Technical Report Overview

Report: Fording River Operations Local Aquatic Effects Monitoring Program (LAEMP) 2021 Report

Overview: This report presents the 2021 results of the local aquatic effects monitoring program (LAEMP) developed for Teck's Fording River Operations (FRO). The report presents data and evaluation of current conditions and collects baseline data to support future evaluations of changes related to commissioning of an active water treatment facility that will be treating water from Cataract, Swift, and Kilmarnock creeks.

This report was prepared for Teck by Minnow Environmental Inc. and Lotic Environmental Ltd.

Lotic, Senior Aquatic Biologist

EXECUTIVE SUMMARY

The Fording River Operation local aquatic effects monitoring program (FRO LAEMP) was developed to monitor aquatic conditions related to ongoing mining and the future commissioning of the active water treatment facility (AWTF) and is a requirement in Permit 107517.

The first FRO LAEMP study design, and associated study questions, was submitted in accordance with Permit 107517 on June 1, 2016 (Minnow 2016) and covered 2016 to 2018 (a LAEMP 'cycle'). This study design was subsequently approved by Environment and Climate Change Strategy (ENV) on October 24, 2016. With the delay in construction and operation of the Fording River Operation – South Active Water Treatment Facility (FRO-S AWTF), the second FRO LAEMP study design for 2019 and 2020 (cycle 2) was submitted on May 31, 2019 to cover the extended pre-commissioning period (Minnow and Lotic 2019a). During the FRO LAEMP cycle 3 (2021 to 2023) study design development the study questions were updated based on evaluations of data from previous reports and input from the Environmental Monitoring Committee (EMC; December 3, 2020; February 3 and 23, 2021) and subject matter experts (SMEs) to reflect current conditions in the study area (e.g., commissioning of the Fording River Operation - North Saturated Rock Fill [FRO-N SRF], the Westslope Cutthroat Trout [WCT] population decline; Minnow and Lotic 2021a). Study questions in the current FRO LAEMP cycle are as follows:

1. Are nitrate concentrations in the study area changing and do they have the potential for adverse effects on biota?
2. Is water treatment affecting biological productivity downstream in the Fording River?
3. Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?
4. How is temperature changing over time in the FRO LAEMP study area?

   4a. Is water temperature measurably different (greater than 1 degree Celsius) downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition?

   4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF)?
5. What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?
6. What are the factors influencing fish health and population in the upper Fording River?

Annual LAEMP reports are required to be submitted on May 31st each year since 2017. Each annual report has expanded on the understanding of potential causes of the observed changes in the benthic invertebrate community, and sampling plans and data analyses were updated annually to reflect new learnings and knowledge gaps within the FRO LAEMP study area (Minnow 2017b, Minnow 2018a, Minnow and Lotic 2019a, Minnow and Lotic 2020a, 2021a).

Since the initial 2017 FRO LAEMP report, benthic invertebrate community abundance and richness has consistently been within the normal range throughout the study area; however, the relative abundance of mayflies (% Ephemeroptera) in September, has consistently been below the regional normal range in the upper Fording River (from the historical Cataract Creek confluence to upstream of Ewin Creek since 2015 Minnow 2017a, Minnow 2018, Minnow and Lotic 2018, Minnow and Lotic 2019b, Minnow and Lotic 2020b, 2021b). Areas with reduced % Ephemeroptera often corresponded with greater Plecoptera abundance. As a result of higher Plecoptera abundance, the relative proportion of combined Ephemeroptera-Plecoptera-Trichoptera (EPT) has remained within the regional normal range but has fallen below the site-specific (habitat adjusted) normal ranges throughout most of the study area. Strong negative correlations between key BIC endpoints, including % Ephemeroptera, and multiple mine-related constituents (nitrate, sulphate, total dissolved solids [TDS], selenium) have been identified, with many constituents also correlating positively with Plecoptera endpoints (Minnow and Lotic 2019b, 2020b, 2021b). Constrained multivariate ordinations have demonstrated that both habitat and water quality factors have significant influence on BIC structure throughout the study area, but covariation among habitat variables and mine-related stressors (i.e., changing in an upstream to downstream direction) has made identifying the individual contributions of each factor challenging. Drying surveys in 2019 and 2020 identified spatial and temporal variability in instream drying (Minnow and Lotic 2020b, 2021b), but while BIC differed in areas where seasonal drying occurs compared to those that remain wetted year-round, most BIC endpoints recovered within two to eight weeks post-rewatering (Minnow and Lotic 2021b).

The 2021 FRO LAEMP continued to provide existing conditions data for pre-commissioning of FRO-S AWTF, as well as insights into physical, chemical, and biological conditions in the upper Fording River. The evaluation of data related to Study Question #1 found that although nitrate concentrations have increased at some areas compared to previous years, these changes were not commensurate with changes in BIC community at individual study areas. Taken together, while nitrate should not be considered the sole cause of observed effects to BIC endpoints, evidence suggests that nitrate is contributing to variations in benthic invertebrate community structure within the study area, and sensitive taxa (i.e., Ephemeroptera and EPT endpoints) are the lowest in areas where nitrate concentrations are the highest. Chronic toxicity testing has not demonstrated a link between nitrate concentrations and adverse responses to fish endpoints, particularly during early life stages of WCT.

Existing conditions data to address Study Questions #2 and #4 were collected during the 2021 FRO LAEMP sampling programs. To date, total phosphorus and orthophosphate concentrations as well as benthic invertebrate productivity have been consistent over time in the study area. Although mean annual water temperatures have remained relatively consistent throughout the study area at individual locations, large seasonal variations in water temperature have been identified throughout the upper and middle study areas, with more limited seasonal fluctuations in the lower study area where there are significant influences from groundwater. Upon commissioning of the FRO AWTF-S, pre-commmissioning data will be used for comparisons to post-commissioning data to identify any potential changes as a result of treatment.

Evaluation of data related to Study Question #3 found that benthic invertebrate tissue selenium concentrations within the FRO LAEMP study area were as expected based on water chemistry in most areas in 2021, except in the Greenhouse Side Channel, downstream of the Swift-Cataract diversion, and downstream of the Multiplate culvert. Elevated tissue selenium concentrations at the Greenhouse Side Channel were explained by the presence of annelids in composite-taxa samples; however, the cause of elevated tissue selenium concentrations at downstream of the Swift-Cataract diversion and downstream of the Multiplate culvert are not clearly understood. Tissue selenium concentrations were highest at monitoring areas where total and bioavailable (reduced) selenium species were detected at the highest concentrations (i.e., downstream of highly mine-influenced inputs such as the Swift-Cataract Diversion). Future sampling will continue to monitor tissue selenium concentrations in the study area, and current data will be used as a basis for comparison post commissioning of the FRO AWTF- S.

The results of the 2021 FRO LAEMP to support Study Question #5 identified relative abundances of Ephemeroptera below the regional normal range from historical Cataract Creek confluence downstream to Ewin Creek. Abundance metrics (total, EPT, Ephemeroptera, Plecoptera, Trichoptera, Chironomidae) were within the normal ranges and have remained consisted over time. Many areas with low % Ephemeroptera had high percent and abundance of Plecoptera families (e.g., Nemouridae and Perlodidae), especially in the middle and lower study areas, but % EPT was below the site-specific normal ranges throughout most of the FRO LAEMP study area. Relative abundance of EPT in the Fording River downstream of Henretta Creek (RG_FODHE) and upstream of Shandley Creek (RG_FOUSH) returned to historical levels in 2021 after falling below the regional normal range in recent years. Lower % EPT at RG_FODHE has been linked to habitat changes associated with changes in flow paths related to channel braiding, but the cause of reduced % EPT at RG_FOUSH in previous years is currently unknown.

The evaluation of the BIC data in the FRO LAEMP study area has clearly demonstrated that both habitat and water quality factors are affecting variation in BIC communities, and although it remains difficult to separate the effect of individual contributions of each variable to the observed effects on BIC, the weight of evidence suggests that the key factors influencing shifts in BIC in the middle and lower study areas are elevated nitrate concentrations (middle and lower study area) and total nickel concentrations (middle study area), changes in substrate size and station gradient related to the Chauncey Creek alluvial fan (lower study area), and seasonal differences in water temperature and other habitat variables related to groundwater influence among areas. Several key habitat variables were identified as significantly contributing to the variation in BIC, including water velocity, water depth, water temperature, substrate size, embeddedness, station gradient, watershed slope, and watershed area. Continued evaluation of BIC following an improvement in water quality related to the commissioning of the FRO AWTF-S, as well as the use of BIC predictive modelling tools currently being developed under the RAEMP (Minnow 2021a) will aid in the interpretation of monitoring data to support answering Study Question #5.

Evaluation of data and key findings from studies related to Study Question #6 found that Westslope Cutthroat Trout (WCT) in the FRO LAEMP study area were in good condition and had a general absence of external anomalies based on the 2021 fishing efforts under the RAEMP. Muscle selenium concentrations were lower than the site-specific effects benchmark for WCT in all fish caught in the Fording River mainstem in 2021 except one (i.e., at the Multiplate culvert) and concentrations were consistent with previous years. Fish sampled opportunistically from Clode Creek, which received mine-influenced water from Clode Sedimentation Ponds, however, did have higher muscle selenium concentrations compared to other areas. Drying in the study area has varied spatially and temporally but annual drying usually occurs in the northern and southern drying sections between early October and late December each year, respectively, and may represent barriers to fish migration to key overwintering areas in the northern survey area. The WCT population appears to be recovering from the steep population decline in winter 2018/2019 and annual population monitoring will continue to track recovery.

WSQG – Working Sediment Quality Guidelines

1 INTRODUCTION

1.1 Background

Teck Coal Limited (Teck) operates four steelmaking coal mines in the Elk River watershed, which are the Fording River Operations (FRO), Greenhills Operations (GHO), Line Creek Operations (LCO), and Elkview Operations (EVO; Figure 1.1). A fifth mine, Coal Mountain Mine (CMm), is also owned by Teck and located in the Elk River watershed; however, it is no longer in operation and has been moved into the care and maintenance designation. Discharges from the mines to the Elk River watershed are authorized by the British Columbia Ministry of Environment and Climate Change Strategy (ENV) through permits that are issued under provisions of the *Environmental Management Act*. Permit 107517 specifies the terms and conditions associated with discharges from Teck's five Elk Valley mine operations.

Permit 107517 required that Teck develop a local aquatic effects monitoring program (LAEMP) related to ongoing mining at FRO and the future commissioning of the Fording River Operation - South Active Water Treatment Facility (FRO-S AWTF) that will treat waters from Cataract, Swift, and Kilmarnock Creeks (Figure 1.2). As a result, the first FRO LAEMP study design was developed, which encompassed the 2016 to 2018 sampling years. A second study design was developed to cover the period between the first cycle and the expected commissioning of the FRO-S AWTF (2019 to 2020). Permit 107517 was amended in March 2021 (Teck 2021a) to include the third cycle of FRO LAEMP monitoring, and Section 8.3.2 outlines the LAEMP requirements as follows:

> *"The Permittee must complete to the satisfaction of the director a study design for a LAEMP which will focus on the upper Fording River for 2021-2023 by April 1, 2021. The study design must be reviewed by the EMC[1] and be designed to an appropriate temporal scale to capture short term, local effects to the immediate receiving environment."*

Also, Section 9.5 of Permit 107517 states:

> *"The LAEMP Annual Reports must be reported on in accordance with generally accepted standards of good scientific practice in a written report and submitted to the director by May 31 of each year following the data collection calendar year."*

[1] The Environmental Monitoring Committee (EMC) was established after the first RAEMP design was approved and implemented in 2015, and consists of representatives from Teck, ENV, the Ministry of Energy, Mines, and Petroleum Resources, the Ktunaxa Nation Council (KNC), Interior Health Authority, and an Independent Scientist. The EMC reviews submissions and provides technical advice and input to Teck and the ENV Director, as stipulated in Section 11.2 of Permit 107517.

The first FRO LAEMP study design was submitted in accordance with the Permit requirement on June 1, 2016 (Minnow 2016) and subsequently approved by ENV on October 24, 2016. This first cycle represented a period of monitoring of current conditions with respect to the future FRO-S AWTF. In addition to the need for monitoring data prior to active water treatment, there were also concerns related to potential increases in aqueous nitrate concentrations in the Fording River prior to initiation of water treatment, as projected in the Elk Valley Water Quality Plan (EVWQP; Teck 2014). Changes in biota related to changing flows in portions of the Fording River as a result of re-direction of water (i.e., re-direction of flows from Cataract, Swift, and Kilmarnock creeks for treatment or water management purposes) were also considered in the LAEMP study design. Seasonal drying surveys were added to the FRO LAEMP at the end of the first cycle (i.e., Fall 2017) to document the spatial and temporal extent of drying in the study area, and to contribute to the understanding of the potential effects of drying on biota. A study design for the second FRO LAEMP cycle was submitted on May 31, 2019 (Minnow and Lotic 2019a). This second study design was developed to cover the remaining period (2019 to 2020) prior to the commissioning of the FRO-S AWTF and, as such, continued to focus on monitoring of current conditions pre-treatment, the effects of nitrate and other mine-related constituents on the benthic invertebrate community (BIC), and the spatial and temporal patterns in seasonal drying throughout the study area (Minnow and Lotic 2019a, 2020a). Drying surveys were added in the Fording River side channel #2 and a 3 km section of Henretta Creek upstream of Henretta Lake (i.e., upstream of FRO licensed water use) at the end of the second FRO LAEMP cycle. A study design for the third FRO LAEMP cycle was submitted on April 1, 2021 (Minnow and Lotic 2021a). The third study design was developed to understand conditions in the upper Fording River post-commissioning of the FRO-S AWTF and Fording River Operation - North Saturated Rock Fill (FRO-N SRF); however, forward flow of treated waters from the FRO-S AWTF did not begin until December 22, 2021, and Phase 2 commissioning of the FRO-N SRF will not begin until Q4 2022so the present report represents current conditions in the study area.

After Phase 2 commissioning, the FRO-N SRF will treat water from Eagle 6 Pit, Clode Primary Pond, Liverpool Ponds, and Post Ponds and return treated water to Clode Secondary Pond prior to discharge to the Fording River via Clode Creek (Teck 2022a). To assess biological conditions related to FRO-N SRF commissioning, a biological monitoring area was added to the FRO LAEMP upstream of the Clode Creek confluence in 2019, which will be compared to downstream (RG_FOUNGD and RG_FODNGD) monitoring areas. The FRO-N SRF will be commissioned in 2022 and future FRO LAEMPs will evaluate pre- and post-commissioning conditions in the Fording River. Additional biological monitoring areas may be added to the FRO LAEMP in 2022 in anticipation of FRO-N SRF commissioning.

