Report: Fording River Operations Local Aquatic Effects Monitoring Program (LAEMP) 2022 Report

Overview: This report monitors aquatic conditions related to ongoing mining and the commissioning of the FRO-South (FRO-S) Active Water Treatment Facility (AWTF); existing conditions in relation to the future FRO-North (FRO-N) Saturated Rock Fill (SRF) are also monitored.

This report was prepared for Teck by Minnow Environmental Inc and Lotic Environmental Ltd.

EXECUTIVE SUMMARY

The Fording River Operation local aquatic effects monitoring program (FRO LAEMP) was developed to monitor aquatic conditions related to ongoing mining and the commissioning of the FRO-South (FRO-S) active water treatment facility (AWTF) and is a requirement in Permit 107517. Existing conditions in relation to the future FRO-North (FRO-N) Saturated Rock Fill (SRF) are also monitored under the FRO LAEMP. The primary focus of the FRO LAEMP is to monitor local aquatic ecosystem condition, particularly as it relates to conditions post-commissioning of water treatment compared to conditions prior to commissioning. This report includes FRO LAEMP monitoring data up to the end of the 2022 calendar year to evaluate the study questions detailed below.

Study Question #1 (Are nitrate concentrations in the study area changing, and do they have the potential for adverse effects on biota?) was evaluated through monitoring of water chemistry in relation to effects concentrations, benthic invertebrate community (BIC) data, and chronic toxicity. While nitrate concentrations have increased over time throughout the FRO LAEMP study area, some decreases have been observed in the lower study area related to FRO-S AWTF operation, although not to concentrations lower than base years for comparison (2012). Evidence for direct effects of nitrate on biota, however, is limited and interpretation is confounded by the covariation of multiple mine-related constituents with nitrate and a change in habitat throughout the study area concurrent with changes in BIC structure. Nitrate concentrations were below concentrations expected to cause effects in sensitive species in the majority of samples throughout the study area, and 2022 chronic toxicity studies did not identify any effects that could be attributed to nitrate. As treatment continues to be implemented in the FRO LAEMP study area, nitrate concentrations are expected to decrease, thus the potential for adverse effects to biota is expected to remain low.

Study Question #2 (Is water treatment affecting biological productivity downstream in the Fording River?) was evaluated through monitoring of aqueous nutrient concentrations (i.e., total phosphorus and orthophosphate), periphyton presence and thickness, and benthic invertebrate biomass and density. An increase in aqueous phosphorus concentrations was identified post-commissioning of the FRO-S AWTF directly downstream of the outfall compared to upstream and pre-commissioning conditions but decreased with distance downstream. Benthic invertebrate productivity was higher immediately downstream of the outfall, but remained within the range observed throughout the study area, and no evidence of increased periphyton growth was observed. An increase in secondary biological (benthic invertebrate) productivity downstream of the FRO-S AWTF outfall location may be attributed to an increase in treatment-related phosphorus concentrations, but the effect was spatially limited.

Study Question #3 (Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?) was evaluated through monitoring of aqueous selenium concentrations, including selenium speciation, and composite-taxa benthic invertebrate tissue selenium concentrations throughout the study area. Total and dissolved selenium concentrations decreased at most mainstem FRO LAEMP monitoring areas downstream of the FRO-S AWTF outfall compared to the pre-commissioning period and immediately upstream, however, there was a qualitative increase in organoselenium concentrations downstream of treatment that decreased with distance from the outfall until it was no longer detected ~2 km downstream. Benthic invertebrate tissue selenium concentrations have remained unchanged at all monitoring areas downstream of the FRO-S AWTF outfall compared to upstream and pre-commissioning, and concentrations have been consistent with predictions throughout the study area based on aqueous selenium concentrations. Monitoring under the FRO LAEMP has indicated that benthic invertebrate tissue selenium concentrations downstream of treatment (and throughout the study area) were consistent with predictions after the first year of FRO-S AWTF commissioning.

Study Question #4 (How is temperature changing over time in the FRO LAEMP study area? 4a. Is water temperature measurably different [greater than 1 degree Celsius] downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition? 4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF?) was evaluated through monitoring of water temperature data collected from loggers located throughout the study area. With few exceptions, water temperatures have remained stable throughout the FRO LAEMP study area since 2017. Minor differences in water temperature were observed when comparing areas immediately downstream and upstream of treatment pre- and post-commissioning, but temperature differences were rarely (i.e., only 3 of 363 days post commissioning) greater than the 1°C threshold indicating minimal influence of FRO-S AWTF operation on water temperatures in the receiving environment downstream. Monitoring under the FRO LAEMP has indicated that monthly mean water temperatures have increased slightly at three of twelve mine-exposed stations in the study area but increases were not related to the FRO-S AWTF.

Study Question #5 (What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?) was evaluated through monitoring of BIC endpoints relative to water quality and habitat variables (e.g., calcite, substrate size, water depth, flow, and temperature). Consistent with previous years, community structure in the upper Fording River changed from upstream to downstream in 2022, and was defined by a notable shift in the relative abundance of Ephemeroptera (mayfly; decrease) and Plecoptera (stonefly; increase) taxa that corresponded to shifts in the abundance of other non-Ephemeroptera-Plecoptera-

Trichoptera (EPT) taxa. While these changes in BIC structure occurred simultaneously with changes in concentrations of mine-related constituents, some of which were above established effects levels during low flows, there was no clear indication of direct effects of water quality on BIC abundance (e.g., toxicity). While a similar spatial pattern in total Ephemeroptera abundance and relative abundance was observed, total abundance and abundance of EPT taxa endpoints remained within their respective normal ranges and consistent over time throughout the study area. In addition, temporally consistent abundance of all key taxa, including EPT, indicated no limitations to food available to fish throughout the study area. Significant relationships between water chemistry and relative abundance metrics may be reflecting a more generalized response to water quality whereby more tolerant taxa thrive (e.g., increase in Dipteran taxa abundance) rather than more sensitive taxa decline (e.g., no observed change in EPT abundance). Key BIC endpoints were also associated with changes in habitat that covaried with changes in water quality throughout the study area, including substrate size, water temperature, water depth, and calcite, suggesting that habitat may be a key factor influencing the BIC but making it difficult to tease apart the influence of individual variables. Most habitat variables were associated with BIC variation throughout the full study area, however, substrate size and water temperature had a particularly strong relationship with BIC variation in the lower study area (i.e., downstream of the Greenhouse Side Channel) where the BIC is characterized by high % Plecoptera and low % Ephemeroptera. Monitoring under the FRO LAEMP indicates that multiple factors, including both mine-related stressors and habitat features, contribute to the variation in BIC in the FRO LAEMP study area, and the shift in the community is largely related to increases in the abundance of non-EPT taxa, rather than a loss or change in the abundance of EPT taxa themselves.

Study Question #6 (What are the factors influencing fish health and population in the Upper Fording River?) was evaluated through an integration of fish studies in the upper Fording River (i.e., UFR westslope cutthroat trout [WCT] Population Monitoring Program) with relevant data (seasonal drying, benthic invertebrate tissue chemistry, and water chemistry) from the FRO LAEMP and the RAEMP (WCT muscle selenium concentrations, condition factor, and observations of external anomalies) within the FRO LAEMP study area. With respect to fish habitat, Henretta Lake has been identified as providing important overwintering habitat for WCT in the upper Fording River watershed (Cope et al. 2016), as well as habitat for resident WCT (Penman et al. 2022). While anoxic conditions were present under the ice in Henretta Lake at the lowest depths (i.e., between 5.5 m and 8.5 m), additional information on water quality under ice is required to assess overwintering habitat for WCT (being conducted winter 2023). The majority of the lake was considered suitable oxygenated habitat for resident WCT during the open-water season. Instream drying has been observed since surveys began in the Fording River (2017 and 2019 in the southern and northern survey areas, respectively) and Henretta Creek

(2020) upstream of the FRO mine boundary. Annual monitoring of seasonal drying identified year-to-year variability on timing of drying that may, at times, limit WCT movement, but once low flows are established in early winter, dry sections only expand spatially at consistent locations with no new dry areas appearing. Overall, based on muscle selenium concentrations, meristic, and anomaly data from adult fish collected under the RAEMP, as well as information collected from chronic toxicity testing, WCT in the FRO LAEMP study area appear to be in good health. Population monitoring has indicated a continued increase in the subadult and adult population in the upper Fording River in 2022, now up to ~2,300 fish from ~330 in 2019. The 2022 age-1 abundance was similar to the previous two years, while the number of fish in the 100 to 200 mm range (age-1 and age-2+) has increased between 2021 and 2022, which may lead to continued increases in adult abundance. The estimated number of eggs deposited by WCT has increased steadily since 2019 (inferred from adult abundance and size). A decline in estimated egg to age-1 survival for the 2021 cohort relative to 2019 and 2020 suggests there may be a density-dependent response as the population approaches its carrying capacity. The estimated number of nests in redds in 2022 was lower compared to 2021 and may be associated with cold early season water temperatures.

Overall, concentrations of nutrients (increase in total phosphate and orthophosphate), selenium (decrease in total and dissolved selenium; increase in methylseleninic acid), and nitrate (decrease) have changed downstream of the FRO-S AWTF outfall post-commissioning relative to the area immediately upstream. No associated changes in BIC structure or benthic invertebrate tissue selenium concentrations were observed, but secondary productivity (benthic invertebrate biomass and density) increased immediately downstream of the FRO-S AWTF outfall, likely a result of increased phosphorus. This increase, however, was limited to just one monitoring area, and measures of productivity (density and biomass) remained within the range observed across the FRO LAEMP study area. Consistent with previous years, BIC structure changed from upstream to downstream in the Fording River, simultaneous with changes in concentrations of mine-related constituents and habitat features, but the total abundance of benthic invertebrates and key BIC endpoints remain high throughout the study area. The WCT population has continued to recover from the 2019 decline (e.g., increased abundance of fish at multiple age classes and broad distribution of redds) and fish appear to be in good health.

TOC – Total Organic Carbon
UFR – Upper Fording River
WCT – Westslope Cutthroat Trout
WCT RWG – Westslope Cutthroat Trout Recovery Working Group
WSQG – Working Sediment Quality Guidelines

1 INTRODUCTION

1.1 Background

Teck Coal Limited (Teck) operates four steelmaking coal mines in the Elk River watershed, which are the Fording River Operations (FRO), Greenhills Operations (GHO), Line Creek Operations (LCO), and Elkview Operations (EVO; Figure 1.1). A fifth mine, Coal Mountain Mine (CMm), is also owned by Teck and located in the Elk River watershed (Figure 1.1); however, it is no longer in operation and has been moved into the care and maintenance designation. Discharges from the mines to the Elk River watershed are authorized by the British Columbia Ministry of Environment and Climate Change Strategy (ENV) through permits that are issued under provisions of the Environmental Management Act. Permit 107517 specifies the terms and conditions associated with discharges from Teck's five Elk Valley mine operations.

Permit 107517 required that Teck develop a local aquatic effects monitoring program (LAEMP) related to ongoing mining at FRO and the commissioning of the Fording River Operation - South Active Water Treatment Facility (FRO-S AWTF) designed to treat waters from Cataract, Swift, and Kilmarnock Creeks (Figure 1.2). As a result, the FRO LAEMP was developed in 2016 to assess site-specific conditions on a frequent and localized basis, particularly in relation to water treatment, and has been updated since to include the future FRO-N SRF. Permit 107517 was amended in December 2021 (Teck 2021) to include the third cycle of FRO LAEMP monitoring, and Section 8.3.2 outlines the LAEMP requirements as follows:

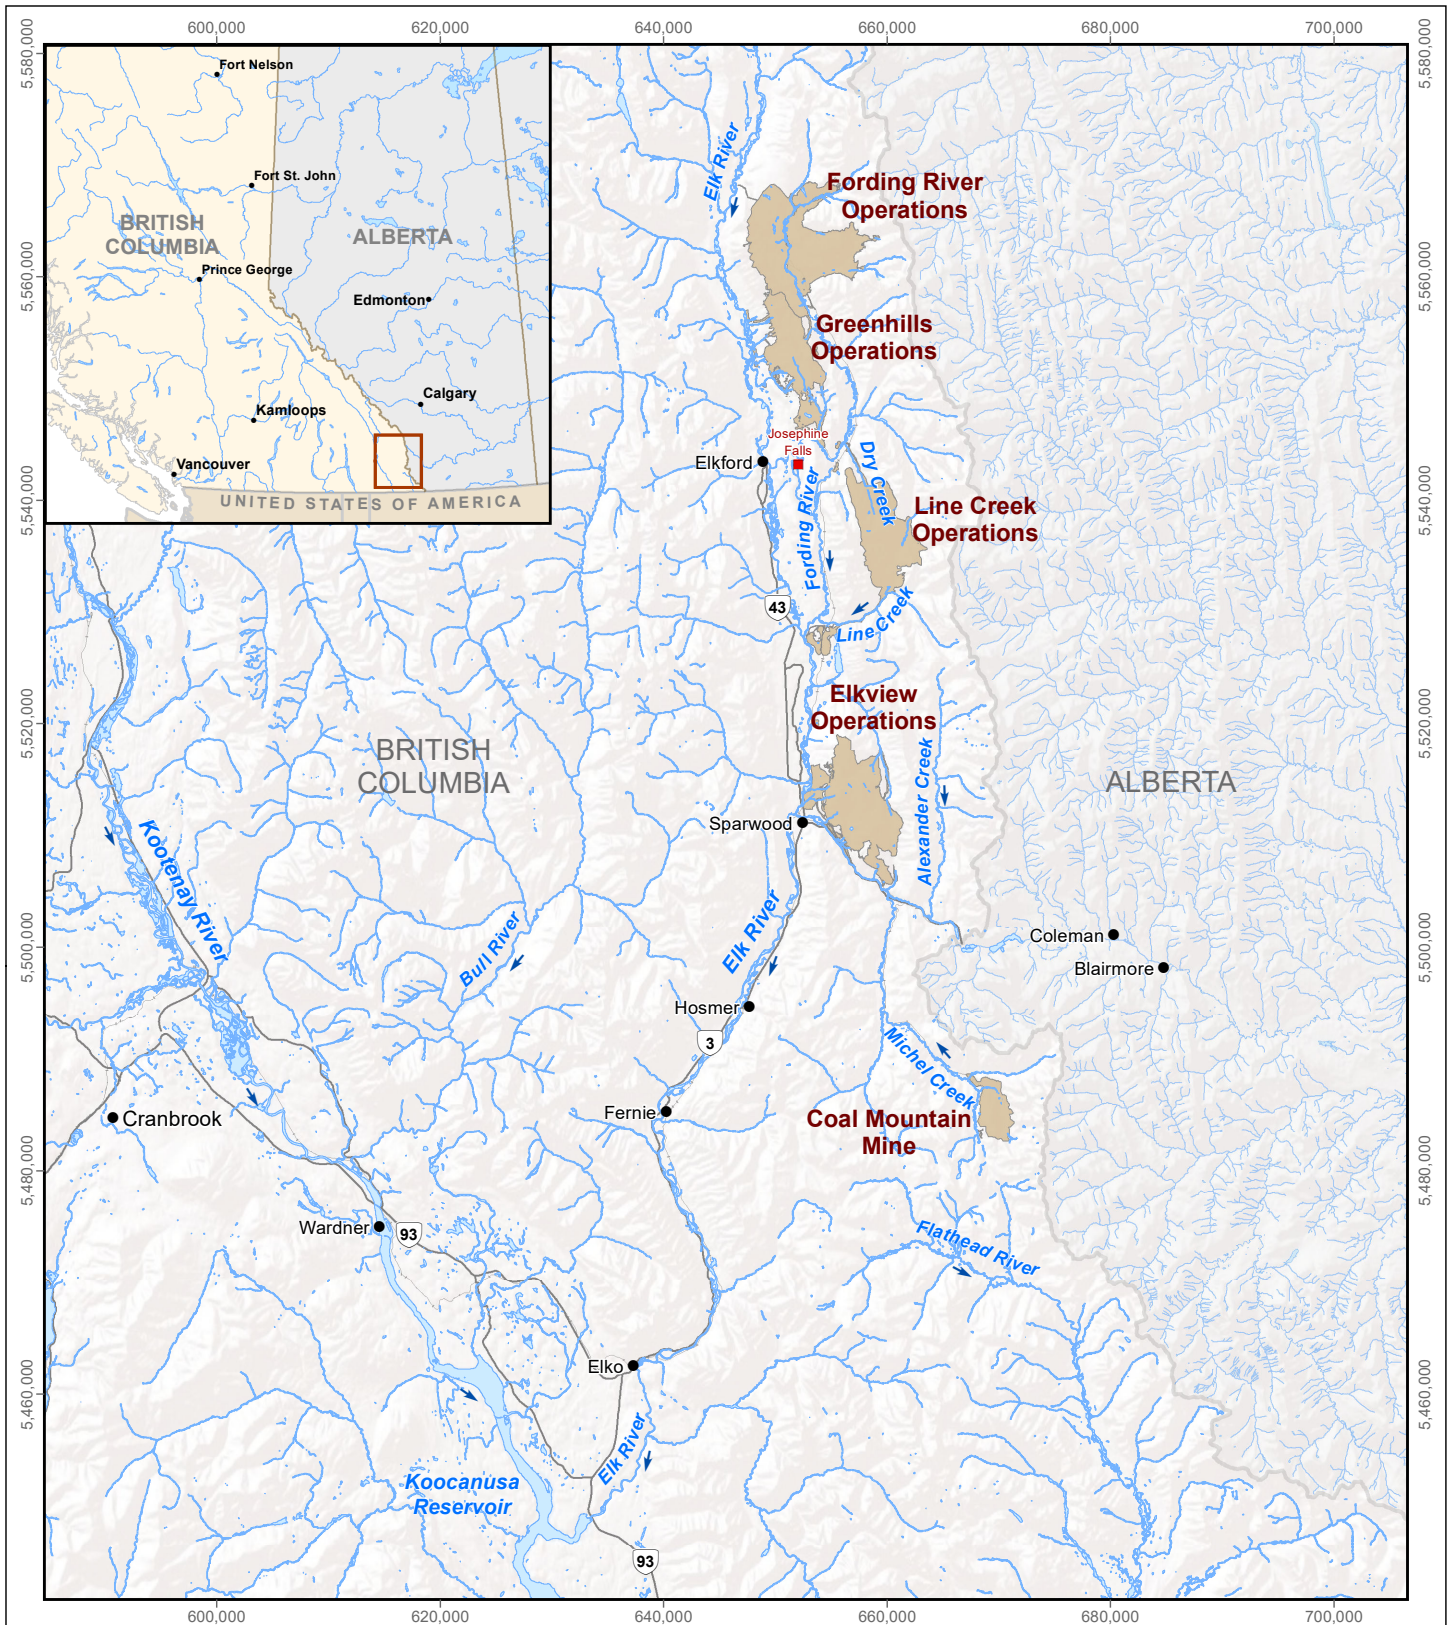

“The Permittee must complete to the satisfaction of the director a study design for a LAEMP which will focus on the upper Fording River for 2021-2023 by April 1, 2021. The study design must be reviewed by the EMC¹ and be designed to an appropriate temporal scale to capture short term, local effects to the immediate receiving environment. Any changes to the approved study design must be reported in the annual LAEMP report.”

Also, Section 9.5 of Permit 107517 states:

“The LAEMP Annual Reports must be reported on in accordance with generally accepted standards of good scientific practice in a written report and submitted to the director of each year following the data collection calendar year on the following dates: FRO LAEMP: May 31.”

¹ The Environmental Monitoring Committee (EMC) was established after the first RAEMP design was approved and implemented in 2015, and consists of representatives from Teck, BC Ministry of Environment and Climate Change (ENV), the Ministry of Energy and Mines, Environment Canada, the Ktunaxa Nation Council (KNC), Interior Health Authority, and an Independent Scientist. The EMC reviews submissions and provides technical advice and input to Teck and the ENV Director, as stipulated in Section 11.2 of Permit 107517.

Figure 1.2

Three study design cycles have been implemented since the FRO LAEMP was initiated in 2016 (Minnow 2016, Minnow and Lotic 2019a, 2021a). The first two cycles (2016 to 2018 and 2019 to 2020; Minnow 2016, Minnow and Lotic 2019a) consisted of pre-commissioning monitoring for the FRO-S AWTF and the FRO-N SRF, as well as monitoring to address questions related to the potential for mine-related effects on biota, particularly benthic invertebrate communities (BIC; Minnow 2016, Minnow and Lotic 2019a, 2021a). A key finding of previous FRO LAEMP reports was a spatial shift in key BIC metrics (i.e., decreasing % Ephemeroptera and subsequent increase in % Plecoptera) from upstream to downstream (Minnow and Lotic 2019b, 2020b, 2021b, 2022). The gradual shift in community structure throughout the middle study area and continuing downstream to the lower study area was attributed to differences in key water quality and habitat variables.

The third FRO LAEMP cycle (2021 to 2023) includes the first year (2022) of post-commissioning sampling in relation to FRO-S AWTF water treatment, with the anticipated commissioning of FRO-N SRF beginning in 2023 (Minnow and Lotic 2021a). The FRO-S AWTF was commissioned on December 22, 2021, and has a maximum treatment capacity of 21,035 m³/d; however, the facility was not operating at full capacity in 2022 because of timelines associated with commissioning, availability of influent water sources, and intermittent operational issues. In addition to post-commissioning monitoring, the third cycle of the FRO LAEMP also incorporates findings from other studies (e.g., RAEMP, UFR WCT Population Monitoring Program) to help understand factors affecting WCT health and populations within the study area (Minnow and Lotic 2021a).

The goal of the FRO LAEMP is to assess site-specific conditions on a frequent and localized basis, as required, until sufficient data have been collected, concerns no longer exist, or relevant monitoring can be incorporated into the regional aquatic effects monitoring program (RAEMP). The primary focus of the FRO LAEMP is to monitor aquatic ecosystem condition, particularly as it relates to conditions post-commissioning of water treatment compared to conditions prior to commissioning. Study questions from the first and second FRO LAEMP cycles were updated during the preparation of the third FRO LAEMP cycle to better reflect important considerations in the study area (e.g., the commissioning of the FRO-N SRF and the WCT population decline; Minnow and Lotic 2021a). Through the evaluation of data from previous reports, and EMC (December 3, 2020; February 3 and 23, 2021) and subject matter experts (SMEs), the FRO LAEMP study questions were updated as follows:

1. Are nitrate concentrations in the study area changing and do they have the potential for adverse effects on biota?
2. Is water treatment affecting biological productivity downstream in the Fording River?

3. Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?
4. How is temperature changing over time in the FRO LAEMP study area?
 - 4a. Is water temperature measurably different (greater than 1 degree Celsius) downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition?
 - 4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF)?
5. What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?
6. What are the factors influencing fish health and population in the upper Fording River?

The general approach, including context around each study question, specific monitoring areas in relation to sample types, and an overview of how data were considered for evaluation are summarized in Table 1.1. Relevant information obtained under other programs, such as the regional calcite and chronic toxicity monitoring programs are also summarized in the LAEMP. The results of the seventh year (2022 calendar year – January to December) of monitoring for the FRO LAEMP are the subject of this report, which includes comparison to previous years of data.

1.2 Conceptual Site Model

A conceptual site model (CSM) is a written and/or illustrative depiction of relationships between human activities that disturb the environment and the ways such disturbances can alter the ecosystem and affect biological receptors. Potential effects on aquatic receptors in the UFR, both prior to and after the commissioning of the FRO-S AWTF and FRO-N SRF were considered in a CSM (Figure 1.3). Assessment endpoints are the valued attributes of an ecosystem upon which management actions focus (USEPA 1998, 2003). Assessment endpoints considered in the FRO LAEMP are outlined in Table 1.1 and are evaluated using measurement endpoints. Typically, multiple measurement endpoints are used to support evaluation and interpretation of each assessment endpoint to conclude if the assessment endpoints/receptors are being protected.

As illustrated by the CSM, assessment and measurement endpoints may be affected through physical and/or chemical processes related to mining and operation of the AWTF (Figure 1.3). Biological measurements relating directly to population or community characteristics are referred to as direct indicators. Mine-related stressors (including tissue selenium concentrations) are also

1. Are nitrate concentrations in the study area changing, and do they have the potential for adverse effects on biota?	EVWQP projections identified an increasing trend in nitrate concentrations in the upper Fording River. Treatment plans have been finalized within the study area (FRO AWTF S and Eagle 4 SRF) and aqueous nitrate concentrations are expected to decrease following commissioning compared to pre-commissioning concentrations. Nitrate concentrations above EVWQP benchmarks have the potential to adversely affect biota.	Benthic invertebrate community relative to nitrate concentrations in the upper Fording River, and various organisms response to chronic toxicity testing.	Nitrate concentrations in water, surface water chronic toxicity tests (quarterly and semi-annually)	Routine water sampling at FR_UFR1, FR_HC3, FR_FR1, FR_MULTIPLATE, FR_FRNTP, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRRD, FR_FRABCH, GH_PC2, FR_FR5; Water sampling concurrent with biological sampling at RG_FRSCH2, RG_FRGHSC, RG_FOUCL, RG_FOUNGD, RG_FODNGD, and RG_FRCP1SW, Chronic toxicity tests at FR_UFR1, FR_FRCP1 and FR_FRABCH	Benthic invertebrate community structure (September) and chronic toxicity testing	CABIN kick and sweep benthic invertebrate community (BIC) sampling at RG_FO26 (Ref), RG_HENUP (Ref), RG_UFR1 (Ref), RG_FODHE, RG_FOUCL, RG_FOUNGD, RG_FODNGD, RG_MP1, RG_FOUSH, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, RG_FRUPO, RG_FODPO, RG_FO22, RG_FOU EW; chronic toxicity tests at RG_UFR1, RG_FOBCP and RG_FO22	<ol style="list-style-type: none"> 1. Evaluated nitrate concentrations relative to updated effects concentrations. 2. Determined changes of nitrate concentrations relative to baseyear and water treatment commissioning at each station throughout the study area. 3. Compared nitrate concentrations upstream and downstream of water treatment, and pre- and post-commissioning. 4. Determined if BIC endpoints are outside of regional and/or site-specific normal ranges or moving away from the reference ranges in accordance with observed nitrate concentrations. 5. Determined if BIC results correspond with expectations based on nitrate concentrations in water relative to the updated effects concentration for nitrate. 6. Compared BIC endpoints upstream and downstream from water treatment, and pre- and post-commissioning. 7. Used statistical tools (e.g., correlations, constraining ordination) to evaluate the potential impact of nitrate on BIC (see study question 5). 8. Interpret chronic toxicity results in the context of nitrate concentrations in the study area.
2. Is water treatment affecting biological productivity downstream in the Fording River?	Phosphorus will be added to the FRO AWTF-S and FRO Eagle 4 SRF to facilitate microbial growth. Increased phosphorus concentrations in the effluent has the potential to cause increased algae growth in the upper Fording River, changing the trophic status and overall health.	Phosphorus concentrations in water upstream and downstream of water treatment pre- and post-commissioning. Biological invertebrate productivity downstream from the FRO AWTF-S and FRO Eagle 4 SRF discharge locations post- compared to pre-commissioning and relative to productivity observed upstream from the discharge locations.	Nutrient concentrations, particularly total phosphorus and orthophosphate (phosphorus is the limiting nutrient in the upper Fording River)	Routine water sampling at FR_UFR1, FR_HC3, FR_FR1, FR_MULTIPLATE, FR_FRNTP, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRRD, FR_FRABCH, GH_PC2, FR_FR5; Water sampling concurrent with biological sampling at RG_FRSCH2, RG_FRGHSC, RG_FOUCL, RG_FOUNGD, RG_FODNGD, and RG_FRCP1SW	Benthic invertebrate biomass, benthic invertebrate community structure, periphyton scores (all in September only)	BIC sampling as above; Biomass and density (HESS) sampling at RG_FO26 (Ref), RG_HENUP (Ref), RG_FOUCL, RG_FOUNGD, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, RG_FRUPO, RG_FO22	<ol style="list-style-type: none"> 1. Compared total phosphorus and orthophosphate concentrations upstream and downstream from water treatment, and pre- and post-commissioning. 2. Determined changes of total phosphorus and orthophosphate concentrations relative to baseyear and water treatment commissioning at each station throughout the study area. 3. Compared biomass/density upstream and downstream from water treatment, and pre- and post-commissioning.
3. Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?	Treatment plans (FRO AWTF S and Eagle 4 SRF) are expected to remove up to 50% of total selenium downstream in the Fording River; however, treatment could also result in an increase in the concentrations of more bioavailable selenium species (i.e., reduced selenium), resulting in increases of benthic invertebrate tissue selenium concentrations.	Benthic invertebrate tissue selenium concentrations downstream from the FRO AWTF-S and FRO Eagle 4 SRF locations post- compared to pre-AWTF commissioning and relative to concentrations observed upstream from the discharge locations. Selenium concentrations and species in water upstream and downstream of water treatment and pre- and post-commissioning.	Total and dissolved selenium concentrations, and selenium speciation	Routine water sampling at FR_UFR1, FR_HC3, FR_FR1, FR_MULTIPLATE, FR_FRNTP, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRRD, FR_FRABCH, GH_PC2, FR_FR5; Water sampling concurrent with biological sampling at RG_FRSCH2, RG_FRGHSC, RG_FOUCL, RG_FOUNGD, RG_FODNGD, and RG_FRCP1SW	Benthic invertebrate tissue selenium concentrations (composite-taxa samples)	Benthic invertebrate tissue sampling at RG_FO26 (Ref), RG_HENUP (Ref), RG_UFR1 (Ref), RG_FRSCH2, RG_FRGHSC, RG_FODHE, RG_FOUCL, RG_FOUNGD, RG_FODNGD, RG_MP1, RG_FOUSH, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, RG_FRUPO, RG_FODPO, RG_FO22, RG_FOU EW	<ol style="list-style-type: none"> 1. Determined if benthic invertebrate tissue selenium concentrations are outside the regional normal range or above EVWQP benchmarks. 2. Compared benthic invertebrate tissue selenium concentrations upstream and downstream from water treatment, and pre- and post-commissioning. 3. Compared aqueous selenium concentrations upstream and downstream from water treatment, and pre- and post-commissioning. 4. Compared benthic invertebrate tissue selenium concentrations to expected concentrations based on the selenium bioaccumulation model. 5. If tissue selenium concentrations were higher than those predicted by the bioaccumulation model, determined if differences in tissue selenium concentrations are related to changes in selenium species concentrations (i.e., the B-tool was used to compare measured versus modelled benthic invertebrate tissue selenium concentrations).

^b Additional locations will be monitored under programs outside of the LAEMP.

monitored as part of the FRO LAEMP and are referred to as indirect indicators. Laboratory chronic toxicity data (semi-direct indicators) are incorporated into the FRO LAEMP, as appropriate. Measurement of indirect and semi-direct indicators contribute to understanding if observed effects on individual receptors are mine-related. Effects may act alone or in combination to influence aquatic populations and/or communities by changing the abundance or resilience of aquatic receptors and are evaluated by monitoring benthic invertebrates as biological receptors EVWQP within the FRO LAEMP. The study questions (Section 1.1) were developed in consideration of the potential effects identified in the CSM.

1.3 Linkages to the Adaptive Management Plan for Teck Coal in the Elk Valley

As required in Permit 107517 Section 10, Teck developed an Adaptive Management Plan (AMP) to support implementation of the Elk Valley Water Quality Plan (EVWQP) to achieve water quality targets including calcite targets, ensure that human health and the environment are protected, and where necessary, restored, and to facilitate continuous improvement of water quality in the Elk Valley. The AMP was most recently updated in December 2021 (Teck 2021a). Adaptive management is a systematic, rigorous approach to environmental management that maximizes learning about uncertainties while simultaneously striving to meet multiple management objectives and adapt management actions based on what is learned. The adaptive management cycle comprises six stages: assess, design, implement, monitor, evaluate and adjust. The AMP identifies six Management Questions (MQs) that are re-evaluated at regular intervals. Evaluating these MQs collectively articulates whether Teck is on track to meet the environmental objectives of the EVWQP.

The FRO LAEMP was designed to monitor conditions in the upper Fording River in relation to water treatment and answer specific questions on an annual basis (Section 1.2). Each annual LAEMP cycle (results are reported on May 31st of each year for the preceding calendar year) is also used for tracking issues for which a potential need for an adjustment, using the response framework, has been identified, including biological triggers assessments. The following are examples of adaptive management in the FRO LAEMP study area:

- Seasonal drying between Swift and Cataract Creeks was observed in late 2018, resulting in flows in the Fording River at the FRO Compliance Point consisting predominantly of water from Cataract Creek. To evaluate the potential effects on biota in the area downstream of Cataract Creek, two additional biological sampling events were included (Stage 6: Adjust) in December 2018 and February 2019 (Minnow and Lotic 2020).
- In June of 2020, benthic invertebrate tissue selenium concentrations were anomalously high in three out of five replicates at the area upstream of the Greenhouse Side

channel confluence (RG_FRCP1SW), which was observed in other results at some areas within the Elk Valley. As a result, a broader investigation of annelid presence in composite-taxa benthic invertebrate tissue samples and the effects on selenium concentrations was conducted (Luoma 2021; Golder 2021).

- Polyaromatic hydrocarbon and, to a lesser extent, selenium concentrations were significantly higher at the area immediately downstream of the FRO-S AWTF outfall (RG_SCOUTDS) in September 2022 so confirmatory sampling was conducted in February 2023 to verify anomalous results. A review of sampling and laboratory protocols was also conducted.

Biological triggers are intended as a simple and consistent way to flag potential unexpected monitoring results that may require additional investigation and adjustment. In the current report, % EPT and composite-taxa benthic invertebrate tissue selenium concentrations were assessed to determine whether a biological trigger has been reached (additional information and methods pertaining to this analysis can be found in Appendix K). Reaching a trigger may lead to an adjustment (Stage 6: Adjust) using the AMP response framework. Implementation of management actions is not constrained to the AMP or LAEMP annual reporting cycles but may be (and have been) triggered at any time during the monitoring and reporting cycle. This is the main report for conveying biological trigger results within the FRO LAEMP study area under the AMP.

In addition to addressing questions specific to the FRO LAEMP on an annual basis, aquatic monitoring data from the LAEMP will contribute to the broader data set assessed every three years within the RAEMP. The RAEMP is designed to evaluation MQ 5: *“Does monitoring indicate that mine-related changes in aquatic ecosystem conditions are consistent with expectations?”* Data from the LAEMP and RAEMP also contribute to answering MQ 2: *“Will aquatic ecosystem health be protected by meeting the long-term SPOs?”*

Please refer to the 2021 AMP Update (Teck 2021a) for more information on the adaptive management framework, including Management Questions, key uncertainties, and continuous improvement; linkages between the AMP and other EVWQP programs; and AMP reporting. Progress on gaining new knowledge and reducing key uncertainties is described in annual AMP reports (submitted July 31) and evaluating the answers to MQs are reported in MQ evaluation reports (various submission dates).

2 METHODS

2.1 Overview

The general approach for the FRO LAEMP includes presentation of the collected data and data evaluation in relation to each of the study questions. Permit 107517 requires that Teck prepare an annual FRO LAEMP report that summarize monitoring data collected during the preceding calendar year at all locations specified in the permit; this report includes all historical data up to the end of the 2022 calendar year for all endpoints. Data were compared to EVWQP benchmarks, BC water quality guidelines for protection of aquatic life and, where applicable, updated effects concentrations (ECs), screening values, and proposed benchmarks. Effects concentrations for nitrate and sulphate were updated in 2022 using the most current toxicity information (WSP Golder 2022).

Monitoring in 2022 was consistent with the 2021 to 2023 FRO LAEMP study design (Minnow and Lotic 2021b) and approved amendments (Minnow and Lotic 2022), with some exceptions (Tables 2.1 and 2.2). The FRO-S AWTF commissioning sampling occurred in December (2021), January, February, and March, and included water quality (including selenium speciation) and benthic invertebrate tissue chemistry sampling (Table 2.2). In September, sampling included sediment and water quality (including selenium speciation), benthic invertebrate biomass and density (Hess), and BIC (kick and sweep), while in June and December, only benthic invertebrate tissue chemistry and water quality (including selenium speciation) sampling was conducted, as per the FRO LAEMP study design and amendments (Minnow and Lotic 2021a; Minnow and Lotic 2022). Samples were taken from established biological monitoring areas within the study area, where applicable (Tables 2.1 and 2.2; Minnow and Lotic 2021a; Minnow and Lotic 2022), which extended from the Fording River and Henretta Creek upstream of FRO, through the operations and downstream to between Chauncey Creek and Ewin Creek (Figure 2.1; Table 2.1). Deviations from study design are summarized below (Table 2.2):

- 1) Seasonal drying and/or ice conditions prevented sampling at RG_FRCP1SW in December (2021 and 2022), January, February, and March, at RG_FOBCP in January, February, and December (2022), and at RG_FODHE in December 2022.
- 2) Geohazards associated with the Turnbull landslide prohibited access, and therefore sampling, in Henretta Creek (RG_HENUP) in June.
- 3) A strong freshet (high and fast flowing waters) prevented sampling at RG_FO22 (associated with the Compliance point FR_FRABCH) and RG_FOU EW in June.

Table 2.1: Summary of Samples Collected for the FRO LAEMP, 2022

Notes: '-' indicates sample that was not taken because it was not a part of the sampling design; 'x' indicates sample that was not taken because of unsafe sampling conditions, drying and/or ice conditions.
^a RG_UFR1 was used as a reference area in winter months when there was no access to RG_FO26 or RG_HENUP. It was added for June and September for additional pre-FRO AWTF-S commissioning data.
^b n=5 for composite-taxon tissue samples in areas associated with the FRO AWTF-S and the FRO-N SRF commissioning sampling plans.
^c The water quality monitoring station is the same for biological monitoring stations RG_FO26 and RG_UFR1.
^d Routine water quality monitoring stations associated with biological monitoring areas are outlined in brackets.
^e BIC monitoring at RG_FRSC2 was added in September 2022 at the request of the EMC.
^f Triplicate samples of periphyton for both ash free dry mass and chlorophyll-a analysis taken during the RAEMP
^g Periphyton scores of n=5 were taken at each biological monitoring area in September.
^h Water and benthic invertebrate tissue monitoring was added within 30 m downstream of the FRO AWTF-S outfall at the request of the EMC; this sampling was not a part of the study design.
ⁱ Benthic invertebrate community sampling in June and December was discontinued in 2022 as approved by the EMC during 2021 meetings.

Table 2.2: Summary of Samples Collected to Support the FRO-S AWTF Commissioning Sampling Plan, 2022

Notes: the FRO AWTF-S outfall is located between RG_FOBKS and RG_SCOUTDS; 'x' indicates sample that was not taken because of drying and/or ice conditions.

^a RG_UFR1 was used as the reference location because of limited access to RG_FO26 or RG_HENUP during winter months.

^b Mine-exposed sampling areas upstream of FRO-S AWTF.

^c sampling was conducted two weeks before FRO AWTF-S forward flow.

^d Routine water quality monitoring stations associated with biological monitoring areas are outlined in brackets.

- 4) Drying surveys in Henretta Creek could not be conducted in November or December 2022 because of hazards associated with the Turnbull landslide.

Water level (flow) and temperature were monitored continuously at established gauges throughout the study area. Drying surveys were conducted monthly between January and reconnection, and from August through December 2022 within the Southern, Northern, and upper Henretta drying survey areas (Table 2.3; Figure 2.2). One logger failure occurred at FR_FRCP1SW in 2022 for the M5 logger over winter, however, data was collected from the backup Hobo logger, thus filling any data gaps. Additionally, stilling wells were washed away at FR_FRDSCC1 and FR_FOUCL during freshet but were replaced on July 27, 2022, resulting in a data gap at these two stations from June 6th to July 27th, 2022.

2.2 Water Quality

2.2.1 Sample Collection

Water quality and selenium speciation samples, as well as *in situ* water quality data (i.e., temperature, flow, pH, conductivity, and DO), were collected concurrently with all biological sampling (Tables 2.1 and 2.2). In addition, routine water quality monitoring data collected by Teck and that corresponded with many biological sampling areas were included in the FRO LAEMP (Table 2.4; Figure 2.1). Water quality samples were collected to understand potential changes to concentrations of nutrients and mine-related constituents in accordance with Permit 107517, while selenium speciation samples were collected to provide understanding of speciation in the study area in relation to commissioning of the FRO-S AWTF and the FRO-N SRF, and to compare to benthic invertebrate tissue selenium concentrations (see Appendix B1.2 and B1.3 for detailed methodology).

2.2.2 Laboratory and Data Analysis

Water samples were analyzed by ALS Environmental, Calgary, Alberta, for constituents consistent with Permit 107517 (i.e., conventional parameters, major ions, nutrients, and total and dissolved metals) using standard methods (see Appendix B1.2 for detailed methodology).

Water samples were analyzed by Brooks Applied Labs, Seattle, Washington for selenium speciation analysis (including concentrations of selenate, selenite, dimethylselenoxide (DMSeO), methylseleninic acid (MeSe(IV)), methaneselenonic acid, selenocyanate, selenomethionine, selenosulphate, and unknown selenium species; see Appendix B1.2 for detailed methodology).

Water quality data were downloaded from Teck's EQulS database and included both routine monitoring results collected by Teck and samples collected concurrently with biological sampling.

