volume. October water quality parameters increased from June, likely owing to the onset of low flow conditions decreasing water volume, increasing retention time and reducing mixing.

There were no spatial trends observed in Henretta Lake water quality. Water quality parameters had similar concentrations between all three sites. Therefore, minimal to no spatial differences in concentrations were observed between the three sites.

Objective 3: To determine selenium speciation found within the lake.

Selenite and selenate were the only two inorganic forms of selenium detected during selenium speciation. Two organic forms, methylseleninic acid and dimethylselenoxide, were also identified. No unknown selenium species were detected. Selenate and selenite were detected at all lake depths and in all months sampled. Methylseleninic acid was detected in 67% of samples collected, at varying depths and within each month sampled. No trend in methylseleninic acid concentrations was observed. Dimethylselenoxide was identified in 33% of samples collected and was only found in February and October at or below 3.5 m depth. The dominant selenium species detected in Henretta Lake at all depths and within each season was selenate.

Objective 4: To compare water quality results to the BC ambient water quality guidelines for the protection of freshwater aquatic life, in regards of whether any exceedances occurred.

There were five water quality parameters that did not meet the criteria for BC ambient water quality guidelines for the protection of freshwater aquatic life. Total selenium exceeded the BC guideline in 100% of the samples. Temperature did not meet the optimal criteria in 89% of the samples. Nitrate exceeded the BC guideline in 74% of the samples. DO and sulphate exceeded BC water quality guidelines in 11% of the samples collected.

Objective 5: To compare water quality results to Teck's specific water quality limits for total selenium, nitrate and sulphate from Permit 107517 (the Permit) for the FRO compliance point (FR FRABCH) closest to Henretta Lake.

Total selenium and sulphate met both the daily maximums and monthly averages of the Teck specific limits in all months sampled. Nitrate exceeded both the daily maximum and monthly average Teck specific limits at all sites in February at the 7 m depth. The remaining nitrate concentrations measured met the Teck specific limits.

Appendix 3. Water Quality Data Quality Assurance and Quality Control Review

QA/QC Methods

To maintain quality assurance and quality control (QA/QC) of the water quality grab samples, trip blanks, field blanks and duplicate samples were collected once per sampling event (i.e., one of each QA/QC sample during winter, summer and fall sampling events). Water quality field blanks were collected using laboratory issued de-ionized water. Field and trip blank values three times greater than the reportable detection limit (RDL) were considered an alert level (Province of BC 2013), indicating possible sample contamination during field collection, lab analysis, or from the sample containers used.

Duplicate water samples were collected to detect heterogeneity within the environment and to allow the precision of the measurement process to be estimated. Duplicate sampling involved collecting and field processing water from the same location at the same time. One of two approaches were used to analyse the duplicate results:

1. When at least one set of duplicate values were ≥ 5 times the RDL, the relative percent difference (RPD) of each set of duplicate results was calculated (Equation 1). RPD values $>20\%$ indicated a possible problem, whereas $>50\%$ indicated a definite problem, most likely due to either contamination or lack of sample representativeness (Province of BC 2013). Both ranges, 20 – 50% and $>50\%$ were distinguished separately.

Equation 1: Relative percent difference (RPD)

$$RPD = \left(\frac{\text{Duplicate 1} - \text{Duplicate 2}}{[(\text{Duplicate 1} + \text{Duplicate 2}) \div 2]} \right) \times 100$$

2. When at least one set of duplicate values were < 5 times the RDL, the difference between the sample and duplicate values was flagged if it exceeded twice the RDL (BC MOE 2013).

QA/QC Results

Quality assurance analyses indicated that field sampling and lab analysis procedures were accurate and precise (Appendix 3). Trip blank data review was conducted for 195 lab analysed samples, of these, 100% were contaminant free and analysed with precision. Field blank data review was conducted for 285 lab analysed samples, of these, 99.6% were contaminant free and/or analysed with precision. Of the 291 field duplicate sets reviewed, 97.9% had a RPD below 20% indicating a high degree of precision in data collection and lab procedures. Of the 2.1% of duplicate results flagged, 1.4% had a RPD within the 20 - 50% potential concern level, and 0.7% had a $> 50\%$ RPD indicating an issue. Four of the six flagged incidences of RPD $>20\%$ occurred in February, with none in June and two in October. Five parameters were flagged: total Kjeldahl nitrogen (TKN) twice, once in February and once in October, total lithium, total manganese and total uranium in February, and lastly, the ion balance in October. There were no trends observed in duplicate exceedances of the RPD. Sample variability due to the heterogeneity of the field environment was presumed to be the general cause for the duplicate differences.