The first six years of the FRO LAEMP were focused on understanding conditions prior to the commissioning the FRO-S AWTF and how habitat, water quality constituents (including nitrate), and seasonal drying may affect BIC in the study area. Contrary to EVWQP projections, nitrate concentrations have not increased in the upper Fording River and have not changed concurrently with observed temporal changes in BIC endpoints (% Ephemeroptera and % Ephemeroptera-Plecoptera-Trichoptera [EPT] combined; Minnow and Lotic 2019b, 2020b, 2021b). A major finding of the FRO LAEMP has been an effect on % Ephemeroptera, whereby their relative proportions have been lower than the regional normal range from downstream of Cataract Creek to upstream of Ewin Creek since 2015 (Minnow 2017, Minnow 2018, Minnow and Lotic 2018, 2019b, 2020b, 2021b). Although several mine-related water quality constituents (nitrate, total selenium, sulphate, and total dissolved solids [TDS]) have been identified as correlating strongly and negatively with % Ephemeroptera (Minnow and Lotic 2018, 2019b, 2020b, 2021b), a strong co-variation between habitat and water quality factors has been identified making it difficult to understand individual contributions of water quality and habitat on BIC variation (Minnow and Lotic 2020b, 2021b)

In addition to monitoring conducted under the FRO LAEMP, fish population monitoring is also ongoing within the upper Fording River. The 2019 Westslope Cutthroat Trout (WCT) population monitoring program identified a steep decline in the WCT population numbers in 2019 compared to 2017 (74% lower for juveniles and 93% lower for subadults) within the upper Fording River, including the FRO LAEMP study area (Cope 2020). As a result, an evaluation of cause (EoC) was conducted and determined that “the decline occurred in February to March 2019 and was caused by the interaction of extreme ice conditions (due to extreme, prolonged, cold air temperatures; seasonal, winter low flows, and lower winter snowpack), sparse overwintering habitats and restrictive fish passage conditions during the preceding migration period in fall 2019” (Evaluation of Cause Team 2021). Two actions have been initiated as a result of findings from the EoC: 1) the development of an internal WCT recovery plan with consultation from regulators; and 2) restructuring of monitoring designs to consider reduced fish handling and improved statistical population assessment. Teck continues to work collaboratively with the Ktunaxa Nation Council (KNC), government regulators, the EMC, the Elk Valley Fish and Fish Habitat Committee (EVFFHC), and independent experts to gather more data and address ongoing protection of fish. The WCT Recovery Working Group (WCT RWG) has since been established, which is composed of experts from the above groups with the primary goal of facilitating the recovery of the WCT population in the upper Fording River.

The goal of the FRO LAEMP is to assess site-specific conditions on a frequent and localized basis, as required, until sufficient data have been collected, concerns no longer exist, or relevant monitoring can be incorporated into the RAEMP. The primary focus of the FRO LAEMP is to monitor aquatic ecosystem condition, particularly as it relates to conditions post-commissioning of water treatment compared to conditions prior to commissioning. Study questions from the first and second FRO LAEMP cycles were updated during the preparation of the third FRO LAEMP cycle to better reflect important considerations in the study area (e.g., the commissioning of the FRO-N SRF, the WCT population decline; Minnow and Lotic 2021a). Through the evaluation of data from previous reports, and EMC (December 3, 2020; February 3 and 23, 2021) and subject matter experts (SMEs), the FRO LAEMP study questions were updated as follows:

7. Are nitrate concentrations in the study area changing and do they have the potential for adverse effects on biota?
8. Is water treatment affecting biological productivity downstream in the Fording River?
9. Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?
10. How is temperature changing over time in the FRO LAEMP study area?

    4a. Is water temperature measurably different (greater than 1 degree Celsius) downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition?

    4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF)?

11. What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?
12. What are the factors influencing fish health and population in the upper Fording River?

Study question 1 has been investigated through monitoring of nitrate concentrations and BIC structure as part of annual sampling in the FRO LAEMP. Water quality samples collected concurrently with BIC samples were combined with Teck's routine water quality monitoring data from stations along the upper Fording River to augment the temporal dataset.

Study questions 2 to 4 relate specifically to water treatment, and since forward flow from the FRO-S AWTF did not occur until December 22, 2021, and phase 2 of commissioning of the FRO-N SRF will not occur until Q4 2022, these study questions will be addressed as existing conditions in the present report. Monitoring under the LAEMP up to and including 2021 to support these questions have captured pre-treatment aquatic conditions to which data will be compared once the facilities are operational.

Study question 5 has been addressed through detailed evaluations of the BIC in the FRO LAEMP study area, and through interpretations of the results compared to regional and site-specific normal ranges, water quality, and habitat variables (e.g., seasonal drying reaches, flow, substrate type, calcite, temperature).

Study question 6 was added as a new study question in the third cycle of the FRO LAEMP to better integrate data collected among multiple programs to summarize the current understanding of factors influencing fish health and populations in the study area. This study question will evaluate FRO LAEMP data (e.g., benthic invertebrate abundance and tissue chemistry, water chemistry, temperature, seasonal drying) in conjunction with findings from other related studies (RAEMP, Environment and Climate Change Canada [ECCC] tri-annual tissue sampling, Upper Fording River [UFR] WCT Population Monitoring Program, and the FRO-S AWTF Flow Related Monitoring and Assessment Plan).

Relevant information obtained under other programs, such as the regional calcite and chronic toxicity monitoring programs are also summarized in the LAEMP. The results of the sixth year (2021 calendar year – January to December) of monitoring for the FRO LAEMP are the subject of this report, which includes comparison to previous years of data.

1.2 Conceptual Site Model

A conceptual site model (CSM) is a written and/or illustrative depiction of relationships between human activities that disturb the environment and the ways such disturbances can alter the ecosystem and affect biological receptors. Potential effects on aquatic receptors in the upper Fording River, both prior to and after the commissioning of the future FRO-S AWTF and FRO-N SRF were considered in a CSM (Figure 1.3). Assessment endpoints are the valued attributes of an ecosystem upon which management actions focus (USEPA 1998, 2003). Assessment endpoints considered in the FRO LAEMP are described in Section 2.1 and are evaluated using measurement endpoints. Typically, multiple measurement endpoints are used to support evaluation and interpretation of each assessment endpoint to conclude if the assessment endpoints/receptors are being protected.

As illustrated by the CSM, assessment and measurement endpoints may be affected through physical and/or chemical processes related to mining and operation of the AWTF (Figure 1.3). Biological measurements relating directly to population or community characteristics are referred to as direct indicators. Mine-related stressors (including tissue selenium concentrations) are also monitored as part of the FRO LAEMP and are referred to as indirect indicators. Laboratory chronic toxicity data (semi-direct indicators) are incorporated into the FRO LAEMP, as appropriate. Measurement of indirect and semi-direct indicators contribute to understanding if

Document Path: C:\Users\mlapalme\Trinity Consultants, Inc\Teck - 217202.0011 - Teck FRO LAEMP 2021\D - GIS\Report\Graphics\21-11 Figure 1.3 Conceptual Site Model.pdf observed effects on individual receptors are mine-related. Effects may act singly or in combination to influence aquatic populations and/or communities by changing the abundance or resilience of aquatic receptors (Figure 1.3) and are evaluated by monitoring benthic invertebrates as biological receptors within the FRO LAEMP. The study questions (Section 1.1) were developed in consideration of the potential effects identified in the CSM (Figure 1.3).

1.3 Linkages to the Adaptive Management Plan for Teck Coal in the Elk Valley

As required in Permit 107517 Section 10, Teck has developed an Adaptive Management Plan (AMP) to support implementation of the EVWQP to achieve water quality and calcite targets, protect human health, groundwater, and aquatic ecosystem health (Teck 2018, 2021a). Following an adaptive management framework, the AMP identifies six Management Questions that are re-evaluated at regular intervals as part of AMP updates through the EVWQP implementation. The AMP also identifies key uncertainties that need to be reduced to fill gaps in current understanding and support achievement of the EVWQP objectives.

The FRO LAEMP was designed to monitor conditions in the upper Fording River in advance of water treatment and answer specific questions on an annual basis (Section 1.2). Each annual LAEMP cycle (results are reported on May 31st of each year for the preceding calendar year) are also used for tracking issues for which a potential need for responses under the AMP framework has been identified, including the biological triggers assessments. Biological triggers are intended as a simple and consistent way to flag potential unexpected monitoring results that may require additional evaluation and action under the adaptive management response framework. As an example of adaptive management, seasonal drying between Swift and Cataract Creeks was observed in late 2018, resulting in flows in the Fording River at the FRO Compliance Point consisting predominantly of water from Cataract Creek. To evaluate the potential effects on biota in the area downstream of Cataract Creek, two additional biological sampling events were included in December 2018 and February 2019 (Minnow and Lotic 2020b). In June of 2020, benthic invertebrate tissue selenium concentrations were anomalously high in three out of five replicates at RG_FRCP1SW. These results were included in a broader investigation of annelid presence in composite-taxa benthic invertebrate tissue samples and the effects on selenium concentrations (Luoma 2021; Golder 2021). In the current report, % EPT and composite-taxa benthic invertebrate tissue selenium concentration were assessed against their respective biological triggers (additional information and methods pertaining to this analysis can be found in Appendix H).

In addition to addressing questions specific to the FRO LAEMP on an annual basis, monitoring data from the LAEMP will contribute to the broader data set assessed every three years within the RAEMP. The RAEMP is designed to evaluate AMP Management Question #5 (i.e., "Does monitoring indicate that mine-related changes in aquatic ecosystem conditions are consistent with expectations?"). During the development of the AMP, a number of uncertainties related to Management Question #5 were identified that were summed up as Key Uncertainty 5.1 (i.e., "How will monitoring data be used to identify potentially important mine-related effects on the aquatic ecosystem?"). Teck continues to work with its consultants and the EMC to address and reduce Key Uncertainty 5.1 and its underlying uncertainties.

Data from the LAEMP and RAEMP will also contribute to answering AMP Management Question #2 (i.e., "Will aquatic ecosystem health be protected by meeting the long-term site performance objectives?). A Key Uncertainty associated with Management Question #2 is "How will the science-based benchmarks be validated and updated?" with underlying uncertainty about how aquatic monitoring data will be used to validate and update the benchmarks. Progress on reducing these uncertainties, and associated learnings, will be described in Annual AMP Reports.

The third annual AMP report was submitted in July 2021, which summarized data from 2020, identified early warning triggers (EWTs) for nitrite, total dissolved solids (TDS), and uranium at the historical[2] Fording River Compliance Point (FR_FRCP1; Teck 2021b). The annual surface water quality report for 2021, however, only identified an EWT for TDS at the new compliance point (RG_FRABCH; Teck 2022b). Implementation of adaptive management actions is not constrained to the AMP or LAEMP annual reporting cycles but may be (and have been) triggered at any time during the monitoring and reporting cycle.

Please refer to the 2021 AMP update (Teck 2021b) for more information on the adaptive management framework, the Management Questions, the key uncertainties, the response framework, continuous improvement, linkages between the AMP and other EVWQP programs, and AMP reporting.

[2] The Fording River Operation compliance point changed from FR_FRCP1 to FR_FRABCH on March 11, 2021 (Permit 107517; Teck 2022b)

2 METHODS

2.1 Overview

The general approach for the FRO LAEMP (Table 2.1) includes explanation of the collected data and data evaluation in relation to each of the study questions. This report includes data up to the end of the 2021 calendar year for all endpoints. Historical data are also presented where appropriate. Biological samples (BIC and benthic invertebrate tissue) were collected in June, September, and December as per the FRO LAEMP study design (Minnow and Lotic 2021a) from established biological monitoring areas within the study area extending from the Fording River and Henretta Creek upstream of FRO, through the operations and downstream to between Chauncey Creek and Ewin Creek (Figure 2.1; Table 2.2). Consistent with previous years, winter conditions prevented access to RG_FO26 and RG_HENUP in December 2021, so RG_UFR1 was used as the reference area for that sampling program. Also consistent with previous years, BIC samples were not collected at RG_FOBCP and benthic invertebrate tissue and water samples were not collected at RG_FRCP1SW in December 2021 because ice was too thick to access riffles and/or the area was dry (Table 2.2).

Benthic invertebrate community samples were collected at each FRO LAEMP biological monitoring area in June and September[3], and a subset of biological monitoring areas upstream and downstream of the old Compliance point (FR_FRCP1) in December 2021 (Table 2.2). Benthic invertebrate community sampling in 2021 was consistent with previous years, except for the addition of sampling at the new Compliance Point (FR_FRABCH) in December.

Benthic invertebrate tissue[4] and water quality, including selenium speciation, sampling occurred at all FRO LAEMP biological monitoring areas in June, September, and December. In addition, sampling was added in the Greenhouse side channel (RG_FRGHSC) and Fording River side channel two (RG_FRSCH2) in September as part of the FRO AWTF- S commissioning sampling plan (pre-commissioning sampling, Minnow and Lotic 2021a), and because these side channels have been identified as potential WCT habitat (Table 2.2).

Benthic invertebrate biomass and density sampling, as well as sediment sampling, was conducted in September at a sub-set of biological monitoring areas (Table 2.2). Benthic invertebrate biomass and density sampling was added upstream (RG_FOUCL) and downstream

[4] Replicates of five were taken at areas associated with the FRO-S AWTF commissioning sampling plan to facilitate strong statistical comparisons pre- and post-commissioning.