Table 2.3: Stations Associated with Drying Surveys, Manual Flow Measurements, and Hydrometric and Water Temperature Loggers, FRO LAEMP, 2022

Notes: Q = quarterly; M = monthly; W/M = weekly during freshet (March 15 to July 15); Q - quarterly; N/A - Not Applicable; "-" indicates no data available.

^a Dissolved oxygen, temperature, specific conductance, pH.

^b Total and dissolved metals, total and dissolved organic carbon, nutrients, and major ions as per Table 18 of Permit 107517.

^c Chronic toxicity as per Permit 107517 requirements.

^d Not required by Permit 107517; FR_UFR1 is used as a reference location in the chronic toxicity program. Frequency may change depending on the needs of the program.

^e Non permitted location, frequency may change in 2022.

^f Chronic toxicity started in Q4 2018 at this location.

^g This sampling location, previously called GH_FR3, was merged to FR_FR3 for data management purposes.

^h Biological monitoring areas associated with water quality monitoring stations are outlined in brackets.

ⁱ Stations paired for correlation and multivariate analyses but are presented separately in report figures because of their distance from one another.

Analyses of water quality data were completed using the following approaches (see Appendix B section B1.3 for detailed methodology):

- Tabular and graphical (temporal) comparison to applicable benchmarks², updated ECs, screening values, proposed benchmarks, and BCWQGs. A summary of EVWQP benchmarks is also included for reference;
- Principal Component Analysis (PCA) to condense water quality results for use in benthic invertebrate community correlation analysis;
- Graphical spatial comparisons of order constituents (nitrate, total selenium, dissolved cadmium, and sulphate), TDS, total and dissolved nickel, and selenium species;
- Before-after control-impact (BACI) assessment of water quality downstream of treatment pre- and post-commissioning of the FRO-S AWTF using a censored analysis of variance (ANOVA);
- Evaluation of temporal trends in monthly mean water quality concentrations using two tests:
 - Non-parametric seasonal Kendall test (for nitrate concentrations);
 - Two-way censored regression analysis of variance (2-way ANOVA).

2.2.3 Chronic Toxicity Testing

Chronic toxicity testing was conducted by Nautilus Environmental for the annual Regional Chronic Toxicity Study as required by Permit 107517 (WSP 2023). Endpoints for water flea (*Ceriodaphnia dubia*) survival and reproduction, amphipod (*Hyalella azteca*) survival and dry weight, rainbow trout (*Oncorhynchus mykiss*) survival, viability, length, and weight, and fathead minnow (*Pimephales promelas*) hatch, survival, biomass, length, and development were tested for water quality (see Appendix B section B1.6 for detailed methodology). Chronic toxicity tests were completed with water from FR_UFR1 (reference), FR_FRPC1, and FR_FRABCH according to the following: *C. dubia* and *P. subcapitata* were tested quarterly; *O. mykiss* and *H. azteca* were tested in the second and fourth quarter; *P. promelas* was tested in the first and third quarter. See Appendix B section B1.4 for detailed methodology.

² In 2022, potential risks to aquatic life associated with selenium were assessed by evaluation of tissue selenium results in biota as compared to primarily using EVWQP benchmarks for aqueous selenium.

2.3 Hydrology

2.3.1 Drying and Stranding Surveys

In 2022, monthly drying surveys were completed (January to April and August to December) to evaluate surface water connectivity (i.e., seasonal drying) along the Fording River, the Greenhouse Side Channel, Fording River Side Channel 2, and Henretta Creek in the FRO LAEMP study area (Table 2.3; Figure 2.2). Stranding surveys also evaluated surface water connectivity each month (i.e., approximately two weeks apart from drying surveys) at the same FRO LAEMP study area locations (Figure 2.2), except in the Fording River downstream of FR_FRRD, the Greenhouse Side Channel, or Fording River Side Channel 2. Henretta Creek could not be assessed during the FRO LAEMP or stranding surveys by field crews in November or December 2022 due to hazards associated with the Turnbull landslide. During the surveys, field crews walked each section to delineate any extent of drying, isolated pools, fish, and wildlife observations. Additionally, several hydrological measurements were collected by field crews: water level, flow, and temperature (see Appendix B section B.2.1 for detailed methodology). Analyses of drying survey data were completed using the following approaches (see Appendix B section B2.1.1 for detailed methodology).

- Tabular summaries of dry days for each survey section and hydrometric station for each year from 2017 to 2022;
- Dry areas were mapped for each month when drying was observed.

2.3.2 Water Level and Temperature Loggers

Water level and temperature were continuously monitored at 13 hydrometric stations within the Fording River in 2022 using a combination of three loggers (Table 2.3; Figure 2.2). The loggers were programmed to record water level and water temperature at 15-minute intervals. Data was downloaded from the loggers pre-freshet in April, post-freshet in July, and October before freeze-up to avoid data loss (see Appendix B section B.2.2 for detailed methodology). Analyses of water level and temperature logger data were completed using the following approaches (see Appendix B section B2.2.2 for detailed methodology):

- A water temperature, stage, and discharge time series were plotted for each station;
- Non-parametric seasonal Kendall test for changes in water temperature at monitoring stations;
- Daily mean water temperature differences downstream compared to upstream (RG_SCOUTDS – RG_FOBKS) of the FRO-S AWTF outfall was tabulated and plotted to screen for any 1°C temperature difference;

- Changes in the difference of daily mean water temperature upstream (RG_FOBKS) and downstream (RG_SCOUTD) of the FRO-S AWTF outfall based on model predictions and corresponding confidence intervals pre- and post-commissioning.

2.4 Substrate Quality

2.4.1 Sediment

2.4.1.1 Sample Collection

Sediment quality samples were collected concurrently with benthic invertebrate sampling at eight areas in September 2022 (RG_HENUP, RG_FO26, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBCP, RG_FRUPO, and RG_FO22; Table 2.1). Five replicates were collected at mine-exposed areas, and three replicates were collected at reference areas, consistent with methods outlined in the 2021 to 2023 RAEMP study design (Minnow 2021). See Appendix B section B3.1.1 for detailed methodology.

2.4.1.2 Laboratory and Data Analysis

Sediment samples were analyzed by ALS Environmental in Calgary, Alberta, and analyses included physical and chemical parameters (e.g., moisture content, particle size, total organic carbon [TOC], metals and metalloids, and polyaromatic hydrocarbons [PAHs]). Analyses of sediment quality data were completed using the following approaches (see Appendix B sections B3.1.2 and B3.1.3 for detailed methodology):

- Tabular and graphical comparison to British Columbia Sediment Quality Guidelines (WSQGs), except for selenium concentrations which were compared to an alert concentration considered equivalent to an upper WSQG. The sediment data were also compared to regional normal ranges.
- Graphical spatial comparisons of chemical parameters;
- BACI assessment of sediment quality downstream of treatment pre- and post-commissioning of the FRO-S AWTF using a censored ANOVA;

2.4.2 Calcite

Calcite presence and concretion was measured on 100 pebbles at each biological station concurrent with benthic invertebrate community sampling and the associated pebble counts. For detailed methodology see Appendix B section B3.2:

- Calcite indices were tabulated for temporal comparisons;
- Calcite indices for 2022 were plotted for spatial comparisons.

2.5 Benthic Invertebrates

2.5.1 Community Structure

2.5.1.1 Sample Collection

Triplicate BIC samples were collected from each biological monitoring area in September, except at RG_FOBCP and RG_FO22 where replicates of five were taken (Table 2.1). Benthic invertebrate community sampling followed the CABIN protocol, which involved a 3-minute travelling kick into a net with a triangular aperture measuring 36 cm per side and a mesh having 400-µm openings (Environment Canada 2012). Replicates were collected from stations within a biological monitoring area either in separate riffles or in riffle sections a minimum of 50 m apart. Supporting measures, including habitat characterization, were also collected concurrent with sampling. For detailed methodology, see Appendix B section B4.2.1.

2.5.1.2 Laboratory and Data Analysis

Benthic invertebrate community samples were analyzed by Cordillera Consulting (lead taxonomist Scott Finlayson), in Summerland BC, for sorting and taxonomic identification. Total organism abundance was reported for every distinct taxon identified in each sample. Benthic invertebrate community structure was evaluated based on total abundance, taxonomic richness (to the lowest practicable level of taxonomy), and the abundances and proportional abundances (%) of major taxonomic groups. Analyses of benthic invertebrate community data were completed using the following approaches (see Appendix B sections B4.2.2 to B4.2.4 for detailed methodology):

- Graphical comparison of data relative to regional³ and site-specific normal ranges⁴;
- Evaluation of temporal changes in endpoints from mine-exposed and reference areas using a two-way ANOVA;
- BACI assessment of BIC downstream of treatment pre- and post-commissioning of the FRO-S AWTF using an ANOVA.

³ The reference normal range as presented in the RAEMP represents the 2.5th and 75th percentiles of the distribution of reference area data (pooled 2012 to 2019 data) reported in the 2017 to 2019 RAEMP report (Minnow 2020).

⁴ Site-specific normal ranges represent the 2.5th and 97.5 percentile for a given area as determined by habitat predictors for a given site in relation to the complete set of Elk Valley monitoring areas. The site-specific normal ranges were estimated using regression modelling as presented in the RAEMP (Minnow 2020).

2.5.2 Biomass and Density

2.5.2.1 Sample Collection

Benthic invertebrate biomass and density samples were collected in September from 2017 to 2022 to assess biological productivity before and after commissioning of the FRO-S AWTF and the FRO-N SRF. Samples for analysis of benthic invertebrate density and biomass were collected using a Hess sampler (0.1 m² sampling area) with 500 µm mesh. Ten replicate stations were sampled at each of twelve biological monitoring areas in September 2022 for analysis of benthic invertebrate biomass and density (Table 2.1; Figure 2.1). For detailed methodology, see Appendix B section B4.3.1.

2.5.2.2 Laboratory and Data Analysis

Benthic invertebrate biomass and density samples were sent to Zeas Inc. (lead taxonomist Danuta Zaranko), in Nobleton ON, for sorting and taxonomic identification. Analyses of benthic invertebrate productivity data were completed using the following approaches (see Appendix B sections B4.3.2 and B4.3.3 for detailed methodology):

- Graphical comparison of benthic invertebrate biomass and density changes temporally and spatially;
- BACI assessment of benthic invertebrate biomass and density downstream of treatment pre- and post-commissioning of the FRO-S AWTF using an ANOVA.

2.5.3 Tissue Selenium Concentrations

2.5.3.1 Sample Collection and Analysis

Benthic invertebrate samples were collected for tissue chemistry using the kick and sweep sampling method (described in greater detail in Appendix B section B4.2.1), except collections were not timed, and kicking continued until sufficient organisms were collected for analysis. All sampling events included collection of a composite sample of a variety of benthic invertebrate taxa. For detailed methodology, see Appendix B section B4.4.1.

2.5.3.2 Laboratory and Data Analysis

Benthic invertebrate tissue samples were analyzed by TrichAnalytics Inc. in Saanichton, BC for various chemical parameters. Analyses of composite-taxa benthic invertebrate tissue selenium data were completed using the following approaches (see Appendix B sections B4.4.2 and B4.4.3 for detailed methodology):

- Graphical comparison of tissue selenium concentrations relative to applicable benchmarks and the regional normal range;

- Comparison of observed tissue selenium concentrations to those predicted using a selenium bioaccumulation model and selenium bioaccumulation tool;
- BACI assessment of benthic invertebrate tissue selenium concentrations downstream of treatment pre- and post-commissioning of the FRO-S AWTF using an ANOVA.

2.6 Henretta Lake

A bathymetry survey was conducted to improve understanding of water depths in Henretta Lake. Water samples at various depths, *in situ* water profiles, and data loggers were used to understand water chemistry and temperature-oxygen dynamics within Henretta Lake and to assess fish habitat availability. For detailed methodology, see Appendix B section B.5.

2.7 Fish

2.7.1 Tissue Sample and Meristic Data Collection

Non-lethal sampling of WCT tissue was conducted to measure muscle tissue concentrations, as is required under the RAEMP, once per monitoring cycle (Minnow 2021), and as part of the AMP response framework for confirmatory sampling at the Multiplate Culvert in 2022. Westslope cutthroat trout tissue sampling was also conducted in Henretta Lake in September 2022 as part of the RAEMP lentic study. All fish caught under the RAEMP were assessed for anomalies (deformities, erosions [fin and gill], lesions, tumors, injuries, infections and/or parasites) and body condition was determined. In addition to fish sampling under the RAEMP, Teck collects tissue (dorsal muscle and whole body) samples from WCT incidental mortalities (e.g., found or incidentals from fish salvages) when relevant, to add valuable information to the dataset on fish selenium concentrations. For detailed methodology, see Appendix B section B6.1.

2.7.1.1 Laboratory and Data Analysis

Westslope Cutthroat Trout tissue samples were analyzed by TrichAnalytics Inc. in Saanichton, BC for various chemical parameters. Analyses of WCT tissue selenium, meristic, body condition, and anomaly data collected under the RAEMP were completed using the following approaches (see Appendix B sections B6.2 and B6.3 for detailed methodology):

- Graphical comparison of tissue selenium concentrations relative to applicable site-specific muscle benchmark and, where applicable, to the British Columbia guideline for fish muscle;

- Graphical comparison of Fulton’s condition factor among RAEMP areas, including reference areas. Body condition of WCT was calculated using Fulton’s condition factor (see Section B6.3);
- Tabulation of RAEMP WCT meristic, condition, and anomaly data

2.7.2 Fish Population Monitoring

In 2022 the Westslope Cutthroat Trout Population Monitoring Program in the upper Fording River continued to implement the standard protocols introduced in 2021 (e.g., more systematic redd surveys as well as single-pass electrofishing at large [~300 m] open sites [Thorley et al 2022a]). The program was further expanded to include increased electrofishing coverage as well as night snorkeling; as an alternative and less invasive method of enumerating juveniles, night-time dip-net surveys; to inform the length distributions of age-0, and Passive Integrated Transponder tagging captured fish; to better understand capture efficiencies, movement, growth, and survival and angling in Henretta Lake to supplement snorkeling data for fish >200 mm, to improve the understanding of WCT use of Henretta Lake (Penman et al. 2022; Thorley et al. 2023a; Thorley et al. 2022b). The expanded monitoring program helped to reduce uncertainty about status and trends of the upper Fording River Cutthroat Trout population as well as to answer key questions to assess the carrying capacity, intrinsic productivity, and viability of the population. A brief summary of analyses conducted as part of the Population Monitoring Program is provided below. For detailed methodology see Appendix B section B6.4 and Thorley et al 2023a.

- The timing of spawning and spatial distribution of redds in the UFR mainstem and tributaries were documented from the redd surveys and an estimate of the number of unique nests present was modeled using the Area Under the Curve model (Hilborn et al. 1999; Su et al. 2001, Thorley et al. 2023a).
- The length, weight, distribution, and density of age-1 and age-2+ fish were estimated based on electrofishing and night snorkeling. The length of age-0s were estimated based on available electrofishing and night dip-net surveys.
- Body condition of age-1 and age-2+ (90 to 169 mm fork length) was estimated using an allometric mass-length model that uses a site-specific scaling factor for this size class⁵ (He et al. 2008; Thorley et al., 2023a; Thorley et al., 2023b)

⁵ Body condition for adults was calculated using Fulton’s condition index which uses a defined scaling factor of 3.

- Sub adult and adult (≥ 200 mm fork length) abundance was estimated based on daytime snorkel surveys. Age-1 and age-2+ abundance were estimated from electrofishing and nighttime upstream snorkel surveys.
- Egg to age-1 survival (Pulkkinen et al. 2013) was calculated by dividing the estimate of the age-1 individuals by the total egg deposition the previous year. As such, the egg to age-1 survival was reported for fish spawned in 2021.

2.8 Integrated Analysis

Factors contributing to BIC variation within the FRO LAEMP study area were evaluated by comparing BIC endpoints with water quality, and where applicable, habitat variables. Correlation analysis and canonical correspondence analysis (CCAs) were conducted on data from the full study area, and then three individual study areas (upper, middle, and lower) within the full study area. The upper, middle, and lower study areas were grouped based on spatial differences of habitat (water depth, water flow/velocity, water temperature, substrate size, etc.) and water quality identified in previous FRO LAEMP reports (Minnow and Lotic 2019b, 2020b, 2021b, 2022). Integrated analyses were completed using the following approaches (for detailed methodology, see Appendix B section B7):

- Spearman Rank Correlations were conducted between key BIC endpoints and physical and chemical variables (Only significant [corrected $\alpha = 0.05/38 = 0.00132$] and strong ($r_s \geq |0.6|$) correlations were considered in the interpretation);
- A CCA was performed to investigate patterns in BIC in September of 2018 to 2022 relative to habitat and physical and chemical variables. Importance of individual stressor and habitat variables were investigated with permutation-based ANOVAs.

3 RESULTS AND DISCUSSION

3.1 FRO-S AWTF Overview

The FRO-S AWTF began commissioning on December 22, 2021, and has a maximum hydraulic capacity of 21,053 m³/d. Total water treatment was ~2,400 m³/d at the beginning of 2022 during the commissioning period (Figure 3.1). The facility began operating near capacity in September 2022, treating the majority of available influent water (~17,000 m³/d) before decreasing to ~13,000 m³/d by the end of the year when available influent flows decreased (Figure 3.1). There were intermittent periods where no or significantly reduced discharge rates occurred throughout 2022, when the facility was in recirculation for various reasons (e.g., maintenance). Water from Swift-Cataract Creek represented the majority of water treated throughout the first six months of FRO-S AWTF operation, but treatment of Kilmarnock Creek was initiated in the latter half of 2022, with volumes dependent on operational requirements for temperature and treatment performance. The percentage of treated water from the FRO-S AWTF in the Fording River downstream of the outfall (i.e., at FR_SCOUTDS) ranged from 0% during shutdown or recirculation periods to as high as 13% during periods of low flow (i.e., over winter; Appendix Figure E.15). Treated water from both the Fording River and Kilmarnock Creek outfalls have the potential to influence flows further downstream (e.g., via the Greenhouse Side Channel) through complex groundwater to surface water interactions that are being studied elsewhere (see SNC Lavalin 2022). Although the FRO-S AWTF was designed to remove nitrate and selenium, it also doses antiscalant to prevent calcite precipitation within the treatment facility and downstream, and this antiscalant contains molybdenum.

3.2 Study Question #1

Study Question #1 (Are nitrate concentrations in the study area changing, and do they have the potential for adverse effects on biota?) was evaluated through monitoring of water chemistry in relation to BIC data, as well as chronic toxicity.

3.2.1 Aqueous Nitrate Concentrations

Nitrate concentrations increased gradually within the FRO LAEMP study area since 2012, but concentrations were below the updated ECs for nitrate throughout most of 2022. Nitrate concentrations have increased the most over time in the section of the study area between the Multiplate Culvert (RG_MP1) and downstream of the former Cataract Creek confluence (RG_FOBCP), with smaller increases in the lower study area (i.e., downstream of the Greenhouse Side Channel confluence to Ewin Creek; Figure 2.2; Appendix Table D.1). Concentrations have decreased over time at the area downstream from the Henretta Creek confluence with the

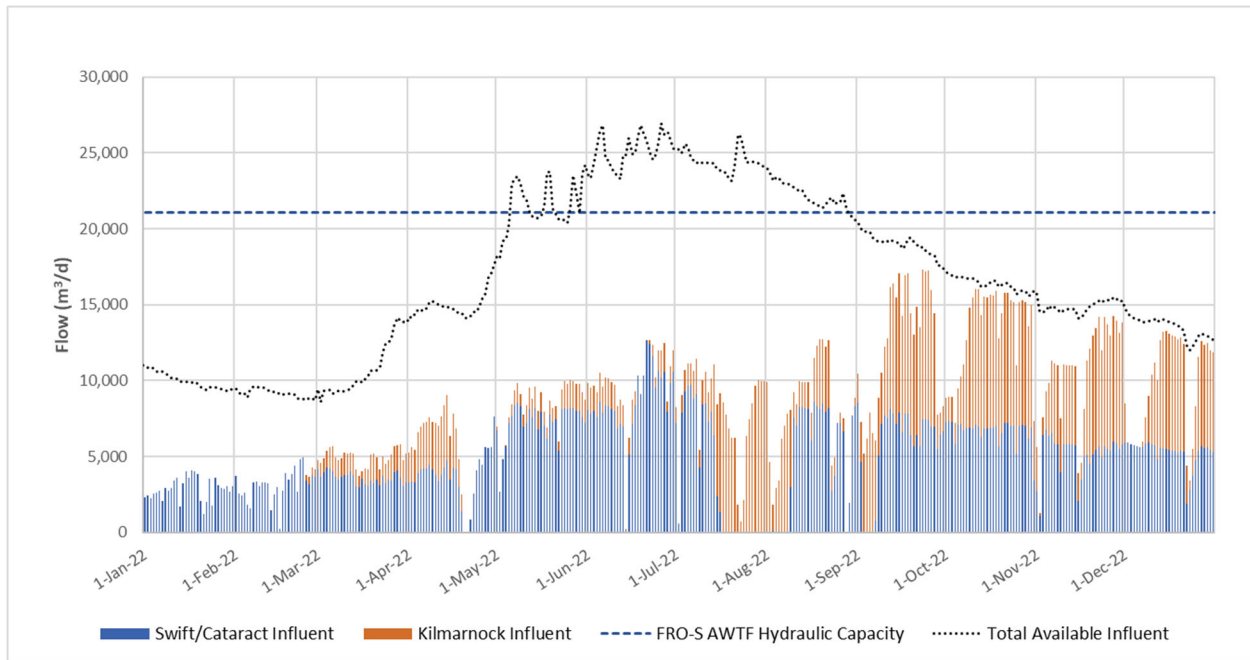

Figure 3.1: FRO-S AWTF Discharge Rates Relative to Total Available Influent, FRO LAEMP 2022

Notes: Total hydraulic capacity of the FRO-S AWTF was 21,035 m³/d. The Swift/Cataract Influent was approximately equal to the discharge rates at the Fording River Outfall, while the Kilmarnock Creek Influent was approximately equal to the discharge rates at the Kilmarnock Creek Outfall.

Fording River (RG_FODHE), which is the furthest upstream mine-exposed monitoring area (Appendix Tables D.1 and D.2; Appendix Figure D.14). In 2022, nitrate concentrations were below the updated ECs in all samples collected from monitoring areas between RG_FODHE and RG_FOUNGD (downstream of the Concrete Arch). Some exceedances of Level 1 (RG_FODNGD, RG_MP1, RG_FOUSH, RG_FRUPO), Level 2 (RG_FOBCP), and Level 3 (RG_SCOUTDS, RG_FOBSC, RG_FO22) updated ECs occurred at other monitoring areas in 2022, however, they were in a small proportion of samples confined to periods of seasonal low flow (Appendix Table D.3; Appendix Figure D.14). For EVWQP nitrate benchmark concentrations see Appendix Table D.5.

Reduced nitrate concentrations compared to previous years were observed at some areas downstream of the FRO-S AWTF outfall relative to the area (RG_FOBKS) immediately upstream of treatment in 2022 following the commissioning of water treatment. Before-after control-impact (BACI) analysis identified significantly lower nitrate concentrations at most FRO LAEMP monitoring areas downstream of the Greenhouse Side Channel confluence (i.e., the lower study area) relative to pre-commissioning concentrations and relative to RG_FOBKS; however, concentrations between immediately downstream of the outfall (RG_SCOUTDS) and upstream of the Greenhouse Side Channel confluence (RG_FRCP1SW) did not change significantly compared to pre-commissioning concentrations (Figure 3.2; Appendix Table D.4; Appendix Figures D.14 and D.55). The spatial differences in nitrate concentrations are likely related to the influence of treated Kilmarnock Creek water (Figure 3.1) through the groundwater pathway to the lower study area (SNC Lavalin 2022). Changes in nitrate concentrations downstream of the FRO-S AWTF outfall will continue to be assessed through future FRO LAEMP monitoring.

3.2.2 Biota

3.2.2.1 Benthic Invertebrate Community

Key metrics used to assess BIC (e.g., % Ephemeroptera, Ephemeroptera abundance) correlated strongly with nitrate concentrations in the FRO LAEMP study area, however, relationships among nitrate and other factors (e.g., habitat variables, other water quality constituents) precludes a direct causal link between nitrate and BIC structure. Benthic invertebrate community structure is notably different (Figure 3.3; Appendix Figures G.1 to G.32; more detail in Section 3.6.1 below) in areas with elevated nitrate concentrations compared to areas with relatively lower concentrations, including reference areas (Appendix Figure D.14); however, interpretation is confounded by elevated concentrations of other mine-related constituents (i.e., above concentrations expected to potentially cause effects in biota; Figure 3.4; Appendix Figures D.1 to D.22; Section 3.6.2 below) and habitat changes that occur concurrently with changes in nitrate concentrations (Appendix Tables I.1 to I.5; more detail

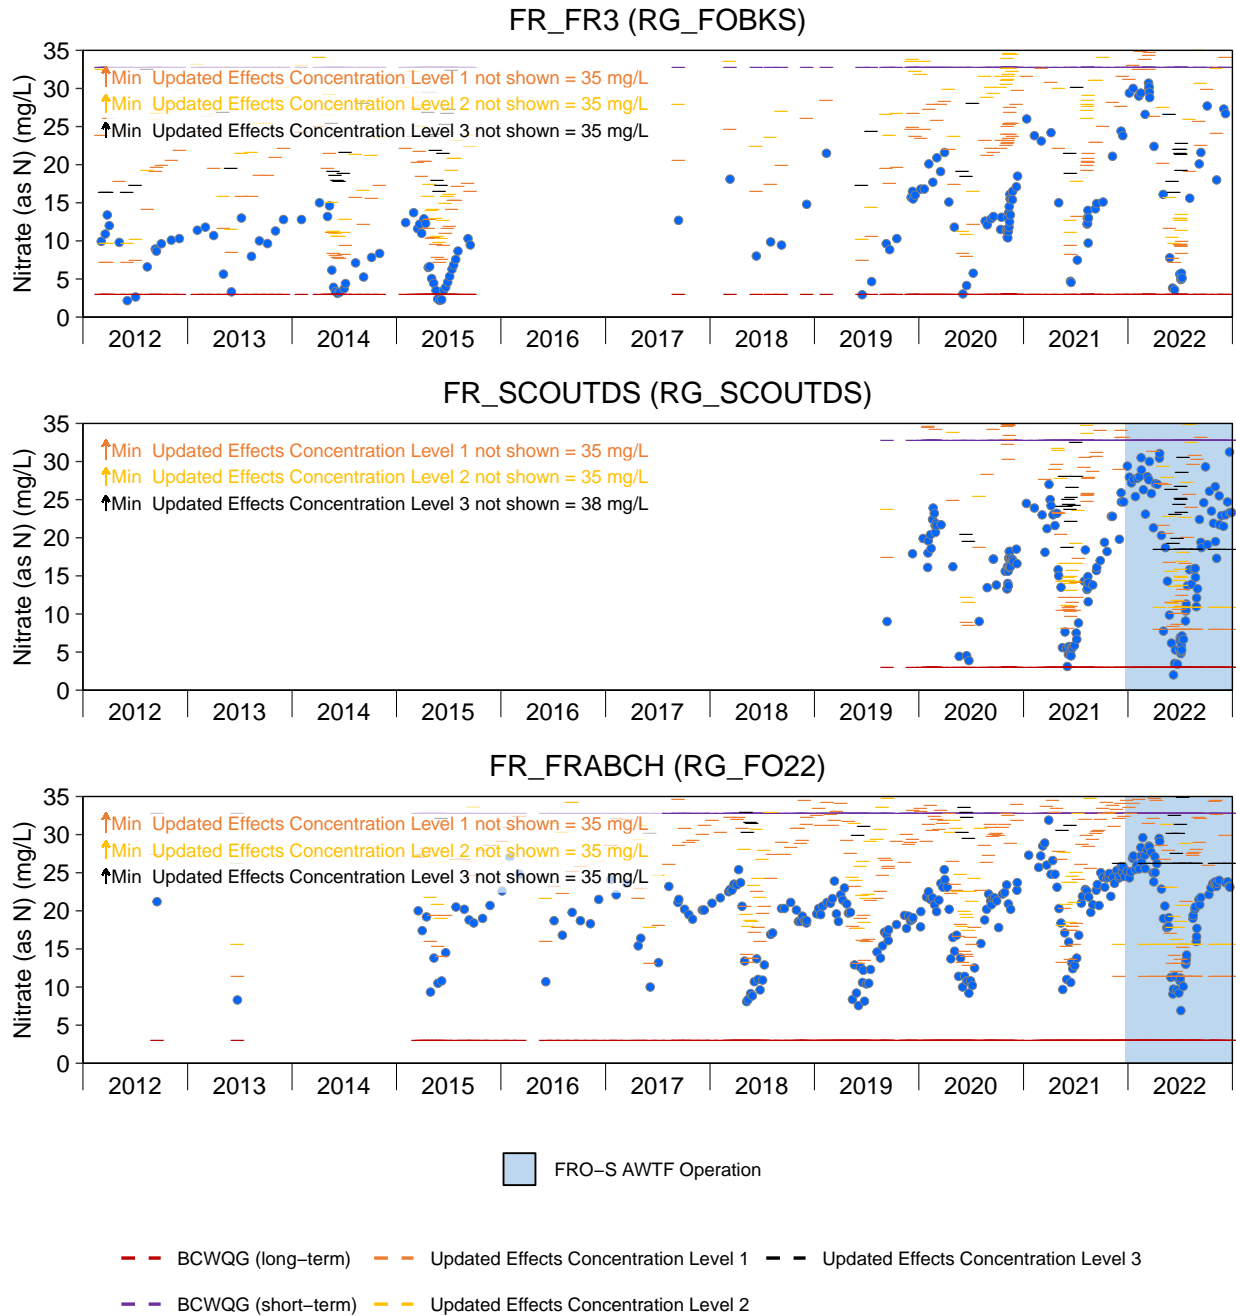

Figure 2: Time Series Plots for Nitrate Concentrations from FRO LAEMP Sampling Areas, 2012 to 2022

Notes: Green data points are used for reference sites and blue data points are used for mine-exposed sites. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Guidelines are dependent on water hardness. Constituent was plotted because it was identified as a mine-related constituent in the Adaptive Management Plan and an early warning trigger was defined (Azimuth 2018). When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

Figure 3.3: Benthic Invertebrate Community Percent Composition, FRO LAEMP, September 2022

Notes: Green colors represent Ephemeroptera taxa, blue colors represent Plecoptera taxa, red colors represent Tricoptera taxa, purple color represent Chironomidae taxa, brown colour represents Psychodidae taxa, orange color represents Coleoptera taxa (Elmidae), yellow color represents Oligochaeta taxa, and grey color represents other remaining taxa. Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

Figure 4: Seasonal Means for Select Water Quality Constituents, FRO LAEMP, 2022

Notes: Winter is comprised of December 2021 to March 2022. Only annual means are depicted with a black bar and are only presented when data is available from all four seasons. Reference areas are shown in green and mine-exposed areas are shown in blue. Censored values are shown with hollow shapes. Solid black line separates biological monitoring areas upstream (left side) and downstream (right side) of the FRO-S AWTF outfall location. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

in Section 3.6 below). Nitrate concentrations correlated strongly and negatively with Ephemeroptera (i.e., mayfly) endpoints, but correlated positively with Plecoptera (i.e., stonefly) endpoints, suggesting that if nitrate was contributing to differences in BIC structure among areas, its primary influence is on mayflies (Beketov 2004; Camargo et al. 2005), and other factors (e.g., substrate size, water temperature, depth, and velocity, channel width) may be influencing the presence and abundance of other taxa (Appendix Table H.2; Appendix Figures H.6 to H.10; more detail in Section 3.6 below). The lowest relative abundance of Ephemeroptera and the highest relative abundance of Plecoptera were observed through the middle and lower study areas, which stretch from downstream of the South Tailings Pond (STP; RG_FOUKI) to Ewin Creek (RG_FOU EW), with the biggest differences observed downstream of the Greenhouse side channel confluence in the lower study area (Figure 3.3; Appendix Figures G.1 to G.32). This difference in community structure may also be related, in part, to taxa differences in sensitivity to mine-related constituents (Clements et al. 2000; Clements 2004; Pond et al. 2008; Cormier et al. 2013; Boehme et al. 2016; Minnow and Lotic 2021b, 2022), including nitrate (Beketov 2004; Camargo et al. 2005), and taxa-differences in habitat preferences as the physical structure of the Fording River changes from upstream to downstream (Peckarsky 1979; Vannote et al. 1980; Kaller and Harman 2003; Dewson et al. 2007; Alvarez-Cabria et al. 2017; Leszczynska et al. 2017; Cummins 2019; Minnow and Lotic 2021b, 2022).

Before-after control-impact assessments of BIC related to water treatment did not identify any notable (i.e., increases or decreases in sensitive taxa) statistical changes in BIC endpoints related to FRO-S AWTF commissioning, even in the lower study area where nitrate concentrations decreased (Appendix Table G.1; Appendix Figures G.33 to G.48; more detail in Section 3.6 below).

3.2.2.2 Chronic Toxicity

Nitrate concentrations have been associated with adverse effects to biological endpoints under the Chronic Toxicity Program using water from stations within the FRO LAEMP study area in previous years, but recent chronic toxicity studies have not identified nitrate as a potential causative factor (Appendix Figure D.56; WSP 2023). At the station located downstream of the former Cataract Creek confluence with the Fording River (FR_FRCP1), adverse effects associated with nitrate concentrations have not been observed in any test since 2020 (Appendix Figure D.56). From 2015 to 2020, however, nitrate, combined with other constituents such as sulphate, TDS, and/or nickel, were identified as contributing to possible or likely effects to water flea (*C. dubia*) reproduction (most years) and amphipod (*H. azteca*) dry weight (2016, 2017, and 2018) during low flow periods, which were largely driven by concentrated water

from Cataract Creek prior to diversion in August 2019. In 2022, algae (*P. subcapitata*) cell yield was the only possible adverse effect identified at FR_FRCP1 (Q1 and Q4), but the cause of this effect was unknown. Fewer adverse effects from water quality in 2022 compared to previous years may be a result of water quality changes (nickel and selenium concentrations were lower at FR_FRCP1 post-commissioning of the FRO-S AWTF [Appendix Table D.4; Appendix Figure D.55]). Further downstream at the Compliance Point (FR_FRABCH), nitrate concentrations have not been associated with adverse effects to biota in recent years (Appendix Figure D.56). Overall, nitrate concentrations have not been identified as likely contributing to effects to biota within the FRO LAEMP study area based on quarterly chronic toxicity tests on algae, water fleas, amphipods, fathead minnow, and rainbow trout.

3.2.3 Summary

Although nitrate concentrations have increased throughout the FRO LAEMP study area, evidence for direct effects of nitrate on biota is limited and interpretation is confounded by the covariation of multiple mine-related constituents with nitrate and a change in habitat throughout the study area concurrent with changes in BIC structure. In addition, while nitrate concentrations exceeded one or more updated ECs at a number of areas within the FRO LAEMP study area during low flow months (i.e., late fall and winter), concentrations in the majority of samples were below concentrations expected to cause effects in sensitive species. Overall, no effects on taxa abundance were observed, and chronic toxicity studies identified very few effects with water from the study area, of which none were attributed to nitrate concentrations in recent years. In response to Study Question #1, monitoring under the FRO LAEMP has indicated that yes, nitrate concentrations have increased in the study area, but whether nitrate is having a direct effect on biota cannot be conclusively answered given the covariation among multiple stressors and habitat variables. As such, this part of Study Question #1 is more appropriately addressed under both Study Question #5 (Section 3.6) and Study Question #6 (Section 3.7). As treatment continues to be implemented in the FRO LAEMP study area, nitrate concentrations are expected to decrease, thus the potential for adverse effects to biota is expected to remain low.

3.3 Study Question #2

Study Question #2 (Is water treatment affecting biological productivity downstream in the Fording River?) was evaluated through monitoring of aqueous nutrient concentrations (i.e., total phosphorus and orthophosphate), periphyton presence and thickness, and benthic invertebrate biomass and density.

3.3.1 Aqueous Nutrient Concentrations

Total phosphorus and orthophosphate concentrations increased downstream of the FRO-S AWTF outfall relative to immediately upstream of treatment (RG_FOBKS). Before-after-control-impact analysis identified statistically significant increases in both total phosphorus and orthophosphate concentrations at RG_SCOUTDS (immediately downstream of the FRO-S AWTF outfall) to RG_FOBKP (downstream of the former Cataract Creek confluence) relative to concentrations pre-commissioning and relative to RG_FOBKS (Figure 3.5; Appendix Table D.4; Appendix Figures D.16, D.17, and D.55). These increases were spatially limited, however, and not observed further downstream.

3.3.2 Productivity

Benthic invertebrate productivity increased immediately downstream of the FRO-S AWTF outfall relative to upstream. Before-after control-impact analysis identified statistically significant increases in both benthic invertebrate biomass and density at RG_SCOUTDS relative to pre-commissioning and relative to RG_FOBKS, while biomass increased slightly at the Compliance Point (RG_FO22), density was similar relative to RG_FOBKS (Figure 3.6; Appendix Table G.2; Appendix Figures G.49 to G.53). Increased benthic invertebrate productivity did not correspond with a noticeable change in periphyton visual scores, as areas downstream of the outfall were similar to areas upstream and largely scored as a 2 (rocks slightly slippery, periphyton thickness between 0.5 mm and 1 mm) or 3 (rocks noticeably slippery, periphyton thickness between 1 mm and 5 mm; Appendix Table I.3).

3.3.3 Summary

An increase in aqueous phosphorus concentrations and benthic invertebrate productivity was identified post-commissioning of the FRO-S AWTF. Total phosphorous and orthophosphate concentrations were significantly elevated at monitoring areas between the FRO-S AWTF outfall to the Greenhouse side channel confluence but decreased with distance downstream. Increased benthic invertebrate productivity was localized to the area immediately downstream of the outfall location (RG_SCOUTDS) but visual periphyton assessments were not elevated downstream of treatment. The increased benthic invertebrate productivity was likely driven by higher phosphorus concentrations, however, values remained within the range observed throughout the study area, and no evidence of increased periphyton or algal growth was observed. In response to the study question, monitoring under the FRO LAEMP indicated that water treatment has led to an increase in secondary (benthic invertebrate) productivity downstream of the FRO-S AWTF outfall location based on the first year of

Figure 5: Time Series Plots for Orthophosphate Concentrations from FRO LAEMP Sampling Areas, 2012 to 2022

Notes: Green data points are used for reference sites and blue data points are used for mine-exposed sites. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis. The interim screening value for orthophosphate (0.006 mg/L) represent the 97.5th percentile of concentrations observed in reference areas over the growing season (Minnow 2020).

commissioning. Future monitoring will continue to assess effects of the FRO-S AWTF and potential effects related to the future commissioning of the FRO-N SRF.

3.4 Study Question #3

Study Question #3 (Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?) was evaluated through monitoring of aqueous selenium concentrations, including selenium speciation, and composite-taxa benthic invertebrate tissue selenium concentrations throughout the study area.

3.4.1 Aqueous Selenium Concentrations

Total and dissolved selenium concentrations decreased at most areas downstream of the FRO-S AWTF outfall relative to immediately upstream of treatment (RG_FOBKS) in 2022 (Figure 3.7). No statistically significant differences were identified between pre- and post-commissioning for selenite and methylseleninic acid (MeSe(IV))⁶ concentrations, but qualitative observation of the data showed a notable increase in the frequency of detection of methylseleninic acid and, to a lesser extent, dimethylselenoxide (DMSeO) at some areas downstream of the AWTF during operation in 2022 compared to pre-commissioning (Figure 3.8; Appendix Table D.4; Appendix Figures D.25, D.27, and D.55). Overall, concentrations of organoselenium species were highest just downstream of the FRO-S AWTF, and decreased with distance to below detection limits within ~2 km of the outfall (Appendix Figure D.24 to D.27).

Consistent with previous years, total selenium concentrations were higher at three distinct areas within the Fording River in 2022 compared to other monitoring areas: 1) downstream of the Lake Mountain Creek influence (RG_FODNGD); 2) downstream of the FRO-S AWTF outfall (RG_SCOUTDS⁷); and 3) downstream of the Greenhouse Side Channel confluence (RG_FRUPO; Figure 3.4). Concentrations of selenite were also higher at RG_FODNGD and at RG_SCOUTDS compared to other monitoring areas but were lower downstream of the Greenhouse Side Channel confluence (Figure 3.9). Although seasonal differences in selenium concentrations were apparent (i.e., higher concentrations during low flows), spatial patterns were similar among monitoring areas throughout the year.

⁶ BACIs could not be conducted for organoselenium and DMSeO concentrations because there were not enough samples above detection limits. Statistical power was low for selenium speciation comparisons due to limited sampling during the pre-commissioning period.

⁷ The difference between the areas upstream (RG_FOBKS) and downstream (RG_SCOUTDS) of the outfall was much lower in 2022 compared to what the difference was last year (Minnow and Lotic 2022).