Table 2.1: Summary of the 2021 FRO LAEMP

Study Questions	Context	Assessment Endpoints	Measurement Endpoints[a]: Water	Measurement Endpoints[a]: Water Sampling Stations and Water Temp/Flow Loggers	Measurement Endpoints[a]: Biological	Measurement Endpoints[a]: Biological Sampling Areas	How Data Will be Evaluated to Address Study Question
1. Are nitrate concentrations in the study area changing, and do they have the potential for adverse effects on biota?	EVWQP projections identified an increasing trend in nitrate concentrations in the upper Fording River. Treatment plans have been finalized within the study area (FRO AWTF S and Eagle 4 SRF) and aqueous nitrate concentrations are expected to decrease following commissioning compared to pre-commissioning concentrations. Nitrate concentrations above EVWQP benchmarks have the potential to adversely affect biota.	Benthic invertebrate community relative to nitrate concentrations in the upper Fording River, and various organisms response to chronic toxicity testing.	Nitrate concentrations in water, surface water chronic toxicity tests (quarterly and semi-annually)	Routine water sampling at FR_UFR1, FR_HC3, FR_FR1, FR_MULTIPLATE, FR_FRNTP, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRRD, FR_FRABCH, GH_PC2, FR_FR5; Water sampling concurrent with biological sampling at RG_FRSCH2, RG_FRGHSC, RG_FOUCL, RG_FOUNGD, RG_FODNGD, and RG_FRCP1SW, Chronic toxicity tests at FR_UFR1, FR_FRCP1 and FR_FRABCH	Benthic invertebrate community structure (September) and chronic toxicity testing	CABIN kick and sweep benthic invertebrate community (BIC) sampling at RG_FO26 (Ref), RG_HENUP (Ref), RG_UFR1 (Ref), RG_FODHE, RG_FOUCL, RG_FOUNGD, RG_FODNGD, RG_MP1, RG_FOUSH, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, RG_FRUPO, RG_FODPO, RG_FO22, RG_FOUEW; chronic toxicity tests at RG_UFR1, RG_FOBCP and RG_FO22	1. Evaluate nitrate concentrations relative to EVWQP predictions. 2. Determine changes of nitrate concentrations relative to baseyear and water treatment commissioning at each station throughout the study area. 3. Determine if BIC endpoints are outside of regional and/or site-specific normal ranges or moving away from the reference ranges in accordance with observed nitrate concentrations. 4. Determine if BIC results correspond with expectations based on nitrate concentrations in water relative to the site-specific benchmark for nitrate. 5. Use statistical tools (e.g., correlations, constraining ordination) to evaluate the potential impact of nitrate on BIC (see study question 5). 6. Interpret chronic toxicity results in the context of nitrate concentrations in the study area.
2. Is water treatment affecting biological productivity downstream in the Fording River?	Phosphorus will be added to the FRO AWTF-S and FRO Eagle 4 SRF to facilitate microbial growth. Increased phosphorus concentrations in the effluent has the potential to cause increased algae growth in the upper Fording River, changing the trophic status and overall health.	Phosphorus concentrations in water upstream and downstream of water treatment pre-commissioning. Biological invertebrate productivity downstream from the FRO AWTF-S and FRO Eagle 4 SRF discharge locations pre-commissioning and relative to productivity observed upstream from the discharge locations.	Nutrient concentrations, particularly total phosphorus and orthophosphate (phosphorus is the limiting nutrient in the upper Fording River)	Routine water sampling at FR_UFR1, FR_HC3, FR_FR1, FR_MULTIPLATE, FR_FRNTP, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRRD, FR_FRABCH, GH_PC2, FR_FR5; Water sampling concurrent with biological sampling at RG_FRSCH2, RG_FRGHSC, RG_FOUCL, RG_FOUNGD, RG_FODNGD, and RG_FRCP1SW	Benthic invertebrate biomass, benthic invertebrate community structure, periphyton scores (all in September only)	BIC sampling as above; Biomass and density (HESS) sampling at RG_FO26 (Ref), RG_HENUP (Ref), RG_FOUCL, RG_FOUNGD, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, RG_FRUPO, RG_FO22	1. Determine changes of total phosphorus and orthophosphate concentrations relative to baseyear throughout the study area. 2. Compare biomass/density upstream and downstream from water treatment pre-commissioning.
3. Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?	Treatment plans (FRO AWTF S and Eagle 4 SRF) are expected to remove up to 50% of total selenium downstream in the Fording River; however, treatment could also result in an increase in the concentrations of more bioavailable selenium species (i.e., reduced selenium), resulting in increases of benthic invertebrate tissue selenium concentrations.	Benthic invertebrate tissue selenium concentrations downstream from the FRO AWTF-S and FRO Eagle 4 SRF locations pre-AWTF commissioning and relative to concentrations observed upstream from the discharge locations. Selenium concentrations and species in water upstream and downstream of water treatment and pre- and post-commissioning.	Total and dissolved selenium concentrations, and selenium speciation	Routine water sampling at FR_UFR1, FR_HC3, FR_FR1, FR_MULTIPLATE, FR_FRNTP, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRRD, FR_FRABCH, GH_PC2, FR_FR5; Water sampling concurrent with biological sampling at RG_FRSCH2, RG_FRGHSC, RG_FOUCL, RG_FOUNGD, RG_FODNGD, and RG_FRCP1SW	Benthic invertebrate tissue selenium concentrations (composite-taxa samples)	Benthic invertebrate tissue sampling at RG_FO26 (Ref), RG_HENUP (Ref), RG_UFR1 (Ref), RG_FRSCH2, RG_FRGHSC, RG_FODHE, RG_FOUCL, RG_FOUNGD, RG_FODNGD, RG_MP1, RG_FOUSH, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, , RG_FRUPO, RG_FODPO, RG_FO22, RG_FOUEW	1. Determine if benthic invertebrate tissue selenium concentrations are outside the regional normal range or above EVWQP benchmarks. 2. Compare benthic invertebrate tissue selenium concentrations to expected concentrations based on the selenium bioaccumulation model. 3. If tissue selenium concentrations are higher than those predicted by the bioaccumulation model, determine if differences in tissue selenium concentrations are correlated with changes in selenium species concentrations. 4. Use B-tool to compare measured versus modelled benthic invertebrate tissue selenium concentrations relative to concentrations of reduced selenium.

			Water	Water Sampling Stations and Water Temp/Flow Loggers	Biological	Biological Sampling Areas	
4. How is temperature changing over time in the FRO LAEMP study area 4a. Is water temperature measurably different (greater than 1 degree Celsius) downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition? 4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF)?	Water temperatures in the study area have the potential to change as a result of influences from the FRO AWTF-S and FRO Eagle 4 SRF effluent. These temperature changes have the potential to adversely affect WCT downstream if they are greater than specific threshold temperatures (i.e., greater than 1 degree Celsius downstream relative to upstream) and occur at specific times of the year relative to WCT migrations.	Water temperatures throughout the study area	Water temperature data loggers	Temperature and flow data loggers at FR_UFR1, FR_FR1, FR_FOUCL FR_FRDSCC1, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRCP1SW, FR_FRRD, GH_PC2, FR_FRABCH	-	-	1. Evaluate overall temporal changes in water temperatures throughout the study area. 2. Integrate results from FRO-S Flow Related Monitoring and Assessment Plan, where appropriate, to help answer the question.
5. What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?	Shifts in community structure have been observed in areas throughout the study area in previous FRO LAEMPs. Variations in BIC throughout the study area may be associated with specific habitat variables and/or water quality stressors.	BIC endpoints, chronic toxicity testing, tissue chemistry, water chemistry, sediment chemistry, and habitat (e.g., seasonal drying, flow, substrate type, calcite, temperature).	Order Constituents, plus nickel and other WQ constituents with Early Warning Triggers (EWT) in surface water, chronic toxicity tests (quarterly and semi-annually), water temperature and flow, seasonal drying surveys.	Routine water sampling at FR_UFR1, FR_HC3, FR_FR1, FR_MULTIPLATE, FR_FRNTP, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRRD, FR_FRABCH, GH_PC2, FR_FR5; Water sampling concurrent with biological sampling at RG_FRSCH2, RG_FRGHSC, RG_FOUCL, RG_FOUNGD, RG_FODNGD, and RG_FRCP1SW, Chronic toxicity tests at FR_UFR1, FR_FRCP1 and FR_FRABCH, Temperature and flow data loggers at FR_UFR1, FR_FR1, FR_FOUCL FR_FRDSCC1, FR_FR2, GH_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRCP1SW, FR_FRRD, GH_PC2, FR_FRABCH	BIC structure and composite-taxa benthic invertebrate tissue selenium concentrations	CABIN kick and sweep benthic invertebrate community (BIC) sampling at RG_FO26 (Ref), RG_HENUP (Ref), RG_UFR1 (Ref), RG_FODHE, RG_FOUCL, RG_FOUNGD, RG_FODNGD, RG_MP1, RG_FOUSH, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, RG_FRUPO, RG_FODPO, RG_FO22, RG_FOUEW; chronic toxicity tests at RG_UFR1, RG_FOBCP and RG_FO22, Benthic invertebrate tissue sampling at RG_FO26 (Ref), RG_HENUP (Ref), RG_UFR1 (Ref), RG_FRSCH2, RG_FRGHSC, RG_FODHE, RG_FOUCL, RG_FOUNGD, RG_FODNGD, RG_MP1, RG_FOUSH, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, , RG_FRUPO, RG_FODPO, RG_FO22, RG_FOUEW	1. Determine if BIC endpoints are outside of regional and/or site-specific normal ranges or moving away from the reference ranges in accordance with potential water quality stressors and/or habitat variables. 2. Determine changes of concentrations of constituents identified as EWTs relative to baseyear at each station throughout the study area. 3. Determine if chemical/physicals stressors and/or habitat variables correlate with key BIC metrics. 4. Use statistical tools (e.g., redundancy analysis) to understand the factors that are causing variations in BIC endpoints throughout the study area. 5. Use chronic toxicity testing results to further interpret how water quality may be affecting biota in the study area.

Notes: '-' indicates sample that was not taken because it was not a part of the sampling design; 'x' indicates sample that was not taken because of drying and/or ice conditions.

[a] RG_UFR1 was used as a reference area in winter months when there was no access to RG_FO26 or RG_HENUP. It was added for June and September for additional pre-FRO AWTF-S commissioning data.

[b] n=5 for composite-taxon tissue samples in areas associated with the FRO AWTF-S commissioning sampling plan.

[c] The water quality monitoring station is the same for biological monitoring stations RG_FO26 and RG_UFR1.

[d] Routine water quality monitoring stations associated with biological monitoring areas are outlined in brackets

[e] RG_FRSCH2 and RG_FRGHSCH were added in September 2021 to support the FRO AWTF-S commissioning sampling plan and to understand side channel habitat quality (Minnow and Lotic 2021a).

[f] triplicate samples of periphyton for both ash free dry mass and chlorophyll-a analysis taken during the RAEMP

[g] periphyton scores of n=5 were taken at each biological monitoring area in September, except at RG_FRGHSC.

(RG_FOUNGD) of Clode Creek influences in September 2021 to assess conditions pre-commissioning of the FRO-N SRF.

Water level (flow) and temperature were monitored continuously at established gauges throughout the study area. Water level and temperature data loggers were consistent with the previous year, except an additional logger was added near RG_FOUCL to capture water level and temperature upstream of Clode Creek to support the FRO-N SRF outfall (Table 2.3; Figure 2.2). Drying surveys were conducted monthly between January and reconnection, while bi-weekly surveys[5] were conducted October through December 2021 within the Southern (12.6 km long), Northern (6.1 km long), and upper Henretta (3 km long) drying survey areas (Table 2.3; Figure 2.2).

2.2 Water Quality

2.2.1 Sample Collection

Water quality and selenium speciation samples, as well as *in situ* water quality data (i.e., temperature, flow, pH, conductivity, and DO), were collected concurrently with all biological sampling (Table 2.2). In addition, routine water quality monitoring data collected by Teck and that correspond with many biological sampling areas were included in the FRO LAEMP (Table 2.4 and Figure 2.1). Water quality samples were collected to understand potential changes to concentrations of constituents with EWTs in accordance with Permit 107517, while selenium speciation samples were collected to provide a baseline understanding of speciation in the study area before the commissioning of the FRO-S AWTF and the FRO-N SRF, and to compare to benthic invertebrate tissue selenium concentrations.

All water samples collected concurrent with biological sampling were collected by wading into the river and filling sampling bottles from below the surface of the water. For water quality samples, preservatives were added to samples for total and dissolved metals, total organic carbon, and dissolved mercury, while field filtering was applied to all samples being analyzed for dissolved constituents. For selenium speciation sampling, samples for dissolved selenium were field filtered and stored at 4°C, samples for total selenium were stored at 4°C, and samples for selenium speciation were field filtered and frozen. Water quality and selenium speciation samples were not collected at RG_FRCP1SW in December 2021 because the riffles were dry and/or frozen, so sampling for benthic invertebrates was not possible.

[5] The second survey for that month was for the fish stranding surveys, which also documented drying; however, the fish stranding surveys did not include side channels so is limited to only mainstem areas.

Table 2.3: Stations Associated with Drying Surveys, Manual Flow Measurements, and Hydrometric and Water Temperature Loggers, FRO LAEMP, 2021

Notes: Q = quarterly; M = monthly; W/M = weekly during freshet (March 15 to July 15); Q - quarterly; N/A - Not Applicable; "-" indicates no data available.
[a] Dissolved oxygen, temperature, specific conductance, pH.
[b] Total and dissolved metals, total and dissolved organic carbon, nutrients, and major ions as per Table 18 of Permit 107517.
[c] Chronic toxicity as per Permit 107517 requirements.
[d] Not required by Permit 107517; FR_UFR1 is used as a reference location in the chronic toxicity program. Frequency may change depending on the needs of the program.
[e] Non permitted location, frequency may change in 2022.
[f] Chronic toxicity started in Q4 2018 at this location.
[g] This sampling location, previously called GH_FR3, was merged to FR_FR3 for data management purposes.
[h] Biological monitoring areas associated with water quality monitoring stations are outlined in brackets.
[i] Chronic Toxicity started Q1 2021 as part of the UFR Chronic Toxicity Study.
[j] Stations paired for correlation and multivariate analyses but are presented separately in report figures because of their distance from one another.

2.2.2 Laboratory Analysis

Water samples were analyzed by ALS Environmental (ALS; Calgary, AB) for constituents consistent with Permit 107517 (i.e., conventional parameters, major ions, nutrients, and total and dissolved metals; Table 2.5) using the following methods indicated in parentheses:

- total organic carbon (TOC) and dissolved organic carbon (DOC) (combustion method; American Public Health Association [APHA] 5310 for TOC);
- Total suspended solids (TSS) and total dissolved solids (TDS; gravimetric method; APHA 2540 D and C for TSS and TDS, respectively);
- alkalinity (potentiometric titration; APHA 2320);
- turbidity (nephelometric method; APHA 2130 Turbidity);
- hardness, as $CaCO_3$ (by calculation; APHA 2340 B);
- total and dissolved metals[6], (collision cell inductively coupled plasma - mass spectrometry and inductively coupled plasma - optical emission spectrophotometry; APHA 3030 B&E/ Environmental Protection Agency [EPA] SW-846 6020A, and EPA 3005A/6010B, respectively);
- bromide, chloride, fluoride, and sulphate (ion chromatography; APHA 4110 B);
- ammonia, as N (fluorescence; J. Env. Monit., 2005, 7:37-42);
- nitrate and nitrite, as N (ion chromatography; EPA 300.0);
- total Kjeldahl nitrogen (TKN) (fluorescence; APHA 4500-NORG D.); and
- orthophosphate and total phosphorus (colourimetric method; APHA 4500-P Phosphorus).

Selenium speciation analysis was conducted by Brooks Applied Labs (Bothell, Washington) using ion chromatography inductively coupled plasma collision reaction cell mass spectrometry (IC-ICP-CRC-MS). Analytes included selenate, selenite, dimethylselenoxide, methylseleninic acid, methaneselenonic acid, selenocyanate, selenomethionine, selenosulphate, and unknown selenium species. Selenium species were first separated on an ion exchange column and then detected using a collision/reaction cell-equipped inductively coupled plasma mass spectrophotometry (ICP-MS). The applied method was optimized to provide interference-free quantitation of individual selenium species at part-per-trillion (ppt) levels. Total (filtered and unfiltered) selenium analyses were also performed by Brooks Applied Labs

[6] Here and elsewhere in this document, “metals” includes metalloids, such as selenium.

Table 2.5: Water Quality Parameters Required Under Permit 107517[a]

Category	Parameters
Field Parameters	water temperature, specific conductance, dissolved oxygen (DO), pH
Conventional Parameters	specific conductance, total dissolved solids, total suspended solids, hardness, alkalinity, dissolved organic carbon, total organic carbon, and turbidity
Major Ions	bromide, fluoride, calcium, chloride, magnesium, potassium, sodium, and sulphate
Nutrients	ammonia, nitrate, nitrite, total Kjeldahl nitrogen (TKN), orthophosphate, and total phosphorus
Total and Dissolved Metals	aluminum, antimony, arsenic, barium, beryllium, bismuth, boron, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, tin, titanium, uranium, vanadium, zinc

[a] Parameters are consistent with those outlined in Table 27, Appendix 3 of Permit 107517.

using inductively coupled plasma triple quadrupole mass spectrometry (ICP-QQQ-MS). Water samples were collected into borosilicate glass containers and preserved to a pH < 2 with nitric acid. An aliquot of each preserved sample was further digested with nitric and hydrochloric acids in a closed vessel (bomb) prior to analysis. The applied sample collection, preservation, digestion, and analytical procedures are designed to accurately quantify selenium in the presence of potential interferences (e.g., chloride and bromide) and regardless of the chemical form of selenium present in solution (e.g., ionic, particulate, or volatile molecular forms).

Quality Assurance/Quality Control (QA/QC) associated with routine water sampling is described by Teck in annual water quality reports submitted under Permit 107517. Duplicate water quality samples taken concurrently with biological samples were reviewed in Appendix A. Overall, water chemistry data were of acceptable quality and considered acceptable for this study.

2.2.3 Chronic Toxicity Testing

Chronic toxicity testing was conducted by Nautilus Environmental for the annual Regional Chronic Toxicity Study as required by Permit 107517 and for the Upper Fording River (UFR) Chronic Toxicity supporting study in 2021[7] (summarized under a single report; Golder 2022a). Endpoints for water flea (*Ceriodaphnia dubia*) survival and reproduction, amphipod (*Hyalella azteca*) survival and dry weight, rainbow trout (*Oncorhynchus mykiss*) survival, viability, length, and weight, and fathead minnow (*Pimephales promelas*) hatch, survival, biomass, length, and development were tested for water quality. Chronic toxicity testing with *Pseudokirschneriella subcapitata* was not required in the upper Fording River chronic toxicity program in 2021 and was only included in the regional program in accordance with Permit 107517. Chronic toxicity tests were completed with water from seven water quality stations within the FRO LAEMP study area under the two programs in 2021:

- FR_FRCP1, FR_FRABCH, and FR_UFR1 (reference) for the regional program, and;
- FR_MULTIPLATE and FR_FR2 upstream of the Swift-Cataract Diversion[8] and FR_FR4 and FR_FRRD downstream of the Swift-Cataract Diversion for the upper Fording River chronic toxicity supporting study (Golder 2022a).

Chronic toxicity testing in 2021 was conducted and summarized quarterly and annually in accordance with Permit 107517 (Golder 2022a).

[7] Conducted to inform whether extent and magnitude of potential chronic effects in the upper Fording River are being captured in the routine Regional Chronic Toxicity Monitoring Program.

[8] Cataract Creek was diverted through Swift Ponds to Swift Creek in August of 2019 because of low flow conditions and seasonal drying between Swift and Cataract Creeks.

2.2.4 Data Analysis

Water quality data were downloaded from Teck's EQuIS database and included both routine monitoring results collected by Teck and samples collected concurrently with biological sampling. Analyses of water quality data were completed using the following approaches (see Appendix J for detailed methodology):

- Tabular and graphical comparison to EVWQP benchmarks, interim screening values (nickel) and screening values (TDS) and British Columbia Water Quality Guidelines (BCWQGs);
- Graphical spatial comparisons of seasonal mean concentrations of order constituents (nitrate, total selenium, dissolved cadmium, and sulphate) and total nickel, as well as selenium species concentrations collected concurrently with biological monitoring;
- Principal Component Analysis (PCA) to condense water quality results for use in benthic invertebrate community correlation analysis;
- Evaluation of temporal trends in monthly mean water quality concentrations using a two-way censored regression Analysis of Variance (2-way ANOVA).

2.3 Hydrology

2.3.1 Seasonal Drying

Monthly drying surveys for this reporting period began in late fall 2020 and were continued until the Fording River and Henretta Creek were reconnected, then restarted in September until December 2021 (surveys continue in 2022, however are not included in this report). Additional drying survey field visits were added in October 2021 allowing for biweekly observations from October to December 2021. One additional site visit was completed in June to collect high flow discharge measurements and another site visit in July to complete a post-freshet download and to assess any damage that may have occurred to data loggers during freshet. Drying dates were determined for each survey section with logger data and overall drying observations for each section of the Fording River.

2.3.1.1 Field Methods

In 2021, monthly drying surveys were completed (January to April and September to December) to evaluate surface water connectivity along the Fording River and Henretta Creek in the FRO LAEMP study area. The drying survey sections in the FRO LAEMP study area are broken down into three sections: the southern survey, the northern survey, and the Henretta Creek survey. The southern survey covers a 12.8 km section of the Fording River from the

Chauncey Creek confluence (FR_FRABCH) upstream to the south tailings pond (FR_FR2). The southern survey also includes two side channels of the Fording River that were added in November 2020: Side channel #2 and the Greenhouse side channel. The northern survey covers a 6.1 km section of the Fording River from the Multiplate culvert (FR_MULTIPLATE) to a location on the Fording River upstream of the Henretta Creek confluence (FR_UFR1). The Henretta Creek survey covers a 3.5 km section of Henretta Creek upstream of Henretta Lake (i.e., upstream of FRO licensed water use; Table 2.3; Figure 2.2). Additional seasonal drying surveys were added from October to December 2021, allowing for biweekly monitoring of the drying conditions; however, these additional surveys excluded Side channel 2 and the Greenhouse side channel. Methods followed those used in previous years; field crews walked each section to delineate any extent of drying, isolated pools, fish, and wildlife observations by marking them with a handheld global positioning system (GPS) and on an iPad with geo-referenced map to facilitate mapping (Minnow and Lotic 2019b, 2020b, 2021b). Drying sections were also recorded as GPS tracks on an iPad to facilitate mapping and estimate the extent of drying.

2.3.1.2 Data Analysis

Coordinates (taken by GPS) and tracks collected during the drying surveys were mapped to display the monthly/biweekly conditions and any observed drying sections of the Fording River. The results of monthly surveys were used, in combination with water level logger data and trail cameras, to determine the exact dates when a section of the Fording River had become dry between visits. Dry days for each survey section and hydrometric station were summarized for each year from 2017 to 2021. Dry days were calculated for each low flow season (e.g., winter of 2020/21) not per calendar year.

2.3.2 Water Level and Temperature

2.3.2.1 Data Collection

Water level and temperature were continuously monitored at 13 hydrometric stations in 2021 using a combination of three types of level loggers, which were installed in stilling wells (Figure 2.2). The combination of loggers was included for protection against the loss of data in the event of a logger malfunction and included Solinst M5 loggers (primary), Solinst 3250 LevelVent Dataloggers (secondary), and Onset Hobo U-20 level-loggers (tertiary; Table 2.3). The loggers were programed to record water level and water temperature at 15-minute intervals. Data was downloaded from the loggers pre-freshet in April, post-freshet in July, and October before freeze-up to avoid data loss.

A new hydrometric station was installed in the northern survey area at FR_FOUCL in April 2021. The station is located upstream of the Clode Creek confluence, which will receive treated water from the FRO-N SRF outfall once commissioned in 2022. In the southern survey area, the stilling well at FR_FRCP1 was damaged during freshet in June 2021, but all data was recovered and a new stilling well was installed.

2.3.2.2 Data Analysis

Continuous water level data were collected and corrected for barometric pressure from October 2017 to October 2021, where applicable. For each hydrometric station, a log-linear stage-discharge curve was generated using manual stage and discharge measurements. Stage (m) and discharge (m^3/s) values were manually verified and measurements with suspected errors or high uncertainty (e.g., flows conducted under ice conditions) were removed from further analyses. All stage measurements below 0.001 m were treated as 'dry' and were excluded. Benchmarks were checked for each site and shifts were corrected. The water level record was also verified by comparing to manual measurements and spikes and other erroneous readings were cleaned. Hourly discharge and stage records were compared against manual observations to calculate the Offset (m), Absolute Error (m^3/s), and the mean Relative Error (Absolute Error divided by Measured Flow; %; Schaefer and Chernos 2022).

Solinst M5 loggers and barometers were installed in 2021 as the new primary logger to extend water level and temperature records as they provide an increased measurement accuracy compared to the Hobo U20 level loggers and the same level of accuracy as the Solinst LevelVent (+/- 0.03cm and +/- 0.05˚C). Solinst LevelVent loggers internally correct for barometric pressure, and therefore do not require a barometer for barometric correction after they are downloaded. In 2020, Solinst LevelVent loggers were observed to malfunction if submerged (i.e., freshet). If submerged, Solinst LevelVent loggers were unable to accurately internally correct for barometric pressure or would no longer communicate due to water damage. Solinst LevelVent loggers and Hobo U20 level logger records were used in the event of data loss or logger malfunction of the primary logger. Solinst M5 water level data were corrected for barometric pressure manually in Microsoft Excel using the barometric record and a reference water stage relative to the staff gauge. Correcting the data for atmospheric pressure created a continuous record of water stage in meters. Stage is a locally reference water level relative to the staff gauge at a given location, however, stage records are only relative to that station and cannot be used to compare water level or quantity between sites. Stage is subsequently converted to discharge using stage-discharge relationships to generate annual hydrographs (Section 3.2). Water level and temperature records were used in combination with field observations to determine the date when a site was observed to be dry or rewetted between drying surveys.

2.3.3 Flow

2.3.3.1 Data Collection

Monthly discharge measurements were collected by field crews at each station using a Hach EM950 velocity meter, where surface flow conditions permitted (i.e., wadable and limited ice cover). Flow measurement methods were consistent with those reported previously (Minnow and Lotic 2018, 2019b, 2020b, 2021b), following the Manual of British Columbia Hydrometric Standards (RISC 2009). The Hach EM950 profiler function was used to determine if flow panels exceeded 10% of the discharge in the field to increase hydrological data grading in 2021. During ice covered visits, a transect was cut into the ice by hand or a minimum of five holes were drilled through the ice with an auger to get an estimate for discharge; however, winter flow measurements under ice are unlikely to serve as reliable data points and are for informational purposes only. Ice affected discharge measurements were flagged and were not used in stage-discharge development. One high flow measurement was collected at each site in June 2021 using a Sontek M9 ADP unit to enable flows to be collected without wading and to assist in developing the upper end of each rating curve. Benchmark surveys were completed three times a year at each site before level loggers were downloaded to determine if the stilling well had shifted and to comply with Resources Information Standards Committee (RISC) standards (RISC 2009).

2.3.3.2 Data Analysis

Paired stage readings and manual discharge measurements at each site were used to develop site specific power function stage-discharge relationships. The stage discharge relationship was used to convert the continuous water level records recorded at each site into a discharge record. Stage (m) and discharge (m^3/s) values were manually verified and qualitatively determined outliers (relative to the existing relationship) or measurements with high uncertainty (e.g., flows conducted under ice conditions) were removed from the stage-discharge relationship. All stage measurements below 0.001 m were treated as ‘dry’ and were excluded. A discharge time series (i.e., hydrograph) was plotted for each site. Lotic retained MacDonald Hydrology Consultants for senior review and quality grading of the hydrological data. Grades were assigned for each site following British Columbia Ministry of Environment Hydrological RISC Standards (RISC 2009).

2.4 Substrate Quality

2.4.1 Sediment

2.4.1.1 Sample Collection

Sediment quality samples were collected concurrently with benthic invertebrate sampling at eight areas in September 2021 (RG_HENUP, RG_FO26, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBCP, RG_FRUPO, and RG_FO22; Table 2.2). Five replicates were collected at mine-exposed areas, and three replicates were collected at reference areas, consistent with methods outlined in the 2021 to 2023 RAEMP study design (Minnow 2021a). Sediment samples were collected using a stainless-steel spoon and were transferred into glass jars for analysis of polycyclic aromatic hydrocarbons (PAHs), and into polyethylene bags for all other analyses (i.e., metals, moisture content, total organic carbon, and particle size distribution). Surficial sediment was collected by slowly and carefully placing the spoon on the sediment surface in a manner that minimized disturbance and inserting the spoon into the sediment to capture sediment to a depth of 1 to 2 cm. The spoon was then slowly lifted to the surface to avoid sample washout. The content of each spoonful was inspected to confirm that it was predominantly fine sediment (i.e., no pieces of vegetation, woody debris, or rocks, and minimal sand), and, if acceptable, was placed into a clean plastic tub. This procedure was repeated to form a composite sample representative of the sampling area with sufficient material for analysis, and the stainless-steel spoon was used to homogenize the sediment. Sampling equipment was rinsed with site water between stations. Due to shear stress and deposition characteristics of lotic environments in the upper Fording River, sediment was collected in small pockets of depositional areas, predominantly along the riverbank and often behind habitat structures that reduced flow. These areas were generally found within 10 to 100 meters of riffles where biological samples were collected.

For QA/QC purposes, one duplicate (split) sample was collected at a frequency of approximately 3% of the total number of samples for monitoring areas in the FRO LAEMP (i.e., two duplicate samples), but an overall frequency of 10% was sampled in the Elk River watershed as part of the greater RAEMP and LAEMP sampling in September 2021 and will be evaluated in the 2020 to 2022 RAEMP report. Following collection, samples were placed in a refrigerator at approximately 4°C until submission to the analytical laboratory.

2.4.1.2 Laboratory Analysis

Samples for chemical analysis were sent to ALS Environmental (ALS; Calgary, AB). The laboratory was instructed to thoroughly homogenize each sediment sample (according to standard laboratory protocols), to confirm the aliquots taken for analysis were representative and comparable.

Sediment samples were analyzed using the following methods: metals by CRC ICP-MS (EPA 200.2/6020A), mercury by Cold Vapour Atomic Fluorescence Spectroscopy (CVAFS; EPA 200.2/245.7), TOC by combustion method (Bartels and Sparks 2009), and PAHs by rotary extraction using hexane/acetone (EPA 3570/8270) followed by capillary column gas chromatography with mass spectrometric detection (GC/MS). Particle size distribution was determined by dry sieving (coarse particles), wet sieving (sand), and the pipette sedimentation method (fine particles). Moisture content was determined gravimetrically by drying the sample at 105°C.

Sediment chemistry data collected for the 2021 FRO LAEMP were of acceptable quality as characterized by appropriate LRLs, excellent laboratory precision and accuracy, good field precision and reproducibility, and no hold time exceedances (Appendix A). Overall, the associated data were considered acceptable for this study.

2.4.1.3 Data Analysis

Sediment quality data were tabulated, summarized, and compared to British Columbia Working Sediment Quality Guidelines (WSQGs), except for selenium concentrations which were compared to an alert concentration considered equivalent to an upper WSQG (BCMOECCS 2019, 2021). The sediment data were also compared to reference area normal ranges, which were the 2.5th and 97.5th percentiles of pooled reference area distribution after removal of outliers (Minnow 2021b). Normal ranges could not be calculated for several PAHs because most of the values were below laboratory reporting limits (LRL). Data from 2017 to 2021 were plotted for all constituents for which a WSQG was available and visually assessed for temporal changes.

2.4.2 Calcite

Measurements of calcite presence and concretion were conducted on 100 particles (pebbles) at each biological sampling location concurrent with (and using the same particles as) the 100-pebble count. Calcite presence (Cp) has historically been a binary assessment (i.e., presence [score = 1] or absence [score = 0]; Teck 2016, Lotic 2021). In 2021, an additional method for assessing calcite presence in lotic environments was included (Cp', Lotic 2021, Zathey et al. 2021, Robinson et al. 2022) that scored the percent of the particle surface area covered by calcite as a decimal to the nearest 10th percentile (0.1, 0.2, 0.3, etc.; see Appendix G). The degree of concretion (Cc) was assessed by determining if the particle was removed with negligible resistance (not concreted; score = 0), noticeable resistance but removable (partially concreted; score = 1), or immovable (fully concreted; score = 2). If distinct particles were not visible due to heavy calcification, values of 1 (for presence) and 2 (for concretion) were recorded. If fines were encountered and calcite presence could not be visually confirmed, values of 0 (for presence) and 0 (for concretion) were recorded. If rocks were visible under fine material, the rock was selected for calcite measurements.