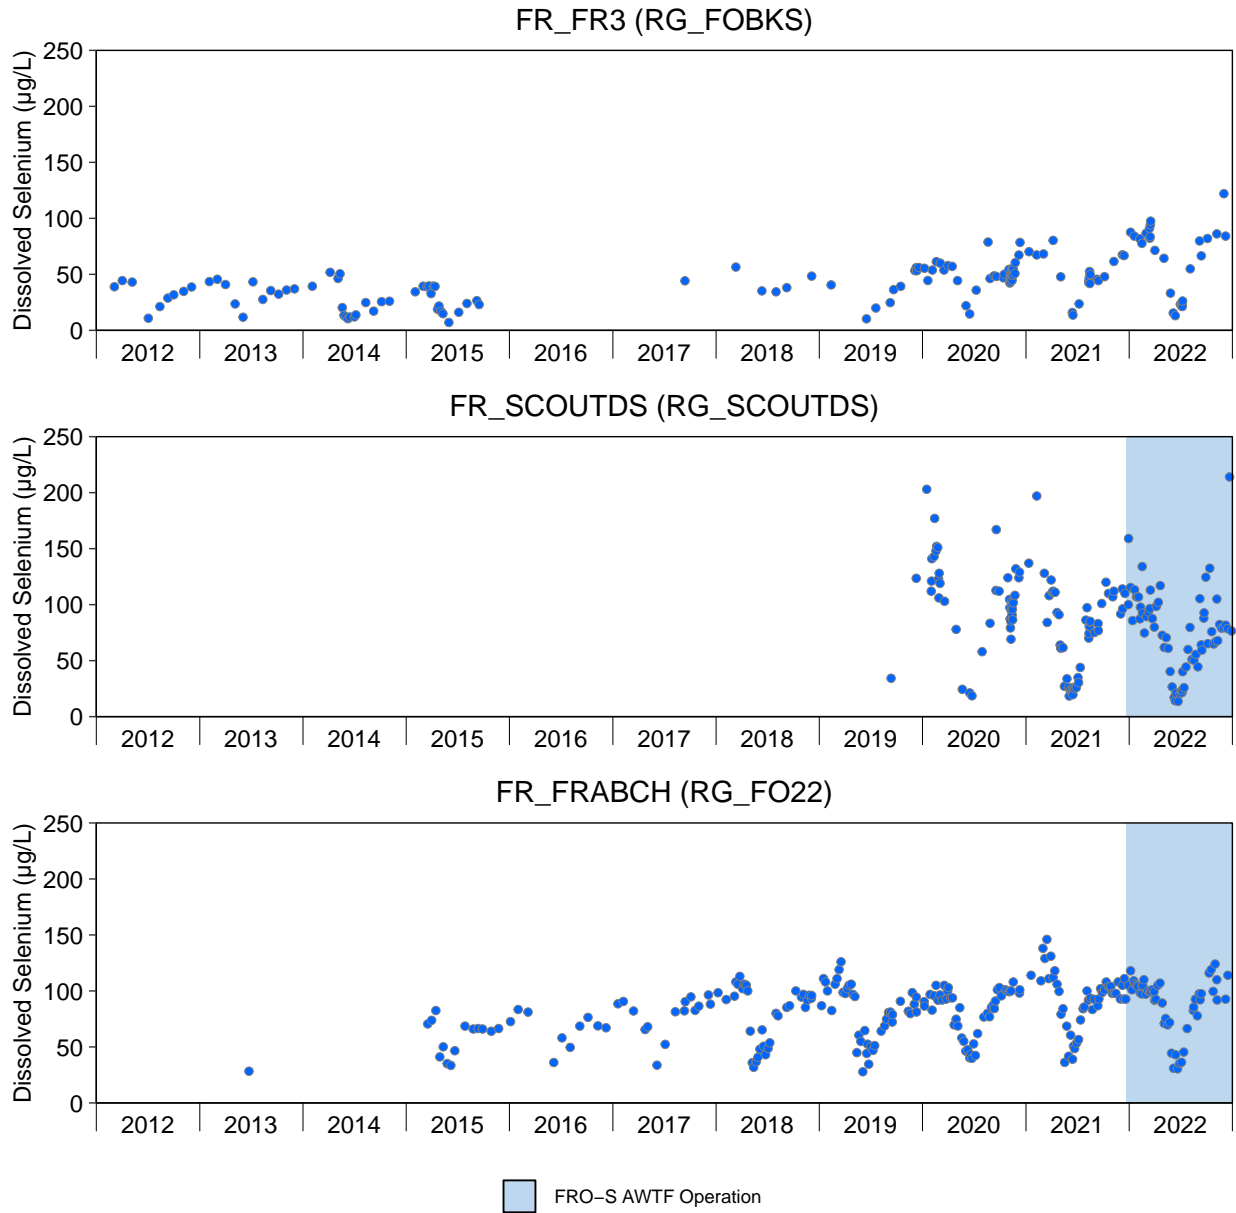

Figure 7: Time Series Plots for Dissolved Selenium Concentrations from FRO LAEMP Sampling Areas, 2012 to 2022

Notes: Green data points are used for reference sites and blue data points are used for mine-exposed sites. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

Figure 3.8: Time Series Plots for Methylseleninic Acid Concentrations from FRO LAEMP Sampling Areas, 2012 to 2022

Notes: Green data points are used for reference sites and blue data points are used for mine-exposed sites. Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

Figure 3.9: Concentrations of Selenium Species in June, September, and December, FRO LAEMP, 2022

Notes: Reference areas are shown in green and mine-exposed areas are shown in blue. Censored values (samples whose values were below the laboratory detection limits) are shown with open shapes. Selenium species always below the laboratory detection limit were not plotted. Solid black line separates biological monitoring areas upstream and downstream of the FRO-S AWTF outfall location. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

3.4.2 Benthic Invertebrate Tissue Selenium Concentrations

Selenium concentrations in composite-taxa benthic invertebrate tissue samples collected in the FRO LAEMP study area were largely below EVWQP benchmarks in 2022. Of the 444 benthic invertebrate tissue samples collected in 2022, 419 (94%) of them were below the EVWQP Level 1 benchmark for dietary effects to juvenile fish (11 mg/kg dw), and 11 of the 25 samples above benchmarks contained annelids (Figure 3.10; Appendix Table G.3) known to bioaccumulate selenium at a greater rate than other taxa (Luoma 2021). All non-annelid containing composite samples that were above a benchmark were above the Level 1 benchmark for dietary effects to juvenile fish but below the Level 1 benchmark for effects to benthic invertebrates, except for one of five samples collected in each of the January (above Level 2 benchmark for dietary effects to juvenile fish) and December (Level 1 benchmark for effects to benthic invertebrates) sampling events in the Greenhouse Side Channel (RG_FRGHSC). Of the seven sampling events in 2022, the highest selenium concentrations overall were observed in September (Appendix Figure G.54), which represents the end of the growing season and is consistent with previous years.

In response to a request from the EMC, composite-taxa benthic invertebrate tissue samples were collected within ~30 m of the FRO-S AWTF outfall in December 2022 to understand potential for localized effects on BIT selenium from aqueous organoselenium entering the Fording River from the FRO-S AWTF buffer pond. One of five replicates had tissue selenium concentrations above the EVWQP Level 1 benchmark for dietary effects to juvenile fish (11 mg/kg dw), while the other four replicates were below the benchmark (Appendix Table G.22). Overall, these benthic invertebrate tissue samples had selenium concentrations that were similar to the biological monitoring area (RG_SCOUTDS) ~200 m downstream.

3.4.3 Benthic Invertebrate Tissue Selenium Concentrations in Relation to Aqueous Selenium Concentrations

No changes in benthic invertebrate tissue selenium concentrations were identified downstream of the FRO-S AWTF outfall relative to immediately upstream (RG_FOBKS), despite changes in aqueous selenium concentrations (e.g., decrease in total and dissolved selenium, small increase in organoselenium). Before-after control-impact analysis determined that most comparisons⁸ of tissue selenium concentrations downstream of treatment were not significantly different than to concentrations upstream of treatment (RG_FOBKS) pre- and post-commissioning or different

⁸ The BACI was conducted by comparing the differences of tissue selenium concentrations for each sampling event pre- and post-commissioning at areas downstream of treatment relative to immediately upstream (RG_FOBKS); therefore, there are many comparisons for each monitoring area but most of them demonstrated no significant differences.

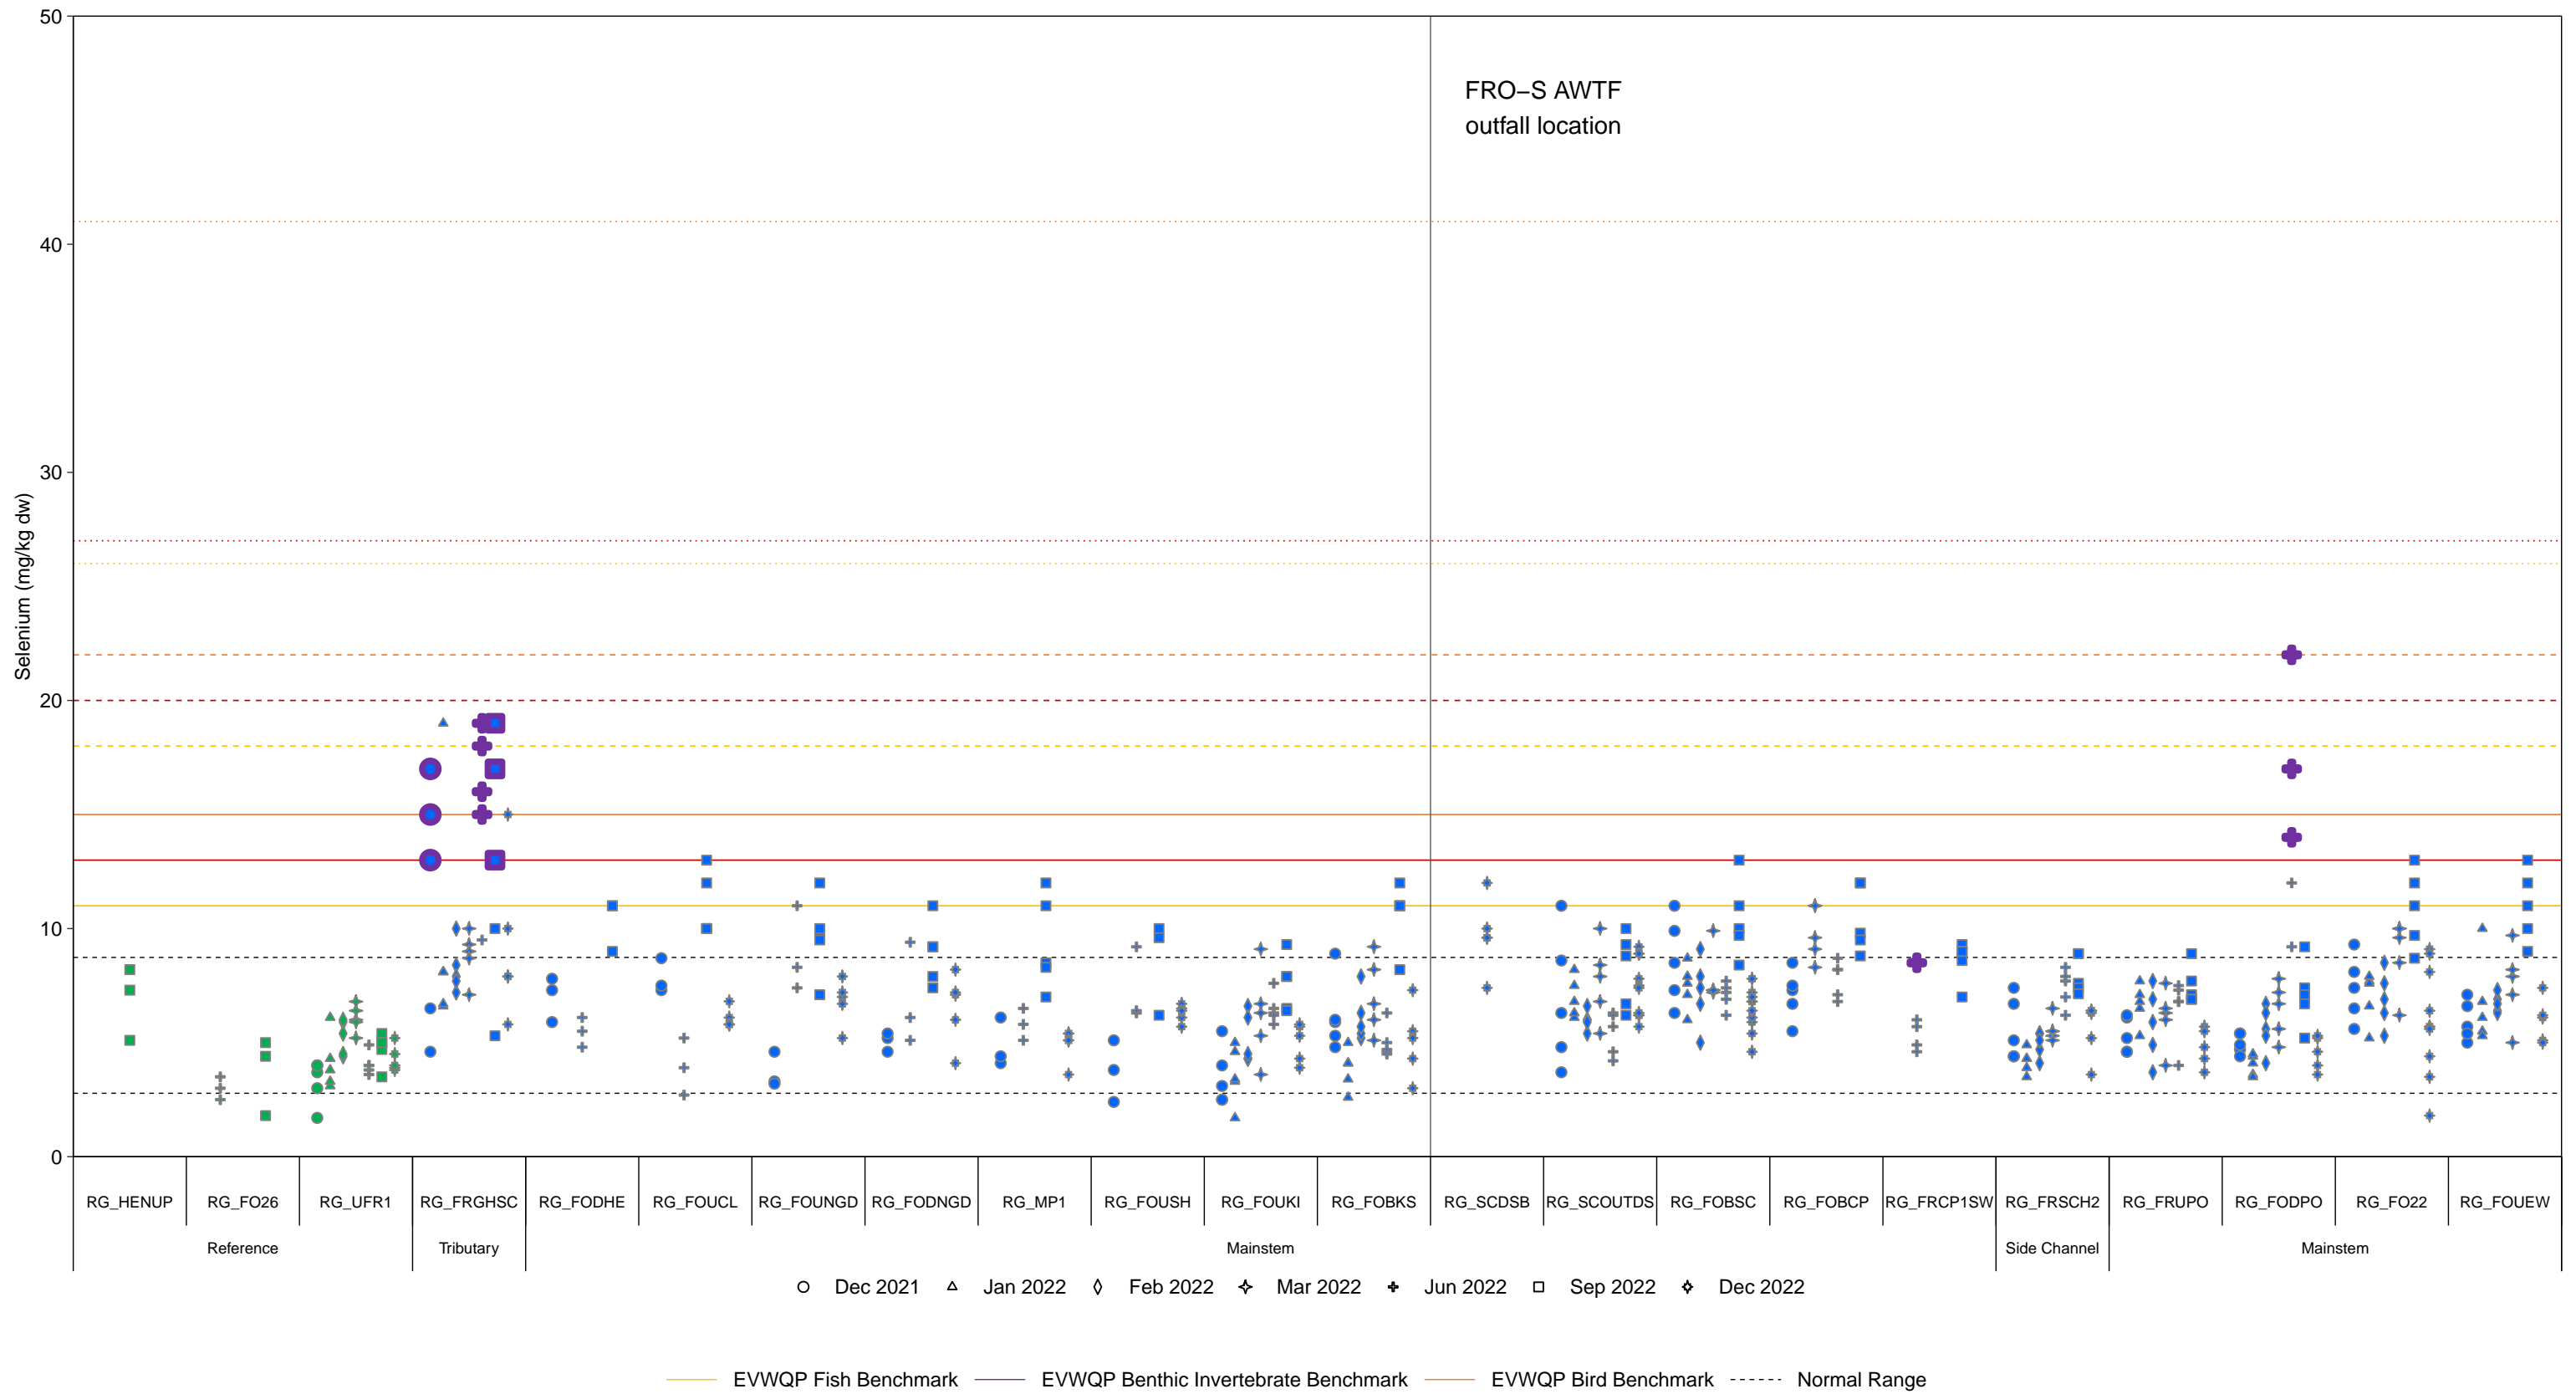

Figure 3.10: Composite-taxa Benthic Invertebrate Tissue Selenium Concentrations Pre- and Post-Commissioning of the Active Water Treatment Facility, FRO LAEMP, 2021 to 2022

Notes: Dashed black lines represent the normal range defined as the 2.5th and 97.5th percentiles of the 2012 to 2019 reference area data from the Regional Aquatic Environmental Monitoring Program (RAEMP). Green represents reference stations and blue represents mine-exposed stations. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line. RG_FRCP1SW and RG_FOBCP could not be consistently sampled due to ice/dry conditions. Samples containing an Oligochaete in September 2022 and after are outlined in purple, samples prior to this date were not necessarily identified as having an Oligochaete. RG_FRSC2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO. Week 0 of the FRO-S AWTF commissioning sampling plan occurred in December 2021, while week 4, 8, and 12 sampling occurred in January, February, and March, respectively.

within the same area compared to the pre-commissioning period (Appendix Table G.4; Appendix Figures G.54 and G.55). Overall, 88% (340 of 387 comparisons) of tissue selenium concentration pre- and post-commissioning comparisons were not significant, and of the comparisons that were significantly different, most occurred relative to January 2022 when BIT selenium concentrations were unusually low at RG_FOBKS, or when annelids were present in composite samples (e.g., RG_FODPO in June 2022). Benthic invertebrate tissue selenium concentrations have not changed downstream of FRO-S AWTF treatment compared to pre-commissioning concentrations and compared to immediately upstream of treatment.

When considering the full study area, there was some indication that benthic invertebrate tissue selenium concentrations were higher in areas with higher concentrations of reduced selenium, however, this was not consistent across all areas. For example, areas in the upper part of the study area (e.g., upstream of RG_FODNGD) had relatively high benthic invertebrate tissue selenium concentrations compared to other areas but low selenite concentrations (Figure 3.9 and 3.10; Appendix Table G.3).

Benthic invertebrate tissue selenium concentrations in the FRO LAEMP study area have remained consistent with predictions based on aqueous total selenium concentrations. Except for composite-taxa samples containing annelids (n=3 at RG_FODPO in June; n=1 at RG_FRCP1SW in June; n=4 and n=3 at RG_FRGHSC in June and September, respectively), almost all (436 of 437) non-annelid tissue samples collected within the study area in 2022 were within the prediction limits of the selenium bioaccumulation model (Figure 3.11; Appendix Table G.5; Golder 2020a), which was consistent with previous years (Appendix Figure G.56). The only sample that did not contain annelids but was above the prediction limits was collected in the Greenhouse Side Channel and could not be explained by water chemistry, with no organoselenium detected and low selenite concentrations (Figure 3.9). Measured tissue selenium concentrations throughout the study area were also consistent with those predicted by the bioaccumulation tool (i.e., the 'B-tool'; predicts tissue selenium concentrations accounting for selenium speciation and sulphate concentrations [Golder 2020b]), except for samples that contained annelids (Appendix Table G.6). Overall, both models predicted higher benthic invertebrate tissue selenium concentrations in areas and/or seasons with the highest aqueous (total and reduced) selenium concentrations consistent with measured benthic invertebrate tissue selenium concentrations.

3.4.4 Summary

Total and dissolved selenium concentrations have decreased at most mainstem Fording monitoring areas downstream of the FRO-S AWTF outfall compared to the pre-commissioning period and immediately upstream at RG_FOBKS, however, there was a qualitative increase in

Figure 3.11: Observed and Modelled Selenium Concentrations in Benthic Invertebrate Composite Samples Relative to Aqueous Selenium Concentrations at Stations Upstream and Downstream of Fording River Operations, FRO LAEMP, 2022

Notes: Mean benthic invertebrate selenium concentrations (solid black line) were estimated using a one-step water to benthic invertebrate selenium accumulation model: $\log_{10}[\text{Se}]_{\text{benthic invertebrate}} = 0.717 + 0.072 \times \log_{10}[\text{Se}]_{\text{aq}}$ (Golder 2020). The 95% prediction limits for a single value from the one-step water to benthic invertebrate selenium accumulation model are plotted as dashed red lines. Reference areas are shown in green. RG_FRSCH2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO

organoselenium concentrations downstream of treatment that decreased with distance from the outfall until it was no longer detected ~2 km downstream. Benthic invertebrate tissue selenium concentrations have remained unchanged at all areas downstream of treatment compared to upstream and pre-commissioning of the FRO-S AWTF, and concentrations have been consistent with predictions throughout the study area based on aqueous selenium concentrations. In response to the study question, monitoring under the FRO LAEMP has indicated that benthic invertebrate tissue selenium concentrations downstream of treatment (and throughout the study area) were consistent with predictions after the first year of FRO-S AWTF commissioning and continued monitoring will assess any potential future changes as well as changes associated with the future FRO-N SRF.

3.5 Study Question #4

Study Question #4 (How is temperature changing over time in the FRO LAEMP study area? 4a. Is water temperature measurably different [greater than 1 degree Celsius] downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition? 4b. If changes in water temperature are observed, are these changes attributed to mitigations [i.e., AWTF and/or SRF]?) was evaluated through monitoring of water temperature data collected from loggers located throughout the study area. Further information related to water temperatures associated with the FRO-S AWTF will be summarized in the FRO-S AWTF Outfall report (WSP Canada 2023).

3.5.1 Water Temperature

Water temperatures have remained stable throughout most of the FRO LAEMP study area since 2017⁹, except for three stations in the middle study area; upstream (RG_FOUKI) and downstream (RG_FOBKS) of the former Kilmarnock Creek confluence, and upstream of the former Cataract Creek confluence (RG_FOBSC), where small but statistically significant increases in temperature over time have been observed (Appendix Table E.1; Appendix Figure E.1). Temperatures at other stations within the middle study area (RG_SCOUTDS, RG_FOBCP, and RG_FRCP1SW) have not changed, suggesting that temperature changes are localized and not indicative of a shift in water temperatures within the larger watershed.

Water temperatures were above the 1°C threshold¹⁰ downstream of treatment compared to upstream post-commissioning of the FRO-S AWTF on only three occasions in 2022.

⁹ Temperatures loggers were installed at RG_UFR1, RG_FODHE, RG_FRDSCC1, and RG_SCOUTDS in August 2020, and at RG_FOUCL in April 2021.

¹⁰ The 1°C threshold difference of water temperature immediately downstream compared to immediately upstream of the FRO-S AWTF outfall was integrated into Study Question #4 after discussions with the EMC as an indicator of change when developing the 2021 to 2023 FRO LAEMP study design.

These occurred in late February 2022 when downstream daily mean water temperatures were approximately 1.2°C colder than upstream and in early December when the downstream daily mean water temperature was 1.01°C warmer than upstream (Figure 3.12; Appendix Table E.3).

Statistically, water temperatures were warmer¹¹ at RG_SCOUTDS downstream of treatment compared to RG_FOBKS upstream of treatment from March to July when comparing post-commissioning (2022) to pre-commissioning temperatures (2021 only), and colder from August to October comparing post-commissioning temperature differences to 2020 pre-commissioning data (Appendix Table E.2; Appendix Figure E.2 to E.4), but the differences were small (i.e., <1°C) so unlikely to be ecologically significant. Overall, water treatment has had minimal effects on water temperature downstream of the outfall location in the Fording mainstem.

3.5.2 Summary

With few exceptions, water temperatures have remained stable throughout the FRO LAEMP study area since 2017. Minor differences in water temperature were observed when comparing areas immediately downstream (RG_SCOUTDS) and upstream (RG_FOBKS) of treatment pre- and post-commissioning, but temperature differences were rarely (i.e., only 3 of 363 days post commissioning) greater than the 1°C threshold indicating minimal influence of FRO-S AWTF operation on water temperatures in the receiving environment downstream. Monitoring under the FRO LAEMP has indicated that water temperatures have increased at three of twelve mine-exposed stations in the study area but increases were not related to the FRO-S AWTF. Future monitoring will continue to assess changes in water temperatures and deviations from the 1°C threshold outlined in study question #4.

3.6 Study Question #5

Study Question #5 (What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?) was evaluated through monitoring of BIC endpoints relative to water quality and habitat variables (e.g., calcite, substrate size, water depth, flow, and temperature).

3.6.1 Benthic Invertebrate Community Summary

The majority of BIC endpoints were similar among monitoring areas throughout the FRO LAEMP study area, although a clear spatial pattern from upstream to downstream was apparent for

¹¹ Differences were based on non-overlapping 95% confidence intervals of the estimated mean difference of water temperatures from the downstream (RG_SCOUTDS) and upstream (RG_FOBKS) areas for years of comparison.

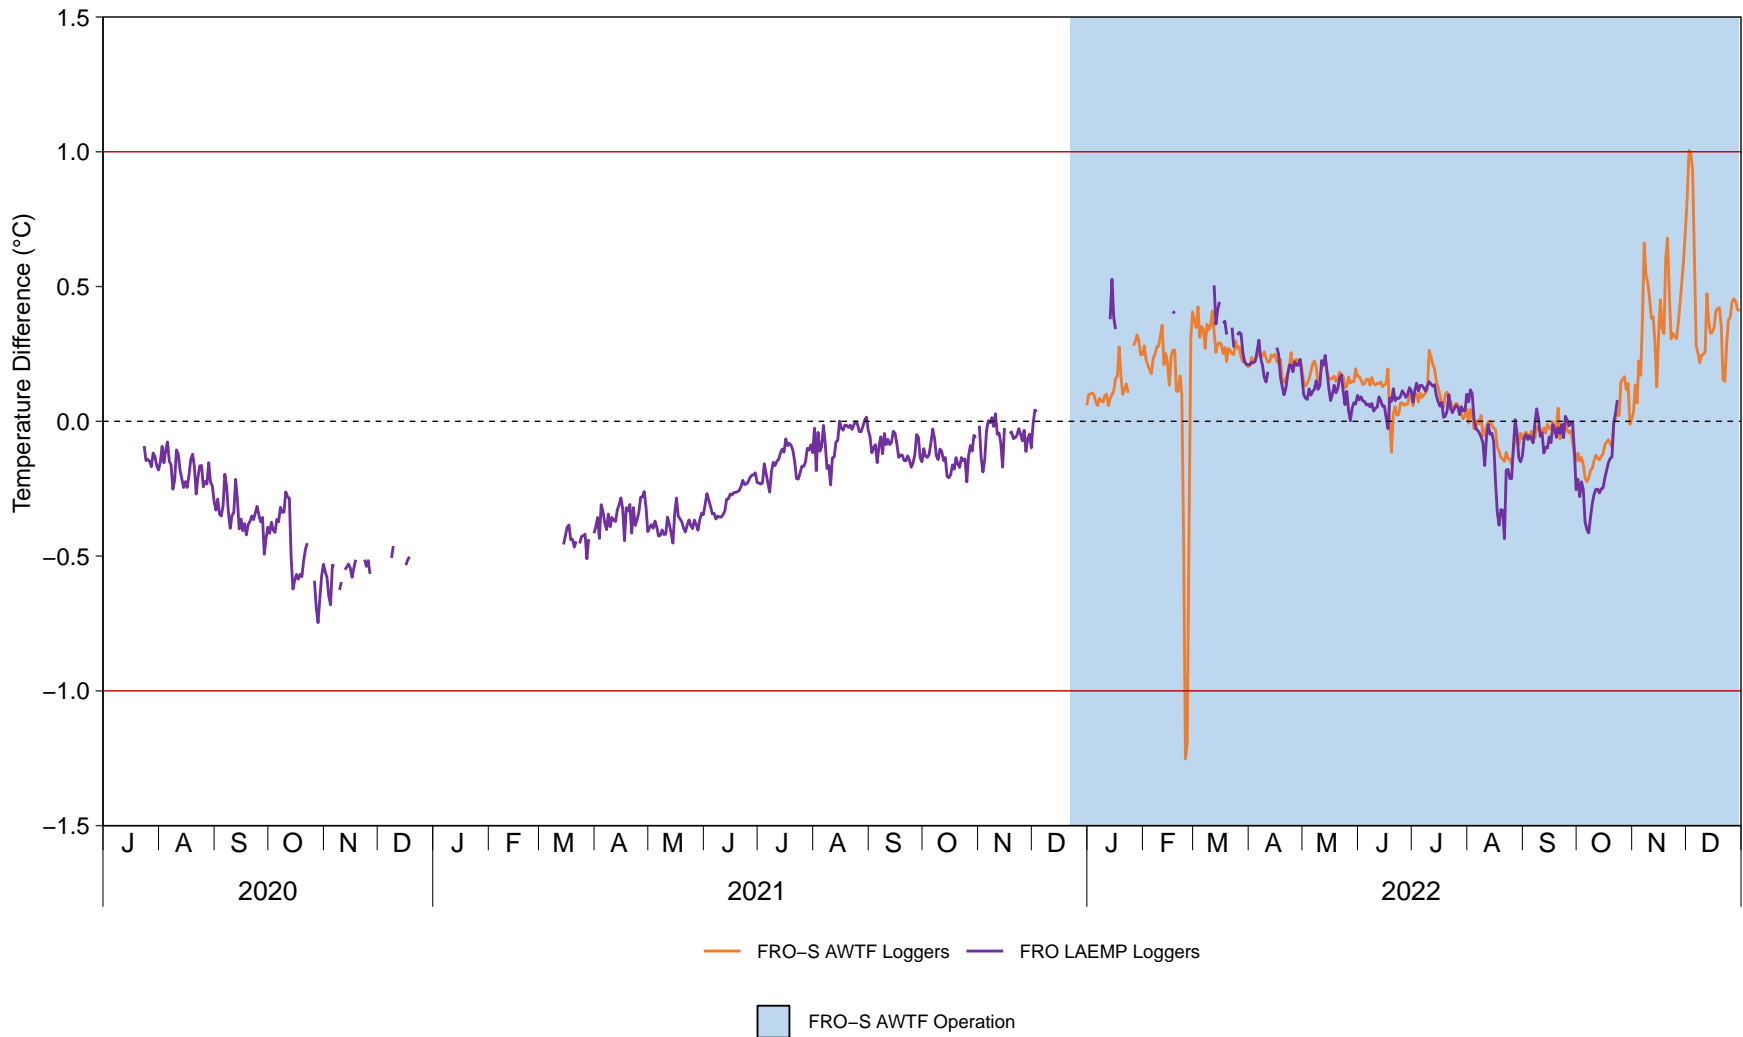

Figure 2: Mean Daily Temperature Difference Between Downstream (RG_SCOUTDS) and Upstream (RG_FOBKS) of the FRO-S AWTF , FRO LAEMP, 2020 to 2022

Notes: Temperature differences were calculated as RG_SCOUTDS – RG_FOBKS. A positive difference indicates a temperature increase downstream and a negative difference indicates a temperature drop downstream. The FRO-S AWTF loggers were managed by the water treatment facility and were supplemental to the FRO LAEMP loggers which were managed by Lotic Environmental and were a part of the original FRO LAEMP study design.

% EPT, % Ephemeroptera, and % Plecoptera, consistent with previous years (Minnow and Lotic 2019b, 2020b, 2021b, 2022). All other taxonomic endpoints assessed (e.g., total abundance, taxa richness, % Trichoptera and % Chironomids, and abundance of EPT, Ephemeroptera, Plecoptera, Trichoptera, Chironomidae, Baetidae, Heptageniidae, and Ephemerellidae) fell within the site-specific and/or regional normal ranges (Figure 3.13; Appendix Figures G.1, G.3 to G.8, G.11, G.12, G.16 to 25) and have not changed significantly over time (Appendix Table G.7, G.8, G.12 to G.21). Relative abundance of EPT, however, was below site-specific normal ranges from RG_FOUNGD downstream of the Concrete Arch to the lower extent of the FRO LAEMP study area (RG_FOU EW) in 2022, with the values also dropping below the regional normal range (except for RG_FOBKS) between RG_FOUSH (upstream of Shandley Creek) and RG_FOBSC (Figure 3.13). This represented a decrease in % EPT throughout the upper and middle study areas compared to previous years (Appendix Table G.9; Appendix Figure G.13). Percent Ephemeroptera was also below the site-specific normal ranges from RG_FOUSH to RG_FOU EW and was below regional normal ranges from RG_FRCP1SW (upstream of the Greenhouse Side Channel) to RG_FOU EW (Figure 3.13). Like % EPT, % Ephemeroptera was lower relative to normal ranges at some areas in the upper and middle study areas compared to previous years but followed a similar upstream to downstream pattern of decreasing relative abundance as previously identified (Appendix Table G.10; Appendix Figure G.14). Consistent with previous years, % Plecoptera was near or above the upper limit of the regional normal range from RG_FRCP1SW to RG_FOU EW but was below the normal range and lower than previous years at some areas in the upper and middle study areas (Appendix Table G.11; Appendix Figure G.15). The shift in community structure in the downstream section of the upper study area and the upstream section of the middle study area coincided with an increase in the total and relative abundance of fly larvae from the family Psychodidae compared to previous years (Minnow and Lotic 2021b, 2022), which also occurred at the reference area RG_FO26 (Figure 3.3) and may therefore be related to environmental conditions. The shift in community structure did not, however, result in the total abundance of any EPT taxa falling outside the respective normal ranges in any part of the study area. Instead, the decrease in the relative abundance of EPT taxa was related to an increase in other taxa. Percent EPT remained within the regional normal range in the lower study area despite low % Ephemeroptera, which is normally the most abundant EPT taxon, because of higher Plecoptera abundance relative to other areas, suggesting no effect on food availability for fish throughout the study area.

Few statistically significant and biologically meaningful changes in BIC endpoints were identified when monitoring areas downstream of the FRO-S AWTF outfall were compared to pre-commissioning and to RG_FOBKS immediately upstream, and none could be directly attributed to water treatment. Before-after control-impact analysis identified increases in taxa

Figure 3.1 : Benthic Invertebrate Community Metrics, FRO LAEMP, September 2022

Notes: Vertical black line denotes upstream and downstream of the FRO-S AWTF outfall location. Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines. RG_FRSC2 is located in Fording River Side Channel 2, which has an upstream confluence with the Fording River located downstream of RG_FRCP1SW and a downstream confluence with the Fording River located downstream of RG_FRUPO.

richness at most but not all areas downstream of the FRO-S AWTF outfall relative to richness pre-commissioning and relative to RG_FOBKS, while Baetidae abundance (Ephemeroptera) and % Chironomidae were higher at RG_FOBSC compared to pre-commissioning, and higher at most areas in some years only (Appendix Table G.1; Appendix Figures G.33, G.34 to G48). Occasional significant comparisons were observed for % Ephemeroptera, depending on the pre-commissioning year in the comparison¹². Most other endpoints did not change significantly post-commissioning or changed only in a limited number of comparisons that likely reflected the annual variability in BIC data rather than an effect of treatment. In addition, the observed significant changes could not be explicitly explained by concurrent changes in water quality (also see Sections 3.6.5). Overall, commissioning of the FRO-S AWTF did not have a notable effect on BIC downstream.

3.6.2 Water Quality

Decreases in nitrate and selenium concentrations and increases in total phosphorus and orthophosphate concentrations were observed downstream of the FRO-S AWTF outfall, but did not result in any changes to BIC structure. Nitrate concentrations post-commissioning were similar among areas post-commissioning and compared to previous years between the outfall downstream and the Greenhouse Side Channel and were lower compared to upstream and pre-commissioning throughout the lower study area (see Section 3.2.1). Total and dissolved selenium concentrations were lower at all areas downstream of water treatment, while organoselenium and phosphorus (total phosphorus and orthophosphate) were higher from the outfall downstream to the Greenhouse Side Channel (see Sections 3.3.1 and 3.4.1) compared to pre-commissioning concentrations and compared to upstream (RG_FOBKS). Very few significant differences of other mine-related water quality constituents were observed downstream of treatment post-commissioning. Exceptions were decreases in dissolved nickel at three areas downstream (but an increase at one area downstream) post-commissioning and relative to RG_FOBKS upstream and increases in nitrite and total molybdenum (a component of anti-scalant) at most areas downstream (Appendix Table D.4; Appendix Figure D.55). Overall, no changes in water chemistry post commissioning of the FRO-S AWTF could be attributed directly to an influence on BIC structure downstream.

Concentrations of several key mine-related constituents, including most Order constituents, increased gradually from upstream to downstream between RG_FODNGD (downstream of Lake Mountain Creek influence) and the lower extent of the study area (RG_FOU EW). An exception to this is dissolved nickel concentrations and, to some extent dissolved cadmium, which were

¹² If there was an interaction between year and the treatment term (i.e., there was effect of year on treatment), rather than no effect of year, then comparisons were made per year.

lower throughout the lower study area (i.e., downstream of the Greenhouse Side Channel confluence) compared to concentrations in the middle study area where they were the highest (Figure 3.4). In the upper study area, concentrations of most mine-related constituents, including Order constituents, rarely exceeded their respective updated ECs, proposed benchmarks, or screening values, except for nitrate which was above the Level 1 updated EC from RG_FODNGD to RG_FOUSH (5% to 20% of samples across the range of monitoring areas) and dissolved nickel which exceeded the Level 2 proposed benchmark from RG_FOUNGD to RG_FOUSH (33% to 67% of samples; Appendix Table D.3). Throughout the middle study area, dissolved nickel exceeded the Level 2 proposed benchmark (up to 67% of samples) while TDS exceeded the Level 1 screening value (up to 48% of samples; Appendix Table D.3). Occasionally, nitrate and sulphate concentrations exceeded updated ECs between RG_SCOUTDS and RG_FOBCP (nitrate: Level 2 updated EC in 2% of samples at RG_FOBSC and RG_FOBCP; Level 3 updated ECs in 6% of samples at RG_SCOUTDS; sulphate: Level 1 updated ECs in 4% to 10% of samples between RG_SCOUTDS and RG_FOBCP) in the middle study area. In the lower study area, dissolved nickel only exceeded the Level 2 proposed benchmark at RG_FODPO (8% of samples), while TDS exceeded the Level 1 screening value from RG_FRUPO to RG_FO22 (4% to 25% of samples). Additionally, sulphate never exceeded updated ECs in the lower study area in 2022, but nitrate exceeded the Level 1 updated EC at RG_FRUPO (10% of samples) and Level 3 updated ECs at RG_FO22 (2% of samples). For EVWQP constituent benchmark concentrations see Appendix Table D.5.