2.4.2.1 Data Analysis

The results for the 100 particles were expressed as a Calcite Index (CI and CI') based on the following equations (Lotic 2021, Zathey et al. 2021, Robinson et al. 2022):

$$CI = C_p + C_c \text{ or } CI = C_p{}' + C_c$$

Where:

$$CI \text{ or } CI' = Calcite\ Index^{9}$$

$$C_p = Calcite\ Presence\ Score = \frac{Number\ of\ particles\ with\ calcite}{100\ (binary\ score)}$$

$$C_p{}' = Calcite\ Presence\ Score = \frac{Number\ of\ particles\ with\ calcite}{100\ (proportional\ score)}$$

$$C_c = Calcite\ Concretion\ Score = \frac{Sum\ of\ particle\ concretion\ scores}{100}$$

Calcite data collected as part of the Regional Calcite Monitoring Program (Lotic 2022) were reported but were not used in analyses as the calcite measurements taken concurrently with biological sampling were deemed more appropriate because they are representative of the areas sampled for benthic invertebrates (i.e., riffles).

2.5 Benthic Invertebrates

2.5.1 Community Structure

2.5.1.1 Sample Collection

Triplicate BIC samples were collected at each of the FRO LAEMP biological monitoring areas in June and September 2021, except for RG_FOBCP and RG_FO22 where five replicates were collected in September to fulfill requirements under the 2021 to 2023 RAEMP study design (Table 2.2; Minnow 2021a). Triplicate samples were also collected in December 2021 at select areas in the lower part of the study area (Table 2.2). Sampling of BIC deviated from the study design on two occasions; BIC samples were not collected at biological monitoring area RG_FOBCP (located at the old Compliance Point) in December due to very thick ice

[9] CI refers to the binary assessment of Cp and CI' refers to the proportional assessment of Cp'.

conditions at the time of sampling, and BIC sampling was added at RG_FO22 (the new Compliance Point) in December.

Benthic invertebrate community sampling followed the Canadian Aquatic Biomonitoring Network (CABIN) method, which involved 3-minute travelling kick sampling in riffle habitats into a net with a triangular aperture measuring 36 cm per side and mesh having 400 µm openings (Environment Canada 2012a). During sampling, the field technician moved across the stream channel (from bank to bank, depending on stream depth and width) in an upstream direction. With the net being held immediately downstream of the technician's feet, the detritus and invertebrates disturbed from the substrate were passively collected in the kick-net by the stream current. After three minutes of sampling time, the sampler returned to the stream bank with the sample. The kick-net was rinsed with water to move debris and invertebrates into the collection cup at the bottom of the net. The collection cup was then removed and the contents poured into a labelled plastic jar and preserved to a level of 10% buffered formalin in ambient water. Replicate samples were spaced either in separate riffles or a minimum of 50 m apart (when the area was a continuous riffle).

2.5.1.2 Laboratory Analysis

Benthic invertebrate community samples were sent to Cordillera Consulting (lead taxonomist Scott Finlayson), in Summerland BC, for sorting and taxonomic identification. Organisms were identified to the lowest practical level (LPL; typically genus or species). At the beginning of the sorting process, each sample was examined and evaluated for estimation of total invertebrate numbers. If the total number was estimated to be greater than 600, then the laboratory's sub-sampling protocol was followed. A minimum of 5% of each sample was sorted, in accordance with Quality Assurance/Quality Control (QA/QC) requirements of Environment Canada (Environment Canada 2014). Sorting efficiency and sub-sampling accuracy and precision were quantified using methods specified by Environment Canada (Environment Canada 2012b, 2014).

A data quality review (DQR) was conducted on the 2021 BIC data (Appendix A). Overall, benthic invertebrate community structure data were of acceptable quality and the associated data can be used with a high level of confidence in the derivation of conclusions.

2.5.1.3 Supporting Measures

Consistent with the requirements of the CABIN sampling protocol, supporting habitat information (i.e., water velocity and depth, *in situ* water quality [temperature, dissolved oxygen [DO], conductivity, pH], and substrate characteristics [Wolman 100-pebble count and substrate embeddedness]) was collected concurrent with BIC sampled in riffle habitats

(Environment Canada 2012a). Periphyton scores were also ascribed to each biological monitoring area during September sampling, and according to CABIN sampling protocol (Environment Canada 2012a). The scoring was ascribed as follows:

1 – rocks not slippery, no obvious colour (<0.5mm thick);

2 – rocks slightly slippery, yellow-brown to light green in colour (0.5-1mm thick);

3 – rocks have noticeable slippery feel, patches of thicker green to brown algae (1-5mm thick);

4 – rocks are very slippery, numerous clumps (5-20mm thick); and

5 – rocks mostly obscured by algae mat, may have long strands (>20mm thick).

2.5.1.4 Data Analysis

Benthic invertebrate community structure was evaluated based on total abundance, taxonomic richness (to the lowest practicable level of taxonomy), the abundances and relative abundances (%) of major taxonomic groups, and habitat and feeding indices (Table 2.6; Appendix Table E.1). Analyses of benthic invertebrate community data were completed using the following approaches (see Appendix J for detailed methodology):

- Graphical (temporal and spatial) comparison of data relative to regional[10] and, when applicable, site-specific normal ranges[11];Graphical comparison of seasonal changes in BIC endpoints (2018 to 2021)
- Evaluation of temporal changes in BIC endpoints using a two-way ANOVA with post-hoc contrasts testing for differences among years for each station;
- Assessment of BIC structure using correspondence analysis.

Benthic invertebrate community data collected in September were the focus of data analyses and interpretation. Data from other seasons (June and December) were used in seasonal visual data evaluations

[10] The reference normal range as presented in the RAEMP represents the 2.5th and 75th percentiles of the distribution of reference area data (pooled 2012 to 2019 data) reported in the 2017 to 2019 RAEMP report (Minnow 2020).

[11] Site-specific normal ranges represent the 2.5th and 97.5 percentile for a given area as determined by habitat predictors for a given site in relation to the complete set of Elk Valley monitoring areas. The site-specific normal ranges were estimated using regression modelling as presented in the RAEMP (Minnow 2020).

Table 2.6: Benthic Invertebrate Community Index Descriptions, FRO LAEMP, 2021

Index	Description
Autotrophic to Heterotrophic Index	Reflects the ratio of energy use by the benthic invertebrate community (BIC) as primary productivity within the stream from algae growth to heterotrophic energy sources (e.g., leaves and sticks)
Shredder Index	Reflects the ratio of coarse particulate organic matter (CPOM) to fine particulate matter (FPOM) used by BIC
Filtering Collector Index	Reflects the ratio of suspended Fine Particular Organic Matter (FPOM) to depositional FPOM used by the BIC
Predator Index	Reflects the abundance of predators
Benthic to Hyporheic Index	Reflects the ratio of habitats used by BIC, reflects sediment stability and flow permanence

2.5.2 Tissue Selenium Concentrations

2.5.2.1 Sample Collection

Composite-taxa benthic invertebrate tissue samples were collected in June, September, and December from mine-exposed and reference areas included in the FRO LAEMP and to support pre-commissioning monitoring for the FRO-S AWTF (Table 2.2; Minnow and Lotic 2021a). Replicates of five tissue samples were collected at areas associated with the FRO AWTF- S commissioning sampling plan (Minnow and Lotic 2021a) to increase statistical power for pre- and post-commissioning comparisons. This included mine-exposed areas located between downstream of the South Tailings Pond (RG_FOUKI) and upstream of Ewin Creek (RG_FOUEW) as well as the Greenhouse side-channel (RG_FRGHSC) and side channel 2 (RG_FRSCH2), and the reference area located immediately upstream of mining in the Fording River (RG_UFR1). Triplicate samples were collected at the remaining areas. Benthic invertebrate tissue samples were not collected at RG_FRCP1SW in December 2021 because the riffles were dry or frozen.

Composite-taxa benthic invertebrate tissue samples were collected for selenium analysis using the kick sampling method described in Section 2.5.1, except that the sampling was not timed, and kicking continued until sufficient sample was collected. Replicate samples were collected either in separate riffles or a minimum of 50 m apart (when the area was a continuous riffle)[12]. Invertebrates were picked free of debris in the field, placed into sterile labelled cryovials and stored in a cooler with ice packs until they were transferred to a freezer later in the day. Approximately 2 g of wet tissue were collected for each sample where possible, and composite-taxa samples were representative (proportional) of the invertebrates collected from the kick and sweep.

2.5.2.2 Laboratory Analysis

Benthic invertebrate tissue samples were kept in a freezer until they were shipped in coolers on ice to TrichAnalytics Inc. (Trich) in Saanichton, BC. At the laboratory, samples were freeze-dried and analyzed for metals (including selenium) using laser ablation inductively coupled plasma spectrometry (LA-ICPMS). Results were reported on a dry weight (dw) basis, along with moisture content (based on the difference between wet and freeze-dried sample weights).

A DQR was conducted on the 2021 benthic invertebrate tissue data (Appendix A). Benthic invertebrate tissue data collected for the 2021 FRO LAEMP were of good quality as

[12] Benthic invertebrate tissue samples at RG_FOBCP in December 2021 were all collected within the same riffle because it was the only riffle that could be accessed after breaking through approximately 30 cm of ice.

characterized by appropriate LRLs and excellent laboratory precision and accuracy, and the data can therefore be used with a good level of confidence in the derivation of conclusions.

2.5.2.3 Data Analysis

Composite-taxa benthic invertebrate tissue selenium concentrations were plotted for each FRO LAEMP monitoring area sampled in 2021 relative to:

- the regional normal (reference area) range, defined as the 2.5th and 97.5th percentiles of tissue selenium concentrations measured in reference areas that have not been disturbed by mining in historical studies completed in the Elk River watershed from 1996 to 2019 reported in RAEMP (Minnow 2020);
- data from previous sampling periods from 2012 to present, where available;
- the Level 1 EVWQP benchmarks for effects to invertebrates (13 milligrams/kilogram [mg/kg] dry weight [dw]), dietary effects to birds (15 mg/kg dw), and dietary effects to juvenile fish (11 mg/kg dw; Golder 2014);
- the Level 2 EVWQP benchmarks for effects to invertebrates (20 milligrams/kilogram [mg/kg] dry weight [dw]), dietary effects to birds (22 mg/kg dw), and dietary effects to juvenile fish (18 mg/kg dw; Golder 2014); and
- the Level 3 EVWQP benchmarks for effects to invertebrates (27 milligrams/kilogram [mg/kg] dry weight [dw]), dietary effects to birds (41 mg/kg dw), and dietary effects to juvenile fish (26 mg/kg dw; Golder 2014).

Tissue selenium concentrations were paired with corresponding water selenium concentrations and compared to predictions from selenium bioaccumulation model (Golder 2020a) and the bioaccumulation tool (i.e., the ‘B-tool; predicts selenium tissue concentrations accounting for differences in selenium species and sulphate concentrations [Golder 2020b]).

2.5.3 Biomass

2.5.3.1 Sample Collection

Benthic invertebrate biomass and density samples were collected in September from 2017 to 2021 to assess biological productivity before commissioning of the FRO-S AWTF and the FRO-N SRF. Ten replicate stations were sampled at each of twelve biological monitoring areas (mine exposed: RG_FOUCL, RG_FOUNGD, RG_FOUKI, RG_FOBKS, RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, RG_ FRUPO, and RG_FO22; reference: RG_FO26, RG_HENUP) in September 2021 for analysis of benthic invertebrate biomass and density (Table 2.2; Figure 2.1). Benthic invertebrates were collected using a Hess sampler with 500 µm mesh, for measurement of biomass and community endpoints relative to the area sampled. Stations were located a minimum of 5 m a part, so they were representative of the overall monitoring area. A single sample was collected at each station by carefully inserting the base of the Hess sampler into the substrate to a depth of approximately 5 to 10 cm. Gravel or cobble enclosed within the Hess sampler was carefully washed while allowing the current to carry dislodged organisms into the mesh collection net. Organisms collected into the net were rinsed into the bottom of the net, and then into a labelled wide-mouth plastic jar. Samples were preserved to a level of 10% buffered formalin in ambient water within approximately 6 hours of collection to ensure that biomass was not lost through predation or decomposition of tissues before the samples were sorted at the laboratory.

2.5.3.2 Laboratory Analysis

Benthic invertebrate biomass and density (Hess) samples were sent to Zeas Inc. (lead taxonomist Danuta Zaranko), in Nobleton ON, for sorting and taxonomic identification. At the laboratory, preserved organisms in each sample were sorted from the sample debris, identified, and weighed at the family-level of taxonomy. Each family group of organisms was placed onto a fine cloth to drain excess surface moisture before being weighed to the nearest 0.1 mg. Total and family-level density and biomass were reported for each sample (preserved wet weight; see Appendix K for laboratory reports).

2.5.3.3 Data Analysis

Laboratory data for benthic invertebrate biomass and density samples were converted to units of number of organisms per square meter (org/m^2) based on the known area sampled. Biomass and density data from 2017 to 2021 were plotted and changes were visually compared to assess spatial and temporal patterns pre-commissioning of the FRO-S AWTF.

2.6 Fish

2.6.1 Sample Collection

Non-lethal sampling of mature WCT for muscle selenium concentrations is required under the RAEMP once per monitoring cycle (Minnow 2021a). In September 2021, samples were collected from WCT sampling areas around RG_FODGH13 and RG_FOBCP14,15 for monitoring water quality under Permit 107517, and at two reference areas (Bull River, Flathead River), in accordance with the approved RAEMP study design (n=8 per area; Minnow 2021a). In addition to regular RAEMP sampling, adult female WCT were collected non-lethally during the spring spawning window (June) in accordance with ECCC direction to collect three samples at two areas of the upper Fording River. The first area was Clode Flats (RG_CLFL), located between Henretta Creek and the Multiplate culvert, and the second area was located in the Fording River S6 Oxbow area (RG_FROXB). In addition to fish sampling under the RAEMP, Teck collects tissue (dorsal muscle and whole body) samples from WCT incidental mortalities and fish salvages when relevant, to add valuable information to the dataset on fish selenium concentrations.

Sampling methods followed those outlined in the RAEMP study design (Minnow 2021a). Upon capture, fish were anesthetized using clove oil prior to processing. Measures of body weight were collected using appropriately sized spring scales (e.g., 100 g, 500 g, 1,000 g), and total and fork lengths were recorded using a measuring board equipped with a meter stick (± 1 mm). All fish were inspected for any external anomalies such as deformities, erosions (fin and gill), lesions, tumors, injuries, infections and/or parasites during processing and representative photographs were collected (Minnow 2021a). A biopsy punch was used to collect a non-lethal muscle sample from each fish, and Vetbond™ tissue adhesive was used to seal the wound and prevent infection. Skin was removed from each muscle sample using a scalpel and the remaining tissue was placed into a sterile microcentrifuge tube. Samples were stored on ice in the field and transferred to a freezer later in the day. Tissue samples were kept in a freezer until they were transported overnight in coolers with ice packs to an accredited laboratory.