Although concentrations of most mine-related constituents have remained unchanged over the time period assessed (2012 to present in most cases) throughout the FRO LAEMP study area, concentrations of several key mine-related constituents (i.e., dissolved cadmium, nitrate, total selenium, sulphate; dissolved nickel, and TDS) have increased since the base year (2012 in most cases), particularly in the downstream extent of the upper study area and the upstream extent of the middle study area (Appendix Table D.2; Appendix Figures D.1 to D.22) where shifts in BIC structure have occurred (Section 3.6.1).

3.6.3 Habitat

The morphological features of the Fording River vary from upstream to downstream in relation to spatial patterns in BIC structure throughout the FRO LAEMP study area. This change in habitat features can affect the habitat for benthic invertebrate communities (e.g., nutrient dynamics, physical habitat) and likely has an influence on the individual taxa present (Vannote et al. 1980, Cummins 2019). Specifically, the upper study area (Figure 2.1), is characterized by steep gradients (Ecofish 2022) facilitating shallow, fast flowing water with relatively

coarse substrate (Appendix Table I.2, and I.4). Additionally, water temperatures in the upper study area are typically lower in the winter and higher in the summer compared to the lower study area (Appendix Figure E.1) because of the shallower water depths and minimal groundwater influence (SNC Lavalin 2021). The middle study area is generally characterized by shallower gradients (Ecofish 2022) facilitating more slow flowing and deeper water compared to the upper study area (Appendix Table I.2), which supports finer substrate (Appendix Table I.4) and different nutrient dynamics (i.e., fine particulate organic matter from upstream; Vannote et al. 1980, Cummins 2019); however, the lower extent of the middle study areas is also prone to extensive seasonal drying because river gradients become more level (Ecofish 2022) and subsurface flows (SNC Lavalin 2021) cause water depths to become shallow, particularly during low flow seasons. The lower study area is characterized by slow flowing, deep water, and small substrate (Appendix Tables I.2 and I.4) as a result of an upward sloping riverbed gradient at the confluence of Chauncey Creek in the Fording River, slowing water down and allowing for more deposition (Ecofish 2022). These more depositional downstream areas have more allochthonous food sources (i.e., leaves, woody debris, particulate organic matter from upstream) ideal for shredders common to Plecopteran families (Cummins 2019). The smaller substrate size in these depositional waters is also ideal habitat for Plecopterans (Peckarsky 1979). The lower study area is also characterized by water temperatures that have smaller seasonal fluctuations (Appendix Figure E.1) that typically result from ambient cold and warm temperatures in the winter and summer, respectively, leading to a distinct temperature regime compared to the upper and middle study areas. Like water chemistry changes, these very distinct habitat changes from upstream to downstream closely follow spatial changes in BIC structure in the FRO LAEMP study area, and are likely influencing the composition of the community independent of water quality.

3.6.4 Substrate Quality

Concentrations of most metals and PAHs in sediment collected from mine-exposed areas in 2022 exceeded BCWSQGs (lower for metals and upper for PAHs) but did not change over time in most areas (Appendix Figures F.1 and F.2). Sediment metals and PAH concentrations were similar downstream of the FRO-S AWTF outfall post-commissioning compared to pre-commissioning and relative to the area (RG_FOBKS) immediately upstream, except for PAHs at RG_SCOUTDS and RG_FO22 (Appendix Table F.2; Appendix Figures F.3 and F.4). Further analysis of the sediment data, particularly from RG_SCOUTDS, demonstrated a strong relationship between moisture content, % fines, and PAH concentrations in the samples (Appendix Table F.1; Appendix Figure F.4). Results from confirmatory sampling at RG_SCOUTDS in February 2023 showed PAHs that were largely consistent with previous years (Appendix Figure F.5).

Although concentrations of some metals and PAHs did exceed BCWSQGs¹³, it is not expected that sediment is a dominant exposure pathway in erosional lotic environments such as the upper Fording River, where depositional material represents less than 10% of the substrate surface (Golder 2022). In addition, toxicity testing on both *Hyalella azteca* and *Hexagenia sp.* with sediments from the areas of the FRO LAEMP study area with the highest concentrations of both metals and PAHs (e.g., RG_FOUKI) did not identify any toxic effects that could be contributed to sediment chemistry (Golder 2022). As such, sediment toxicity is not a reliable predictor for explaining variations in BIC structure (Golder 2022).

Consistent with previous years, both the Regional Calcite Monitoring Program and the FRO LAEMP showed an increase in the presence of calcite, reflected in higher calcite index, moving from upstream to downstream within the FRO LAEMP study area in 2022 (Appendix Tables F.3 and F.4; Appendix Figure F.6). Overall, calcite scores have remained stable within each monitoring area throughout the study area since 2018 (Appendix Table F.3).

3.6.5 Integrated Analysis

Benthic invertebrate community structure was closely related to changes in both water quality and habitat from upstream to downstream, confounding the interpretation of the influence of individual variables, as indicated in previous FRO LAEMP reports. Correlations between BIC endpoints and water quality and habitat variables were explored to understand whether relationships could help explain the effects observed in BIC structure throughout the FRO LAEMP watershed. Correlations of water quality constituents with key BIC endpoints continue to identify strong, significant relationships with mine-related constituents, most notably through negative correlations with % Ephemeroptera, Ephemeroptera abundance and, to a lesser extent % EPT, but positive correlations with % Plecoptera (Figures 3.3 and 3.13; Appendix Table H.1; Appendix Figures H.1 to H.5). Other correlations between water quality constituents and BIC endpoints meeting the cutoff for significance and strength (i.e., $p < 0.001$; $Rho > \pm 0.6$) occurred infrequently and in no consistent pattern. Several habitat variables also correlated significantly with % Ephemeroptera and % Plecoptera, supporting previous findings indicating that habitat plays an important role in BIC structure in the FRO LAEMP study area. Substrate size was generally larger upstream where there was higher % Ephemeroptera and smaller downstream where there was higher % Plecoptera (Appendix Table I.4), resulting in a significant positive correlation with % Ephemeroptera and a significant negative correlation with % Plecoptera and Plecoptera abundance throughout the full study area (Appendix Table H.1; Appendix Figure H.1). Several habitat variables also significantly correlated with % Plecoptera and/or Plecoptera

¹³ Alert concentration for selenium in sediment.

abundance within the individual study areas, including calcite presence and index in the upper study area (positive), calcite concretion in the middle study area (positive), minimum winter water temperature in the middle (negative) and lower study (positive) area, and water depth in the lower study area (negative; Appendix Table H.1; Appendix Figure H.3). Taken together, a clear relationship between BIC endpoints and both water quality and habitat was apparent, but, similar to previous years, analyses have not been able separate the individual contributions of each variable as the majority of the explanatory power of water quality and habitat predictors are shared (Appendix Figure H.6) and difficult to separate. Canonical correspondence analysis identified a significant effect of all water quality stressors and habitat variables that were assessed on BIC variation in the full study area, except for calcite concretion (Appendix Table H.2; Appendix Figures H.7 to H.10). Overall variations in benthic invertebrate community structure was associated with only nitrate (after controlling for habitat) and several habitat variables (bankfull width, station gradient, watershed area) in the upper study area, but most water quality stressors (after controlling for habitat) and habitat variables had a significant influence on BIC variation in the middle study area (Appendix Table H.2; Appendix Figures H.7 to H.10), where water chemistry and habitat changed significantly (Section 3.6.2 and 3.6.3). In addition to nitrate, selenium, and sulphate concentrations, BIC variation in the lower study area was strongly associated with substrate size (D-16) and summer and winter mean water temperatures (Appendix Table H.2), and these habitat variables are markedly different throughout this section of the upper Fording River where very high % Plecoptera and low % Ephemeroptera are observed. Overall, analysis continues to suggest that both water quality and habitat variables are contributing to variations in BIC structure in the FRO LAEMP study area but the effects of individual variables remain hard to define given the covariation among the different factors and no causal link between individual water quality or habitat metrics and BIC structure is possible at this time.

3.6.6 Summary

Benthic invertebrate community data has been collected since 2012 throughout the FRO LAEMP study area to address questions around the factors affecting BIC variation. Monitoring since that time has continued to show spatial gradients in key relative abundance endpoints (e.g., % EPT, % Ephemeroptera, and % Plecoptera) from upstream to downstream within the FRO LAEMP study area but while a similar spatial pattern in Ephemeroptera abundance and relative abundance was observed, all abundance endpoints were within their respective reference normal ranges and have remained stable over time (Minnow and Lotic 2018, 2019b, 2020b, 2021b, 2022). Changes in the relative abundance of EPT taxa often corresponded to shifts in the abundance of other non-EPT taxa and, together with consistently high abundance in all key taxa, including EPT, represent no limitations of food available to fish throughout the study area.

Upstream to downstream changes in % EPT, % Ephemeroptera, and % Plecoptera continue to occur simultaneous with changes in concentrations of mine-related constituents, including those that were above established effects levels (nitrate and dissolved nickel in the lower section of the upper study area; nitrate, dissolved nickel, sulphate and TDS throughout most of the middle study area; nitrate, dissolved nickel, and TDS at some monitoring areas in the lower study area) during low flows, and variations of habitat, including substrate size, water temperature, water depth, and calcite. Both water quality stressors and habitat variables were associated with BIC structure variation, particularly through the full study area and the middle study area, but the effect from individual predictors was difficult to separate. While there was no clear indication of direct effects of water quality on BIC abundance (e.g., toxicity), benthic invertebrates more tolerant of mine-influenced stressors may opportunistically thrive compared to sensitive organisms (e.g., Psychodidae), leading to a shift in BIC structure. Most habitat variables affected BIC variation throughout the full study area, however, substrate size and water temperature had a particularly strong effect on BIC variation in the lower study area where high % Plecoptera and low % Ephemeroptera continue to be observed. Although the FRO-S AWTF changed the concentrations of phosphorus, nitrate, and selenium (total and reduced species) in 2022 relative to pre-commissioning, these changes did not cause any changes in BIC structure relative to pre commissioning. In direct response to the study question, monitoring under the FRO LAEMP continues to indicate that multiple factors, including both mine-related stressors and habitat features, contribute to the variation in BIC in the FRO LAEMP study area, but covariation among these factors precludes the determination of the contribution of each individually.

3.7 Study Question #6

Study Question #6 (What are the factors influencing fish health and population in the Upper Fording River?) was evaluated through an integration of fish studies in the upper Fording River (i.e., UFR WCT Population Monitoring Program) with relevant data (seasonal drying, benthic invertebrate tissue chemistry, and water chemistry) from the FRO LAEMP and the RAEMP (WCT muscle selenium concentrations, condition factor, and observations of external anomalies) within the FRO LAEMP study area.

3.7.1 Henretta Lake

3.7.1.1 Overview

Henretta Lake is a constructed lentic habitat within Henretta Creek that was built as part of the lower Henretta Valley watershed reclamation during the mid-1990's. Since its construction, the lake has undergone significant morphological change, most notably the realignment of its inlet channel and the rehabilitation of the creek, lake, and surrounding floodplains in 2017

(Evaluation of Cause 2021). Henretta Lake has been identified as providing important overwintering habitat for WCT in the upper Fording River (Cope et al. 2016), as well as habitat for resident WCT (that have been observed within Henretta Lake during the summer and early fall; Penman et al. 2022). Previous monitoring has identified low dissolved oxygen (DO) concentrations occurring during winter months at the bottom of Henretta Lake (Teck 2021b), which can reduce the amount of available overwintering habitat for WCT. Monitoring in 2022 was focused on better characterizing water quality, lake mixing, and the potential for selenium bioaccumulation within Henretta Lake.

3.7.1.2 Henretta Lake Bathymetry

Henretta Lake has a total volume of 97,046.8 m³ and a maximum depth of 9.4 m (Table 3.1, Appendix Figure L.1). The deepest area of the lake is located along the northwest shoreline, where the bathymetry is steep (sharply decreasing to the maximum depth of the lake in approximately 16 m from the shoreline). The northeast and southern areas of the lake have a more gradual change in water depth, with the majority of the lake area south of the Henretta Creek inflow having a maximum depth of 5 m or less (Appendix Figure L.1). Data from the recent bathymetry survey of Henretta Lake suggest that there is a relatively small amount of lake volume in areas of the lake where the maximum depth is > 7.5 m (Table 3.1). Specifically, the volume of the lake below the depth of 7.5 m represents ~3.5% of the total lake volume.

The assessment of lake bathymetry was conducted in 2022 to better understand the suitability of the *in situ* logger chain location, which was deployed at FR_HENLAKE3 on May 4, 2022 as a continuous all-season monitoring location (Appendix Figure B.1). The logger chain at FR_HENLAKE3 supports a maximum logger depth of 7.5 m; however, there was concern that the deepest portion of the lake (where DO concentrations would be lowest) was not adequately captured. Data from the 2022 bathymetric survey indicates that the *in situ* logger deployment at FR_HENLAKE3 is suitable in capturing conditions throughout the Henretta Lake water column (only excluding conditions in a relatively small proportion of the lake compared to the total lake volume). Relocating the *in situ* deployment to the deepest area of the lake may also be problematic as this area occupies a narrow footprint (~20 m wide; Appendix Figure L.1) so the likelihood of the deepest loggers drifting into shallow areas (and becoming buried in sediment) is higher. Thus, moving the logger deployment to the deepest area of the lake is not recommended as it would only provide a small amount of additional data, may present data quality challenges, and would compromise the ability to make temporal comparisons before and after relocation.

Table 3.1: Henretta Lake Bathymetry, 2022

Depth (m)	Volume (m ³)	% of Total Lake Volume
0	97,047	100
0.5	87,572	90
1	78,645	81

3.7.1.3 Summary of *In Situ* Measures and Habitat Availability Assessment

During the winter of 2022, the water column of Henretta Lake was inversely stratified with the top 3 m of the water column well-oxygenated during all sampling events (ranging between 8 and 10 mg/L). In January, DO concentrations decreased to below the critical threshold of 5 mg/L for the protection of aquatic life (BC MOE 1997) at depths below 3.5 m, and in February and March, DO concentrations were typically < 1 mg/L below a depth of 5.5 m. The data-logger deployment in Henretta Lake in May 2022 presented unusual temporal and vertical trends in temperature and oxygen within the lake (Brooks et al. 2022a), that were atypical of expected conditions following ice-out (Wetzel 2001). Specifically, the warmest temperatures, highest DO concentrations, and highest measures of conductivity were present at the bottom of Henretta Lake (at a depth of 7.5). These unusual oxythermal dynamics may be indicative of a high-density water source, such as a groundwater intrusion, that would sink under the well-mixed epilimnion and result in isolated effects to hypolimnetic water quality. The atypical oxythermal regime was somewhat transient during early spring as an incomplete mixing effect occurred in the top 6 m of the water column between May 27th and 29th, 2022, and a full mixing event occurred between June 5th and 6th, 2022.

The temperature, DO, and conductivity data from July to October (summarized below) are presented in Brooks et al. 2022b, Brooks and Gordon 2022a, and Brooks and Gordon 2022b. During July and August, temperatures at all logger depths warmed in Henretta Lake following the June mixing event (Brooks et al. 2022b). By early August, warmer temperatures were typically observed at a depth of 6.25 m relative to shallower loggers. Moving into September, temperatures at 6.25-m and 7.5-m depth were higher than rest of the water column above, with temperatures at 6.25-m depth slightly warmer than those measured at 7.5 m depth (Brooks and Gordon 2022a). This phenomenon persisted until the last data download, at the end of October, despite cooling water temperatures measured at the lakes surface to a depth of 5 m (Brooks and Gordon 2022b).

In situ profiles collected in January, June and October of 2022 were compared to assess spatial variability in measures of temperature, DO, and conductivity (Appendix Table L.1). *In situ* measures were collected in eleven locations in January, and at three locations (FR_HENLAKE1, FR_HENLAKE2, and FR_HENLAKE3) in June and October. On average, spatial differences in temperature and DO were less than 1 °C and 1 mg/L, respectively (Appendix Table L.1). Conductivity measures varied spatially by 16.7 µs/cm in June and 19.2 µs/cm in October on average (Appendix Table L.1). Greater spatial variability in conductivity was observed during February, however this is likely associated with measures collected from 5-m depth (which ranged from 359 to 803 µs/cm; Appendix Table L.1). These data support the conclusion made

by Arnett 2023 (Appendix N), that the FR_HENLAKE3 data logger location is representative of lake-wide conditions.

For most of the deployment period (i.e., May to October), 100% of the Henretta Lake volume was considered to have low to no DO risk to WCT (i.e., above the chronic DO BC WQGL of 8 mg/L; Figure 3.14). Dissolved oxygen concentrations were below the chronic DO BCWQG (8 mg/L) in early May (prior to water column mixing) and during the June mixing event; however, ~60% and ~40% of the lake volume was still characterized as having little risk to WCT during those periods, respectively (Figure 3.14). Despite the reduction in the amount of high-DO habitat in June, the mixing event was brief, and thus chronic effects to WCT are not expected; however, additional logger data are required to identify low-oxygen risk during the overwintering prior to spring mixing (these data were collected over the 2022 to 2023 winter but were not available for inclusion in this report). Dissolved oxygen concentrations suggestive of an acute risk to WCT (i.e., < 5 mg/L) were only observed in early May prior to mixing and were isolated to ~10% of the lake volume (Figure 3.14). During September, the bottom data logger in the deployment was buried in sediment and thus, it is only possible to confidently state that ~90% of the lake had DO concentrations that would present low to no risk to WCT (as an assessment of the entire lake was not possible; Figure 3.14). The assessment of WCT habitat availability focused on DO concentrations since temperatures in Henretta Lake were consistently lower than the lethal temperature criteria for WCT between May and October (maximum temperature observed in Henretta Lake was 10.08 °C; Appendix N).

Overall, DO measures collected under ice were below the critical threshold of 5 mg/L DO for the protection of aquatic life when vertical profiles were collected in January, February, and March of 2022. Anoxic conditions (DO < 1 mg/L) were also present in February and March between the maximum depth of 8.5 and 5.5 m depth, and DO concentrations were less than the 5 mg/L DO criteria below a depth of ~ 3.5 m. In contrast, the continuous logger data from May to October 2022 suggest that Henretta Lake had suitable oxygenated habitat for resident WCT (at all depths) during the open-water season.

3.7.1.4 Summary of Water Chemistry Data

Water chemistry samples were collected in Henretta Lake from three locations (FR_HENLAKE1, FR_HENLAKE2, and FR_HENLAKE 3; Appendix Figure B.1) and at three depths (1 m, 3.5 m, and 7 m) in February, June, and October 2022 (Appendix Figure L.2). Water chemistry data are summarized in Minnow 2022 and Arnett 2023 (Appendix N). In brief, the concentrations of various water quality constituents increased with depth in February 2022. Among constituents of interest (i.e., Order constituents and nickel), concentrations of nitrate, sulphate, total and dissolved cadmium, nickel, and selenium were highest in the water sample collected from 7-m depth

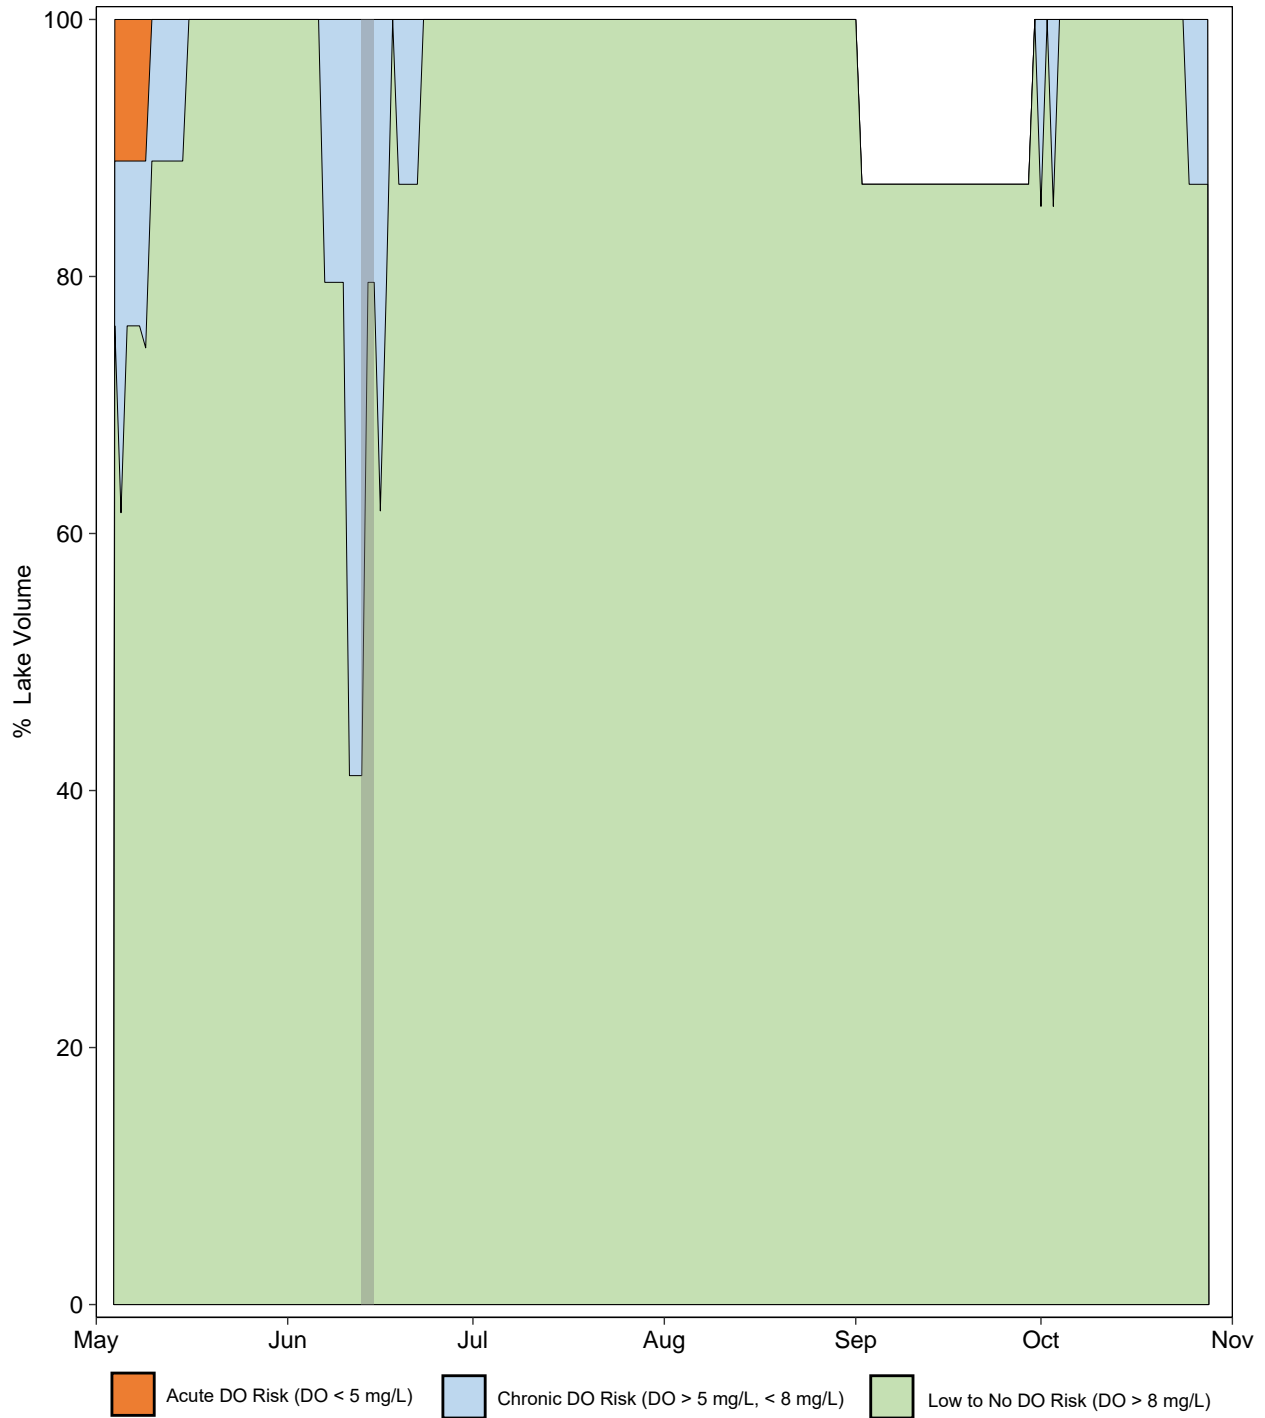

Figure 3.1 : Westslope Cutthroat Trout Habitat Availability using Dissolved Oxygen Criteria, Henretta Lake, May to October 2022

Notes: DO = dissolved oxygen. Suitability was assessed based on daily means. Loggers were deployed at 1.25 m, 2.5 m, 3.75 m, 5 m, 6.25 m, and 7.5 m. Shaded grey area indicates the June mixing event. To assess the proportion of lake suitable for westslope cutthroat trout, total lake volume was divided into horizontal strata based on logger deployment depths. Dissolved oxygen for a given horizontal slice as estimated based on data recovered at the base of the lake strata (e.g., temperature measure at 1.25 m depth was assumed to be constant for the 0 to 1.25 m depth horizontal slice). The deepest interval encompassed both 6.25 m to 7.5 m water depth as well as 7.5 m to the maximum depth of the lake; no data logger was deployed at the maximum lake depth. In some cases the total volume assessed does not represent 100% of the lake due to missing data.

(Appendix Figure L.2). Concentrations of nitrate exceeded the level 2 updated EC at 7-m depth and concentrations of dissolved nickel exceeded the proposed level 2 nickel benchmark at 7-m depth. It is atypical to observe relatively higher concentrations of nitrate and sulphate under anoxic conditions (such as those observed at depth when Henretta Lake is ice covered) as nitrate should be reduced to ammonia and sulphate should be reduced to sulphide (Wetzel 2001). Concentrations of ammonia also increase with depth in February 2022 (Minnow 2022; Appendix N) and confirm anoxic conditions at depth in Henretta Lake. The water chemistry data, particularly nitrate and sulphate results, suggest there is another input to Henretta Lake occurring at depth.

Concentrations of selenite also increased with depth during the winter of 2022 (consistent with 2021 findings summarized in Minnow 2022; Appendix N). The water chemistry sample collected from 7-m depth in February 2022 had detectable concentrations of both dimethylselenoxide and methylseleninic acid (with concentrations above the interim screening value for bioavailable selenium; Appendix Figure L.2). All other samples had concentrations of selenium species below the LRL.

The June water chemistry data had similar constituent concentrations with depth and were indicative of a well-mixed water column (Appendix Figure L.2). These water chemistry data support the *in situ* logger data which suggest a homogeneous water column following the early-June mixing event. Concentrations of Order constituents and nickel do not exceed respective screening criteria (i.e., updated EC, EVWQP benchmarks [dissolved cadmium], or proposed benchmarks [dissolved nickel]) at any depth or sampling station in June. There were also no changes in selenite with depth, and concentrations of organoselenium species were all below the LRL (Appendix Figure L.2).

Patterns in water chemistry were similar in October and February, with concentrations of Order constituents (nitrate, sulphate, total selenium, total cadmium) and total and dissolved nickel increasing with depth (Appendix Figure L.2). Concentrations of nitrate and dissolved nickel were above the level 1 updated EC and proposed level 1 benchmark, respectively, in all sampling areas at a depth of 7 m. Aqueous concentrations of selenite, dimethylselenoxide, and methylseleninic acid were also higher at 7-m depth relative to concentrations observed at 1-m and 3-m depth (Appendix Figure L.1) despite the absence of reducing conditions (DO concentrations were > 12 mg/L at 7.5-m depth; Appendix Table L.1). Despite the presence of detectable concentrations of organoselenium species, modelled benthic invertebrate tissue selenium concentrations (derived using the Golder 2022b B-tool) were below the Level 1 benchmark for effects to juvenile fish (based on water chemistry data collected at all depths in Henretta Lake; Appendix Figure L.3).

3.7.2 Drying Surveys

After five years of drying surveys in the FRO LAEMP study area, there is now a comprehensive understanding of the spatial and temporal extent of drying within the FRO LAEMP study area, including in Henretta Creek upstream of FRO operations and water use licenses. Specifically, multiple years of monitoring have identified year-to-year variability on the timing of drying (Appendix Table E.4); however, once low flows are established in early winter, dry sections expand but no new dry areas are observed throughout the season (Figure 3.15; Appendix Figures E.5 to E.13; Minnow and Lotic 2019b, 2020b, 2021b, 2022). The timing and location of drying in the FRO LAEMP study area in 2022 was similar to previous years and may have limited fish movement. Drying was first observed in the Fording River upstream of the Greenhouse Side Channel confluence (southern survey area) in late September and downstream of the Clode Creek confluence (northern survey area) in mid-October (Figure 3.15; Appendix Table E.4; Appendix Figures E.5 to E.9¹⁴). Consistent with previous years, areas in Henretta Creek upstream of the FRO boundary dried first in 2022 and had the largest number of dry days over the year (Appendix Table E.5).

3.7.3 Westslope Cutthroat Trout Health

3.7.3.1 Tissue Selenium Concentrations

Tissue selenium concentrations from WCT captured in Henretta Lake and mine-exposed areas in the Fording River under the RAEMP indicated low risk to fish health. Except for one anomalously high tissue selenium concentration collected at the Multiplate (RG_MP1) in each of 2021 (29 mg/kg dw) and 2022 (17 mg/kg dw), selenium concentrations in all tissue samples collected from mine-exposed areas (4.7 mg/kg dw to 12 mg/kg dw; n=38 fish), including Henretta Lake (5.3 mg/kg dw to 11 mg/kg dw; n=5 fish), were below the species-specific WCT benchmark¹⁵ (15.5 mg/kg dw; muscle equivalent based on egg EC10; Nautilus and Interior

¹⁴ Although Figures E.9 and E.10 show drying in the northern survey area in August and September, respectively, drying in these areas were in sections of the former mainstem of the Fording River but the river was still connected by an adjacent avulsion channel.

¹⁵ Measurement of selenium in eggs or ripening ovaries is the most direct way to evaluate potential effects of selenium on fish reproduction compared to measurement of selenium in water or other tissue types (Janz et al. 2010; Golder 2014; USEPA 2016). For this reason, a site-specific benchmark was derived based on the EC10 for fish egg/ovary concentrations (25 mg/kg dw; Nautilus and Interior Reforestation, 2011). Non-lethal expression of eggs is not always possible, therefore, monitoring of selenium in fish has often involved non-lethal collection of muscle plugs for selenium analysis and compared to the site-specific benchmark converted to a muscle-equivalent based on the muscle:egg selenium concentration ratio of 1:1.6 in WCT (Nautilus and Interior Reforestation 2011). Typically, non-lethal muscle sampling is conducted during the same timeframe just prior to spawning, however, a comparison of WCT muscle selenium concentrations from May (i.e., prior to spawning) and late August/September (i.e., post-spawning) in 2015 under the RAEMP showed no differences among seasons (Minnow 2018a).

Figure 3.15: Summary of Seasonal Drying Along the Fording River, FRO LAEMP, 2022

Notes: Figure includes both the drying survey and stranding survey drying data along the Fording River, but does not include side channels or the Henretta Creek drying data. Hydrometric stations are located along the x-axis.

Reforestation 2011) for potential effects of selenium on reproduction (Figure 3.16; Appendix Table J.1). These results indicate a low potential risk of effects to WCT egg and embryo development. Selenium concentrations in muscle tissue from WCT caught in Henretta Lake in 2022 were generally lower than those collected from fish at the Multiplate culvert (RG_MP1) and lower than those collected from fish captured at other mine-exposed areas within the FRO LAEMP study area in previous years (2018 and 2021; Figure 3.16; Appendix J.1). The cause of the two elevated tissue selenium concentrations from fish captured at the Multiplate culvert (one in 2021 and one in 2022) is currently unknown (i.e., selenium concentrations in water and benthic invertebrate tissue could not explain the elevated selenium concentration in fish muscle) and confirmatory sampling in 2022 resulted in similar results (1 of 8 samples above level 1 benchmark).

Similar to the previous year, muscle samples were collected from WCT incidental mortalities found during routine monitoring or fish salvage and sampling programs within the FRO LAEMP study area in 2022. Overall, twenty-one fish were recovered for tissue selenium analysis, eighteen of which were mortalities opportunistically sampled from fish sampling or salvage programs and three of which were mortalities found during routine monitoring programs (Appendix Table J.2; Appendix Figure J.1). If fish were in a suitable condition to be sampled (i.e., little to no decomposition), dorsal muscle tissue was analyzed for selenium concentrations; however, the data should be interpreted with caution due to uncertainty around several factors (e.g., size class of fish, where fish may have lived or moved from prior to being found, duration between mortality and sampling) that may influence accuracy or interpretation of results. Only four fish were found in 2022 that were too decomposed to complete additional analysis. The study team is currently looking into how to prioritize sampling of incidental fish mortalities to maximize value of this dataset, including methods of interpreting the data in meaningful ways.

3.7.3.2 RAEMP WCT Anomalies, Meristics, and Condition Factor

Westslope Cutthroat Trout sampled by angling for non-lethal tissue plugs under the RAEMP were also assessed for external anomalies and meristic data (weight and fork length, used to calculate Fulton's condition factor). Of the WCT captured within mine-exposed areas in the FRO LAEMP study area under the RAEMP in 2022 (13 total fish), an anomaly (substantially shortened/missing operculum on one side of the fish) was detected in one fish from the Multiplate culvert (Appendix Table J.1); however, condition factor for this fish was similar to other fish captured within the study area (Figure 3.17 Appendix Table J.1), suggesting it was otherwise healthy.

WCT Caught Under the RAEMP

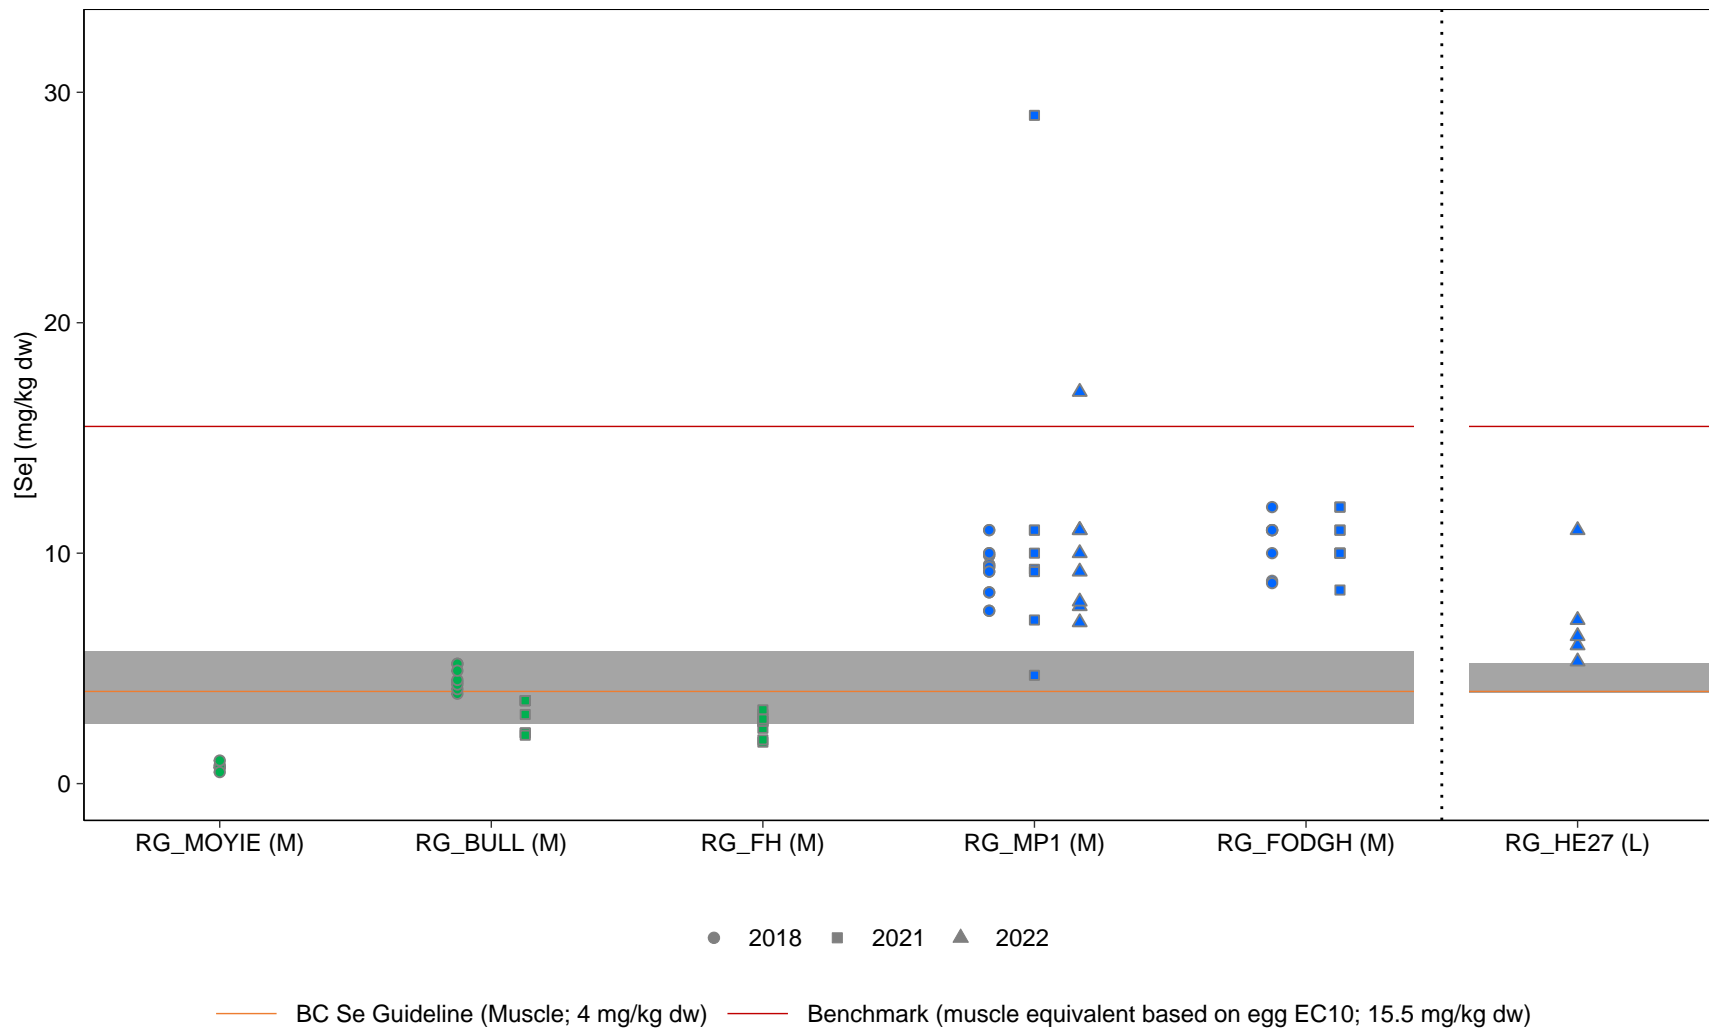

Figure 3. : Westslope Cutthroat Trout Muscle Selenium Concentrations, FRO LAEMP, 2018, 2021, and 2022

Notes: Green represents reference stations and blue represents mine-exposed stations. All muscle samples were collected as non-lethal muscle plugs. Gray shading represents the reference area normal range of lotic/lentic environments defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. M = Mainstem, T = Tributary, (L) = Lentic.

WCT Caught Under the RAEMP

Figure 7: Westslope Cutthroat Trout Condition, FRO LAEMP, 2018, 2021, and 2022

Notes: Green represents reference stations and blue represents mine-exposed stations. M = Mainstem, T = Tributary, L = Lentic. A Fulton's Condition Factor greater than 1 was considered a healthy fish based on comparisons to other healthy freshwater salmonids (He et al. 2008)

Fulton's¹⁶ condition factor for all WCT captured at mine-exposed areas under the RAEMP, as well as fish angled from Henretta Lake, were similar or slightly higher than those captured at reference areas (Figure 3.17; Appendix Table J.1) and were similar to other healthy freshwater salmonids (He et al. 2008). Fish captured under other programs were also assessed for anomalies, but data are currently being processed and will be reported under the RAEMP. Anomalies and condition factor were not assessed for fish sampled from incidental mortalities (Appendix Table J.2). Overall, based on the information available for WCT under the RAEMP within the FRO LAEMP study area, there was no indication of mine-related effects on fish health.

3.7.3.3 Chronic Toxicity Testing

Chronic toxicity testing of water collected from stations throughout the upper Fording River indicated that concentrations of mine-related constituents were unlikely to cause toxicity to fish. At FR_FRCP1, downstream of the former Cataract Creek confluence, and FR_FRABCH, the Compliance Point upstream of Chauncey Creek, no adverse effect to any rainbow trout (*O. mykiss*) or fathead minnow (*P. promelas*) reproduction, survival, or health endpoint was observed in 2022 (Appendix Figure D.56). Although there were several fish endpoints affected by water quality at FR_FRCP1 prior to the diversion of Cataract Creek¹⁷, few chronic toxicity tests have had adverse effects since diversion, and most that demonstrated adverse effects were confounded by microbial contamination (Appendix Figure D.56). Likewise, very few adverse effects have been identified in water from FR_FRABCH in previous years, and most that demonstrated adverse effects were a direct result of microbes or confounded by microbial contamination. Furthermore, in previous years adverse effects to fish health endpoints occurred during Q1 and Q4 and these seasons do not align with when WCT early life stages are expected to be present in the upper Fording River (Evaluation of Cause Team 2021). Chronic toxicity testing was conducted on 30-d early life stage rainbow trout and fathead minnow, and observed adverse effects are not expected to translate to other life stages present during Q1 and Q4.

3.7.4 Westslope Cutthroat Trout Population Monitoring

3.7.4.1 Redd Surveys

The distribution of redds, each of which may have more than one nest, was widespread throughout the mainstem and into tributaries of the upper Fording River, including LCO Dry Creek,

¹⁶ Fulton's condition factor was used to summarize body conditions for WCT captured under the RAEMP because adult fish were targeted (different than the age classes summarized in the Population Monitoring Program) and to retain comparability of data to other fish captured under the RAEMP and the Aquatic Data Integration Tool (ADIT).

¹⁷ Cataract Creek was diverted through Swift Ponds to Swift Creek (i.e., upstream of FR_SCOUTDS and FR_FR4) in August of 2019.

Ewin Creek¹⁸, and Chauncey Creek in both 2021 and 2022 (Figure 3.18). The distribution of redds in 2020 was more limited than either 2021 or 2022, but due to a difference in methods the number of estimated nests cannot be directly compared. The estimated total unique nest counts in most subpopulations in 2022 were lower than those in 2021, particularly for Chauncey and Fish Pond Creeks (Figure 3.19). In 2021, there were an estimated 240 unique nests (95% CI 172-338) which can be compared with an estimated 118 unique nests (95% CI 75-174) in 2022. This decrease in nest counts in 2022 relative to 2021 may be associated with the cold early season water temperatures (Thorley et al 2023a). Spawning was estimated to have started on June 8th and continue until August 8th in 2022, which was later in the season than usual in some streams (Thorley et al. 2023a). Redds were first recorded in early July in the mainstem UFR, rather than early June as seen in 2021. Only Fish Pond Creek and Greenhills Creek recorded redds before mid-June.

3.7.4.2 Length at Age-0

The size of age-0 fish at the onset of winter has implications for population dynamics, with WCT less than ~28 mm fork length expected to have poor overwinter survival¹⁹ (Coleman and Fausch 2007a, 2007b). Relatively little data are available for age-0s over the years from monitoring in the upper Fording River as sampling methodologies have not historically targeted age-0s, though dip-net sampling that targets this age-class fish was implemented in 2022. All fish lengths are fork lengths unless otherwise stated.

The estimated average fork length of an age-0 fish in the mainstem UFR on October 1st varied between a low of 40 mm (95% CI 32-54) in 2022 and a high of a 46 mm (95% CI 36-66) in 2019 (Figure 3.20). The low in 2022 can be compared with fork lengths of ~46 (95% CI 35-63) in 2020 and 2021. The short age-0s in 2022 are consistent with the shorter growing season due to colder than usual early season temperatures.

The length of age-0 fish is sensitive to local conditions, in particular temperature, as indicated by the range of length at age-0s measured across the UFR (Figure 3.21). The estimated fork lengths for age-0 fish in tributaries in an average year were longest in lower Greenhills Creek at 64 mm (95% CI 58-69) and Lake Mountain and lower Henretta, all of which are pond (or lake) influenced and likely have warmer summer water temperatures. The estimated fork lengths were

¹⁸ It is not clear if Ewin Creek was surveyed in 2020, but it is likely that Chauncey Creek was up to the highway culvert (Cope 2020).

¹⁹ The total length reported by Coleman and Fausch 2007a, 2007b was converted to fork length using a base on Mayhood 2012

Figure 3.21: Estimated Fork Length for Typical Age-0 fish on October 1 in a Typical Year by Subpopulation (with 95% CI)

Source: Thorley et al. 2023a.

shortest for Chauncey Creek, at 23 mm (95% CI 19-26) and in LCO Dry after the main channel was bypassed around the sediment ponds in 2020 (LCO Dry Creek-Post Pond), at 24 mm (95% CI 21-27). Prior to 2020 the estimated fork length for the age-0 fish in LCO Dry Creek in an average year was 30 mm (95% CI 25-36) (Thorley et al 2023a). The relationship between age-0 growth and water temperatures will be a focus of the population monitoring program going forward.

3.7.4.3 Body Condition

Body condition is a measure of fish health based on the ratio of fish weight to length. All else being equal, fish with higher body condition would be expected to have more energy stores for growth, reproduction, and metabolic processes than fish of a similar length but lower body condition. Body condition of age-1 and age-2+ (90 to 169 mm fork length) was estimated using an allometric mass-length model that uses a site-specific scaling factor based on data from the population monitoring program for this size class. It is expressed as the predicted weight of a 100 mm WCT to estimate the percent difference in body condition relative to the average for the sub-populations in an average year (Thorley et al 2023a). Body condition was estimated to be slightly above average in 2022 at 1% (95% CI -6-6; Figure 3.22). Fish condition was estimated to be slightly higher for fish in UFR 1-7, Upper Greenhills Creek, LCO Dry Creek and Fish Pond Creek whereas condition was lower for fish in Lower Greenhills Creek, UFR sections 8-9, and Lower Henretta Creek although the differences were small relative to the uncertainty (Figure 3.23 Appendix Figure J.2). The estimated body condition of a 100 mm fish in 2022 was higher than in 2021 for all sub-populations except for UFR 8-9 (Figure 3.6).

3.7.4.4 Abundance

In 2022, the total age-1 abundance of the upper Fording River population was estimated to be 2,300 fish (95% CI 1,200-5,100) and the age-2+ abundance was estimated to be 4,100 fish (95% CI 2,300-8,800). These values are similar to 2021 and within the historical range of variability (Figure 3.24), although still below the highest estimated abundance for age-1 fish in 2015 at 8,400 fish (95% CI 4,100-23,000) and in 2017 for age-2+ fish at 21,000 individuals (95% CI 12,000-45,000; Thorley et al 2023a).

(Sub)adult (>300 mm) abundance followed a similar trend as age-1 and age-2+ fish and peaked in 2017, at 5,200 fish, before dropping by ~93% to 330 fish in 2019 after the population decline (Figure 3.25; Thorley et al 2023a). Snorkel data indicated a continued increase in the subadult and adult population in 2022, which has increased from ~330 in 2019 to ~2,300 fish in 2022 and was higher in 2022 than in 2021 (Figure 3.25). The fork length distribution of fish counted in the

Figure 3.25: The Estimated Fall (Sub)Adult Abundance by Year Assuming an Efficiency of 42% for 2012, 23% for 2012 and 32% for 2014, 2017 and 2019 to 2022

Source: Thorley et al. 2023a.

upper Fording River also showed a greater proportion of fish in the age-2+ size range as well as more adults >300 mm in 2022 than in 2021 (Figure 3.26).

In addition to the annual population monitoring surveys, in 2022 an angling survey was conducted in Henretta Lake to improve the understanding of WCT use in that waterbody. According to subadult and adult population estimates, approximately 4% of the adult WCT UFR population was caught and sampled during the Henretta Lake angling survey (65 unique WCT caught /1,500 estimated WCT population size; Thorley et al. 2022b). Mean fork length of WCT was 363 ± 83 mm and the range was 227-502 mm, which suggests that large, old WCT use Henretta Lake (Penman et al 2022).

3.7.4.5 Egg to age-1 Survival

Egg to age-1 survival refers to the number of age-1 fish present in the fall of a given year, which were produced by spawning in the previous year (i.e., the spawn year). The estimated egg to age-1 survival rates are plotted in Figure 3.27. Survival was lower for the 2021 spawning cohort, at 1% (95% CI 1-2) than the previous two spawn years which were at ~3%. Egg to age-1 survival was highest for the 2019 spawning cohort at 4% (95% CI 2-10; Figure 3.27), after the population decline when egg densities were very low (Thorley et al 2023a). Survival trends show a density dependent relationship, with high survival rates in years of low egg deposition, and lower survival in years of high egg deposition.

3.7.5 Summary

The FRO LAEMP aims to provide an integrated understanding of WCT health and population in the study area using relevant fish and fish habitat data collected under multiple programs. With respect to fish habitat, Henretta Lake has been identified as providing important overwintering habitat for WCT in the upper Fording River watershed (Cope et al. 2016), as well as habitat for resident WCT (Penman et al. 2022). While anoxic conditions were present in January, February and March under the ice in Henretta Lake at the lowest depths (i.e., below 5.5 m) and additional information on water quality under ice is required to assess overwintering habitat for WCT, there were high volumes of suitable oxygenated habitat for resident WCT during the open-water season. Instream drying has been observed since surveys began in the Fording River (2017 and 2019 in the southern and northern survey areas, respectively) and Henretta Creek (2020) upstream of the FRO mine boundary. Annual monitoring of seasonal drying identified year-to-year variability on timing of drying that may, at times, limit WCT movement, but once low flows are established in early winter, dry sections only expand spatially with no new dry areas appearing. Overall, based on muscle selenium concentrations, meristic, and anomaly data from adult fish collected under the RAEMP, as well as information

collected from chronic toxicity testing, WCT in the FRO LAEMP study area, including Henretta Lake, appears to be in good health. Population monitoring has indicated a continued increase in the subadult and adult population in the upper Fording River in 2022, now up to ~2,300 fish from ~330 in 2019. The estimated number of eggs deposited by WCT has increased steadily since 2019 (inferred from adult abundance and size). The 2022 age-1 abundance was similar to the previous two years, while the number of fish in the 100 to 200 mm range (age-1 and age-2+) increased between 2021 and 2022, which may lead to continued increases in adult abundance. A decline in estimated egg to age-1 survival for the 2021 cohort relative to 2019 and 2020 suggests there may be a density-dependent response as the population approaches its carrying capacity. The decrease in the estimated number of nests in 2022 compared to 2021 is likely associated with cold early season water temperatures. A more detailed presentation and discussion of the 2022 upper Fording River Population monitoring program are provided in Thorley et al. (2023b). Overall, monitoring in the FRO LAEMP study area will continue to provide information to evaluate WCT health and populations in the upper Fording River.

4 INTEGRATED SUMMARY AND CONCLUSIONS

The FRO LAEMP report outlines current biological conditions within the study area in relation to the study questions and also from a Management Unit perspective in the upper Fording River. The following findings are of importance when considering the FRO LAEMP study area and the upper Fording River in general, as a whole:

- The temporally consistent spatial shift in BIC structure from upstream to downstream;
- Changes in measurement endpoints (used to support evaluation and interpretation of each assessment endpoint) following the commissioning of the FRO-S AWTF; and,
- The status of WCT health and population in the upper Fording River.

A key finding of the FRO LAEMP is the distinct shift in the spatial (i.e., upstream to downstream) pattern of BIC structure that was first identified in 2015 (relative to 2012) and has since persisted (Minnow 2018, 2017; Minnow and Lotic 2018, 2019b, 2020b, 2021b, 2022). Root-cause investigations since 2015 have failed to identify one individual causal factor. Instead, the weight-of-evidence approach suggests the temporal shift in BIC structure is largely driven by distinct changes in habitat from upstream to downstream, and may be related to elevated concentrations of mine-related constituents, namely nitrate and nickel, that are periodically greater than effects concentrations in some areas (i.e., during low flow periods).

The shift in BIC structure was primarily characterized by a decrease in the relative abundance of Ephemeroptera (mayflies) from upstream to downstream, which was partially attributed to a decrease in the abundance of Heptageniidae and Ephemerellidae. Members of these Ephemeroptera families are clingers that prefer fast-flowing waters (USGS 2016) and are sensitive to anthropogenic stressors including metals (Clements et al. 2000; Clements 2004; Pond et al. 2008; Cormier et al. 2013) and nitrate (Beketov 2004). The shift in community structure, however, also corresponded with increases in the abundance of other taxa, which exacerbated the observed difference in % Ephemeroptera throughout the study area more so than when abundance was taken into consideration. A notable increase in the abundance of individuals from the Family Psychodidae (Order Diptera) was observed in 2022 compared to previous years within the upper and middle study areas, leading to lower % Ephemeroptera and % EPT in those areas. Although no direct causal pathway to explain the increase in Psychodidae was identified, Psychodids are highly tolerant of anthropogenic contaminants based on the Hilsenhoff Biotic Index (HBI; Hilsenhoff 1987) which may allow them to thrive in areas where other organisms may not. When considering the changes in community composition throughout the study area, the lower study area (downstream of the Greenhouse side channel confluence) has distinctly different habitat relative to the upper and middle study areas, which may be further contributing

to the observed variations in BIC. The lower study area is characterized by lower gradients associated with the Chauncey Creek alluvial fan (e.g., slower flow, deeper water, smaller substrate; Ecofish 2022), groundwater influences (SNC Lavalin 2021) leading to smaller seasonal fluctuations (i.e., warmer winter and cooler summer) in water temperatures compared to other areas, and an increase in allochthonous food sources such as leaves, woody debris, and particulate organic matter (Cummins 2019). These habitat features likely contribute to the higher absolute abundance and relative abundance of Plecoptera (stoneflies) observed in this area compared to upstream. Despite the changes in BIC structure identified above, total abundance and abundance of key BIC endpoints remain high throughout the study area, resulting in no limitations of food available to fish.

The 2022 FRO LAEMP report covered the first year of monitoring post-commissioning of the FRO-S AWTF and included a thorough evaluation of measurement endpoints downstream of treatment compared to both upstream and pre-commissioning conditions. Changes in the concentrations of several water quality constituents were identified downstream of treatment, namely nutrients (total phosphorus and orthophosphate), selenium (total and dissolved; organoselenium species), and nitrate. Total phosphorus and orthophosphate concentrations increased with treatment immediately downstream of the outfall and were associated with a concurrent increase in benthic invertebrate density and biomass, indicating an increase in secondary productivity, although no change in primary production (periphyton coverage) was detected. Despite a spatially limited (only within a few hundred meters of the FRO-S AWTF outfall) increase in secondary productivity immediately downstream compared to pre-commissioning, the overall biomass and density was within the range observed across the full study area, and returned to pre-commissioning conditions with distance further downstream, indicating that the change was unlikely to be ecologically meaningful on a regional scale. Following the commissioning of the FRO-S AWTF, concentrations of total and dissolved selenium decreased at most monitoring areas downstream of the outfall location within the FRO LAEMP study area; however, bioavailable selenium (e.g., methylseleninic acid) concentrations increased directly downstream of the outfall and concentrations between the outfall and the Greenhouse Side Channel confluence were qualitatively higher than pre-commissioning and upstream concentrations. Overall, benthic invertebrate tissue selenium concentrations were unchanged relative to areas upstream of treatment and historical concentrations within each area and were consistent with expectations based on water quality. No changes in nitrate concentrations were detected immediately downstream of treatment but significant decreases in nitrate concentrations compared to pre-commissioning were observed in the lower study area. No changes in BIC structure could be directly attributed to FRO-S AWTF commissioning in 2022, but annual

monitoring of benthic invertebrate endpoints will provide information to understand any changes to the community that may be associated with continued water treatment.

The status of the WCT population in the upper Fording River has been under more routine evaluation since the population decline was identified in 2019 (Evaluation of Cause Team 2021). In addition to monitoring the population itself, key habitat features such as overwintering habitat (e.g., Henretta Lake) and seasonal drying have been identified in the context of population recovery under various ongoing programs. The need to evaluate and understand metrics of fish health historically captured under the RAEMP has also been highlighted as an important consideration when assessing WCT population. Overall, population monitoring has indicated that the abundance of sub-adult and adult WCT has been increasing since 2019. An increase in the number of fish in the 100 to 200 mm range (age-1 and age-2+) between 2021 and 2022, may lead to continued increases in adult abundance which would in turn result in increased egg deposition. Estimated egg to age-1 survival declined in 2022 presumably due to a density-dependent response as the population approaches its carrying capacity. The assessment of fish condition under the RAEMP suggests that fish in the upper Fording River are in good health and in 2022 body condition was better than the historic average. All but one fish sampled in 2022 under the RAEMP had tissue selenium concentrations that were below the benchmark for potential effects of selenium on reproduction (15.5 mg/kg dw; muscle equivalent based on egg EC₁₀; Nautilus and Interior Reforestation 2011) and selenium concentrations in fish tissue were consistent with expectations based on benthic invertebrate tissue selenium concentrations and aqueous selenium concentrations (bioaccumulation model and B-tool model). Furthermore, quarterly chronic toxicity testing conducted on rainbow trout and fathead minnow with water collected from within the FRO LAEMP study area in 2022 demonstrated no effects on fish reproduction, survival, or health endpoints. Overall, based on assessments of fish health endpoints reported in the LAEMP, there is little indication of a risk to WCT health within the FRO LAEMP study area.

The results from the FRO LAEMP were summarized (Tables 4.1 and 4.2) to support Teck's Adaptive Management Program (Teck 2018). The results from this study also supported the evaluation of biological triggers, which are intended to identify unexpected monitoring results that may lead to responses under the AMP response framework. Of the areas within the FRO LAEMP study area that were assessed for biological triggers, the monitoring area downstream of Henretta Creek in the Fording River (RG_FODHE) was the only one that had replicates (two of three) that did not reach biological triggers for % EPT (Table 4.3; Appendix K). Uncertainty remains around the cause of biological responses associated with the change in % EPT at the areas where biological triggers were reached. Therefore, the % EPT biological trigger, along with other BIC endpoints, will continue to be monitored as part of the 2023 FRO LAEMP and the RAEMP.

Table 4.1: Summary of Results, FRO LAEMP, 2022

Evaluation	Assessment Endpoint	Indicator Type	Measurement Endpoint	Evaluation Criteria	Results	Conclusion
1. Are nitrate concentrations in the study area changing and do they have the potential for adverse effects on biota?	Benthic invertebrate abundance and assemblage	Direct	Benthic invertebrate community (BIC) endpoints	Benthic invertebrate community relative to nitrate concentrations in the upper Fording River	Nitrate concentrations correlated strongly and negatively with Ephemeroptera endpoints and positively with Plecoptera endpoints; however, other mine-related constituents were also correlated along with several habitat variables (e.g., substrate size, water temperature). Covariation among water chemistry, including nitrate concentrations, and habitat meant the contribution of nitrate could not be separated. Lower nitrate concentrations from FRO-S AWTF commissioning were not related to a direct change in BIC.	Nitrate concentrations have increased over time in parts of the FRO LAEMP study area, and were higher than UECs in most areas where %Ephemeroptera was below normal ranges; however, other mine-related constituents were also elevated in these areas in addition to simultaneous changes in habitat, thus confounding the contributions and a direct causal link from nitrate. Covariation among water quality and habitat variables makes contributions from nitrate alone difficult to determine, and while nitrate likely contributes to BIC variation, it cannot be considered the sole cause of effects to BIC endpoints.
		Semi-indirect	Chronic Toxicity Testing	<i>Ceriodaphnia dubia</i> , <i>Hyalella azteca</i> , <i>Oncorhynchus mykiss</i> , and <i>Pimephales promelas</i> relative to water samples at FR_FRCP1 and the Compliance Point (FR_FRABCH).	Recent chronic toxicity studies have not identified nitrate as a potential causative factor in any observed adverse effects at FR_FRCP1 or FR_FRABCH. Previous (2015 to 2020) studies have identified multiple constituents (nitrate, sulphate, TDS, and/or nickel) as simultaneously contributing to possible or likely effects to flea reproduction and amphipod dry weight in water collected during low flow periods.	
		Indirect	Surface water nitrate concentrations	Evaluate changes to nitrate concentrations and concentrations relative to updated effects concentrations (UECs)	Nitrate concentrations have gradually increased throughout the FRO LAEMP study area since 2012 but concentrations were below UECs, except for a portion of samples in the lower section of the upper study area, throughout the middle study area, and in some areas in the lower study area during low flow seasons. Commissioning of the FRO-S AWTF reduced nitrate concentrations in monitoring areas throughout the lower study area.	
2. Is water treatment affecting biological productivity downstream in the Fording River?	Benthic invertebrate biomass and density	Direct	Benthic invertebrate biomass and density	Evaluate benthic invertebrate biomass and density downstream of treatment relative to pre-commissioning and relative to RG_FOBKS upstream of the outfall.	Benthic invertebrate biomass and density increased at the area (RG_SCOUTDS) immediately downstream of the FRO-S AWTF outfall relative to pre-commissioning and relative to RG_FOBKS, and biomass (not density) increased slightly at the Compliance Point RG_FO22.	An increase in aqueous phosphorus concentrations and benthic invertebrate productivity was identified post-commissioning of the FRO-S AWTF, however, productivity increases were localized to the area (RG_SCOUTDS) immediately downstream of the outfall location.
		Semi-indirect	Visual Periphyton Assessments	Evaluate any changes in periphyton CABIN (visual) scores	Periphyton (CABIN) scores did not change relative to areas upstream or previous years.	
		Indirect	Surface water total phosphorus and orthophosphate concentrations	Evaluate total phosphorus and orthophosphate concentrations downstream of treatment relative to pre-commissioning and relative to RG_FOBKS upstream of the outfall	Total phosphorus and orthophosphate concentrations increased from RG_SCOUTDS to RG_FOBCP relative to pre-commissioning and relative to RG_FOBKS upstream of the outfall but these increases did not occur further downstream past the Greenhouse Side Channel confluence.

Table 4.1: Summary of Results, FRO LAEMP, 2022

Evaluation	Assessment Endpoint	Indicator Type	Measurement Endpoint	Evaluation Criteria	Results	Conclusion
3. Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?	Benthic invertebrate tissue selenium concentrations	Direct	Benthic invertebrate tissue selenium concentrations	Benthic Invertebrate tissue selenium concentrations relative to EVWQP benchmarks, selenium bioaccumulation mode, and Bioaccumulation Tool (B-tool) predictions	Benthic invertebrate tissue selenium concentrations did not change downstream of water treatment despite changes in aqueous selenium concentrations. In 2022, tissue selenium concentrations were below EVWQP benchmarks in 94% of samples and many that were above benchmarks contained annelids. Except for samples containing annelids, tissue selenium concentrations were consistent with predictions based on the aqueous total selenium (i.e., the selenium bioaccumulation model) and aqueous reduced selenium (i.e., B-tool) concentrations.	Total and dissolved selenium concentrations have decreased at most monitoring areas downstream of the FRO-S AWTF outfall compared to pre-commissioning and the area (RG_FOBKS) immediately upstream, but there has been a qualitative increase in organoselenium concentrations at some areas immediately downstream. Despite this, benthic invertebrate tissue selenium concentrations have remain unchanged at all areas downstream of treatment and concentrations have been consistent with predictions based on aqueous selenium concentrations throughout the study area
		Indirect	Aqueous total and reduced selenium concentrations	Evaluate aqueous total and selenium concentrations relative to benthic invertebrate tissue selenium concentrations	Total and dissolved selenium concentrations decreased at most areas downstream of the FRO-S AWTF outfall relative to immediately upstream at RG_FOBKS, but qualitative observation of the data identified notable increases of organoselenium concentrations in areas between the outfall and Greenhouse Side Channel confluence. When considering the full study area, total selenium and selenite concentrations were higher at areas downstream of the Lake Mountain Creek influence (RG_FODNGD) and downstream of the FRO-S AWTF outfall (RG_SCOUTDS), and while total selenium was higher downstream of the Greenhouse Side Channel confluence (RG_FRUPO), selenite was lower.	
4. How is temperature changing over time in the FRO LAEMP study area? 4a. Is water temperature measurably different (greater than 1 degree Celsius) downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition? 4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF)?	Water Temperature	Direct	Water temperature	Evaluate changes in water temperature throughout the study area and assess whether water temperature was greater than 1°C different downstream compared upstream of the FRO-S AWTF outfall	Water temperatures have remained stable throughout most of the FRO LAEMP study area, except for three stations in the middle study area where small but statistically significant increases in temperature have been observed since 2017. Water temperatures downstream of treatment compared to upstream only exceeded the 1°C threshold for three days post-commissioning.	With few exceptions, water temperatures have remained stable throughout the FRO LAEMP study area since 2017. Minor differences in water temperature were observed when comparing the areas immediately downstream (RG_SCOUTDS) and upstream (RG_FOBKS) of treatment pre- and post-commissioning, but they rarely exceeded the 1°C threshold indicating minimal influence of FRO-S AWTF operation on water temperatures in the receiving environment.

Table 4.1: Summary of Results, FRO LAEMP, 2022

Evaluation	Assessment Endpoint	Indicator Type	Measurement Endpoint	Evaluation Criteria	Results	Conclusion
5. What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?	Benthic invertebrate abundance and assemblage	Direct	Benthic invertebrate community endpoints (abundance, richness [LPL taxonomy], percent [%] and total abundance of Ephemeroptera-Plecoptera-Trichoptera [EPT], Ephemeroptera, Plecoptera, Trichoptera, and Chironomidae, total abundance of key Ephemeroptera families [Baetidae, Heptageniidae, Ephemerellidae])	Spatial and temporal comparisons to site-specific and regional normal ranges and evaluations over time; evaluation of BIC endpoint changes downstream of treatment post-commissioning of the FRO-S AWTF	Most BIC endpoints assessed, including all abundance endpoints, were within site-specific and/or regional normal ranges and have not changed significantly over time. Percent EPT was below site-specific normal ranges from RG_FOUNGD to RG_FOU EW and below the regional normal range from RG_FOUSH and RG_FOBSC (except RG_FOBKS), while % Ephemeroptera was below the site-specific normal range from RG_FOUSH to RG_FOU EW and below the regional normal range from RG_FRCP1SW to RG_FOU EW. Both %EPT and % Ephemeroptera decreased in sections of the upper and middle study area compared to previous years. Consistent with previous years, % Plecoptera was near or above the upper limit of the normal range from RG_FRCP1SW to RG_FOU EW but was lower than previous years at some areas in the upper and middle study areas. There were few significant and meaningful changes in BIC endpoints downstream of water treatment post-commissioning of the FRO-S AWTF.	Monitoring has continued to show spatial gradients in key relative abundance endpoints (% EPT, % Ephemeroptera, and % Plecoptera) from upstream to downstream within the FRO LAEMP study area but while a similar spatial pattern in Ephemeroptera abundance and relative abundance was observed, all abundance endpoints were within their respective reference normal ranges and have remained stable. Changes in the relative abundance of EPT taxa often corresponded with shifts in the abundance of other non-EPT taxa and, together with consistently high abundance in all key taxa, including EPT, represent no limitation of food available to fish throughout the study area. Consistent with previous years, spatial changes in key relative abundance endpoints occurred simultaneous with changes in concentrations of mine-related constituents, including those that exceeded effects levels during low flows, and variations of habitat, including substrate size, water temperature, water depth, and calcite. Both water quality stressors and habitat variables affected BIC variation, particularly through the full study area and the middle study area, but the effect from individual predictors was difficult to separate. Most habitat variables influenced BIC variation throughout the full study area, however, substrate size and water temperature had a particularly strong effect on BIC variation in the lower study area where very high % Plecoptera and low % Ephemeroptera continue to be observed. Although some nutrient and mine-related constituent concentrations have changed in relation to water treatment, these changes did not cause any notable changes in BIC structure.
	Benthic invertebrate abundance and assemblage	Indirect	Surface water chemistry	Concentrations of mine-related constituents relative to EVWQP effect benchmarks, UECs, proposed benchmarks, screening values, and past observations; evaluation of water quality changes in relation to FRO-S AWTF commissioning	Decreases in nitrate, selenium, and to some extent dissolved nickel concentrations, and increases in total phosphorus, orthophosphate, nitrite, and total molybdenum were observed downstream of the FRO-S AWTF post-commissioning. In the upper study area, concentrations of most mine-related constituents, including Order constituents, rarely exceeded their respective UECs, proposed benchmarks, or screening values, except for nitrate which was above the Level 1 UEC from RG_FODNGD to RG_FOUSH and dissolved nickel which exceeded the Level 2 proposed benchmark from RG_FOUNGD to RG_FOUSH. The middle study area had the most exceedances as the Level 2 proposed benchmark for dissolved nickel, Level 1 screening value for TDS, multiple levels of UECs for nitrate, and Level 1 UECs for sulphate were exceeded at most areas and during the low flow season. The lower study area had fewer exceedances than the middle study area but exceedances included Level 1 screening value for TDS from RG_FRUPO to RG_FO22, Level 1 UECs for nitrate at RG_FRUPO and Level 3 UECs at RG_FO22, and the proposed benchmark at RG_FODPO.	
				Water Temperature	Continuous Monitoring of temperature and discharge at FR_UFR1, FR_FR1, FR_FOUCL, FR_FRDSSC1, FR_FR2, FR_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRCP1SW, FR_FRRD, GH_PC2, FR_FRABCH evaluated over time and in integrated analyses	

Note: NR = Normal Range. BIC = Benthic Invertebrate Community. CA = Correspondence Analysis. CI = Calcite Index. EPT = Ephemeroptera,-Plecoptera-Trichoptera. EVWQP = Elk Valley Water Quality Plan. Evaluation	Assessment Endpoint	Indicator Type	Measurement Endpoint	Evaluation Criteria	Results	Conclusion
<p>5. What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?</p>	<p>Benthic invertebrate abundance and assemblage</p>	<p>Indirect</p>	<p>Calcite</p>	<p>Calcite index relative to known or suspected effect levels and past observations</p>	<p>Calcite indices increased from upstream to downstream in the FRO LAEMP study area but was generally similar to or lower than the previous year and below 1.0 at each area.</p>	
			<p>Correlations between physical and chemical factors, and BIC metrics</p>	<p>Physical: CI, calcite presence, concretion Score, embeddedness, pebble size (D16 and D84), water velocity, water depth, minimum winter temperature, maximum summer temperature, annual temperature; Chemical: PC1, PC2, individual constituents; BIC metrics: total abundance, richness, % Ephemeroptera, % Plecoptera, % Trichoptera, % EPT, and % Chironomidae, Abundance Ephemeroptera, Plecoptera, Trichoptera, EPT, and Chironomidae, Habitat Model Residuals for Abundance, Richness, % Ephemeroptera, % EPT, Ephemeroptera abundance, and EPT abundance, Feeding and Habitat Indices</p>	<p>Consistent with previous years, key BIC endpoints had strong, significant relationships with mine-related constituents, most notably negative correlations with % Ephemeroptera, Ephemeroptera abundance and, to a lesser extent % EPT, but positive correlations with % Plecoptera. Significant correlations with several habitat variables also occurred, including a positive correlation of substrate size and % Ephemeroptera but a negative correlation with % Plecoptera and Plecoptera abundance. Within individual study areas % Plecoptera and/or Plecoptera abundance correlated with calcite presence and index in the upper study area (positive), calcite concretion in the middle study area (positive), minimum winter water temperature in the middle and lower study area (negative and positive, respectively), and water depth in the lower study area (negative).</p>	
			<p>Canonical Correspondence Analysis</p>	<p>Habitat Variables: bankfull width, mean depth, mean velocity, substrate size D16, station gradient, watershed area, station gradient; Stressor Variables: calcite presence, calcite concretion, summer mean temperature, winter mean temperature, total nickel, nitrate, total selenium, sulphate, total dissolved solids, total uranium, dissolved cadmium</p>	<p>Habitat and water quality variables, along with calcite and water temperature, explained 37% of the BIC variation but 22-23% was shared by the predictor groups, making individual contributions difficult to separate. Except for calcite concretion, every habitat and water quality stressor was flagged as influencing BIC variation in the full study area which may be related to the large gradient in the data. The fewest number of habitat and water quality stressors affected BIC variation in the upper study area, while most habitat and water quality stressors affected BIC variation throughout the middle study area. In the lower study area, substrate size and summer and winter mean water temperatures were strongly associated with BIC variation, and these habitat variables are markedly different throughout this section of the Fording River. Notably, dissolved nickel and cadmium were not associated with BIC variation in the lower study area, despite significant contributions in the middle study area.</p>

Table 4.1: Summary of Results, FRO LAEMP, 2022

Evaluation	Assessment Endpoint	Indicator Type	Measurement Endpoint	Evaluation Criteria	Results	Conclusion
6. What are the factors influencing fish health and population in the upper Fording River?	WCT health and population	Direct	WCT population	WCT population monitoring within the study area, including redd surveys, length at age-0, body condition, abundance, egg to age-1 survival (Thorley 2023)	Population monitoring has indicated a continued increase in the subadult and adult population in the upper Fording River in 2022, now up to ~2,300 fish from ~330 in 2019. The estimated number of eggs deposited by WCT has increased steadily since 2019 (inferred from adult abundance and size). The 2022 age-1 abundance was similar to the previous two years, while the number of fish in the 100 to 200 mm range (age-1 and age-2+) increased between 2021 and 2022, which may lead to continued increases in adult abundance. A decline in estimated egg to age-1 survival for the 2021 cohort relative to 2019 and 2020 suggests there may be a density-dependent response as the population approaches its carrying capacity. The decrease in the estimated number of nests in 2022 compared to 2021 is likely associated with cold early season water temperatures. A more detailed presentation and discussion of the 2022 upper Fording River Population monitoring program are provided in Thorley et al. (2023).	Westslope Cutthroat Trout captured within the study area under the RAEMP were considered to be in good health, indicated by low observations of external anomalies and condition factor similar or higher than that of reference areas. Monitoring under the Population Monitoring Program indicated that the WCT population is recovering since the steep population decline of 2019, and overall, the abundance of sub-adult and adult WCT has been increasing since the decline.
		Indirect	Chronic Toxicity Testing	<i>Oncorhynchus mykiss</i> and <i>Pimephales promelas</i> relative to water samples at FR_FRCP1 and the Compliance Point (FR_FRABCH).	No adverse effect to rainbow trout (<i>O. mykiss</i>) or fathead minnow (<i>P. promelas</i>) reproduction, survival, or health endpoints were observed from water collected within the FRO LAEMP study area in 2022, indicating that concentrations of mine-related constituents were unlikely to cause toxicity to fish.	
		Indirect	WCT Critical Habitat (Henretta Lake)	Evaluate WCT habitat quantity and quality using <i>in situ</i> measures (temperature, oxygen, conductivity) and supporting water chemistry data	For most of the 2022 monitoring period, high concentrations of dissolved oxygen (above the 8 mg/L chronic BC WQGL) suggest that Henretta Lake contains high volumes of oxygenated habitat (suitable for resident WCT) during the open-water period.	
		Indirect	Seasonal drying	Determination of timing and spatial extent of drying within the Fording River	Drying was first observed in the Fording River upstream of the Greenhouse Side Channel confluence in late September and downstream of the Clode Creek confluence in mid-October in 2022. The timing and location of drying in the FRO LAEMP study area in 2022 was similar to previous years and may represent a barrier to fish movement. Multiple years of monitoring have identified year-to-year variability on the timing of drying; however, once low flows were established in early winter dry sections expanded but no new dry areas were observed throughout the season.	
		Direct	WCT anomalies	Observation of external anomalies on WCT captured for muscle tissue sampling	Only one of thirteen fish captured in the study area in 2022 had anomalies.	
		Indirect	WCT condition factor	Observation of overall fitness in WCT caught for muscle tissue sampling	WCT condition at mine-exposed areas was similar or higher than those caught at reference areas in 2018 and 2022.	
		Indirect	WCT tissue selenium concentrations	Muscle selenium concentrations of WCT caught at mine-exposed areas within the upper Fording River	Muscle selenium concentrations in all but one WCT sampled in 2022 under the RAEMP were below the site-specific effects benchmark	

Note: NR = Normal Range. BIC = Benthic Invertebrate Community. CA = Correspondence Analysis. CI = Calcite Index. EPT = Ephemeroptera,-Plecoptera-Trichoptera. EVWQP = Elk Valley Water Quality Plan. Table 4.2: Summary of Findings, Responses and Adjustments Related to the FRO LAEMP in 2022

Program Name	Study Question(s)	Data Evaluation Process	Outcome(s)	Responses & Adjustments in 2022	EMC Engagement
FRO LAEMP	1. Are nitrate concentrations in the study area changing and do they have the potential for adverse effects on biota?	Determine if benthic invertebrate community endpoints are outside of site specific and regional normal ranges or moving away from normal ranges in accordance with observed nitrate concentrations.	Nitrate concentrations have increased over time throughout most of the FRO LAEMP study area, and were higher than updated effects concentrations (UECs) in most areas where % Ephemeroptera was below normal ranges; however, simultaneous changes in other mine-related constituents and habitat variables make the contribution of nitrate to BIC variation difficult to determine. Nitrate concentrations likely contribute to observed BIC variation but is not the only factor.	There were no responses and adjustments in 2022	<ul style="list-style-type: none"> - Draft data package of 2017 results submitted to EMC Feb 15, 2018; Additional results for early 2018 presented May 3 and submitted October 23, 2018 - Report of 2017 results submitted to ENV/EMC May 31, 2018 - 2018 Study design submitted to ENV/EMC May 31, 2018 - In-person meetings on Feb 22 and May 2; and conference call on March 27, 2018 - Written input from EMC received between June 1 and July 18, 2018 - Draft data package of additional 2018 results submitted to EMC March 22, 2019 and discussed at in-person meeting March February 22, 2019 - Report of 2018 results submitted to ENV/EMC May 31, 2019 - Second FRO LAEMP study design (2019-2020) submitted May 31, 2019 - Written input from 2018 FRO LAEMP report received July 2019 - Draft data package of 2019 FRO LAEMP report data submitted March 3, 2020 - Written input from 2019 FRO LAEMP data package received March 17, 2020 - Report of 2019 results submitted to ENV/EMC May 31, 2020 - Study design amendment letter for the 2019-2020 FRO LAEMP Study Design submitted to ENV/EMC June 1, 2020 - Conference call December 3, 2020 to discuss study question and study design updates for next FRO LAEMP cycle - Written input from EMC about study question and study design updates received December 17, 2020 - Conference call February 3, 2021 to discuss study question and study design updates for next FRO LAEMP cycle - Written input from EMC about study question and study design updates received February 18, 2021 - Conference call February 23, 2021 to discuss study question and study design updates for next FRO LAEMP cycle - Third FRO LAEMP study design (2021-2023) submitted April 1, 2021 - Draft data package data package of 2020 FRO LAEMP report data submitted April 8, 2021 - Written input from 2020 FRO LAEMP data package received April 22, 2021 - Report of 2020 results submitted to ENV/EMC May 31, 2021
		Determine if benthic invertebrate community results correspond with expectations based on nitrate concentrations in water relative to the updated effects concentrations for nitrate.			
	2. Is water treatment affecting biological productivity downstream in the Fording River?	Evaluate aqueous phosphorus concentrations downstream of the FRO-S AWTF outfall relative to pre-commissioning concentrations and relative to the area (RG_FOBKS) immediately upstream of the outfall.	Total phosphorus and orthophosphate concentrations increased between the FRO-S AWTF outfall and the Greenhouse Side Channel confluence relative to pre-commissioning concentrations and RG_FOBKS (upstream), while benthic invertebrate biomass and density increased at the area immediately downstream from the FRO-S AWTF outfall (RG_SCOUTDS).	There were no responses and adjustments in 2022	
		Evaluate benthic invertebrate biomass and density downstream of the FRO-S AWTF outfall relative to pre-commissioning concentrations and relative to the area (RG_FOBKS) immediately upstream of the outfall.

Table 4.2: Summary of Findings, Responses and Adjustments Related to the FRO LAEMP in 2022

Program Name	Study Question(s)	Data Evaluation Process	Outcome(s)	Responses & Adjustments in 2022	EMC Engagement
FRO LAEMP	3. Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?	Evaluate benthic invertebrate tissue selenium concentrations relative to selenium bioaccumulation model and the selenium bioaccumulation tool (B-tool).	Benthic invertebrate tissue selenium concentrations were consistent with predictions except for samples that contained annelids and one sample taken in the Greenhouse Side Channel in January which could not be explained by sample composition or selenium speciation.	There were no responses and adjustments in 2022	<p>-Draft data package of 2021 FRO LAEMP report data submitted April 6, 2022</p> <p>-Follow up call to discuss FRO LAEMP data package April 12, 2022</p> <p>-Written input from 2021 FRO LAEMP data package received April 20, 2022</p> <p>-Report of 2021 results submitted to ENV/EMC May 31, 2022</p> <p>-Draft data package of 2022 FRO LAEMP report submitted April 5, 2023</p> <p>-Written input from 2022 FRO LAEMP data package received April 19, 2023 (except for from KNC)-</p>
	4. How is temperature changing over time in the FRO LAEMP study area? 4a. Is water temperature measurably different (greater than 1 degree Celsius) downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition? 4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF)?	Evaluate changes in water temperature throughout the study area and temperature differences at the area (RG_SCOUTDS) downstream compared to the area (RG_FOBKS) immediately upstream of the FRO-S AWTF outfall.	Water temperatures have increased slightly at a few stations in the middle part of the FRO LAEMP study areas and although there have been demonstrated water temperature differences downstream compared to upstream relative to pre-commissioning, there were very few exceedances of the 1°C threshold.	There were no responses and adjustments in 2022	
	5. What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?	Determine if benthic invertebrate community endpoints, particularly Ephemeroptera and associated families, are outside of site-specific and regional normal ranges or moving away from the normal ranges.	Consistent with previous years, %EPT, %Ephemeroptera, and %Plecoptera changed significantly from upstream to downstream within the FRO LAEMP study area in 2022, and these changes occurred simultaneous with changes in correlations of mine-related constituents, including those that exceeded established effects concentrations and variations of habitat. Both water quality stressors and habitat variables affected BIC variation, particularly through the full study area and the middle study area, but the effect of individual predictors was difficult to separate.	There were no responses and adjustments in 2022	
		Investigate connection between benthic invertebrate community variation and water chemistry and habitat within the study area.		Polyaromatic hydrocarbon (PAH) and, to a lesser extent, selenium concentrations were significantly higher at the area (RG_SCOUTDS) immediately downstream of the FRO-S AWTF outfall in September 2022 so confirmatory sampling was conducted in February 2023 to verify anomalous results. Samples collected in February had PAH and selenium concentrations that were consistent with previous years so the adjustment that follows will be to evaluate the sediment collection methods in the updated study design next cycle.	