2.6.2 Laboratory Analysis

Fish tissue samples were kept in a freezer until they were shipped in coolers on ice to TrichAnalytics Inc. (Trich) in Saanichton, BC. At the laboratory, samples were freeze-dried and analyzed for metals (including selenium) using laser ablation inductively coupled plasma spectrometry (LA-ICPMS). Results were reported on a dry weight (dw) basis, along with moisture content (based on the difference between wet and freeze-dried sample weights).

---

[13] Fording River between Chauncey Creek and Greenhills Creek.

[14] Monitoring area RG_FOBCP is associated with Teck's water quality station FR_FRCP1. At the time the 2021 to 2023 RAEMP study design was submitted (February 2021), FR_FRCP1 was the Compliance point for FRO; this was changed to FR_FRABCH later in 2021

[15] As sampling success is dependent on where fish are located, WCT associated with RG_FOBCP were caught further upstream at sampling area RG_MP1 (located downstream of the Multiplate culvert) but are still considered representative of fish from the area.

2.6.3 Data Analysis

For the purposes of the FRO LAEMP report, muscle selenium concentrations of WCT from RAEMP fish sampling in the upper Fording River in 2021 were plotted with data from 2018 (where available), reference area data, and in comparison, to the applicable site-specific muscle benchmark (15.5 mg/kg dw; muscle equivalent site-specific benchmark; Nautilus and Interior Reforestation 2011) and the British Columbia selenium guideline for fish muscle (4 mg/kg dw; BCMOE 2014. Additionally, tissue selenium concentrations from incidental mortality WCT samples were plotted with reference area data, and in comparison to the British Columbia selenium guideline for fish muscle. Corresponding meristics data (total weight, length and fork length) were tabulated along with observations of anomalies and calculated Fulton's condition factor. Condition factor was also plotted for visual comparison among areas.

2.7 Integrated Analysis

Factors contributing to BIC variation within the FRO LAEMP study area were evaluated by comparing BIC endpoints with water quality, and where applicable, habitat variables. Correlation analysis and canonical correspondence analysis (CCAs) were conducted on data from the full study area, and then three individual study areas (upper, middle, and lower) within the full study area. The upper, middle, and lower study areas were grouped based on spatial differences of habitat (water depth, water flow/velocity, water temperature, substrate size, etc.) and water quality identified in previous FRO LAEMP reports (Minnow and Lotic 2019b, 2020b). Integrated analyses were completed using the following approaches (see Appendix J for detailed methodology):

- Nitrate concentrations were analyzed with a Linear Model (LM) and BIC endpoints (abundance, richness, % EPT, and % Ephemeroptera) were analyzed with a Linear Mixed-Effects Model (LMM) to identify concurrent changes in nitrate concentrations and BIC endpoints at biological monitoring areas.
- Spearman Rank Correlations were conducted between key BIC endpoints and physical and chemical variables (Appendix Table F.1);
- A CCA was performed to investigate patterns in BIC in June and September of 2018 to 2021 relative to habitat (Tables 2.7 and 2.8) and physical and chemical variables. Importance of individual stressor and habitat variables were investigated with permutation-based ANOVAs.

Table 2.7: Summary of Habitat Variables Used in Canonical Correspondence Analysis of Benthic Invertebrate Community, FRO LAEMP, 2020

3 RESULTS

3.1 Water Chemistry

3.1.1 Water Quality

Water quality data will be interpreted to address Study Questions #1, #2, #3, #5, and #6 (see Sections 4.1, 4.2, 4.3, 4.5, and 4.6). Water quality constituents were summarized, tabulated, and screened against relevant BCWQGs, EVWQP benchmarks, and screening values, where applicable (Appendix Table B.1). Constituents with EWTs and identified as mine-related under the AMP were plotted from 2012 to 2021 and compared with BCWQGs, EVWQP benchmarks, and screening values (Appendix Tables B.1 and B.2; Appendix Figures B.1 to B.18). Concentrations of water quality constituents were typically the highest in the winter months when water flows were lowest (Appendix Figures B.1 to B.18). Of the Order constituents under the EVWQP (dissolved cadmium, sulphate, nitrate, total selenium), dissolved cadmium concentrations were the lowest and concentrations were consistently below the EVWQP Level 1 benchmark at all water quality stations evaluated in the FRO LAEMP in 2021 (Appendix Table B.1; Appendix Figure B.4). Sulphate concentrations were above the EVWQP Level 1 benchmark between FR_SCOUTDS and FR_FRCP1, and at FR_FRRD throughout the winter months only (Appendix Table B.1; Appendix Figure B.16). Except for the freshet period, nitrate concentrations were above the EVWQP Level 1 benchmark at all mine-influenced water quality stations evaluated in the FRO LAEMP, and above the EVWQP Level 2 benchmark at all stations except for FR_FRCP1SW (Appendix Table B.1; Appendix Figure B.11). Total selenium was seasonally (lower flow months of summer, fall, and winter) above the EVWQP Level 1 benchmark from RG_FOUNGD downstream to FR_FR5 (Appendix Table B.1; Appendix Figure B.15). Total nickel concentrations were above the Level 1 interim screening value during low flow months from RG_FOUNGD downstream to FR_FRRD (Appendix Table B.1; Appendix Figure B.10). Total dissolved solids were above the Level 1 screening value between FR_SCOUTDS and GH_PC2 throughout the low flow winter period (Appendix Table B.1; Appendix Figure B.6). Of the remaining mine-related constituents with BCWQGs, nitrite concentrations were above the long-term BCWQG at only three stations within the study area (FR_FRABEC1, FR_FR2, and FR_FR3) during the winter Appendix Table B.1; Appendix Figure B.12), and total zinc was atypically high in one sample at the reference area RG_FO26, which was above the long-term BCWQG (Appendix Table B.1). None of the other mine-related constituents (total antimony, total barium, total boron, dissolved cobalt, total manganese, and total molybdenum) were measured at concentrations greater than their respective guidelines, and no BCWQG is available for total lithium. Except for ammonia at FR_FRNTP, which was above the long-term BCWQG in 6% of samples, no other constituents (total chloride, total beryllium, total lead, total mercury, total silver, total thallium, total uranium, dissolved aluminum, dissolved copper, and dissolved iron) were above BCWQGs, where available (Appendix Table B.1).

Seasonal mean concentrations of Order constituents (nitrate, total selenium, dissolved cadmium, and sulphate) and total nickel in 2021 were plotted spatially (Appendix Figure B.19). Total selenium concentrations were highest between FR_SCOUTDS and FR_FR5, peaking in the middle study area at FR_FRCP1 in winter 2021 (Appendix Figure B.19). Nitrate concentrations were consistently elevated in the Fording River from upstream of Clode Creek (FR_FOUCL) to FR_FR5 throughout the winter, when visually compared to reference areas (Appendix Figure B.19). Sulphate concentrations followed a similar spatial pattern as total selenium with the highest concentrations observed between FR_SCOUTDS and the current Compliance Point at Chauncey Creek (FR_FRABCH) during late summer through to winter (Appendix Figure B.19). Dissolved cadmium concentrations, while below EVWQP benchmarks, were highest in late summer between FR_SCOUTDS and FR_FRCP1, with the highest concentrations observed in between at water quality station FR_FR4 (Appendix Figure B.19). Total nickel concentrations varied spatially, increasing throughout the upper study area (from Henretta Creek to upstream of the South Tailings Pond), then leveling off before increasing between FR_SCOUTDS and FR_FRCP1 in the middle study area, then decreasing substantially in the lower study area (Appendix Figure B.19). Concentrations of dissolved cadmium and total nickel were frequently highest during freshet in the lower study area (FR_FRRD downstream to FR_FR5), while nitrate, sulphate, and total selenium were the highest during low flow seasons (Appendix Figure B.19).

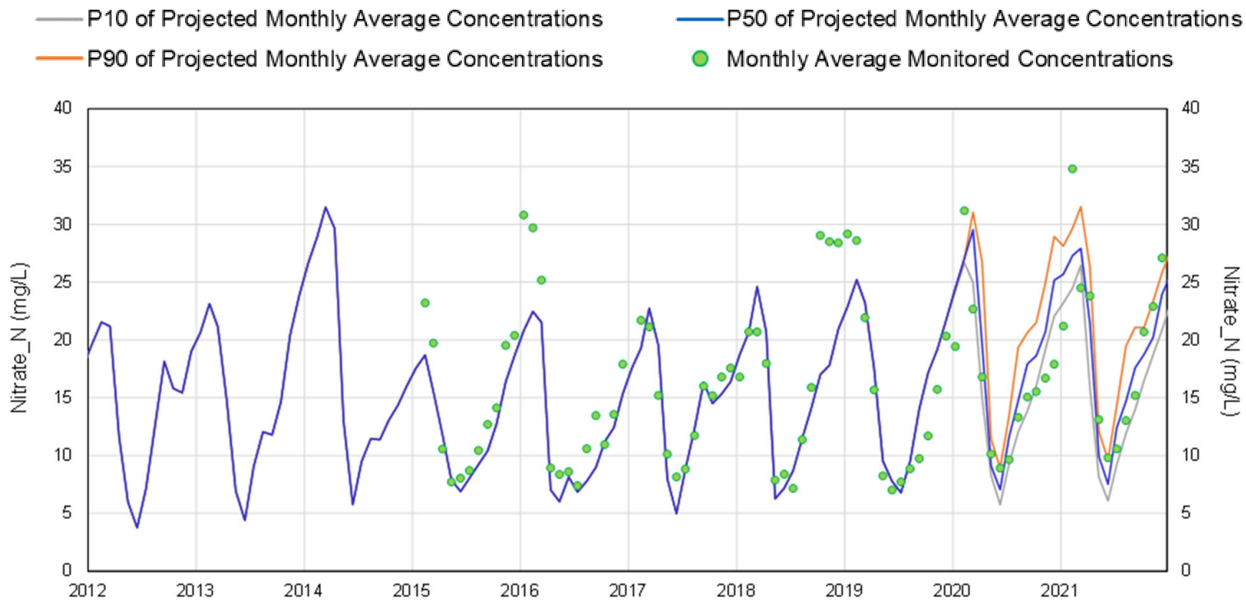
To evaluate changes in water quality over time (2012 to 2021), nutrients and mine related constituents identified under the AMP were statistically analyzed for temporal trends (Appendix Table B.3). Annual mean dissolved cadmium concentrations were significantly higher in 2021 at six stations (FR_MULTIPLATE, FR_FRNTP, FR_FR4, FR_FRCP1, FR_FRRD, and FR_FRABCH) compared to the base year; however, only FR_MULTIPLATE and FR_FRCP1 were higher in 2021 compared to all annual historical means (Appendix Table B.3), and all values were below EVWQP Level 1 benchmark (Appendix Table B.1). Total nickel concentrations in 2021 were higher than the base year at several stations throughout the FRO LAEMP study area (FR_MULTIPLATE downstream to FR_FR4, and at GH_PC2 and FR_FR5), but only concentrations at FR_SCOUTDS were higher than all historical annual means (Appendix Table B.3). Nitrate concentrations in 2021 were significantly higher than the base year at all stations within the FRO LAEMP study area except for the Fording River downstream of Henretta Creek (FR_FR1) and the Fording River downstream of Porter Creek (GH_PC2). Several stations (FR_MULTIPLATE, FR_FRNTP, FR_FR2, FR_SCOUTDS, and FR_FRABCH) had concentrations above the range of annual historical means in 2021 (Appendix Table B.3). Nitrite concentrations were significantly higher than the base year at five stations in 2021 (FR_MULTIPLATE, FR_FRNTP, FR_SCOUTDS, FR_FRCP1, and FR_FRABCH), but only concentrations at the FR_SCOUTDS were greater than all annual historical means and indicated a consistent increase over time (Appendix Table B.3). Total selenium, sulphate, and TDS concentrations were higher than the base year at all stations within the study area in 2021, except for FR_FR1, FR_MULTIPLATE, FR_SCOUTDS, and FR_FRCP1; however, the concentrations in 2021 were similar to one or more historical annual means and have not indicated a consistent increasing temporal trend (Appendix Table B.3). Although total uranium concentrations were also higher than the base year at all stations within the study area except FR_FR1, FR_SCOUTDS, and FR_FRCP1 in 2021 (Appendix Table B.3), no concentrations were above BCWQGs (Appendix Table B.1). Annual mean concentrations of total phosphorus and orthophosphate in 2021 were not statistically different than the base year or the annual historical means at any stations throughout the study area (Appendix Table B.3). While some statistically significant changes were observed for other constituents with EWTs, concentrations were below guidelines or benchmarks.

Principal component analysis (PCA) was conducted on water quality samples from 2012 to 2021 (Appendix Table B.4) to summarize water chemistry variables for use in the correlation analysis (Section 3.5). Principal component axis 1 (PC1) and principal component axis 2 (PC2) explained 50% and 26% of the variation in water chemistry, respectively. Almost all mine-related water quality constituents had significant and strong positive correlations with PC1, whereas fewer constituents had a significant and strong correlation with PC2 (Appendix Table B.4). Given that most constituents included in the PCA correlated strongly with PC1, the explanatory power of PC1 was high, but the influence of individual constituents remained low.

3.1.1.1 Modelled Nitrate Concentrations

Nitrate concentrations are currently modelled in the upper Fording River at the former FRO Compliance point (FR_FRCP1), the current FRO Compliance point (FR_FRABCH), and the GHO Fording River Compliance point (GH_FR1; Fording River Order Station under Permit 107517). Measured concentrations at each station were plotted with modelled concentrations to assess current conditions against expectations (Golder 2022b). Nitrate concentrations measured from each station demonstrated seasonal highs during low flow periods (i.e., fall and winter), which were consistently above median (50^{th} percentile; P50) projected monthly average concentrations (Figure 3.1; Golder 2022b). To account for the low flow conditions and the subsequent elevated nitrate concentrations, 90^{th} percentile (P90) monthly average concentration model projections were integrated into modelling beginning in 2020.