Notes: ATWF = Active Water Treatment Facility; LAEMP = Local Aquatic Effects Monitoring Program; EMC = Environmental Monitoring Committee; ENV = Ministry of Environment and Climate Change Strategy; FRO = Fording River Operation; EVWQP = Elk Valley Water Quality Plan; BIC = Benthic Invertebrate Community; CCA = Canonical Correspondence Analysis; EPT = Ephemeroptera-Plecoptera-Trichoptera; WCT = Westslope Cutthroat Trout

Table 4.2: Summary of Findings, Responses and Adjustments Related to the FRO LAEMP in 2022

Program Name	Study Question(s)	Data Evaluation Process	Outcome(s)	Responses & Adjustments in 2022	EMC Engagement
FRO LAEMP	6. What are the factors influencing fish health and population in the upper Fording River?	Evaluate WCT health through tissue selenium concentrations, observed external abnormalities and condition factor of fish caught.	Westslope Cutthroat Trout captured within the study area under the RAEMP were considered to be in good health, indicated by low observations of external anomalies and condition factor similar or higher than that of reference areas. Monitoring under the Population Monitoring Program indicated that the WCT population is recovering since the steep population decline of 2019, and overall, the abundance of sub-adult and adult WCT has been increasing since the decline.	There were no responses and adjustments in 2022 under the FRO LAEMP. Responses and adjustments under other programs are reported therein.	-
		Determine potential limitations to overwintering habitat during fall migration as a result of seasonal drying.			
		WCT population monitoring within the study area, including redd surveys, length at age-0, body condition, abundance, egg to age-1 survival (Thorley 2023)			

Notes: ATWF = Active Water Treatment Facility; LAEMP = Local Aquatic Effects Monitoring Program; EMC = Environmental Monitoring Committee; ENV = Ministry of Environment and Climate Change Strategy; FRO = Fording River Operation; EVWQP = Elk Valley Water Quality Plan; BIC = Benthic Invertebrate Community; CCA = Canonical Correspondence Analysis; EPT = Ephemeroptera-Plecoptera-Trichoptera; WCT = Westslope Cutthroat Trout

Table 4.3: Summary of Biological Trigger Analysis for Percent EPT and Benthic Invertebrate Tissue Selenium Concentrations, FRO LAEMP, 2022

Waterbody	Area		% EPT ^a		Selenium BIT ^b	
			Number Replicates Evaluated	Number of Replicates Reaching Biological Trigger ^c	Number Replicates Evaluated	Number of Replicates Reaching Biological Trigger ^d
Fording River	RG_FO26	Reference	3	3	6	0
	RG_FODHE	Mine-exposed	3	1	6	0
	RG_FOUKI		3	3	30	0
	RG_FOBSC		3	3	35	0
	RG_FOBCP		5	5	15	0
	RG_FODPO		3	3	30	2 ^e
	RG_FO22		5	5	30	0

Notes: % EPT = Percent EPT (Ephemeroptera [mayflies], Plecoptera [stoneflies], and Trichoptera [caddisflies]); Selenium BIT = Selenium concentrations in benthic invertebrate tissue (mg/kg dw).

^a Biological Trigger analysis for %EPT was for the September sampling event.

^b Biological Trigger analysis for Selenium BIT was for the January, February, March, June, September, November, and December sampling events.

^c Number of Replicates Reaching Biological Trigger for % EPT refers to those replicates which were below both triggering steps (i.e., below the lower 2.5th percentile of the habitat-adjusted normal range and expectations [as based on predicted ADIT Scores]). See section K.2.2 for more details.

^d Number of Replicates Reaching Biological Trigger for Selenium BIT refers to those replicates which were above both triggering steps (i.e., above the upper 97.5th percentile prediction limit of the regional normal range and expectations [as based on the predicted 95% percentile from the water to benthic invertebrate selenium bioaccumulation model]). See section K.2.3 for more details.

^e Both samples that exceeded the biological trigger at RG_FODPO contained annelids which are known to accumulate selenium more readily than other taxa (Luoma 2021)

Other efforts are also currently underway (i.e., BIC predictive modeling) to resolve uncertainty around effects of mine-related stressors on BIC endpoints (further information regarding the response for these biological triggers can be found in Appendix K). Benthic invertebrate tissue selenium concentrations did not exceed the biological triggers, except for two of five replicates at the monitoring area (RG_FODPO) located downstream of Porter Creek, (Table 4.3; Appendix K). The two composite-taxa benthic invertebrate samples that exceeded biological triggers at RG_FODPO contained annelids, which are known to more readily accumulate selenium compared to other taxa (Luoma 2021). Overall, results of the biological trigger evaluation were consistent with the findings of the data evaluation conducted under the 2022 FRO LAEMP. Given that current biological triggers were sufficient to identify monitoring areas where biological responses are occurring, no additional biological triggers are recommended at this time.

5 UPDATES TO 2021 TO 2023 FRO LAEMP STUDY DESIGN

No changes to the 2021 to 2023 FRO LAEMP Study design are recommended for 2023.

Permit 107517 was amended in March 2021 to include the third cycle of FRO LAEMP monitoring, and Section 8.3.2 outlines the LAEMP requirements for any changes to the approved 2021 to 2023 study design as follows:

8.3.2: The permittee must complete to the satisfaction of the director a study design for a LAEMP which will focus on the upper Fording River for 2021 to 2023 by April 1, 2021. The study design must be reviewed by the EMC and be designed to an appropriate temporal scale to capture short term, local effects to the immediate receiving environment. Any changes to the approved study design must be reported in the annual LAEMP report.

Several adjustments to the approved FRO LAEMP 2021 to 2023 study design have previously been made (Minnow and Lotic 2022) based on learnings from the LAEMP, input from the EMC, and monitoring needs associated with post-commissioning of the FRO-S AWTF and the future commissioning of the FRO-N SRF:

1. Benthic invertebrate community sampling in June and December was discontinued in 2022 (Table 5.1); data has shown that the largest variations in BIC occur in September across the largest spatial extent. In addition, a large historical and reference dataset is available for September and thus provides the most information for evaluating FRO LAEMP study questions.
2. Benthic invertebrate community sampling was added at the monitoring area in the Fording River Side Channel #2 (RG_FRSch2) in September 2022 because this side channel is becoming an important flow path in this section of the Fording River (Table 5.1).
3. The FRO-N SRF commissioning sampling plan (Table 5.2) will be added to the study design for 2023 monitoring to help understand any potential changes to water and tissue chemistry as a result of commissioning, which is scheduled for Q2 2023 (Teck 2022).
4. Replicates of five benthic invertebrate tissue samples will be collected at areas associated with the FRO-N SRF commissioning sampling plan to provide additional pre- and post-commissioning data for greater statistical power (Tables 5.1 and 5.2).

The above updates to the 2021 to 2023 FRO LAEMP study design reflect agreements between the study team and the EMC during the April 6, 2022, and the April 5, 2023, EMC meeting and the subsequent advice table provided to the study team from the EMC.

Table 5.1: Summary of Proposed Sampling Plan for the FRO LAEMP, 2023

Notes: '-' indicates sample that was not a part of the sampling design.

^a RG_UFR1 will be used as a reference area in winter months when there is no access to RG_FO26 or RG_HENUP.

^b n=5 for composite-taxon tissue samples in areas associated with the FRO AWTF-S Commissioning Sampling Plan and the FRO-N SRF Commissioning Sampling Plan.

^c The water quality monitoring station is the same for biological monitoring stations RG_FO26 and RG_UFR1.

^d Routine water quality monitoring stations associated with biological monitoring areas are outlined in brackets.

^e RG_FRSC2 and RG_FRGHSC will continue to be monitored for water and benthic invertebrate tissue chemistry for post-FRO AWTF-S commissioning monitoring.

^f Triplicate samples of periphyton for both ash free dry mass and chlorophyll-a analysis for RAEMP requirements.

^g Periphyton scores of n=5 will be taken at each biological monitoring area in September.

^h BIC monitoring added in 2022 and will continue to be monitored in 2023.

Table 5.2: FRO-N SRF Commissioning Sampling Plan, 2023

Biological Monitoring Area (Associated Teck Water Station) ^d		Area Description	Biological Monitoring Area UTM Coordinates		Sampling Design											
					Water Chemistry				Water Selenium Speciation				Composite-taxon Selenium

Notes: the FRO-N SRF primary outfall will be through Clode Creek, located downstream of RG_FOUCL and upstream of RG_FRDSCC1.

^a RG_UFR1 will be used as the reference location because of limited access to RG_FO26 or RG_HENUP during winter months.

^b Riffles within tributaries to Fording River may be frozen during winter months.

^c Week zero sampling will be conducted before FRO-N SRF commences water discharge from phase 2 operations.

^d Routine water quality monitoring stations associated with biological monitoring areas are outlined in brackets.

6 ACKNOWLEDGEMENTS

This report was written by Minnow Environmental Inc. (Peter Schnurr, Jennifer Ings, and Clare Nelligan), Lotic Environmental Ltd. (Scott Gordon), and Branton Environmental Consulting (Maggie Branton). Minnow Environmental Inc. was the sole contributing author on sections: 1 Introduction, 2.1, 2.2 and 2.4 to 2.7 in Methods, 3.1 to 3.6 in Results and Discussion, 4 Integrated Summary, and 5 Updates to 2021 to 2023 FRO LAEMP Study Design. Sections 2.3 Hydrology and 3.7.2 Drying Surveys were co-authored by Minnow Environmental and Lotic Environmental Ltd. Sections 2.7 Fish and 3.7 Study Question #6 were co-authored by Minnow Environmental and Branton Environmental Consulting.

A1 INTRODUCTION

A1.1 Background

A variety of factors can influence the physical, chemical, and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Depending on their magnitude, inaccuracy and imprecision have the potential to affect the reliability of conclusions made from data; therefore, it is important to ensure that programs incorporate appropriate steps to control non-natural sources of data variability (i.e., minimize variability that does not reflect authentic spatial and temporal variability in the environment) and thus assure the quality of the data. Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. A data quality review (DQR) involves the comparison of field and laboratory measurement performance to Data Quality Objectives (DQOs) established for a particular study, such as evaluation of Laboratory Reporting Limits (LRL), blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials). Trusted analytical laboratories certified by Canadian Association for Laboratory Accreditation (CALA) or the National Environmental Laboratory Accreditation Program (NELAP) with a rigorous internal quality assurance program were selected to ensure the highest possible data quality. Data Quality Objectives were established *a priori* to reflect reasonable and achievable performance expectations (Table A.1). Programs involving many samples and analytes usually yield some results that exceed DQOs. This is particularly so for multi-element scans, as the analytical conditions are not necessarily optimal for every element included in the scan. Generally, scan results may be considered acceptable if no more than 20% of the parameters fail to meet DQOs. Overall, the intent of a DQR is not to reject any measurement that did not meet a DQO, but to ensure that any questionable data received more scrutiny to determine what effect, if any, this had on interpretation of results within the context of the project.

A1.2 Quality Control Samples

A DQR as conducted on all laboratory data collected as part of the 2022 Fording River Operations (FRO) Local Aquatic Effects Monitoring Program (LAEMP). The objective of a DQR is to define the overall quality of the data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions.

Table A.1: Laboratory Data Quality Objectives for the FRO LAEMP, 2022

Quality Control Measure	Quality Control Sample Type/Check	Study Component				
		Water Chemistry	Selenium Speciation	Sediment Chemistry	Benthic Invertebrate Community	Benthic Invertebrate Tissue Chemistry
		ALS Environmental	Brooks Applied Labs	ALS Environmental	Cordillera Consulting	TrichAnalytics
Analytical Laboratory LRLs	Comparison of actual LRL versus target LRL	LRL for each parameter should be at least as low as applicable guidelines, benchmarks, and screening values	LRL for each parameter should be at least as low as applicable guidelines, benchmarks, and screening values	LRL for each parameter should be at least as low as applicable guidelines and benchmarks	-	LRL for each parameter should be at least as low as applicable guidelines and benchmarks
Blank Analysis	Field, Trip, or Laboratory Blank	Concentrations measured in blank samples should be < LRL	Concentrations measured in blank samples should be < LRL	Concentrations measured in blank samples should be < LRL	-	-
Laboratory Precision	Laboratory Duplicates	< 4% (pH) <10% (conductivity) ≤15% RPD or <2x LRL (ORP, turbidity) ≤20% RPD or <2x LRL (all remaining analytes)	≤25% RPD (selenium species) ≤20% RPD (total selenium)	≤ 5% RPD (pH 1:2soil:water) ≤20% RPD (inorganic carbon, moisture) ≤30% RPD, 40% RPD or diff < 2x LOR (total metals) ≤ 50% RPD, 60-130% RPD or diff < 2xLOR RPD (PAHs)	-	≤60% RPD (calcium and strontium) ≤40% RPD (all remaining analytes)
	Organism Sorting Efficiency	-	-	-	≥ 95%	-
	Organism Sub-Sampling Precision and Accuracy	-	-	-	< 20% between subsamples	-
Accuracy	Recovery of Blank Spike	-	75 to 125% (methylseleninic acid, selenate, selenite, selenocyanate, selenomethionine, total selenium)	-	-	-
	Recovery of Matrix Spike	70 to 130% (TKN, orthophosphate, phosphorus, TOC, DOC, total and dissolved metals) 75 to 125% (ammonia, bromide, chloride, fluoride, nitrate, nitrite, sulphate)	75 to 125% (selenate, selenite, selenocyanate, selenomethionine, total selenium)	-	-	-
	Matrix Spike Duplicate	-	75 to 125% (selenate, selenite, selenocyanate, selenomethionine, total selenium)	-	-	-
	Recovery of Certified Reference Material	-	75 to 125% (total selenium)	40 - 160 % (boron, thallium) 70 130 % (all other analytes) 80 - 120 % (inorganic carbon, total carbon) 96 - 104 % (pH)	-	60 to 140% (antimony, barium, boron, silver, tin, titanium) 90 to 110% (selenium) 70 to 130% (all remaining analytes)
	Laboratory Control Sample	75 to 125% (TKN) 80 to 120% (orthophosphate, phosphorus, DOC, TOC, total and dissolved metals) 85 to 115% (acidity, alkalinity, ammonia, bromide, TDS, TSS, turbidity) 90 to 110% (conductivity, chloride, fluoride, nitrate, nitrite, sulphate) 98.6-101% (pH), 95.4 to 104% (ORP)	-	50 - 130% (naphthalene, naphthalene-d8) 60 - 130% (PAHs) 80 - 120% (all other analytes) 90 - 110% (inorganic carbon, moisture) 97 - 103% (pH 1:2 soil:water)	-	-
	Taxonomic Accuracy	-	-	-	< 5% TIR	-

Notes: LRL = Laboratory Reporting Limit; "-" = not applicable; < = less than; ≤ = less than or equal to; % = percent; RPD = Relative Percent Difference; ORP = oxidation-reduction potential; TKN = Total Kjeldahl Nitrogen; TOC = total organic carbon; DOC = dissolved organic carbon; TSS = total suspended solids; TDS = total dissolved solids; mg/kg dw = milligrams per kilogram dry weight; TIR = total identification error rate.

A DQR involves the examination of analytical results associated with several types of Quality Control (QC) samples collected or prepared in the field and laboratory. General QC samples collected for this project include the following:

- **Blanks** are samples of de-ionized water and/or appropriate reagent(s) that are handled and analyzed in the same way as regular samples. These samples will reflect any contamination of samples occurring in the field (in the case of field or travel blanks) or in the laboratory (in the case of laboratory or method blanks). Analyte concentrations should be below detection.
- **Laboratory Duplicates** are replicate sub-samples created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.
- **Field Duplicates** are samples collected from a randomly selected field station that are homogenized to the extent possible, split and analyzed separately in the laboratory. The duplicate samples are handled and analyzed in an identical manner in the laboratory.
- **Spike Recovery Samples** are created in the laboratory by adding a known amount/concentration of a given analyte (or mixture of analytes) to a randomly selected test sample previously divided to create two sub-samples. The spiked and regular sub-samples are then analyzed in an identical manner. The spike recovery represents the difference between the measured spike amount (total amount in the spiked sample minus the amount in the original sample) relative to the known spike amount (as a percentage). Two types of spike recovery samples are commonly analyzed: spiked blanks (or blank spikes) are created using laboratory control materials whereas matrix spikes (MS) are created using field-collected samples and are sometimes further tested in duplicate (matrix spike duplicates, MSD). The analysis of spiked samples provides an indication of the accuracy of analytical results.
- **Certified Reference Materials (CRM) or Reference Materials (RM)** are commercially prepared (or commercially homogenized) samples containing known chemical concentrations that are processed and analyzed along with batches of environmental samples. The sample results are then compared to the known concentrations to provide a measure of analytical accuracy. The results are reported as the percent of the known concentration that was recovered in the analysis.

- **Laboratory Control Samples** are created in the laboratory to have a known analyte concentration in a matrix free of interferences, such as deionized water or reference sand. The sample results are compared to the target results to confirm that the analytical method is accurate in a purified reference sample. The results are reported as the percent of the known concentration that was recovered in the analysis.
- **Laboratory Sorting Efficiency** are randomly selected grabs of the initially sorted community material. These samples are recounted and the number of invertebrates that were not recovered during the initial sort was determined. In order to reduce bias, recounting is conducted by an analyst uninvolved in the initial sample processing. This check is performed on 10% of samples and determines the accuracy through assessment of recovery (sorting) efficiency and quantifies any under-estimation of organism enumeration.
- **Taxonomic Quality Control Samples** are a randomly selected portion of a benthic invertebrate community field sample to be assessed by the laboratory using an internal quality control audit. A blind re-enumeration and re-identification of random samples is performed by an analyst uninvolved in the original sample processing. This assessment quantifies taxonomic misidentification among laboratory analysts and ensures accurate organism identities are reported.
- **Laboratory Subsamples** are community samples prepared by the laboratory to ensure that the fraction of the total sample examined was an accurate representation of the total number of organisms. By comparing the amount recovered between at least two sub-samples, one can assess the analytical precision. In addition, comparisons of the sub-samples from the whole community sample allows for an evaluation of sub-sampling accuracy.

A2 WATER CHEMISTRY

A2.1 Laboratory Reporting Limits

The analytical reports for water chemistry from ALS Environmental (ALS; see laboratory reports CG2207615, G2208450, CG2208562, CG2212410, CG2212555, CG2212630, CG2212662, CG2212823, CG2212860, CG2212981, CG2215634, CG2216906, and CG2217060 in Appendix M) and Brooks Applied Labs (BAL; see laboratory reports 2206336, 2207059, 2209287, 2209378, 2211135, and 2212301 in Appendix M) were examined to assess LRLs relative to analyte concentrations and applicable guidelines (Tables A.2 and A.3). The LRLs for water quality analytes were assessed relative to British Columbia Water Quality Guidelines (BCWQG; BCMOEECS 2021a,b) for the protection of freshwater aquatic life, Elk Valley Water Quality Plan (EVWQP; Teck 2014) benchmarks, Updated Effects Concentrations (UEC; WSP Golder 2022), screening values for water quality (Teck 2020), and relevant site-specific benchmarks. Several analytes were reported at concentrations below the LRL in 100% of samples (Tables A.2 and A.3). For those analytes with one or more result(s) below the LRL, achieved LRLs were consistently lower than the BCWQG, EVWQP benchmarks, UEC, and screening values for water quality (as applicable), except for total mercury. The LRL for all total mercury samples was 0.000005 µg/L, which is higher than the BCWQG of 0.00000125 µg/L; however, Azimuth (2019) determined that mercury inputs (total and methyl) in the Elk Valley Area are not related to mining activities. Therefore, the achieved LRLs were appropriate for this study.

A2.2 Laboratory and Field Blanks

A total of 243 method blank (MB) samples were analyzed in the ALS laboratory reports (Appendix M). Of the 1,352 reported method blank individual analyte results, only one result was above detection (for total vanadium; see laboratory report CG2212630 in Appendix M). However, this exceedance was below five-times the blank level and the laboratory reporting limit was appropriately adjusted for total vanadium results within this laboratory report. As only one result (0.07% of MB results) did not meet the laboratory DQO and these did not include any primary analytes, these laboratory flags had a negligible impact on ALS water chemistry data reliability and laboratory precision was overall considered excellent.

A total of 53 MB samples were analyzed in the BAL laboratory reports (Appendix M). Of the 245 reported method blank results, only one result was above the LRL (for total selenium; see laboratory report 2207059 in Appendix M) and so did not meet the DQO. As only

Table A.2: Laboratory Reporting Limit (LRL) Evaluation for Water Chemistry Analyses, FRO LAEMP, 2022

Parameter	Units	BC WQG ^a		EVWQP Level 1 Benchmarks/ Relevant Screening Values/UEC ^b	Range of LRLs	No. LRLs > Guideline	No. Sample Results < LRL

Zinc	mg/L	-	-	-	0.001	-	20 (33.3%)

Notes: Only analytes with at least one result < Laboratory Reporting Limit (LRL) or LRL were above guidelines were displayed. The total number of samples in 2022 (n) was 60. EVWQP = Elk Valley Water Quality Plan; "-" = no applicable guideline exists.

^a British Columbia Water Quality Guidelines for the protection of Aquatic Life (BCMOECCS 2021a,b).

^b Where more than one EVWQP Level 1 Benchmark, screening value, or Updated Effects Concentration (UEC; WSP Golder 2022) was applicable, the most conservative (lowest) value was used.

^c Guideline is the most conservative (lowest), based on estimates of a maximum temperature of 20°C and a minimum pH of 8.04.

^d Minimum water quality guidelines for Nitrite (as N) reported in BCMOECCS (2021a) for chloride concentrations < 2 mg/L.

^e Guideline for Chromium VI (0.001 mg/L) was selected, as this is the principal species found in surface waters.

^f Hardness-based guidelines calculated using the minimum hardness observed for all samples (113 mg/L).

^g The most conservative guideline (0.125 µg/L) was applied.

^h Guideline based on minimum field pH (8.04).

Table A.3: Laboratory Reporting Limit (LRL) Evaluation for Selenium Speciation Analyses, FRO LAEMP, 2022

Parameter	Units	Range of LRLs	No. Sample Results < LRL
DMeSeO - Dimethylselenoxide	µg/L	0.01	59 (96.7%)
MeSe(IV) - Methylseleninic Acid	µg/L	0.01	48 (78.7%)
MeSe(VI) - Methaneselenonic Acid	µg/L	0.01	59 (96.7%)
Se(IV) - Selenite	µg/L	0.01 to 0.02	5 (8.20%)
SeCN - Selenocyanate	µg/L	0.01	61 (100%)
SeMe - Selenomethionine	µg/L	0.01	61 (100%)
Selenosulfate	µg/L	0.01	60 (98.4%)
Selenium Unknown	µg/L	0.01	61 (100%)

Notes: Only analytes with at least one result < LRL or an LRL above guidelines were displayed. The total number of samples in 2022 (n) was 61. LRL = Laboratory Reporting Limit. No guidelines exist for any analyte that had at least one result below the LRL.

one result (0.41% of MB results) did not meet the DQO, laboratory contamination was not considered to be of concern and laboratory precision was overall considered excellent.

Eight field blank samples and five trip blank samples were submitted to ALS for water chemistry analyses to assess the potential for field sampling contamination. The same DQOs that were used for laboratory blanks were also used for field blanks (i.e., concentrations should be below the LRL). Of the 744 individual analyte results measured in the field blanks, only seven (0.94% of results; one result each for acidity, total ammonia, total copper, total lead, dissolved copper, dissolved lead, and dissolved zinc) were above the LRL and did not meet the laboratory DQO (Table A.4). Of the 319 individual analyte results for trip blank samples, only three results (0.94% of results; one result for acidity as CaCO₃ and two results for total barium) were above the LRL and did not meet the laboratory DQO (Table A.4). None of the analytes that were above detection in field or trip blank samples were analytes of concern in the FRO LAEMP. Additionally, as relatively few results were above detection (~ 1% in both field and trip blanks), field and laboratory contamination of water samples was considered of little to no concern and laboratory precision was overall considered good.

One field blank sample was submitted to BAL for aqueous selenium speciation analyses to assess potential field sampling contamination. All analytes were below detection and field contamination was not of concern.

A2.3 Data Precision

A total of 38 laboratory duplicate samples were used to evaluate precision within the ALS laboratory reports (Appendix M). All of the 1,308 individual analyte results met the laboratory DQO and ALS laboratory analytical precision was considered excellent. A total of 23 laboratory duplicate samples were used to evaluate precision within the BAL laboratory reports (Appendix M). All of the 87 individual analyte results met the laboratory DQO and BAL laboratory analytical precision was considered excellent.

Eight sets of field duplicate samples were collected to assess field sampling precision for water chemistry analyzed by ALS (Table A.5). Several relative percent differences (RPDs) could not be calculated as both analyte concentrations were below the LRL. Of the 502 RPDs that could be calculated, 40 RPDs were greater than the 30% DQO, including one result each for acidity (as CaCO₃), fluoride, orthophosphate, dissolved and total organic carbon, total aluminum, cadmium, chromium, and zinc, and dissolved aluminum, cadmium, iron, manganese, molybdenum, nickel, and zinc, two results each for total suspended solids, pH, bromide, and total iron, three results each for turbidity, total ammonia, and total phosphorous, and six results for ion balance (Table A.5). As a relatively low number of RPDs (7.97% of all results)

Indicates RPD exceeded 30%.

Notes: RPD = relative percent difference; "-" = no data/not calculated; LRL = Laboratory Reporting Limit. The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were < LRL. Turbidity was not analyzed in duplicate samples.

Indicates RPD exceeded 30%.

Notes: RPD = relative percent difference; "-"= no data/not calculated; LRL = Laboratory Reporting Limit. The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were < LRL. Turbidity was not analyzed in duplicate samples.

Indicates RPD exceeded 30%.

Notes: RPD = relative percent difference; "-" = no data/not calculated; LRL = Laboratory Reporting Limit. The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were < LRL. Turbidity was not analyzed in duplicate samples.

were greater than 30% and most of those analytes were of low concern for the FRO LAEMP, field sampling precision was overall considered good.

Four sets of field duplicate samples were collected to assess field sampling precision for selenium speciation (Table A.6). Relative percent differences could not be calculated for several selenium speciation duplicate samples as the analyte concentrations in both samples were below the LRL. Of the 18 comparisons that could be calculated, only one did not meet the DQO of 30% (methylseleninic acid; Table A.6). As this result represents only 5.56% of all field duplicate comparisons, field sampling precision was overall considered good.

A2.4 Data Accuracy

Data accuracy within the ALS laboratory reports was evaluated based on results of 285 Laboratory Control Samples (LCS) and 39 Matrix Spike (MS) samples (see laboratory reports in Appendix M). Only one of the 1,342 LCS analyte results (total silicon) did not meet the laboratory DQO (total silicon; see laboratory report CG2208562 in Appendix M). However, this DQO exceedance was marginal (by < 10% absolute value) and was for < 10% of analytes in a Multi-Element/Multi-Parameter Scan, which is considered acceptable as per the Ontario Ministry of the Environment, Conservation, and Parks (previously the Ontario Ministry of the Environment; OMOE) and Canadian Council of Ministers of the Environment (CCME; see laboratory report CG2208562 in Appendix M). All 1,208 MS analyte results met the laboratory DQO. Recovery could not be calculated in several MS samples as background levels were greater than or equal to the initial spike concentration. However, as several other QC tests were successful and matrix spike issues due to high background presence is not uncommon, MS recovery not being calculable in several MS samples was not of great concern. Overall, the accuracy achieved by the laboratory was considered excellent.

Data accuracy within the BAL laboratory reports was evaluated based on results of 30 LCS, 23 MS samples, 23 Matrix Spike Duplicate (MSD) samples, and 24 Reference Material (RM) samples (see laboratory reports in Appendix M). All 39 LCS, 26 MS, 26 MSD, and 14 RM individual analyte results met the laboratory DQO. Therefore, the accuracy achieved by the laboratory was considered excellent.

A2.5 Hold Times

The recommended hold times for pH and oxidation-reduction potential (ORP) analyses (0.25 hrs) were exceeded in all samples collected. As *in situ* pH was used for data interpretation, these pH exceedances had no impact on data interpretability. Additionally, ORP is not used in any analyses. The hold times for turbidity were exceeded by one to three days in seven samples. Hold times for dissolved orthophosphate and nitrite were exceeded by two

Table A.6: Field Duplicate Results for Selenium Speciation Analyses, FRO LAEMP, 2022

Unknown Selenium Species	µg/L	0	0	-	0	0	-	0	0	-	0	0	-

 Indicates RPD exceeded 30%.

Notes: RPD = relative percent difference; "-"= no data/not calculated; LRL = Laboratory Reporting Limit. The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were < LRL.

days in eight samples each (see laboratory reports CG2212410 and CG2212823 in Appendix M). The hold time for nitrate was exceeded by two days in one sample (see laboratory reports CG221410, CG2212555, and CG2212823 in Appendix M). None of the above hold time exceedances are expected to impact conclusions derived from the data but will still be taken into consideration during data interpretation. All hold times were met for selenium speciation samples. Overall, few samples exceeded hold times and hold time exceedances are expected to have little effect on the interpretation of results.

A2.6 Other Concerns

Total Kjeldahl nitrogen (TKN) concentrations in several water samples may have been biased low due to high nitrate concentrations (see laboratory reports CG2217060, CG2212555, CG2208450, CG2212630, CG2216906, CG2208562, CG2212981, CG2212860, CG2212410, and CG2212823 in Appendix M). This may have lowered results for TKN in field duplicate samples, thereby increasing the RPD calculated between two of the field duplicate sample pairs (Table A.5). However, no comparison between TKN in field duplicate samples exceeded the DQO, and lowered and undetectable TKN concentrations are expected to have little effect on the overall interpretation of TKN or other water chemistry results.

A2.7 Data Quality Statement

Water chemistry data collected for the 2022 FRO LAEMP were of acceptable quality as characterized by good detectability, appropriate LRLs, minimal evidence of laboratory or field contamination, good laboratory and field precision and accuracy, and few hold time exceedances. Overall, the associated water chemistry data from ALS and BAL can be used with a high level of confidence in the derivation of conclusions.

A3 SEDIMENT CHEMISTRY

A3.1 Laboratory Reporting Limits

The analytical reports for sediment chemistry from ALS (see laboratory reports CG2213010, CG2213410, CG2213498, and CG2213501 in Appendix M) were examined to assess LRLs relative to analyte concentrations and applicable guidelines (Table A.7). The LRLs for these analytes were assessed relative to existing British Columbia Working Sediment Quality Guidelines (BCWSQG; BCMOEECS 2021a). Several analytes were reported at concentrations below the LRL in 100% of samples (Table A.7). Although several metals had at least one result below the LRL, all metal LRLs were above the relevant guidelines and were therefore considered appropriate for this study. However, several LRLs for polycyclic aromatic hydrocarbons (PAHs) were below the BCWSQG Interim Sediment Quality Guideline, including 100% of LRLs for acenaphthene, acenaphthylene, anthracene, benzo(a)pyrene, dibenz(a,h)anthracene, fluorene, and phenanthrene (Table A.7). These relatively high LRLs was likely due to a combination of chromatographic interference due to PAH co-elution effects and high moisture content (resulting in low sample volume) in specific sediment samples. Sediment LRLs were overall considered appropriate for this study, and relatively high LRLs for PAHs will be considered during data interpretation. No LRLs for PAHs were above the BCWSQG Probable Effects Limit. Overall, the achieved LRLs were appropriate for this study.

A3.2 Laboratory Blanks

A total of 43 MB samples were analyzed in the ALS laboratory reports (see laboratory reports CG2213010, CG2213410, CG2213498, and CG2213501 in Appendix M). All 550 individual analyte results met the laboratory DQO, indicating no inadvertent contamination of sediment samples during analysis. Therefore, laboratory precision as determined by laboratory blanks was considered excellent.

A3.3 Data Precision

A total of 25 laboratory duplicate samples were used to evaluate precision within the ALS laboratory reports (see laboratory reports CG2213010, CG2213410, CG2213498, and CG2213501 in Appendix M). All 587 individual analyte results met the laboratory DQO. Therefore, ALS laboratory analytical precision was considered excellent.

Four sets of field duplicate samples were collected to assess field sampling precision for sediment chemistry (Table A.8). Several RPDs could not be calculated as both analyte concentrations in the pair were below the LRL. Of the 225 RPDs that could be calculated, only 14 were greater than 30%, included 13 RPDs for particle size measurements and one RPD

for titanium (Table A.8). As this represents only 6.22% of field duplicate comparisons, sediment data was overall considered to have excellent field precision and reproducibility.

A3.4 Data Accuracy

Data accuracy for sediment chemistry analyses completed by ALS was evaluated based on the analysis of 53 LCS samples, six MS samples, and 34 reference material (RM) samples. All 587 LCS, 168 MS, and 334 RM individual analyte results met the laboratory DQO. Therefore, the accuracy achieved by the laboratory was considered excellent.

A3.5 Hold Times

Recommended preparation holding times for polycyclic aromatic hydrocarbons (PAHs) were exceeded by two to three days in 16 samples each (see laboratory reports CG2213501 and CG2213410 in Appendix M). However, the analysis holding time (40 days) was met. The recommended analysis holding time for mercury (28 days) was exceeded by one day in six samples, two days in three samples, and four days in five samples (see laboratory report CG2213498 in Appendix M). These are expected to have minimal impact on the data. However, this will be considered during interpretation of results.

A3.6 Other Comments

Four samples (RG_FOUKI_SE-1_2022-09-13_N, RG_FOUKI_SE-3_2022-09-13_N, RG_SCOUTDS_SE-3_2022-09-14_N, and RG_RIVER_SE-1_LAEMP_FRO_2022-09-18_N) were submitted to ALS with a limited sample volume available for particle size analysis, and therefore the measurement uncertainty for particle size analysis results for these samples may be higher than usual.

A3.7 Data Quality Statement

Sediment chemistry data collected for the 2022 FRO LAEMP were of acceptable quality as characterized by appropriate LRLs, good detectability, excellent laboratory precision and accuracy, excellent field precision and reproducibility, and few hold time exceedances. Overall, the associated data were considered acceptable for this study.

A4 BENTHIC INVERTEBRATE COMMUNITY

A4.1 Sub-Sampling proportions, Precision, and Accuracy

The analytical reports from Cordillera Consulting Inc. (laboratory report in Appendix M) were examined to assess sub-sampling accuracy. For all samples, Canadian Aquatic Biomonitoring Network (CABIN) protocols were followed for sub-sampling (i.e., identification of a minimum 300 invertebrates), with a minimum of 5% of a sample being assessed, except for one sample that had 1% of sample volume assessed. All 61 benthic invertebrate community structure samples were subsampled (Table A.9). Both the precision and accuracy of the sub-samples randomly chosen for sub-sample assessment (n = 6) met the DQO in all sub-samples (20%; Table A.10). Thus, the precision and accuracy for sub-sampling of the benthic invertebrate community samples was considered excellent.

A4.2 Organism Sorting Efficiency

To measure the effectiveness of the sorters, at least 10% of samples were selected at random for resorting analysis by a different sorter (n = 6). Sorting efficiency (i.e., percent recovery) of benthic invertebrate samples was excellent, achieving an average of 98.3% for the six community structure samples evaluated (Table A.11). Therefore, organism sorting efficiency was considered excellent.

A4.3 Taxonomic Identification Accuracy

Cordillera Consulting Inc. performed an internal audit of taxonomic identification for at least 10% of all community structure samples (n = 6; Table A.12). The analysts reported a total identification error rate (TIR) of 0%, a percent difference in enumeration (PDE) of 0.064 to 0.154%, a percent taxonomic disagreement (PTD) of 0.304 to 0.855%, and a Bray Curtis Dissimilarity Index (BCDI [which is a measure of the differences in identifications between different analysts] of 0.002 to 0.007). The laboratory DQO was based on TIR as per CABIN laboratory methods (< 5% TIR; Environment Canada 2014). As TIR was below 5% for all samples examined, the taxonomic accuracy of the analysis was considered excellent.

A4.4 Data Quality Statement

Benthic invertebrate community data collected for the present study were of excellent quality as characterized by excellent sorting efficiency and excellent taxonomic identification accuracy. Therefore, the associated data can be used with a high level of confidence in the derivation of conclusions.

A5 BENTHIC INVERTEBRATE TISSUE CHEMISTRY

A5.1 Laboratory Reporting Limits

Analytical reports of benthic invertebrate tissue metal concentrations from TrichAnalytics Inc. (see laboratory reports 2022-359, 2022-403, 2022-449, and 2022-425 in Appendix M) were examined to provide an inventory of analyte results below the LRL and to compare the LRLs for these analytes to available benchmarks (Table A.13). Most analyte concentrations were consistently above detection limits, except for several results for arsenic, lead, mercury, thallium, tin, and uranium (0.36 to 22.1% of results for each analyte). However, all results for selenium were above detection and selenium is the only analyte with an applicable guideline. Therefore, the achieved LRLs were appropriate for this study.

A5.2 Data Accuracy and Precision

Data accuracy and precision were evaluated based on the analysis of 20 CRM samples. No CRM results for titanium could be calculated as the certified concentrations were too close to the reportable detection limit (see laboratory reports 2022-359, 2022-403, 2022-449, and 2022-425 in Appendix M). Of the 580 CRM results that could be calculated for other analytes, all met the laboratory DQO. As titanium is not an analyte of concern in benthic invertebrate tissue in the FRO LAEMP, laboratory accuracy and precision as determined by CRM analyses was overall considered excellent.

Laboratory precision was also evaluated by duplicate analysis of 29 benthic invertebrate tissue samples (see laboratory reports 2022-359, 2022-403, 2022-449, and 2022-425 in Appendix M). Several results that could not be calculated due to values below the detection limit. All 768 duplicate results that could be calculated met the laboratory DQO. Therefore, laboratory precision as determined by duplicate analyses was considered excellent.

A5.3 Data Quality Statement

Benthic invertebrate tissue data collected for the 2022 FRO LAEMP were of good quality as characterized by excellent detectability, appropriate LRLs, and excellent laboratory precision and accuracy. Therefore, the associated data can be used with a good level of confidence in the derivation of conclusions for this study.

A6 DATA QUALITY REVIEW SUMMARY

Overall, the quality of the data collected for this project was considered acceptable for the derivation of conclusions associated with the objectives of the 2022 FRO LAEMP.

B1 WATER QUALITY

B1.1 Sample Collection

One water sample was collected concurrently with biological monitoring and included analysis of constituents stipulated in Permit 107517 (Appendix Table B.1), as well as selenium speciation. Sample collection procedures were consistent with those outlined in the British Columbia Field Sampling Manual (Province of British Columbia 2013). *In situ* measurements of temperature, dissolved oxygen (DO), pH, and specific conductance were recorded concurrently with biological monitoring. The water quality meter used to collect *in situ* measurements was calibrated regularly and maintained according to manufacturer instructions.

Water samples were collected far enough upstream or downstream of confluences (tributaries, discharges) to avoid areas of incomplete mixing (lateral, vertical), and upstream from bridges or other structures to avoid the potential for associated influence.

Water samples were collected by wading into a mid-channel area (unless it was not practical or safe to do so), moving from downstream to upstream, to avoid collection of water downstream of disturbed substrates. Samples were collected from mid-depth by inverting sample bottles below the surface before they were taken to shore prior to the addition of applicable preservatives. Water samples being analyzed for dissolved constituents were filtered in the field using a clean syringe affixed with a 0.45- μm membrane. Once filtered, the sample was preserved immediately in the manner specified by the analytical laboratory. Station location (i.e., GPS coordinates), date, time, and identifier were recorded on field sheets. All samples were kept at $\sim 4^{\circ}\text{C}$ until analysis. Samples were shipped to the analytical laboratory daily or every other day to achieve compliance with recommended analytical hold times.

Quality assurance and quality control (QA/QC) samples were collected in the field concurrent with water samples. A minimum of one water chemistry duplicate, one field blank, and one trip blank were collected for every 10 samples (10%).

B1.2 Laboratory Analysis

Water quality samples were analyzed by a qualified third-party Canadian Association for Laboratory Accreditation Inc. (CALA)-certified laboratory (ALS Environmental) for constituents listed in Permit 107517 (Appendix Table B.1). Analysis of selenium species was performed by a qualified third-party laboratory (Brooks Applied Labs, Bothell, WA). Methods were consistent

Table B.1: Water Quality Parameters Required Under Permit 107517^a

Category	Parameters
Field Parameters	water temperature, specific conductance, dissolved oxygen (DO), pH
Conventional Parameters	specific conductance, total dissolved solids, total suspended solids, hardness, alkalinity, dissolved organic carbon, total organic carbon, and turbidity
Major Ions	bromide, fluoride, calcium, chloride, magnesium, potassium, sodium, and sulphate
Nutrients	ammonia, nitrate, nitrite, total Kjeldahl nitrogen (TKN), orthophosphate, and total phosphorus
Total and Dissolved Metals	aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, tin, titanium, uranium, vanadium, zinc

^a Parameters are consistent with those outlined in Table 27, Appendix 3 of Permit 107517.

with the British Columbia Environmental Laboratory Manual (Province of British Columbia 2016), where applicable.

Water samples were analyzed by ALS Environmental (ALS; Calgary, AB) for constituents consistent with Permit 107517 (i.e., conventional constituents, major ions, nutrients, and total and dissolved metals; Appendix Table B.1) using the following methods indicated in parentheses:

- total organic carbon (TOC) and dissolved organic carbon (DOC; combustion method; American Public Health Association [APHA] 5310 for TOC);
- Total suspended solids (TSS) and total dissolved solids (TDS; gravimetric method; APHA 2540 D and C for TSS and TDS, respectively);
- alkalinity (potentiometric titration; APHA 2320);
- turbidity (nephelometric method; APHA 2130 Turbidity);
- hardness, as CaCO₃ (by calculation; APHA 2340 B);
- total and dissolved metals⁶, (collision cell inductively coupled plasma - mass spectrometry and inductively coupled plasma - optical emission spectrophotometry; APHA 3030 B&E/ Environmental Protection Agency [EPA] SW-846 6020A, and EPA 3005A/6010B, respectively);
- bromide, chloride, fluoride, and sulphate (ion chromatography; APHA 4110 B);
- ammonia, as N (fluorescence; J. Env. Monit., 2005, 7:37-42);
- nitrate and nitrite, as N (ion chromatography; EPA 300.0);
- total Kjeldahl nitrogen (TKN) (fluorescence; APHA 4500-NORG D.);
- orthophosphate and total phosphorus (colourimetric method; APHA 4500-P Phosphorus); and
- DMSeO, MeSe(IV), MeSe(VI), Se(IV), Se(VI), SeCN, SeMet, SeSO₃, unknown Se Sp, total Se and Dissolved Se.

Selenium speciation analysis was conducted by Brooks Applied Labs (Bothell, Washington) using ion chromatography inductively coupled plasma collision reaction cell mass spectrometry (ICICPCRC-MS). Constituents included selenate, selenite, dimethylselenoxide, methylseleninic acid, methaneselenonic acid, selenocyanate, selenomethionine, selenosulphate, and unknown selenium species. Selenium species were first separated on an

ion exchange column and then detected using a collision/reaction cell-equipped inductively coupled plasma mass spectrophotometry (ICP-MS). The applied method was optimized to provide interference free quantitation of individual selenium species at part-per-trillion (ppt) levels. Total (unfiltered) and dissolved (filtered) selenium analyses were also performed by Brooks Applied Labs using inductively coupled plasma triple quadrupole mass spectrometry (ICP-QQQ-MS). Water samples were collected into borosilicate glass containers and preserved to a pH < 2 with nitric acid. An aliquot of each preserved sample was further digested with nitric and hydrochloric acids in a closed vessel (bomb) prior to analysis. The applied sample collection, preservation, digestion, and analytical procedures are designed to accurately quantify selenium in the presence of potential interferences (e.g., chloride and bromide) and regardless of the chemical form of selenium present in solution (e.g., ionic, particulate, or volatile molecular forms).

Water chemistry data collected for the 2022 FRO LAEMP were of acceptable quality as characterized by good detectability, appropriate LRLs, minimal evidence of laboratory or field contamination, good laboratory and field precision and accuracy, and few hold time exceedances (Appendix A). Overall, the associated water chemistry data from ALS and BAL can be used with a high level of confidence in the derivation of conclusions.

B1.3 Data Analysis

Water quality assessment focused on constituents with early warning triggers (EWTs) as defined under the AMP (Azimuth 2018) as well as other constituents required to assess study questions. Total mercury was not included as the source of aqueous mercury concentrations in the Elk Valley is not considered mining (Teck 2019). Total phosphorus and orthophosphate were included in water quality assessment to assess productivity relative to water treatment. Data extracted from Teck's EQUIS database were screened for text values and converted to a common unit.

Routine water quality monitoring results were screened against British Columbia Water Quality Guidelines (BCWQG; BCMOEECS 2019, 2021a) as part of Teck's Annual Water Quality Monitoring Report under Permit 107517 (Teck 2022). Water samples taken concurrently with biological monitoring samples were integrated with routine water quality monitoring stations for a more complete data set. Routine water quality monitoring stations were matched with concurrent water samples according to proximity (Table 2.4). Water quality constituents were compared to BCWQGs (BCMOEECS 2019, 2021a), EVWQP benchmarks (Teck 2014), updated effects concentrations (i.e., for nitrate and sulphate), screening values for TDS, and the proposed benchmark for dissolved nickel, as applicable, for the 2022 calendar year. Plots of constituents with EWTs under the AMP (i.e., TDS, sulphate, total

concentrations of antimony, barium, boron, lithium, manganese, molybdenum, nickel, selenium, uranium, and zinc, and dissolved concentrations of cadmium and cobalt; Azimuth 2018), nutrients, and selenium species from 2012 to 2022 were plotted individually for each monitoring station.

Potential changes in water quality constituents at individual stations were analyzed statistically to evaluate (1) if there was an increase or decrease since the base year of monitoring (2012 or the earliest year if monitoring was initiated post-2012), (2) whether the annual mean was within the range of historical annual means, and (3) if the current monitoring year (2022) was different from the previous monitoring year (2021).

Monthly mean concentrations of each constituent were estimated using the Kaplan-Meier (K-M) method. The method involves transforming the left censored (i.e., < value) data set to a right censored (i.e., > value) data set, and then using the K-M estimator (used to estimate the mean survival time in survival analysis) to estimate the mean. The calculation was conducted using the `survfit()` function in the survival package (Therneau 2017) in R and involves calculating the area under the K-M survival curve. The K-M method is non-parametric and can accommodate multiple LRLs. The method of estimating the mean is equivalent to using the distribution of detectable values below the LRL to represent values that are < LRL. For example, the mean of the data set {1, 2, <4, 5} is estimated as the mean of 1, 2, [$\frac{1}{2} \times 1 + \frac{1}{2} \times 2$], and 5 which is 2.375. The value <4 is replaced by the distribution of values below 4 (i.e., 1 and 2 with equal weight of $\frac{1}{2}$). Similarly, the mean of the data set {1, 1.6, 2, 2.1, <4, 5} is estimated as the mean of 1, 1.6, 2, 2.1, [$\frac{1}{4} \times 1 + \frac{1}{4} \times 1.6 + \frac{1}{4} \times 2 + \frac{1}{4} \times 2.1$], and 5 which is 2.229. Again, the value <4 is replaced by the distribution of values below 4 (i.e., 1, 1.6, 2, and 2.1 with equal weight of $\frac{1}{4}$). If there is only one LRL and no detected values below the LRL, then the K-M estimate of the mean is equivalent to replacing the value below the LRL with the LRL (i.e., the best estimate for the values < LRL is the LRL).

Temporal changes in monthly mean concentrations for water quality constituents were evaluated for each station (reference and mine-exposed) from 2012 to 2022. Only years with at least six months and only stations with at least three years of data were included in the analysis. Because of the presence of LRLs for most parameters, a censored regression analysis of variance (ANOVA) model with factors *Year* and *Month* and assuming a log-normal distribution of the response variable was fit with maximum likelihood estimation for each station. The significance of each term in the model was assessed using likelihood-ratio tests to determine if there is a significant change in log-likelihood with the addition of the term in the model. This tested for an overall difference among years (including the *Month* term in the model controlled for seasonal effects within a year). If the *Year* term was significant

($\alpha = 0.05$) then post-hoc contrasts were conducted to test for pairwise differences among years with an $\alpha = 0.05$ in a Tukey's HSD test which corrects for the number of comparisons.

For each year, a percent magnitude of difference from the base year (i.e., first year with minimum number of months) was calculated as:

$$\frac{Year_i - Base\ Year}{Base\ Year} \times 100\%$$

and the significant difference between 2022 and previous years was assessed.

Tests for temporal trends were also conducted using the non-parametric seasonal Kendall test described by Hirsch et al. (1982). The tests were conducted using scripts written in R software (R Core Team 2022). The seasonal Kendall test assesses temporal trends separately for each season (or month in this case) and combines the results for each season into an overall test for trend. The test is non-parametric and assesses whether there is a monotonic increasing or monotonic decreasing trend over time. The test is conducted by calculating the test statistic S_i which is equal to the sum of the number of increases and decreases from a time period t to all time periods after t for each observation in season i . The overall test statistic S is computed as the sum of S_i for all seasons. The significance of the observed S is determined by comparing it to a critical value of S (at the significance level $\alpha = 0.05$) determined from the exact sampling distribution of S (calculated by determining all possible permutations and combinations of S based on the increases and decreases from the number of pairwise comparisons made; Hirsch et al. 1982). If more than 45 pairwise comparisons are made (equivalent to the number of pairwise comparisons for $n = 10$ in a single season), then the normal approximation is used to calculate a p-value and to assess significance (Hirsch et al. 1982). The standard normal deviate Z is calculated as:

$$Z = \begin{cases} \frac{S - 1}{\sqrt{\sigma_S}} & \text{if } S > 0 \\ 0 & \text{if } S = 0 \\ \frac{S + 1}{\sqrt{\sigma_S}} & \text{if } S < 0 \end{cases}$$

Where $\sigma_S = \sum_{i=1}^k \frac{n_i(n_i-1)(2n_i+5) - \sum_{T_i} t_i(t_i-1)(2t_i+5)}{18}$ and n_i is the number of samples in month i , t_i is the number of tied values for each tied value T_i , and k is the number of seasons (Hirsch et al. 1982).

An estimate of the trend slope over time was estimated by computing the median of all slopes between data pairs within the same month (Helsel and Hirsch 2002). The slope was reported

as a percentage change in concentration per year. The intercept of a line through the time series was estimated as the median intercept of all lines through each point with the estimated slope (Pohlert 2016). The trend analysis was only conducted with a minimum number of 5 pairwise comparisons, the minimum number required for all consecutive increases or decrease to be significant at $\alpha = 0.05$.

Potential temporal changes in constituents with EWTs, nutrients (total phosphorus and orthophosphate) and selenium speciation were also evaluated relative to the commissioning of water treatment in December of 2021. Specifically, a censored analysis of variance (ANOVA) was conducted to compare differences in concentrations between the station immediately upstream (RG_FOBKS) and all stations downstream of water treatment (*Treatment* term), and pre- and post-commissioning (*Before-After* term). A term for year (nested in *BA*; *Year(BA)* term) was also included in the model, as well as, month (*Month*) to control for seasonal effects within a year. The analysis was designed to test for interactions between the *Treatment* and the *Before-After* terms. First the interaction between *Year(BA)* and *BA* was assessed with a significant interaction (p-value < 0.05) suggesting that changes upstream and downstream of treatment are different between the pre-commissioning and post-commissioning periods, but the effect is dependent on which years are compared. In that case, post-hoc tests (Tukey corrected for multiple comparisons) were conducted to determine significant differences between years in the before period versus years in the after period. Where there were significant differences a magnitude of difference (MOD) for each year comparison was calculated as:

$$MOD = \frac{MCT_{Treated, After} - MCT_{Predicted, After}}{MCT_{Predicted, After}} \times 100\%$$

; where:

$$MCT_{Predicted, After} = MCT_{Untreated, After} + (MCT_{Treated, Before} - MCT_{Untreated, Before});$$

and the measures of central tendency (MCT) are the estimated marginal means from the full ANOVA model. The MOD captures the change in concentrations at the treated station relative to what was expected given the differences pre-treatment. If the interaction between *Year(BA)* and *BA* was not significant, the *BA x Treatment* term was assessed with a significant interaction (p-value < 0.05) suggesting that changes upstream and downstream of treatment are different between the pre- and post-commissioning periods and this change was consistent across all years. In this case, an overall magnitude of difference was calculated using the formula above, but with MCTs calculated across the pre- and post-commissioning years (i.e., not separately for each year). Testing the significance of the interaction terms is the key

hypothesis of interest in the BACI model as it tests for changes in the relative differences among stations over time. If both interaction terms were not significant it suggested the differences between treated and untreated stations remained consistent pre- and post-commissioning (i.e., there were no BACI effects). Because any effects of treatment are expected to decrease as you move away from the treatment facility a separate model was fit for each downstream station. All analysis was conducted in R (R Core Team, 2021).

A principal components analysis (PCA) is a multivariate approach which transforms a group of 'n' variables into a smaller new set of uncorrelated variables (the principal components; PCs). The principal components are defined to be linear combinations of the original 'n' variables. A PCA was conducted using Kaplan-Meier (KM) mean water chemistry constituents calculated over the year prior to the benthic sampling date. Annual means accounted for seasonality by first defining seasons that were based on changes in water chemistry across a year and designed to capture high and low concentration periods throughout a year. For each year, four seasons were defined: winter (December to March), early spring (May), spring (June) and summer (July). Each season had to have at least one record for an annual concentration to be calculated and used in the PCA. Because a PCA cannot incorporate LRL values, any constituents with >25% of the mean values below the LRL were excluded from the PCA and Kaplan-Meier mean values at the LRL were replaced with the LRL (Farnham et al. 2002). When there was more than one LRL for a given constituent, or detected values were below the highest LRL, these values were replaced with the highest LRL. The contribution of individual constituents to the first two principal components were quantified by calculating their correlation using a Pearson's correlation coefficient. The PCA and correlation analysis were conducted in R (R Core Team 2021).

Seasonal mean concentrations of order constituents (nitrate, total selenium, dissolved cadmium, and sulphate) and total nickel from 2022 were plotted spatially, while selenium species concentrations of samples taken concurrent with biological monitoring in 2022 were also plotted spatially.

B1.4 Chronic Toxicity Testing

The following chronic toxicity tests were completed quarterly or semi-annually for water samples collected at mine-exposed and reference sites, as per the Permit 107517 Chronic Toxicity Program:

- 72-hour growth/inhibition test using a freshwater alga (*Pseudokirchneriella subcapitata*) conducted quarterly using method: EPS1/RM/25; Environment Canada 2007a;

- 7-day test of reproduction and survival using the cladoceran, *Ceriodaphnia dubia* conducted quarterly using method: EPS1/RM/21; Environment Canada 2007b;
- 28-day water-only test of growth and survival using the amphipod, *Hyalella azteca* conducted semi-annually (in Q2 and Q4) using methods adapted from USEPA (2000);
- 30-day early life stage toxicity tests using rainbow trout, *Oncorhynchus mykiss* conducted semi-annually (in Q2 and Q4) using method: EPS 1/RM/28- 1E; Environment Canada 1998; and
- 28-day early life stage toxicity test using fathead minnow, *Pimephales promelas* conducted semi-annually (in Q1 and Q3) using methods: EPA-712-C-96-121; USEPA 1998; and E1241-05; ASTM 2013.

Toxicity tests and associated QA/QC measures were completed by a qualified third-party biological testing laboratory. Water quality samples were collected at the same time to support evaluation of toxicity test results. Results were reported quarterly and summarized annually by Teck in accordance with Permit 107517 requirements.

B2 HYDROLOGY

B2.1 Drying and Stranding Surveys

In 2022, monthly drying surveys were completed (January to April and August to December) to evaluate surface water connectivity (i.e., seasonal drying) along the Fording River and Henretta Creek in the FRO LAEMP study area (Figure 2.2). The drying survey sections in the FRO LAEMP study area are broken down into three sections: the southern survey, the northern survey, and the Henretta Creek survey. The southern survey covers a 12.8 km section of the Fording River from the Chauncey Creek confluence (FR_FRABCH) upstream to the south tailings pond (FR_FR2). The southern survey also includes two side channels of the Fording River that were added in November 2020: Fording River Side Channel 2 and the Greenhouse Side Channel. Stranding surveys also evaluated surface water connectivity each month (i.e., approximately two weeks apart from drying surveys) at the same FRO LAEMP study area locations, except these surveys did not include assessments of the two side channels or the section of the Fording River downstream of FR_FRRD. The northern survey covers a 6.1 km section of the Fording River from the Multiplate culvert (FR_MULTIPATE) to a location on the Fording River upstream of the Henretta Creek confluence (FR_UFR1). The Henretta Creek survey covers a 3.5 km section of Henretta Creek upstream of Henretta Lake (i.e., upstream of FRO licensed water use; Table 2.3; Figure 2.2). Methods followed those used in previous years; field crews walked each section to delineate any extent of drying, isolated pools, fish, and wildlife observations by marking them with a handheld global positioning system (GPS) and on an iPad with geo-referenced map to facilitate mapping (Minnow and Lotic 2019, 2020, 2021a). Drying sections were also recorded as GPS tracks on an iPad to facilitate mapping and estimate the extent of drying.

B2.1.1 Data Analysis

Coordinates (taken by GPS) and tracks collected during the drying surveys were mapped to display the monthly/biweekly conditions and any observed drying sections of the Fording River. The results of monthly surveys were used, in combination with water level logger data and trail cameras, to determine the exact dates when a section of the Fording River had become dry between visits. Dry days for each survey section and hydrometric station were summarized for each year from 2017 to 2022 and were calculated for each low flow season not per calendar year. Dry areas were mapped for each month when drying was observed.

B2.2 Water Levels and Temperature Methods

B2.2.1 Data Collection

Water level and temperature were continuously monitored at 13 hydrometric stations in 2022 using a combination of three types of level loggers, which were installed in stilling wells (Table 2.3; Figure 2.2). The combination of loggers was included for protection against the loss of data in the event of a logger malfunction and included Solinst M5 loggers (primary), Solinst 3250 LevelVent Dataloggers (secondary), and Onset Hobo U-20 level-loggers (tertiary; Table 2.3). The loggers were programmed to record water level and water temperature at 15-minute intervals. Data was downloaded from the loggers pre-freshet in April, post-freshet in July, and October before freeze-up to avoid data loss.

Monthly discharge measurements were collected by field crews at each station using a Hach FH950 velocity meter, where surface flow conditions permitted (i.e., wadable and limited ice cover). Flow measurement methods were consistent with those reported previously (Minnow and Lotic 2018, 2019, 2020, 2021a, 2022), following the Manual of British Columbia Hydrometric Standards (RISC 2009). The Hach FH950 profiler function was used to determine if flow panels exceeded 10% of the discharge in the field to increase hydrological data grading in 2022. During ice covered visits, a transect was cut into the ice by hand or a minimum of five holes were drilled through the ice with an auger to get an estimate for discharge; however, winter flow measurements under ice are unlikely to serve as reliable data points and are for informational purposes only. Ice affected discharge measurements were flagged and were not used in stage-discharge development. One high flow measurement was collected at each site in June 2022 using a Sontek M9 ADP unit to enable flows to be collected without wading and to assist in developing the upper end of each rating curve. Benchmark surveys were completed three times a year at each site before level loggers were downloaded to determine if the stilling well had shifted and to comply with Resources Information Standards Committee (RISC) standards (RISC 2009).

B2.2.2 Data Analysis

Continuous water level data were collected and corrected for barometric pressure from October 2017 to October 2022, where applicable. For each hydrometric station, a log-linear stage-discharge curve was generated using manual stage and discharge measurements. Stage (m) and discharge (m^3/s) values were manually verified and measurements with suspected errors or high uncertainty (e.g., flows conducted under ice conditions) were removed from further analyses. All stage measurements below 0.001 m were treated as 'dry' and were excluded. Benchmarks were checked for each site and shifts were corrected.

The water level record was also verified by comparing to manual measurements, spikes, and other erroneous readings were cleaned. Hourly discharge and stage records were compared against manual observations to calculate the Offset (m), Absolute Error (m^3/s), and the mean Relative Error (Absolute Error divided by Measured Flow; %; Schaefer and Chernos 2022).

Paired stage readings and manual discharge measurements at each site were used to develop site specific power function stage-discharge relationships. The stage discharge relationship was used to convert the continuous water level records recorded at each site into a discharge record. Stage (m) and discharge (m^3/s) values were manually verified and qualitatively determined outliers (relative to the existing relationship) or measurements with high uncertainty (e.g., flows conducted under ice conditions) were removed from the stage-discharge relationship. All stage measurements below 0.001 m were treated as 'dry' and were excluded. A discharge time series (i.e., hydrograph) was plotted for each station. Lotic retained MacDonald Hydrology Consultants for senior review and quality grading of the hydrological data. Grades were assigned for each site following British Columbia Ministry of Environment Hydrological RISC Standards (RISC 2009). A water temperature time series was also plotted for each station.

Changes in temperature and flow from 2017 to 2022 were quantified using seasonal Kendall test using monthly means calculated from 14 data loggers. The analysis tests for monotonic increases or decreases are described in Section B.1.3.

Temporal changes in temperature were also evaluated relative to the commissioning of water treatment in December of 2021. Specifically, the change in the difference of daily mean water temperature upstream and downstream of water treatment ($\text{RG_SCOUTDS} - \text{RG_FOBKS}$) was tabulated and screened against the temperature difference limits (difference of $1\text{ }^\circ\text{C}$) outlined in Study Question #4. The daily differences also varied within years before (2020 and 2021) and after treatment (2022). A non-linear seasonal pattern was observed, however, and thus were statistically compared using a generalized additive model (GAM). Specially, the model included a term for year, a cubic regression smoothing term to account for non-linear changes within a year, and an autoregressive model term (time lag of 1 day) to control for temporal autocorrelation. The predictions and corresponding confidence intervals were used to compare the estimated temperature differences before and after treatment.

B3 SUBSTRATE QUALITY

B3.1 Sediment

B3.1.1 Sample Collection

Sediment quality samples were collected concurrently with benthic invertebrate sampling at eight areas in September 2022 (RG_HENUP, RG_FO26, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBCP, RG_FRUPO, and RG_FO22). Surficial sediment was collected by slowly and carefully placing the spoon on the sediment surface in a manner that minimized disturbance and inserting the spoon into the sediment to capture sediment to a depth of 1 to 2 cm. Samples were collected into glass jars for analysis of polyaromatic hydrocarbons (PAHs) and into polyethylene bags for analysis of metals, moisture content, and particle size distribution. Five sediment samples were collected at each mine-exposed area and three samples were collected in each reference area, consistent with the previous RAEMP cycle (Minnow 2020). Duplicate QC samples (split samples) were collected in the field concurrent with sediment chemistry samples at a rate of 10%. Following collection, samples were placed in a refrigerator at approximately 4°C until submitted to a qualified laboratory (ALS Calgary) for analysis.

B3.1.2 Laboratory Analysis

Sediment samples were analyzed by ALS Environmental in Calgary, Alberta. The laboratory thoroughly homogenized each sample prior to analysis. Methods used were consistent with the British Columbia Environmental Laboratory Manual (BCMOECCS 2020), where applicable, and include analyses of physical and chemical parameters (e.g., moisture content, particle size, total organic carbon [TOC], metals and metalloids, and PAHs).

Sediment samples were analyzed for the following constituents:

- Physical tests (moisture and pH);
- particle size and type (clay, grain size curve, silt, sand, gravel);
- Inorganic carbon, total carbon, total organic carbon, inorganic carbon (IC; as CaCO₃ equivalent);
- metals (aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, calcium, chromium, cobalt, copper, iron, lead, lithium, magnesium, manganese, mercury, molybdenum, nickel, phosphorus, potassium, selenium, silver, sodium, strontium, sulfur, thallium, tin, titanium, tungsten, uranium, vanadium, zinc, zirconium);

- polycyclic aromatic hydrocarbons (acenaphthene, acenaphthylene, acridine, anthracene, benz(a)anthracene, benzo(a)pyrene, benzo(b+j)fluoranthene, benzo(b+j+k)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, fluoranthene, fluorene, indeno(1,2,3-c,d)pyrene, methyl-naphthalene, 1+2-, methyl-naphthalene, 1-, methyl-naphthalene, 2-, naphthalene, phenanthrene, pyrene, quinoline, B(a)P total potency equivalents [B(a)P TPE], IACR (CCME), IACR AB (coarse), IACR AB (fine), PAHs, total (BC Sched 3.4), PAHs, total (EPA 16); *not all projects measure polycyclic aromatic hydrocarbons* and
- polycyclic aromatic hydrocarbons surrogates (acridine-d9, chrysene-d12, naphthalene-d8, phenanthrene-d10). *Not all projects measure polycyclic aromatic hydrocarbons.*

Upon completion of the laboratory analyses, data reports were provided to Minnow and Teck electronically as Adobe Acrobat PDF and Microsoft Excel files.

Sediment samples were analyzed using the following methods:

- Moisture content was determined gravimetrically by drying the sample at 105°C;
- particle size distribution was determined by dry sieving (coarse particles), wet sieving (sand), and the pipette sedimentation method (fine particles);
- metals by Collision Reaction Cell Inductively Coupled Plasma-Mass Spectrometry (CRC ICP-MS; EPA 200.2/6020A);
- mercury by Cold Vapour Atomic Fluorescence Spectroscopy (CVAFS; EPA 200.2/245.7);
- TOC by combustion method (Carter and Gregorich 2008); and
- PAHs by rotary extraction using hexane/acetone (EPA 3570/8270) followed by capillary column gas chromatography with mass spectrometric detection (GC/MS).

Sediment chemistry data collected for the 2022 FRO LAEMP were of acceptable quality as characterized by appropriate LRLs, good detectability, excellent laboratory precision and accuracy, excellent field precision and reproducibility, and few hold time exceedances (Appendix A). Overall, the associated data were considered acceptable for this study.

B3.1.3 Data Analysis

Sediment quality data were tabulated, summarized, and compared to British Columbia Working Sediment Quality Guidelines (WSQGs), except for selenium concentrations which were compared to an alert concentration considered equivalent to an upper WSQG

(BCMOECCS 2019, 2021a). The sediment data were also compared to reference area normal ranges, which were the 2.5th and 97.5th percentiles of pooled reference area distribution after removal of outliers (Minnow 2021b). Normal ranges could not be calculated for several PAHs because most of the values were below laboratory reporting limits (LRL). Data from 2017 to 2021 were plotted for all constituents for which a WSQG was available and visually assessed for temporal changes.

Temporal changes in sediment chemistry were evaluated relative to the commissioning of water treatment in December of 2021. Specifically, a censored analysis of variance (ANOVA) was conducted to compare differences in selenium concentrations between the station immediately upstream (RG_FOBKS) and all stations downstream of water treatment (*Treatment* term), and pre- and post-commissioning (*Before-After* term). A term for year (nested in *BA*; *Year(BA)* term) was also included in the model. The analysis was designed to test for interactions between the *Treatment* and the *Before-After* terms. First the interaction between *Year(BA)* and *BA* was assessed with a significant interaction (p-value < 0.05) suggesting that changes upstream and downstream of treatment are different between the pre-commissioning and post-commissioning periods, but the effect is dependent on which years are compared. In that case, post-hoc tests (Tukey corrected for multiple comparisons) were conducted to determine significant differences between years in the before period versus years in the after period. Where there were significant differences a magnitude of difference (MOD) for each year comparison was calculated as:

$$MOD = \frac{MCT_{Treated, After} - MCT_{Predicted, After}}{MCT_{Predicted, After}} \times 100\%$$

; where:

$$MCT_{Predicted, After} = MCT_{Untreated, After} + (MCT_{Treated, Before} - MCT_{Untreated, Before});$$

and the measures of central tendency (MCT) are the estimated marginal means from the full ANOVA model. The MOD captures the change in concentrations at the treated station relative to what was expected given the differences pre-treatment. If the interaction between *Year(BA)* and *BA* was not significant, the *BA x Treatment* term was assessed with a significant interaction (p-value < 0.05) suggesting that changes upstream and downstream of treatment are different between the pre- and post-commissioning periods and this change was consistent across all years. In this case, an overall magnitude of difference was calculated using the formula above, but with MCTs calculated across the pre- and post-commissioning years (i.e., not separately for each year). Testing the significance of the interaction terms is the key hypothesis of interest in the BACI model as it tests for changes in the relative differences among stations over time.

If both interaction terms were not significant it suggested the differences between treated and untreated stations remained consistent pre- and post-commissioning (i.e., there were no BACI effects). Because any effects of treatment are expected to decrease as you move away from the treatment facility a separate model was fit for each downstream station. All analysis was conducted in R (R Core Team, 2022).

The BACI magnitude of difference (MOD) results were visualized using a heatmap, with colours corresponding to the overall MOD averaged across all years with cells identified as having a significant BACI effect. In order to visualize the similarities among MODs between analytes, the axes show hierarchical clustering diagrams using unweighted paired group mean method with arithmetic mean.

B3.2 Calcite

B3.2.1 Calcite Measurement

Measurements of calcite presence and concretion were conducted on 100 particles (pebbles) at each biological sampling location concurrent with (and using the same particles as) the 100-pebble count. Calcite presence (C_p) has historically been a binary assessment (i.e., presence [score = 1] or absence [score = 0]; Teck 2016, Lotic 2021). In 2021, an additional method for assessing calcite presence in lotic environments was included (C_p' , Lotic 2021, Zathey et al. 2021, Robinson et al. 2022) that scored the fraction of the particle surface area covered by calcite as a decimal to the nearest 10th percentile (0.1, 0.2, 0.3, etc.; see Appendix I). The degree of concretion (C_c) was assessed by determining if the particle was removed with negligible resistance (not concreted; score = 0), noticeable resistance but removable (partially concreted; score = 1), or immovable (fully concreted; score = 2). If distinct particles were not visible due to heavy calcification, values of 1 (for presence) and 2 (for concretion) were recorded. If fines were encountered and calcite presence could not be visually confirmed, values of 0 (for presence) and 0 (for concretion) were recorded. If rocks were visible under fine material, the rock was selected for calcite measurements.

B3.2.2 Data Analysis

The results for the 100 particles were expressed as a Calcite Index (CI and CI') based on the following equations (Lotic 2021, Zathey et al. 2021, Robinson et al. 2022):

$$CI = C_p + C_c \text{ or } CI = C_p' + C_c$$

Where:

CI or CI' = *Calcite Index*¹

$$C_p = \text{Calcite Presence Score} = \frac{\text{Number of particles with calcite}}{100 \text{ (binary score)}}$$

$$C_p' = \text{Calcite Presence Score} = \frac{\text{Number of particles with calcite}}{100 \text{ (proportional score)}}$$

$$C_c = \text{Calcite Concretion Score} = \frac{\text{Sum of particle concretion scores}}{100}$$

Calcite data collected as part of the Regional Calcite Monitoring Program (Lotic 2022) were reported but were not used in analyses as the calcite measurements taken concurrently with biological sampling were deemed more appropriate because they are representative of the areas sampled for benthic invertebrates (i.e., riffles).

¹ CI refers to the binary assessment of C_p and CI' refers to the proportional assessment of C_p' .

B4 BENTHIC INVERTEBRATES

B4.1 Overview

Benthic invertebrates are an important component of the aquatic ecosystem of the Elk River watershed because they can be used as indicators of localized food availability (based on abundance), food quality (based on tissue chemistry) and habitat quality (based on richness, % Ephemeroptera, Plecoptera and Trichoptera [EPT], and % Ephemeroptera, as well as abundance of EPT and Ephemeroptera, Plecoptera, and Trichoptera individually) for receptors at higher trophic levels. Benthic invertebrate monitoring in the FRO LAEMP consisted of community sampling, productivity, and composite-taxa tissue chemistry sampling. Supporting measures, including habitat characterization, were also collected concurrent with benthic invertebrate community samples, as described below.

Benthic invertebrate samples were collected to address study questions related to community structure (as determined via CABIN sampling; Section B4.2), productivity (as determined via Hess sampling; Section B4.3), and invertebrate tissue accumulation of selenium (Section B4.4). Consistent with other LAEMPs and the RAEMP (Minnow 2021a,b, Minnow and Lotic 2021b), benthic invertebrate community and productivity sampling was completed in September; however, benthic invertebrate tissue sampling occurred in June, September, and December. Individual water samples for routine water quality analysis and selenium speciation analysis were collected from each monitoring area during each sampling event, concurrently with the collection of biological samples.

B4.2 Community Structure

B4.2.1 Sample Collection – Canadian Aquatic Biomonitoring Network (CABIN)

Benthic invertebrate community sampling followed the CABIN protocol, which involved a 3-minute travelling kick into a net with a triangular aperture measuring 36 cm per side and a mesh having 400-µm openings (Environment Canada 2012a). During sampling, the field technician moved across the stream channel (from bank to bank, depending on stream depth and width) in an upstream direction. With the net held immediately downstream of the technician's feet, the detritus and invertebrates disturbed from the substrate passively collected in the kick-net by the stream current. After three minutes of sampling time, the sampler returned to the stream bank with the sample. The kick-net was rinsed with water to move debris and invertebrates into the collection cup at the bottom of the net. The collection cup was then removed, and the contents poured into a labelled plastic jar and preserved to a concentration of 10% buffered formalin solution in water.

B4.2.2 Laboratory Analysis

Benthic invertebrate community samples were sent to Cordillera Consulting (lead taxonomist Scott Finlayson), in Summerland BC, for sorting and taxonomic identification. Taxonomists at Cordillera have achieved certification for Group 1 (general Arthropods West), 2 (EPT East and West), and 3 (Chironomids West) benthic organisms in the Taxonomic Certification Program of the Society for Freshwater Science. At the beginning of the sorting process, each sample was examined and evaluated for estimation of total invertebrate numbers. If the total number was estimated to be greater than 600, then the laboratory's sub-sampling protocol was followed. Sorting efficiency and sub-sampling accuracy and precision was quantified using methods specified by Environment Canada (2014). Organisms were identified to the lowest practical level (LPL; typically genus or species).

Benthic invertebrate community data collected for the present study were of excellent quality as characterized by excellent sorting efficiency and excellent taxonomic identification accuracy (Appendix A). Therefore, the associated data can be used with a high level of confidence in the derivation of conclusions.

B4.2.3 Supporting Measures

Consistent with the requirements of the CABIN sampling protocol, supporting habitat information (i.e., water velocity and depth, *in situ* water quality [temperature, dissolved oxygen [DO], conductivity, pH], and substrate characteristics [Wolman 100-pebble count and substrate embeddedness]) were collected concurrently with BIC sampled in riffle habitats (Environment Canada 2012a). Periphyton scores (n=3 at all monitoring areas except RG_FOBCP and RG_FO22 which both had n=5) were also ascribed to each biological monitoring area during September sampling, and according to CABIN sampling protocol (Environment Canada 2012a, Minnow and Lotic 2021b). The scoring was ascribed as follows:

- 1 – rocks not slippery, no obvious colour (<0.5mm thick);
- 2 – rocks slightly slippery, yellow-brown to light green in colour (0.5-1mm thick);
- 3 – rocks have noticeable slippery feel, patches of thicker green to brown algae (1-5mm thick);
- 4 – rocks are very slippery, numerous clumps (5-20mm thick); and
- 5 – rocks mostly obscured by algae mat, may have long strands (>20mm thick).

B4.2.4 Data Analysis

To address the investigation into the changes in BIC structure, endpoints of total sample abundance, richness (LPL taxonomy), percent (%) and total abundance of Chironomidae, EPT, Ephemeroptera, Plecoptera, and Trichoptera individually, and total abundance of key Ephemeroptera families (Baetidae, Heptageniidae, Ephemerellidae) were plotted spatially and temporally. Autotrophic to Heterotrophic Index, Shredder Index, Filtering to Collector Index, Predator Index, and Hyporheic to Benthic Index (Table B.2) were also computed for each biological monitoring area from CABIN kick samples and using the following equations:

$$\text{Autotrophic to Heterotrophic Index} = \log_{10}\left(\frac{\text{Scrapers}}{\text{Shredders} + \text{Collector Gatherers} + \text{Filterers}}\right)$$

$$\text{Filtering Collector Index} = \log_{10}\left(\frac{\text{Filterers}}{\text{Collector Gatherers}}\right)$$

$$\text{Predator Index} = \log_{10}\left(\frac{\text{Predators}}{\text{All other Feeding Groups}}\right)$$

$$\text{Hyporheic to Benthic Index} = \log_{10}\left(\frac{\text{Burrowers}}{\text{Clingers} + \text{Sprawlers}}\right)$$

$$\text{Shredder Index} = \log_{10}\left(\frac{\text{Shredders}}{\text{Collector Gatherers} + \text{Filterers}}\right)$$

Benthic invertebrate community data collected in September were compared to regional normal (reference area) ranges and habitat adjusted site-specific normal ranges. The regional normal range is defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 2012 to 2019 data) reported in the 2017 to 2019 RAEMP report (Minnow 2020). The site-specific normal ranges were calculated as prediction intervals from the final habitat model (Minnow 2020). Ninety-fifth percentile prediction intervals were calculated from linear mixed-effects models using simulations (n=100,000) to generate residual variation in random-effects terms. For Ephemeroptera and EPT Abundance endpoints, the prediction intervals from the % Ephemeroptera and % EPT models were multiplied by the prediction intervals from the Abundance model to generate the taxa specific abundance predictions. Prediction intervals were calculated using the predictInterval() function in the merTools R package (Knowles and Frederick, 2019). The residuals from the habitat models (observed minus model predicted values; on the transformed scale) were used in correlation analyses below.

Endpoints from September were plotted spatially (2022), and temporally (2012 to 2022) for each area where data were available. The relative composition of BIC was plotted spatially by monitoring area where samples were collected in 2022.

Table B.2: Benthic Invertebrate Community Index Descriptions, FRO LAEMP, 2022

Index	Description
Autotrophic to Heterotrophic Index	Reflects the ratio of energy use by the benthic invertebrate community (BIC) as primary productivity within the stream from algae growth to heterotrophic energy sources (e.g., leaves and sticks).
Shredder Index	Reflects the ratio of coarse particulate organic matter (CPOM) to fine particulate matter (FPOM) used by BIC.
Filtering Collector Index	Reflects the ratio of suspended Fine Particular Organic Matter (FPOM) to depositional FPOM used by the BIC.
Predator Index	Reflects the abundance of predators.
Benthic to Hyporheic Index	Reflects the ratio of habitats used by BIC, reflects sediment stability and flow permanence.

Temporal changes in benthic endpoints calculated from September kick and sweep data were evaluated for 2012 to 2022. For some (but not all) years there were replicate data for a given area within a year. Thus, for each endpoint, an ANOVA with factors *Year*, *Area* and *Year × Area* was fit. The best transformation for each endpoint was chosen as the transformation for which a Shapiro-Wilk's test on the residuals gave the highest P-value (i.e., most normally distributed). If there was a significant *Year* term, the variability within years and areas from the full model was used to test for significant differences between all pairwise comparisons of year for each area (i.e., is the difference between year *i* and year *j* greater than would be expected given the variability within areas for all stations for which we have replicates). This assumes the variability to be consistent among areas and years but allows for comparisons between years without replicates. Significance of the pairwise comparisons was assessed with an α of 0.05 in a Tukey's Honestly Significant Difference test (HSD) which corrects for the number of comparisons.

For each year, a magnitude of difference from the base year (i.e., first year with data) was calculated as:

$$\frac{Year_i - Base\ Year}{Pooled\ SD}$$

and the significant differences between 2022 and previous years was assessed. All statistics were conducted in R (R Core Team 2021).

Temporal changes in BIC endpoints were also evaluated relative to the commissioning of water treatment in December of 2021. Specifically, an Analysis of Variance (ANOVA) was conducted to compare differences in endpoints between the station immediately upstream (RG_FOBKS) and all stations downstream of water treatment (*Treatment* term), and pre- and post-commissioning (*Before-After* term). A term for year (nested in *BA*; *Year(BA)* term) was also included in the model. The analysis was designed to test for interactions between the *Treatment* and the *Before-After* terms. First the interaction between *Year(BA)* and *BA* was assessed with a significant interaction (p-value < 0.05) suggesting that changes upstream and downstream of treatment are different between the pre-commissioning and post-commissioning periods, but the effect is dependent on which years are compared. In that case, post-hoc tests (Tukey corrected for multiple comparisons) were conducted to determine significant differences between years in the before period versus years in the after period. Where there were significant differences a magnitude of difference (MOD) for each year comparison was calculated as:

$$MOD = \frac{(MCT_{Treated\ After} - MCT_{Untreated\ After}) - (MCT_{Treated\ Before} - MCT_{Untreated\ Before})}{Pooled\ SD}$$

where the measures of central tendency (MCT) are the estimated marginal means from the full ANOVA model. The MOD captures the change in the difference between treated and untreated stations before and after treatment relative to the variability within a station in a given year. If the interaction between *Year(BA)* and *BA* was not significant, the *BA x Treatment* term was assessed with a significant interaction ($p\text{-value} < 0.05$) suggesting that changes upstream and downstream of treatment are different between the pre- and post-commissioning periods and this change was consistent across all years. In this case, an overall magnitude of difference was calculated using the formula above, but with MCTs calculated across the pre- and post-commissioning years (i.e., not separately for each year). Testing the significance of the interaction terms is the key hypothesis of interest in the BACI model as it tests for changes in the relative differences among stations over time. If both interaction terms were not significant it suggested the differences between treated and untreated stations remained consistent pre- and post-commissioning (i.e., there were no BACI effects). Because any effects of treatment are expected to decrease as you move away from the treatment facility a separate model was fit for each downstream station. All analysis was conducted in R (R Core Team, 2021).