Former FRO Compliance Point (FR_FRCP1; E300071)



Current FRO Compliance Point (FR_FRABCH; E223753)

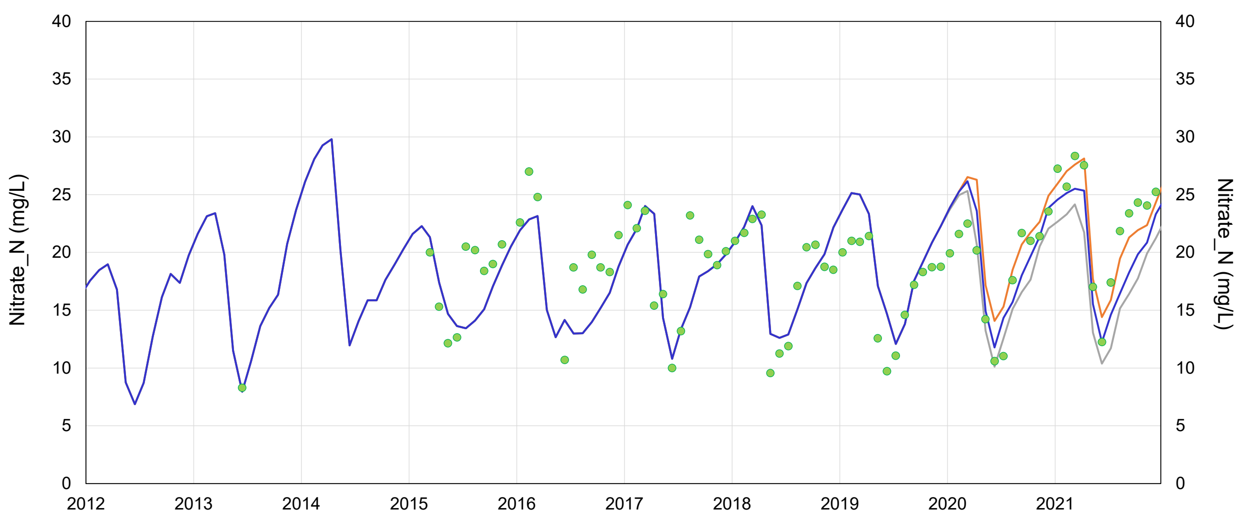


Figure 3.1: Average Monthly Nitrate Concentrations for FR_FRCP1, FR_FRABCH, and GH_FR1 under Low, Medium, and High Flows, FRO LAEMP, 2021[a]

Notes: The solid grey, blue, and orange lines correspond to the P10, P50 and P90 of modelled monthly average concentrations using 20 climate realizations. Monitored monthly average concentrations are indicated by green circles, noting that all 2021 monitored flows are preliminary and are subject to review and adjustment.

[a] Golder 2022a

GHO Fording River Compliance Point (GH_FR1; 0200378)

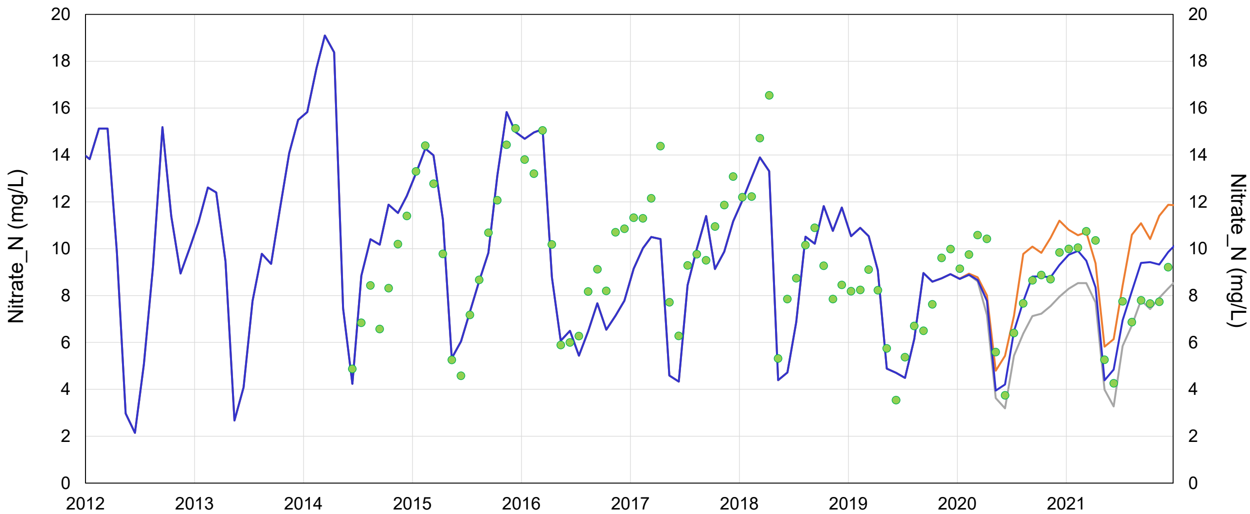

Figure 3.1: Average Monthly Nitrate Concentrations for FR_FRCP1, FR_FRABCH, and GH_FR1 under Low, Medium, and High Flows, FRO LAEMP, 2021[a]

Notes: The solid grey, blue, and orange lines correspond to the P10, P50 and P90 of modelled monthly average concentrations using 20 climate realizations. Monitored monthly average concentrations are indicated by green circles, noting that all 2021 monitored flows are preliminary and are subject to review and adjustment.

[a] Golder 2022a

Monitored nitrate concentrations at FR_FRCP1 have been consistent with the current monthly average model projected concentrations, except for winter 2016, winter 2018 and 2019[16], and Q4 of 2021 (Figure 3.1). Measured nitrate concentrations at FR_FRABCH have varied in relation to the monthly average model projected concentrations, and with concentrations in 2021 higher than the P90 low flow conditions in Q1, Q3 and Q4 (Figure 3.1). Nitrate concentrations measured at GH_FR1 were above the monthly average model projected concentrations periodically between 2016 and early 2021, however, measured nitrate concentrations were below projected values in the last half of 2021 (Figure 3.1). Updated projections for 2014 to 2022 suggested increases in nitrate concentrations at FR_FRCP1 and, to a lesser extent FR_FRABCH relative to expected values; however, concentrations at the Order station (GH_FR1) have been within the projected range and consistent with expectations (Figure 3.1; Golder 2022b).

3.1.2 Selenium Speciation

Aqueous selenium speciation data will be interpreted to address Study Question #3 (see Section 4.3). Selenium concentrations in 2021 varied by season, with higher concentrations in September and December compared to June for all selenium species and at all stations (Appendix Figure B.20; Appendix Table B.5). Selenate was the dominant species present in all samples, with very low concentrations of the more bioavailable reduced forms of selenium such as selenite and organoselenium species (e.g., methylseleninic acid; Appendix Table B.5). Concentrations of selenate increased from upstream to downstream throughout the study area similar to total selenium concentrations and were elevated compared to most other areas in Fording River Side Channel #2 (RG_FRSCH2) and the Greenhouse Side Channel (RG_FRGHSC; Appendix Figure B.20; Appendix Table B.5). Concentrations of selenite were highest at biological monitoring areas in the Fording River from RG_MP1 downstream to RG_FRCP1SW, with lower concentrations measured in the lower study area (RG_FRUPO downstream to RG_FOUEW; Appendix Table B.5; Appendix Figure B.20). Organoselenium species methylseleninic acid was detected at five biological monitoring areas (RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW, and RG_FO22) in September, but concentrations were at or just above the laboratory reporting limit (LRL; Appendix Table B.5). Reference areas had low concentrations of selenate compared to mine exposed areas and only one sample in Henretta Creek upstream of FRO (RG_HENUP) in June had a detectable selenite concentration (Appendix Table B.5).

[16] Nitrate concentrations were elevated during this period because water in the Fording River was predominately from Cataract Creek because of seasonal drying upstream. Cataract Creek was subsequently diverted and continuously elevated nitrate concentrations have not been observed since then at this station.

3.1.3 Chronic Toxicity

Chronic toxicity testing will be interpreted to address Study Questions #1, #5, and #6 (see Sections 4.1, 4.5 and 4.6). Results (reported in the 2021 UFR Chronic Toxicity Report [Golder 2022a]) were categorized by effects ratings of 'no,' 'possible,' and 'likely' adverse response of four organisms (water flea, amphipod, rainbow trout, and fathead minnow) to water sampled from each station outlined above.

Overall, most tests were categorized as having no adverse responses for endpoints of each organism in water from six mine-exposed water quality stations (FR_MULTIPLATE, FR_FR2, FR_FR4, FR_FRCP1, FR_FRRD, and FR_FRABCH) within the FRO LAEMP study area[17] sampled in 2021 (Figure 3.2). At FR_MULTIPLATE, 11 of 13 endpoints assessed had no adverse responses across any quarter (Figure 3.2). Although the likely adverse response for amphipod dry weight at FR_MULTIPLATE in Q3 was not attributed to any water quality constituent, nickel was identified as potentially contributing to the likely adverse response for water flea reproduction in Q4 (Golder 2022a; Figures 3.2 and 3.3). No adverse responses were also observed in 11 of 13 endpoints at FR_FR2 across all quarters (Figure 3.2), and while the likely adverse response for fathead minnow survival in Q1 may have been caused by microbes (no water quality constituent was identified), nickel was again identified as potentially contributing to the possible adverse response for water flea reproduction in Q4 (Golder 2022a; Figure 3.3). Similar to FR_MULTIPLATE and FR_FR2, there were no adverse responses observed in 11 of 13 endpoints at FR_FR4, but nickel showed the greatest evidence of potentially contributing to the possible adverse responses for amphipod dry weight in Q3 and Q4, and the possible and likely adverse responses for water flea reproduction in Q3 and Q4, respectively (Golder 2022a; Figure 3.3). At FR_FRCP1, no adverse responses were observed for 9 of 13 endpoints across quarters, but again nickel showed the greatest evidence of potentially contributing to the likely adverse response for water flea reproduction in Q1, Q3, and Q4 and amphipod dry weight in Q3 (Golder 2022a; Figure 3.3). The possible adverse respond for rainbow trout survival at FR_FRCP1 in Q4 was potentially associated with nitrate concentrations; however, microbe contamination also contributed to the observed response confounding the results. The likely adverse response for fathead minnow survival at FR_FRCP1 in Q1 was not associated with any water quality constituent. At FR_FRRD, no adverse responses were observed in 11 of 13 endpoints, and the two possible adverse responses (water flea reproduction and amphipod dry weight in Q4) could not be attributed to any water quality constituents (Golder 2022a; Figure 3.3).

[17] Figures 3.2 and 3.3 contain two stations (GH_FR1 and LC_LC5) not associated with the FRO LAEMP but were included in the figure taken directly from the Chronic Toxicity Report (Golder 2022b). Testing was also conducted at a FRO LAEMP reference area (FR_UFR1) but the data were not included in the figures.

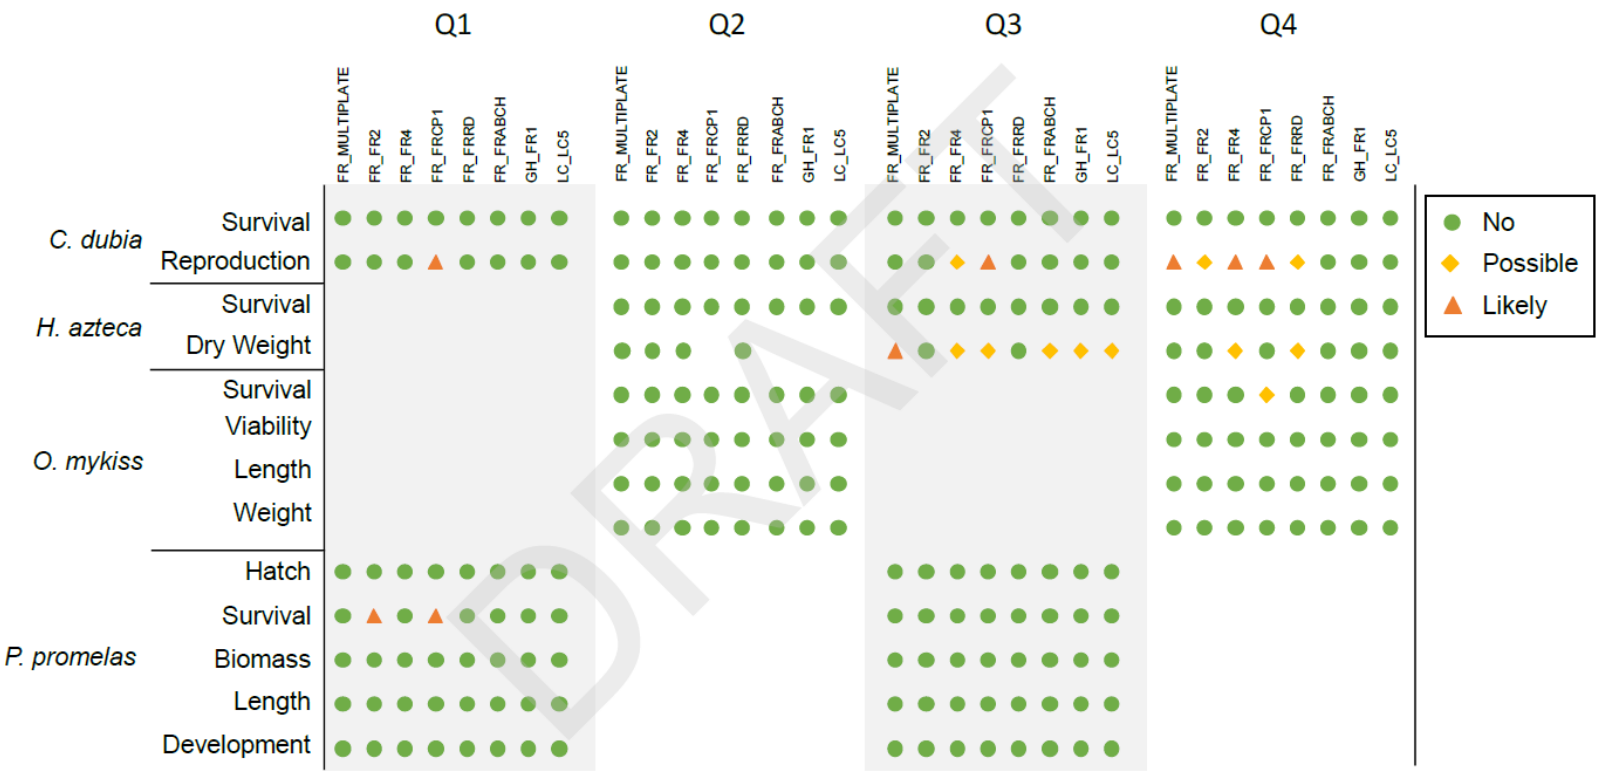

Figure 3.2: Summary of the 2021 Chronic Toxicity Tests in the Upper Fording River, FRO LAEMP, 2021

Notes: Stations GH_FR1 and LC_LC5 were not associated with the FRO LAEMP but were included in the above figure taken directly from the 2021 Chronic Toxicity Report for the Upper Fording River (Golder 2022b). Q2 dry weight measurements of *H. azteca* were disposed of due to a lab technician error; however, four stations (FR_MULTIPLATE, FR_FR2, FR_FR4, and FR_FRRD) were re-tested. There was evidence of microbes in the Q3 *P. promelas* tests and in the Q2 and Q4 *O. mykiss* tests.