B4.3 Biomass and Density (HESS)

B4.3.1 Sample Collection

Samples for analysis of benthic invertebrate density and biomass were collected using a Hess sampler (0.1 m² sampling area) with 500 µm mesh. Ten replicate stations were sampled at each of twelve biological monitoring areas (mine exposed: RG_FOUCL, RG_FOUNGD, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, RG_FRUPO, and RG_FO22; reference: RG_FO26, RG_HENUP) in September 2022 for analysis of benthic invertebrate biomass and density (Table 2.1; Figure 2.1). Stations were located a minimum of 5 m apart to represent the overall area.

A single sample was collected at each station by carefully inserting the base of the Hess sampler into the substrate to a depth of approximately 5 to 10 cm. Gravel or cobble enclosed within the Hess sampler was carefully washed while allowing the current to carry dislodged organisms into the mesh collection net. Organisms collected into the net were rinsed into the bottom of the net, and then into a labelled wide-mouth plastic jar. Samples were preserved to a nominal concentration of 10% buffered formalin in ambient water within approximately 6 hours of collection, so biomass was not lost through predation or decomposition of tissues before the samples were sorted at the laboratory.

B4.3.2 Laboratory Analysis

Benthic invertebrate biomass samples were sent to ZEAS Inc. (lead taxonomist Danuta Zaranko) in Nobleton, ON, for sorting and taxonomic identification. At the laboratory, preserved organisms in each sample were sorted from the sample debris, identified, and weighed at the family-level of taxonomy. Each family group of organisms was placed onto a fine cloth to drain excess surface moisture before being weighed to the nearest 0.1 mg. Total and family-level density and biomass were reported for each sample.

B4.3.3 Data Analysis

Laboratory data for benthic invertebrate biomass and density samples were converted to units of number of organisms per square meter (org/m²) based on the known area sampled. Biomass and density data from 2017 to 2022 were plotted and changes were visually compared to assess spatial and temporal patterns pre-commissioning of the FRO-S AWTF. Biomass and density data from 2022 were also plotted spatially to compared upstream to downstream patterns in the study area.

Temporal changes in benthic invertebrate biomass and density were also evaluated relative to the commissioning of water treatment in December of 2021 using the same approach as described for the BIC endpoints calculated using CABIN kick samples (see Section B.4.2.4 above).

B4.4 Benthic Invertebrate Tissue

B4.4.1 Sample Collection

Benthic invertebrate samples were collected for tissue chemistry using the kick and sweep sampling method described in section B4.2.1, except that sample collection was not timed. Samples were a composite of representative benthic invertebrate taxa in each sampling area. For each sample, clean tweezers were used to pick invertebrates from the debris until about 1 to 2 g wet weight (ww) was obtained. A photo was taken of each sample, and the dominant taxa added to the sample was recorded. Once sufficient tissue was picked from the debris, the sample was placed in a labelled vial and stored in a cooler with ice packs until it could be transferred to a freezer at the end of the day. Tissue samples were stored in a freezer and shipped frozen.

Upon collection of the sample using the kick and sweep sampling method at each replicate station, organisms were carefully removed from sample debris using tweezers until about 0.5 g of wet tissue was obtained. Field crews paid particular attention to proportions of annelids in kick and sweep collections, as these organisms have been known to hyperaccumulate some

metals resulting in potentially biased results (Golder 2021). If annelids occurred at a proportion greater than 5% of the total sample biomass at a given replicate station, then these organisms were included in the composite sample (at that same proportion). Additionally in this scenario, a separate 'annelid only' sample was collected for analysis from the replicate station. If the proportion of annelids represented less than 5% of the sample biomass for a given station, these organisms were not included in the composite-taxa sample.

B4.4.2 Laboratory Analysis

Tissue samples were kept in a freezer until they were transported by courier in coolers with ice packs to TrichAnalytics Inc. in Saanichton, BC. Samples were dehydrated (<60°C) upon receipt by the laboratory and analyzed using Laser Ablation Inductively Coupled Plasma Mass Spectrometry (ICP-MS). Results were reported on a dry weight basis along with moisture content. Quality assurance/quality control measures associated with the tissue chemistry analyses included evaluation of laboratory duplicates and certified reference materials. Benthic invertebrate tissue data collected for the 2022 FRO LAEMP were of good quality as characterized by excellent detectability, appropriate LRLs, and excellent laboratory precision and accuracy (Appendix A). Therefore, the associated data can be used with a good level of confidence in the derivation of conclusions for this study.

B4.4.3 Data Analysis

Composite-taxa benthic invertebrate tissue selenium concentrations were plotted for each FRO LAEMP monitoring area sampled in 2022 relative to:

- the regional normal (reference area) range, defined as the 2.5th and 97.5th percentiles of tissue selenium concentrations measured in reference areas that have not been disturbed by mining in historical studies completed in the Elk River watershed from 1996 to 2019 reported in RAEMP (Minnow 2020);
- data from previous sampling periods from 2012 to present, where available;
- the Level 1 EVWQP benchmarks for effects to invertebrates (13 milligrams/kilogram [mg/kg] dry weight [dw]), dietary effects to birds (15 mg/kg dw), and dietary effects to juvenile fish (11 mg/kg dw; Golder 2014);
- the Level 2 EVWQP benchmarks for effects to invertebrates (20 milligrams/kilogram [mg/kg] dry weight [dw]), dietary effects to birds (22 mg/kg dw), and dietary effects to juvenile fish (18 mg/kg dw; Golder 2014); and

- the Level 3 EVWQP benchmarks for effects to invertebrates (27 milligrams/kilogram [mg/kg] dry weight [dw]), dietary effects to birds (41 mg/kg dw), and dietary effects to juvenile fish (26 mg/kg dw; Golder 2014).

Tissue selenium concentrations were paired with corresponding water selenium concentrations and compared to predictions from selenium bioaccumulation model (Golder 2020a) and the bioaccumulation tool (i.e., the 'B-tool'; predicts selenium tissue concentrations accounting for differences in selenium species and sulphate concentrations [Golder 2020b]).

Temporal changes in benthic invertebrate tissue selenium concentrations were evaluated relative to the commissioning of water treatment in December of 2021. Specifically, an analysis of variance (ANOVA) was conducted to compare differences in selenium concentrations between the station immediately upstream (RG_FOBKS) and all stations downstream of water treatment (*Treatment* term), and pre- and post-commissioning (*Before-After* term). A term for month (within a year and nested in BA; *Time Group(BA)* term) was also included in the model. The analysis was designed to test for interactions between the *Treatment* and the *Before-After* terms. First the interaction between *Time Group(BA)* and *BA* was assessed with a significant interaction (p-value < 0.05) suggesting that changes upstream and downstream of treatment are different between the pre-commissioning and post-commissioning periods, but the effect is dependent on which time groups are compared. In that case, post-hoc tests (Tukey corrected for multiple comparisons) were conducted to determine significant differences between time groups in the before period versus the after period. Where there were significant differences a magnitude of difference (MOD) was calculated as:

$$MOD = \frac{MCT_{Treated, After} - MCT_{Predicted, After}}{MCT_{Predicted, After}} \times 100\%$$

where:

$$MCT_{Predicted, After} = MCT_{Untreated, After} + (MCT_{Treated, Before} - MCT_{Untreated, Before})$$

and the measures of central tendency (MCT) are the estimated marginal means from the full ANOVA model. The MOD captures the change in concentrations at the treated station relative to what was expected given the differences pre-treatment. If the interaction between *Time Group* and *BA* was not significant, the *BA x Treatment* term was assessed with a significant interaction (p-value < 0.05) suggesting that changes upstream and downstream of treatment are different between the pre-commissioning and post-commissioning periods and this change was consistent across all time groups. In this case, an overall magnitude of difference was calculated using the formula above, but with MCTs calculated across the pre- and

post-commissioning periods (i.e., not separately for each Time Group). Testing the significance of the interaction terms is the key hypothesis of interest in the BACI model as it tests for changes in the relative differences among stations over time. If both interaction terms were not significant it suggested the differences between treated and untreated stations remained consistent pre- and post-commissioning (i.e., there were no BACI effects). Because any effects of treatment are expected to decrease as you move away from the treatment facility a separate model was fit for each downstream station. All analysis was conducted in R (R Core Team, 2021).

B5 HENRETTA LAKE

B5.1 Bathymetry

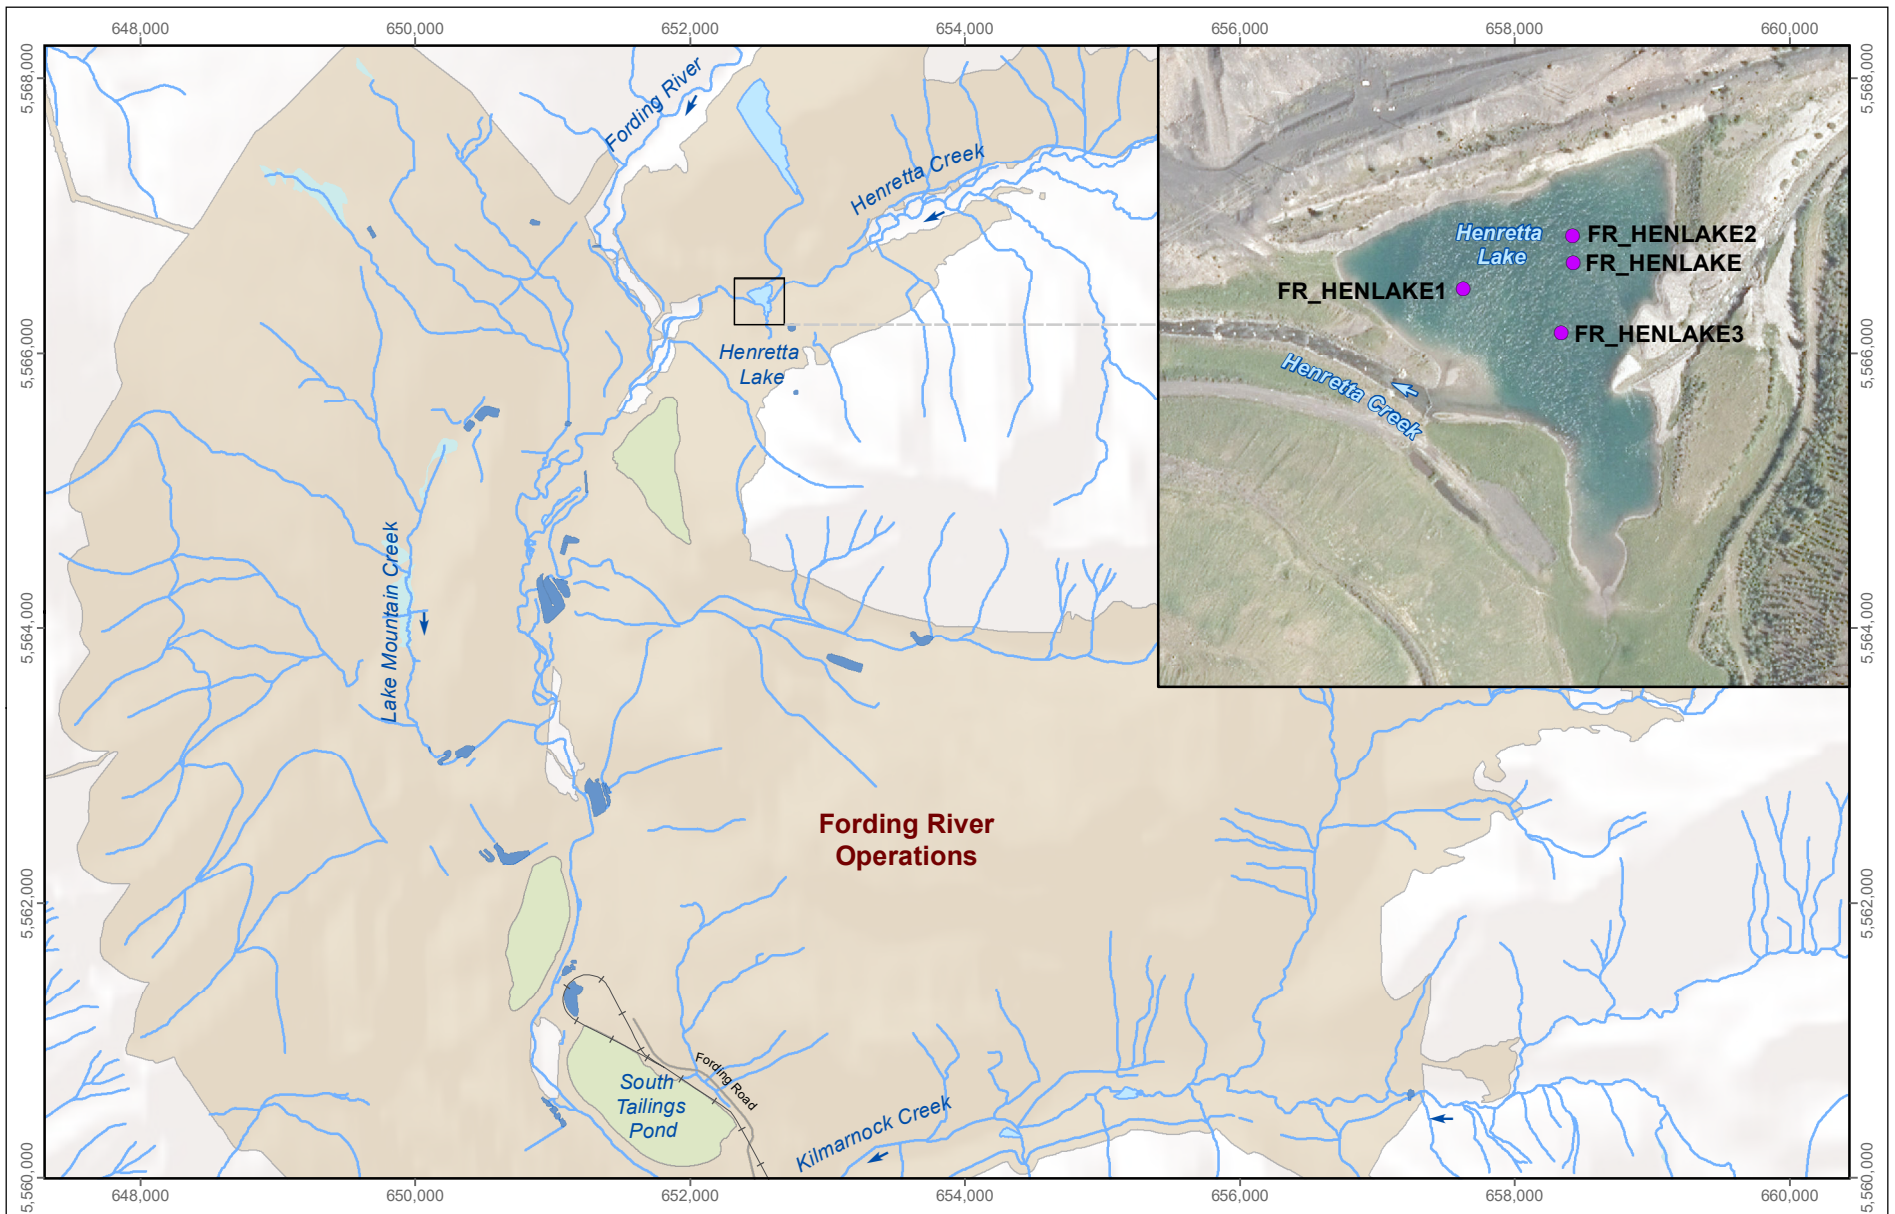

Teck conducted a bathymetry survey of Henretta Lake in November 2022 to improve the spatial understanding of water depths within the lake. Henretta Lake volumes were calculated using ESRI's ArcGIS Spatial Analyst extension at depth intervals of 0.5 m based on a bathymetric raster provided by Teck. Total volumes for each 0.5 m interval and the percentage of each interval out of the total lake volume were calculated. Lake volumes were also calculated at 1.25 m intervals to align with the *in situ* data logger installation (as described in Section B.5.3).

B5.2 Water Chemistry and Temperature-Oxygen Dynamics

Data collection for water chemistry (metals, nutrient, major ions, and selenium speciation) and *in situ* measures of physical parameters (temperature, dissolved oxygen, conductivity, and pH) occurred in various frequencies and sampling locations between 2016 and 2022 (summarized in Minnow 2022). In brief, *in situ* water profiles were typically collected during the winter (February in 2016, 2020, and 2021, and January, February, and March in 2022), from 8 to 11 sampling locations. To confirm that the sampling location HENLAKE3 (the current location of the *in situ* logger installment) was representative of lake-wide conditions, the variability between *in situ* measures were calculated at each location, and at each sampling depth.

Water chemistry samples were collected in February and March of 2021 and in February, June, and October of 2022. Water samples were analyzed for metals, nutrients, and major ions from three depths within the water column (1.0 m, 3.5 m, and 7.5 m). Sampling occurred at one location in 2021 (FR_HENLAKE), and three locations in 2022 (FR_HENLAKE1, FR_HENLAKE2, FR_HENLAKE3; Figure B.1). Methodology associated with the 2022 water chemistry samples is summarized in Arnett, 2023 (Appendix N). Water samples collected for selenium speciation analysis were collected from one location within Henretta Lake (FR_HENLAKE in 2021 and FR_HENLAKE3 in 2022), also from 1.0 m, 3.5 m, and 7.5 m depth. Water quality data collected between February 2021 and June 2022 are summarized in the Summary of Henretta Lake Temperature-Oxygen Data Report (Minnow 2022; Appendix N). However, water chemistry results from October 2022 were not available at the time of reporting. The results section, therefore, provides a summary of the available water chemistry data collected from Henretta Lake (including data from October 2022).

Henretta Lake Water Monitoring Stations

Date May 2023
 Project 227202.0022

Figure B.1

Following ice out in 2022, a vertical chain of HOBO data loggers was installed to collect measures of temperature, oxygen, and conductivity at 6 depths in the water column (1.25 m, 2.5 m, 3.75 m, 5.0 m, 6.25 m, and 7.5 m). The loggers were deployed in May 2022 with the first data download occurring at the end of June 2022. Additional data downloads occurred at the end of August, September, and October 2022 (summarized in Appendix N). On November 4, 2022, a sub-surface vertical chain of *in situ* loggers was deployed for the duration of the winter (the next time data will be retrieved from the deployment will be after ice-off in 2023).

B5.3 Habitat Availability Assessment

As assessment of habitat availability was conducted using the continuous logger data and WCT-specific criteria for dissolved oxygen. Habitat classifications were based solely on criteria for dissolved oxygen because the maximum summer temperature in Henretta Lake was 10.08 °C, and thus always below the WCT lethal limit of 25.0 °C identified for the Upper Fording River (Macnaughton et al. 2021). The continuous logger data and the updated bathymetric volumes for each 1.25 m strata (i.e., volume between loggers) was used to calculate the proportion of lake volume that would be classified as low, medium, and high risk to WCT. The habitat classifications were defined as:

- Oxygenated habitat with low to no risk to WCT: DO concentrations > 8 mg/L (above the chronic dissolved oxygen WQL for the protection of aquatic life; BC MOE 1997);
- Oxygenated habitat with medium to low risk to WCT: DO concentration > 5 mg/L and < 8 mg/L; and
- Oxygenated habitat with high risk to WCT: < 5 mg/L (below the acute critical threshold for the protection of aquatic life; BC MOE 1997).

The total lake volume was divided into horizontal strata based on logger deployment depths and daily mean DO concentrations were screened against the criteria above. Dissolved oxygen was assumed to be constant between 1.25 m depths. No data logger was deployed at the maximum lake depth, and thus the maximum volume of the lake was calculated based on a depth of 7.5 m (i.e., the deepest logger depth).

B6 FISH

B6.1 RAEMP Sample Collection

Non-lethal sampling of mature WCT tissue for muscle selenium concentrations is required under the RAEMP once per monitoring cycle (Minnow 2021a); however, one WCT had high muscle selenium concentrations at the Multiplate Culvert (RG_MP1) in September 2021, prompting confirmatory sampling (n=8) as part of the AMP response framework at this location in September 2022. Westslope cutthroat trout tissue sampling (n=5) was also conducted in Henretta Lake in September 2022 as part of the RAEMP lentic study. Previous (2018 and 2021) WCT muscle sampling occurred around RG_FODGH², RG_FOBCP³, and RG_MP1⁴ for monitoring water quality under Permit 107517, and at two reference areas (Bull River, Flathead River), in accordance with the approved RAEMP study design (n=8 per area; Minnow 2021a). In addition to fish sampling under the RAEMP, Teck collects tissue (dorsal muscle and whole body) samples from WCT incidental mortalities and fish salvages when relevant, to add valuable information to the dataset on fish selenium concentrations.

Sampling methods followed those outlined in the RAEMP study design (Minnow 2021a). Upon capture, fish were anesthetized using clove oil prior to processing. Measures of body weight were collected using appropriately sized spring scales (e.g., 100 g, 500 g, 1,000 g), and total and fork lengths were recorded using a measuring board equipped with a meter stick (± 1 mm). All fish were inspected for any external anomalies such as deformities, erosions (fin and gill), lesions, tumors, injuries, infections and/or parasites during processing and representative photographs were collected (Minnow 2021a). A biopsy punch was used to collect a non-lethal muscle sample from each fish, and VetbondTM tissue adhesive was used to seal the wound and prevent infection. Skin was removed from each muscle sample using a scalpel and the remaining tissue was placed into a sterile microcentrifuge tube. Samples were stored on ice in the field and transferred to a freezer later in the day. Tissue samples were kept in a freezer until they were transported overnight in coolers with ice packs to an accredited laboratory.

² Fording River between Chauncey Creek and Greenhills Creek.

³ Monitoring area RG_FOBCP is associated with Teck's water quality station FR_FRCP1. At the time, the 2021 to 2023 RAEMP study design was submitted (February 2021), FR_FRCP1 was the Compliance point for FRO; this was changed to FR_FRABCH later in 2021.

⁴ As sampling success is dependent on where fish are located, WCT associated with RG_FOBCP were caught further upstream at sampling area RG_MP1 (located downstream of the Multiplate culvert) but are still considered representative of fish from the area.

B6.2 Laboratory Analysis

Fish tissue samples were kept in a freezer until they were shipped in coolers on ice to TrichAnalytics Inc. (Trich) in Saanichton, BC. At the laboratory, samples were freeze-dried and analyzed for metals (including selenium) using laser ablation inductively coupled plasma spectrometry (LA-ICPMS). Results were reported on a dry weight (dw) basis, along with moisture content (based on the difference between wet and freeze-dried sample weights).

B6.3 Data Analysis

For the purposes of the FRO LAEMP report, muscle selenium concentrations of WCT from RAEMP fish sampling in the upper Fording River in 2022 were plotted with data from 2021 and 2018 (where available), reference area data, and in comparison, to the applicable site-specific muscle benchmark (15.5 mg/kg dw; muscle equivalent site-specific benchmark; Nautilus and Interior Reforestation 2011) and the British Columbia selenium guideline for fish muscle (4 mg/kg dw; BCMOE 2019). Additionally, tissue selenium concentrations from incidental mortality WCT samples were plotted with reference area data, and in comparison to the British Columbia selenium guideline for fish muscle. Corresponding meristics data (total weight, length and fork length) were tabulated along with observations of anomalies and calculated Fulton's condition factor. Fulton's condition factor was calculated as:

$$K = \left(\frac{W}{L^3} \right) \times 100$$

Where W = weigh (g) of the individual fish;

L = fork length (cm) of the individual fish

Condition factor was also plotted for visual comparison among areas.

External anomalies in fish may occur for many reasons, and can often be used as a line of evidence in the assessment of fish health (Sanders et al. 1999). These anomalies can include deformities, erosions, lesions, tumours, injuries, infections, and/or parasites. A number of different anomalies have been observed historically in the Elk Valley and Koochanusa Reservoir. These include spinal curvature (scoliosis, lordosis, kyphosis), deformed or missing fin rays, deformed or missing opercula, tumour-like growths, eye anomalies, hemorrhaging, fin erosions, and parasites. Each fish sampled was assessed for anomalies using the severity scale (Appendix Table B.3) which was designed to guide the sampler through a detailed assessment of the fish (Environment Canada 2012b). Additionally, a photograph was taken of each anomaly. Should an anomaly be present that was not described in the severity scale table, then a thorough description and a detailed photograph was provided by

Table B.3: Suggested Classification of Anomalies

Physical		Developmental/ Exposure	Other
Angling	Other (e.g., predation, injury)		
Tears/punctures around mouth	Torn caudal or pectoral fins	Spinal curvature	Parasites
	Torn/hanging maxilla	Wounds to body caused by predators	
Eye anomalies			Infections (fungus, bacteria, virus)
Eye injuries	Erosion	Lesions/Hemorrhaging	
		Tumours	

the sampler. In a case where the severity of an anomaly was difficult to score, or was uncommon or the type was not discernible, additional photos were taken and the observation was flagged for follow-up with a qualified professional (e.g., fish pathologist).

B6.4 Fish Population Monitoring

In 2022 the Westslope Cutthroat Trout population monitoring program in the upper Fording River continued to implement the standard protocols introduced in 2021 (e.g., more systematic redd surveys as well as single-pass electrofishing at large [~300 m] open sites [Thorley et al 2022a]). The program was further expanded to include increased electrofishing coverage as well as night snorkeling; as an alternative and less invasive method of enumerating juveniles, night-time dip-net surveys; to inform the length distributions of age-0, and Passive Integrated Transponder tagging captured fish; to better understand capture efficiencies, movement, growth, and survival and angling in Henretta Lake to supplement snorkeling data for fish >200 mm, to improve the understanding of WCT use of Henretta Lake (Penman et al. 2022; Thorley et al. 2023a; Thorley et al. 2022b). The expanded monitoring program helps to reduce uncertainty about status and trends of the upper Fording River Cutthroat Trout population as well as to answer key questions to assess the carrying capacity, intrinsic productivity, and viability of the population.

B6.4.1 Redd Surveys

Redd surveys are conducted to count the number of redds, which may contain one or more nests, where fish eggs are deposited. These surveys provide information about the spatial distribution and timing of spawning. Prior to 2021, the number of redds was recorded, but not the number of nests within the redd unless more than one spawning pair was observed (Cope 2020). Field and analytical methods were revised in 2021 to improve the estimates of how many unique nests are present in any given year and to allow for comparisons across years (Smit et al. 2022). Beginning in 2021, all visible nests were counted each week, to provide data suitable for the modelling approach that estimates the total count of unique nests that would have been observed over the whole season using an Area-Under-the-Curve (AUC) model (Hilborn et al. 1999; Su et al. 2001, Thorley et al. 2023a).

In 2022, suitable gravels in areas of historically high spawning were monitored for spawning activity starting in the first week of June. Once spawning was confirmed, surveys were conducted once a week in the key areas until spawning activity was judged to have ceased. The key areas included:

- Segments 1 to 11 of the of the Fording River. This includes mainstem habitat from approximately 25 to 75 km upstream of the confluence with the Elk River, and major side channels
- Chauncey Creek from its mouth to approximately 6 km upstream
- LCO Dry Creek from its mouth to approximately 4.5 km upstream
- Greenhills Creek from its mouth to approximately 3 km upstream (excluding the sedimentation pond)
- Porter Creek – first 400 m

Around peak spawning, surveys also included one survey in each of the following lower priority spawning areas:

- Gardine Creek
- Ewin Creek from its mouth upstream to approximately 7 km upstream
- Todhunter Creek from its mouth upstream to end of suitable habitat or practical access
- Chauncey North Tributary from its mouth upstream to approximately 2.5 km upstream
- Henretta Creek from the Fording River to approximately 9 km, in 2022, 3 km immediately upstream of Henretta Lake were not surveyed.
- Fish Pond Creek

B6.4.2 Electrofishing

The size, densities, and distribution of age-1 and age-2+ (referring to fish from the age of 2 until the development of the adult body form) WCT in the UFR were assessed through backpack electrofishing using removal-depletion electrofishing and single open passes (Thorley et al. 2022a).

Removal-depletion electrofishing used stop nets at three single mesohabitat (pool, riffle, glide or cascade; see Cope et al. 2016 for a description) sites of about 10 to 35 m in length (and 100 m² in wetted area) at 25 different index locations (75 sites total) (Thorley et al. 2023a). Between one and three passes, randomly assigned prior to fieldwork, were conducted at each site to estimate capture efficiency based on the decline in catches. Electrofishing effort (seconds) was recorded at the end of each pass.

Eleven ~300 m long open (without stop-nets) sites were sampled: six in the mainstem Fording River, and one site each in Greenhills, LCO Dry, Ewin, Chauncey, and Henretta creeks

(Thorley et al. 2023a). The starting point for each site was randomly generated prior to the field season. A subset of sites were resampled within 24 hours to calculate capture efficiency from the ratio of recaptured fish with Passive Integrated Transponder (PIT) tags.

Fish processing followed the Teck backpack electrofishing protocol (Thorley et al. 2022a) and the 2022 study design for UFR WCT population monitoring (Thorley et al. 2022c). All captured fish were measured for fork length to the nearest 1 mm, weighed to the nearest 0.1 g, scanned for a PIT tag (if larger than 99 mm), and photographed. The total number of fish observed but not captured was also recorded. A PIT tag was inserted into all uninjured fish ≥ 100 mm in fork length. Fish were inspected for any deformities, erosion, lesions, or tumours (anomalies) and the information was recorded using the new anomaly categories and scale (Ings and Weech 2020). Processed fish were allowed to recover before being released as close to their capture location as possible, preferably near cover and in slow moving water.

The data from the backpack electrofishing data (2013 to 2022) were used to estimate the density of age-1 and age-2+ fish using a hierarchical Bayesian removal model (Wyatt 2002). The model estimated capture efficiency using removal-depletion data from the subset of small, closed sites that received more than one electrofishing pass (Thorley et al. 2023a).

Body condition for age-1 and age-2+ fish was analyzed using weight-length regression. Length and weight data for individuals between 90 and 169 mm were analyzed using an allometric mass-length model to estimate body condition (He et al. 2008; Thorley et al., 2023a; Thorley et al., 2023b). The simplified equation for body condition is:

$$\text{Body Condition} = \frac{W}{(\alpha L^\beta)}$$

Where W = is the weight (g) of the individual fish

α = 6.6×10^{-6} , the expected weight (g) of a 1 mm fish

L = is the length (mm) of the individual fish

β = scaling term of 3.1

The α and β terms were calculated for fish from 90 to 169 mm using UFR monitoring data collected from 2013 to 2022 (Thorley et al. 2023a, Thorley et al 2023b). The model was used to estimate the percent difference in body condition of a fish one subpopulation relative to a typical subpopulation in the UFR, in a typical year (Thorley et al 2023a). Additional details are available in the technical appendix to the UFR WCT population monitoring report (Thorley et al., 2023b).

Length data were also used to identify the sizes of different age classes using the electrofishing (2013 to 2022) and dip-net survey data (2022). These data were used in the length frequency histograms (reported in Thorley et al. 2023a) and were used to assign length cutoffs by age class and to calculate the mean length-at-age of age-0s.

Recruitment was estimated based on egg to age-1 survival which is measured for a spawning cohort the calendar year after it is spawned. As such, in the 2022 FRO LAEMP we report on the age to age-1 survival for the 2021 spawning cohort. The egg to age-1 survival (Pulkkinen et al. 2013) was calculated by dividing the estimate of the age-1 individuals by the total egg deposition the previous year. The total annual egg deposition was calculated from the fecundity (eggs per female; see Thorley et al. 2023a) and the estimate of the (sub)adults assuming a 1:1 sex ratio and repeat spawning every other year (Liknes and Graham 1998). For a population to be stable each spawner must on average replace itself with another spawner over its lifetime. The egg-to-age-1 survival required for population replacement was estimated by Thorley et al. (2023a) based on a modification from Ma and Thompson (2021).

B6.4.3 Snorkeling

Subadult and adult WCT numbers were assessed using downstream snorkel surveys during daylight hours. In 2022 the surveys were initiated on August 29th and continued until September 5th. Snorkel surveys were conducted using section boundaries as start and end locations for 16 river segments (see Cope et al. 2016 for a detailed description). These include 11 mainstem upper Fording River sections plus three sections in Henretta Creek, including Henretta Lake and one section in Fish Pond Creek and one section in Fish Pond Tributary. Prior to 2022 Fish Pond Creek and Tributary were considered one section.

Upstream snorkel surveys enumerated small fish (age-1 and age-2+) in shallow habitats at night in late summer to early fall. Upstream snorkel surveys cover more habitat in shorter period of time compared to electrofishing because fish are not captured or processed and can sample deeper habitats, such as pools, more effectively. Surveys were conducted at seven of the large, open electrofishing sites, to compare densities of fish by life stage between the two methods. These included five segments from the UFR mainstem, the lower section of Henretta Creek downstream of Henretta Lake and the lower section of Chauncey Creek downstream of the culvert. These data were used to supplement density data from electrofishing.

B6.4.4 Angling

Three angling surveys were conducted in Henretta Lake on September 29, October 6, and October 13, 2022 as reported in Penman et al. (2022). One week was allowed between

surveys to allow captured fish to recover and mix. For the survey Henretta Lake was stratified into seven shore sections and two boat sections. Sections were divided into sub-sections to ensure that there was no overlap between anglers. There were two angling sessions each day during which each angler was allotted a two-hour session in a sub-section. Anglers were allowed to switch between spin rods and fly fishing gear. Only one hook was allowed per angler at a time and all hooks had to be a single barbed or barbless hook to reduce the risks to WCT. The duration of time using each method was documented for each angler during each survey block. Data collected for each fish included the angler, method, and estimated capture depth. Any missed WCT (hooked but not landed) were also recorded (albeit inconsistently).

Three fish processing stations were set up to process WCT and were distributed evenly around the sections to reduce transfer and handling time for WCT. During the fish processing, WCT were first scanned for PIT tags and if none were present and the individual was longer than 100 mm, one was inserted into the muscle near the dorsal fin. Fork length (mm) and weight (g) were measured prior to insertion of the PIT tag. Fish were inspected for any deformities, erosion, lesions, or tumours (anomalies), which were recorded using the body location categories and severity scale. If a fish was recovering poorly, it was either returned to the lake immediately without being processed, or monitored prior to release in a submerged, dark recovery container with holes to allow for regular transfer of lake water.

Catch per unit effort (CPUE) was calculated as the number of fish caught / angling hours. Morphometrics of recaptured WCT were averaged across captures. Anomaly scores from recaptured fish were also removed from the summary tables (as to not over-inflate the categories).

B6.4.5 Dip Net Surveys

To supplement electrofishing data, night-time dip-net surveys were conducted in the Upper Fording River for the first time in 2022. Data from these surveys provides information about length-at-age, and some limited information on spatial distribution (occupancy, not relative density) of age-0 as well as age-1 fish. Dip-net surveys are conducted by a team of two observers walking the stream margins searching for fish less than 100 mm in length. Surveys were conducted between October 12 and 30, 2022 when fry emergence was complete (Thorley et al 2023a).

Surveys occurred in each of the following 11 sections in the mainstem or key tributaries with suitable habitat for age-0 fish where redds had been constructed.

- Segment 6 of the upper Fording River

- Segment 8 of the upper Fording River
- Section 10/11 of the upper Fording River
- Henretta Creek between the mouth and Henretta Lake
- Henretta Creek upstream of lake and area of mine influence
- Chauncey Creek between road culverts at 0.6 km and 5 km
- LCO Dry Creek in the lower 1 km
- Greenhills Creek below the barrier
- Greenhills Creek above the barrier
- Ewin Creek
- Todhunter Creek

B7 INTEGRATED ANALYSIS

Correlations analysis and CCAs were used to understand how physical and chemical factors may contribute to variations in benthic invertebrate community structure within the FRO LAEMP study area. These analyses were conducted on data across the full study area, and then three individual study areas (upper, middle, and lower) within the full study area. In addition to analysis of the full study area, the three individual study areas were analyzed separately to help tease apart covariation of habitat and water quality factors observed in previous analyses across the full study area (i.e., habitat and water quality factors change simultaneously across the full study area but may not change simultaneously within individual study areas). The upper, middle, and lower Study Areas were grouped based on spatial differences of habitat (water depth, water flow/velocity, water temperature, substrate size, etc.) and water quality identified in previous FRO LAEMP reports (Minnow and Lotic 2019, 2020, 2021b, 2022). The upper study area ranges from downstream of the Henretta Creek confluence with the Fording River (RG_FODHE) to upstream of the South Tailings Pond (RG_FOUSH), the middle study area ranges from downstream of the South Tailings Pond (RG_FOUKI) to the area upstream of the Greenhouse Side Channel (RG_FRCP1SW), and the lower study area ranges from upstream of the Porter Creek confluence with the Fording River (RG_FRUPO) to upstream of Ewin Creek (RG_FOU EW; Figure 2.1).

To determine how physical and chemical characteristics relate to patterns in BIC, Spearman Rank Correlations were conducted between abundance, richness, percent (%) and total abundance of Ephemeroptera, Plecoptera and Trichoptera individually, EPT combined, Chironomidae, and the residuals from the site-specific normal range model for total abundance, richness, percent and total abundance of EPT and Ephemeroptera, and the habitat and feeding indices (Appendix Table B.2) against a variety of physical and chemical parameters (Appendix Table H.1). Correlations were conducted on data across the full study area, and then three individual study areas (upper, middle, and lower) within the Full Study Area. For water chemistry constituents, annual mean concentrations were calculated for different seasons and then averaged across the year prior to the benthic sampling date. Seasons were defined based on changes in water chemistry across a year and designed to capture high and low concentration periods throughout a year. For each year, four seasons were defined: winter (December to March), early spring (May), spring (June) and summer (July). Each season had to have at least one record. Significant correlations were assessed at $\alpha = 0.05$, Bonferroni corrected for 38 independent comparisons (corrected $\alpha = 0.05/38 = 0.00132$). Water chemistry constituents were also analyzed by PCA (Appendix Table H.3) to combine multiple water quality variables into PC1 and PC2 and

included in the correlation analysis. To ensure correlations were comparable among different constituents, only complete records (i.e., a value for every water and BIC endpoint) were included in the analysis. Correlation results were visualized using a heatmap, with colours corresponding to the strengths of the correlation (as measured by the Spearman Rho and varies from -1 to +1). In order to visualize the similarities among correlations between BIC endpoints and physical and chemical characteristics, the axes show hierarchical clustering diagrams using unweighted paired group mean method with arithmetic mean.

A Canonical Correspondence Analysis (CCA) was performed to investigate patterns in BIC in September of 2018 to 2022 relative to habitat (Appendix Table B.4) and stressor variables. The analyses were conducted separately across the Full Study Area and three individual study areas. Lowest Practical Level benthic invertebrate abundances were $\ln(x+1)$ transformed to reduce the effects of the most dominant taxa in order to better understand differences between sites that vary greatly in abundance. Taxa present at fewer than 10% of samples, and those that accounted for less than 1% of the total abundance in the dataset were excluded from the analysis. The CCA constrained CA axes by a suite of predictor variables by applying a multivariate multiple regression to the CA axis. This resulted in a set of new CCA axis that were linear combinations of the predictor variables (i.e., habitat or stressor) that explained a subset of variation of the original CA. Partial CCA (pCCA) was further used to account for the effects of one set of predictors before constraining on a second set (i.e., the variation in one set of predictors was conditioned out of the response, before applying a second set of predictors to the residuals of the first; Legendre and Legendre 2012). The significance of each predictor was evaluated using a permutation-based ANOVA with 10,000 permutations, and the relative importance of individual predictors assessed using the associated pseudo F-statistic (Legendre et al. 2011). Limitations in available data (e.g., field habitat, water quality) resulted in only a subset of sites that had all necessary input data and could therefore be included in the CCA (Appendix Table B.5). The spatial and temporal coverage was enough to provide a general overview of the patterns exhibited by BIC.

Variables were selected for inclusion in the CCA model using a combination of best professional judgement and backwards variable elimination method with permutation-based ANOVA. The Variance Inflation Factor (VIF) of the final variables were all below 20 indicating the variable coefficients were not inflated by the presence of correlation among explanatory variables (i.e., no multicollinearity). For water quality variables, only concurrent water data was included, and only constituents with fewer than 20% of observations below the detection limit were considered. Winter and Summer water temperature summaries from correlation analysis were also included in the CCA analysis. The multivariate multiple

Table B.4: Summary of Habitat Variables Used in Canonical Correspondence Analysis of Benthic Invertebrate Community, FRO LAEMP, 2022

Variable Source	Habitat Variables
Stream Characteristics	Mean Depth
	Bankfull Width
	Mean Velocity
Substrate	Embeddedness
	D16
	D84
GIS	% Watershed greater than 30% slope