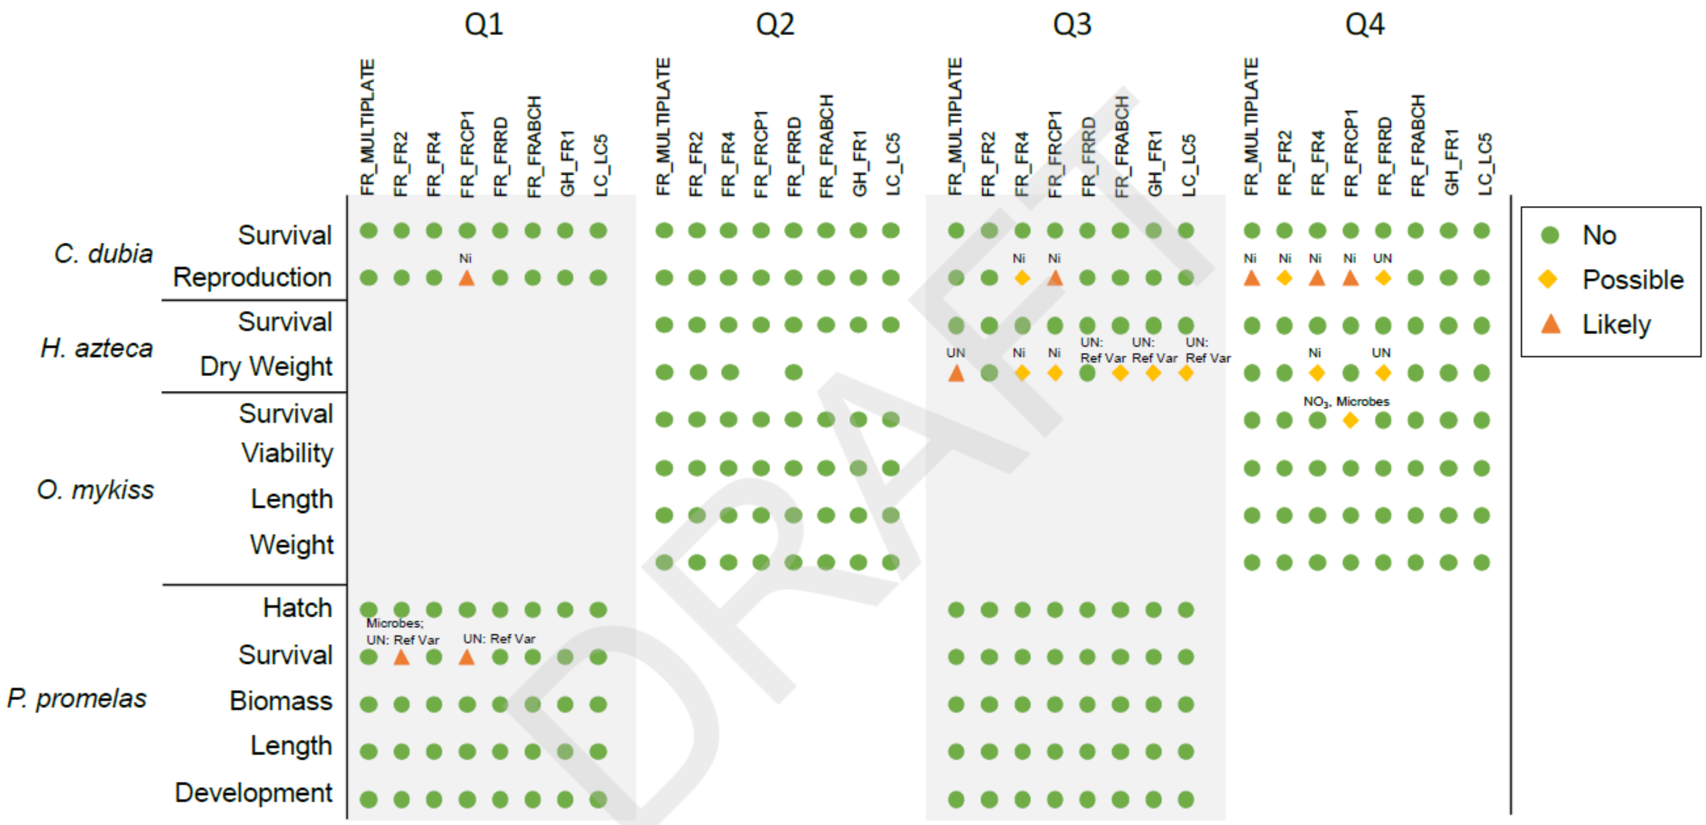

Figure 3.3: **Summary of the 2021 Chronic Toxicity Causation Assessment in the Upper Fording River, FRO LAEMP, 2021[a]**

Notes: Stations GH_FR1 and LC_LC5 were not associated with the FRO LAEMP but were included in the above figure taken directly from the 2021 Chronic Toxicity Report for the Upper Fording River (Golder 2022b). Q2 dry weight measurements of *H. azteca* were disposed of due to a lab technician error; however, four stations (FR_MULTIPLATE, FR_FR2, FR_FR4, and FR_FRRD) were re-tested. Ni = nickel; NO_3 = nitrate; UN: Ref Var = unknown cause in test with high inter-reference variability; UN = unknown, no water quality constituent was identified in causation assessment

At the Compliance point (FR_FRABCH), no adverse responses were observed in 12 of 13 endpoints, and the possible adverse response for amphipod in Q3 could also not be attributed to any water quality constituents (Golder 2022a; Figure 3.3). Overall, the incidence of adverse responses continues to occur in a minority of tests. While nickel showed the greatest evidence of contributing to observed effects in all *C.dubia* tests and some *H. azteca* tests, many cases were associated with elevated uncertainty in toxicity tests and/or weak to negligible evidence for influence of mine-influenced water quality.

Comparisons of chronic toxicity responses over time were made at FR_FRCP1 and FR_FRABCH. Except for Q4 2018 when upstream drying caused flows to come predominately from Cataract Creek, responses at FR_FRCP1 have been relatively consistent over time (Golder 2022a). Seasonal drying and/or reduced flows may have also contributed to the seasonal variability in toxicity testing responses observed at FR_FRCP1 in winter months compared spring and summer (Golder 2022a). Responses at FR_FRABCH have also been relatively consistent over time and responses have been less frequent and to a lower magnitude compared to FR_FRCP1 (Golder 2022a).

3.2 Hydrology

3.2.1 Seasonal Surveys of Dry Sections

Seasonal drying observations will be interpreted to address Study Questions #5 and #6 (see Sections 4.5 and 4.6). In the southern drying survey, a dry section 400 m in length was observed[18] in the mainstem Fording River on December 14, 2020, between FR_FRCP1 and FR_FRRD which also included a 200 m section of Side Channel 2, beginning at the upstream confluence with the Fording River. The maximum extent of drying in the southern section was observed in February 2021 at 950 m in length, extending from 450 m upstream of FR_FRCP1SW to the confluence of the Fording River with the Greenhouse Side Channel (Appendix Figure C.2). The Fording River was observed reconnected through Side Channel 2 during the March 14, 2021, survey, although a 150 m section of the Fording River main stem remained dry downstream of FR_FRCP1SW until April 12, 2021 (Table 3.1; Appendix Figures C.1 to C.4). A second dry section (30 m long) in the Fording River main stem was observed in February 2021, which was located 750 m downstream of FR_FRRD, directly downstream of the Oxbow channel (Appendix Figure C.2). This was the first time this section has been observed to dry since drying surveys began in 2017. During this dry period, the Fording River was flowing into the Oxbow from upstream. This second section was rewetted in March 2021 (Appendix Figures C.2

[18] A refined date of drying for this period was unable to be determined from the logger records due to the logger being entombed in ice.

Dry.
Drying (periodically).
Wet.
No surveys conducted.

Note: " * " indicates the approximate date, and C.3). The southern section remained fully wetted through the summer and fall until October 12, 2021, when a section of the Fording River mainstem between one kilometer downstream of FR_FRCP1SW and FR_FRRD was observed dry (Appendix Figures C.6 and C.7). Connectivity (and therefore fish passage) was maintained as the Fording River remained connected through Side Channel 2 until December 20, 2021, when the side channel became dry in the upstream section (Appendix Figures C.8 and C.9). The Fording River was disconnected during the December 20, 2021, site visit as the dry section in the main stem increased to 900 m downstream of FR_FRCP1 and for a 350 m section of Side Channel 2 (Appendix Figures C.7 to C.9). Trail camera photos were used to narrow the date of drying between an eight-day window from December 13 to December 20, 2021.

The northern survey was added to the drying surveys in October 2019. Since its addition, seasonal drying has been observed to occur between FR_UFR1 and FR_FRUPP. In the northern survey, a dry section 150 m in length was first observed October 13, 2020, between FR_FR1 and FR_FRUPP (Table 3.1), which would have prevented fish passage. In fall 2021, however, this section of the Fording River (i.e., betweenFR_FR1 and FR_FRUPP) remained wetted until December 14, 2021, when the dry section was observed to extend 150 m upstream of FR_FR1. The maximum extent of drying in the northern survey was observed on February 8, 2021, where three dry sections between FR_UFR1 and FR_FRUPP totaled 1.78 km in length (Appendix Figure C.2). The section of the Fording River between FR_UFR1 and FR_FR1 remained dry until approximately March 17, 2021 (Appendix Figures C.1 to C.3). The section between FR_FR1 and FR_FRUPP observed to periodically wet and dry between March 17, 2021, and April 12, 2021 (Table 3.1). A dry section on the Fording River mainstem between the Clode Creek confluence and the Lake Mountain Creek discharge (FR_FRDSCC1) was observed from January 18, 2021, to March 15, 2021, and observed to dry again on October 12, 2021 (Appendix Figures C.1 to C.3). This section downstream of FR_FRDSCC1 remained connected through a second channel throughout the year (Appendix Figures C.1 to C.4). The northern survey remained wetted through summer 2021 until a dry section was observed during the October 12, 2021, survey between FR_FR1 and FR_FRUPP. The exact time of drying was confirmed via trail camera to occur on October 1, 2022. Drying in this section would completely prevent fish passage upstream to Henretta Lake.

Henretta Creek upstream of Henretta Lake was first observed dry in September 2020 during calcite surveys, which would have fully prevented fish passage in Henretta Creek during this period. The maximum length of drying was observed on March 15, 2021, whereby two dry sections were observed for a total length of 1.45 kms (Appendix Figure C.3). Henretta Creek was observed to be reconnected during the May 28, 2021, survey and remained connected until the Aug 11, 2021, survey (Appendix C.5). No level loggers are present in the Henretta survey area to further refine dates of drying between surveys. From the drying surveys, Henretta Creek was only observed to be completely connected during the high flow period between May 28, 2021 and August 11, 2021 (Table 3.1).

The number of dry days in the southern survey for winter of 2020/21 totaled 119 days, which was more than the winters 2017/2018 and 2019/2020, each having 97 and 98 dry days, respectively (Table 3.2). The winter of 2018/19 was excessively dry in the southern survey area, having 185 dry days (Table 3.2), where drying began very early (September) and occurred further upstream to FR_FR4 (Minnow and Lotic 2020b). Drying in the southern survey area during winter of 2020/2021 began in December, which was consistent with previous years (Table 3.1). Dry days in the northern survey for the 2020/21 winter were observed to occur for a longer period (181 dry days) compared to 2019/20 (147 dry days) and occurred further upstream, which included FR_FR1 for an extended period (Table 3.2). The first full season for the Henretta Creek survey occurred in 2020/2021 where Henretta Creek was dry for 269 days, beginning September 1, 2020, until May 28, 2021 (Table 3.2). Although there are fewer years with observations compared to the southern drying survey, the Henretta Creek area appears to dry first and for longer each year, followed by the northern survey section and the south survey section (Table 3.2).

3.2.2 Temperature

Water temperature data will be interpreted to address Study Questions #4 and #6 (see Sections 4.4 and 4.6). Continuous water temperature data records were used to plot daily low, mean, and maximum temperatures from October 2017 to October 2021 (Appendix Figure C.10). Water temperature in 2021 was comparable to previous study years, and the highest summer water temperatures recorded during this period continue to be from 2018, despite the extensive warm weather experienced in summer 2021 (Table 3.3). Three distinct winter thermal regimes in the southern survey were identified in the 2017 FRO LAEMP report (Figure 2.2): 1) the upper portion of the southern survey area, which included FR_FR2 and represented a typical year-round surface flow with low groundwater contribution; 2) areas of seasonal drying represented by FR_FRCP1SW; and 3) the lower portion of the southern survey area from FR_FRRD to FR_FRABCH having areas of higher groundwater contribution (Minnow and Lotic 2018; SNC Lavalin 2021). These temperature regimes have been consistent throughout the study period (2017 to 2021; Appendix Figure C.10). Areas in the lower section of the southern survey have demonstrated less extreme seasonal temperature fluctuations due to the high groundwater contribution compared to the other two regimes that show more extreme high and low seasonal temperatures (Appendix Figure C.10); however, the annual mean temperature was similar between all three areas (Table 3.3). Temperature records in the northern survey are not

extensive enough to determine any particular flow regimes and temperature patterns but a previous study of the area (McPherson and Robinson 2011) and recent observations suggest that there will be year-round surface flow with low groundwater influence in the upper portion of the northern survey at FR_UFR1, areas of seasonal drying between FR_UFR1 and upstream of the Pond Ponds outflow(FR_FRUPP), and year-round surface flow with groundwater influence between FR_FOUCL and FR_FRDSCC1 influenced by the confluence of Fish Ponds and Clode Creek.

3.2.3 Water Level and Flows

Water level and flow data will be interpreted to address Study Questions #5 and #6 (see Sections 4.5 and 4.6). Updated stage-discharge relationships were developed for each site in 2021 (Appendix Figure C.11). Using the stage-discharge relationships, mean, minimum, and maximum discharges (m^3/s) were calculated from the water level records from each station up to October 2021 (Table 3.4; Appendix Figure C.11). The data from the stations installed in 2017 only included October until the end of the year so calculated discharges for 2017 did not include freshet and were skewed to fall flows and were therefore not included in discharges summaries (Table 3.4). Stations at FR_UFR1, FR_FR1, FR_FRDSCC1, and FR_SCOUTDS were installed in August 2020. Calculated discharge for these sites were also skewed to fall seasonal flows for 2020 so were omitted from discharges summaries (Table 3.4). Peak instantaneous and mean annual discharge (maximum and mean values reported in Table 3.4, respectively) for 2021 were the second highest year on record across all sites, with 2020 having the highest average discharges at all stations except at FR_FR4. Stage-discharge relationships were reported for the first time for stations FR_SCOUTDS, FR_FRDSCC1, FR_FOUCL, FR_FR1, and FR_UFR1 (Table 3.4). Calculated discharge values for FR_FR3, FR_ SCOUTDS, FR_FRDSCC1, FR_FOUCL, FR_FR1, and FR_UFR1 are preliminary due to limited manual discharge measurements in the stage-discharge relationship.

3.3 Substrate Quality

3.3.1 Sediment

Sediment chemistry data were collected to support the questions related to BIC structure (Study Question #5; Section 4.5). The concentrations of most metals in sediment samples from biological monitoring areas within the FRO LAEMP study area have consistently been within the normal range and below upper WSQGs (or alert concentration in the case of selenium; Appendix Figures D.2 to D.13). Consistent with previous years nickel concentrations in sediment in 2021 were higher than the lower WSQGs at all mine-exposed areas, and higher than the normal range in one or more replicate at RG_FOUKI, RG_SCOUTDS, and RG_FOBCP

(Appendix Figures D.1, D.11, and D.13; Appendix Table D.1). A similar pattern was observed for cadmium, manganese, and zinc concentrations, but concentrations were within the normal range except for the cadmium concentration in one replicate at RG_SCOUTDS and the manganese concentration in one replicate at RG_FOUKI (Appendix Figures D.1, D.11, and D.13; Appendix Table D.1). Selenium concentrations in sediment were above the alert concentration at RG_FOBCP, with some replicates above alert concentrations at monitoring areas downstream (RG_FRUPO and RG_FO22); however, all concentrations were within the normal range (Appendix Figures D.1, D.11, and D.13; Appendix Table D.1). Of the reference areas, metal concentrations were lower at RG_HENUP compared to RG_FO26 where concentrations were often similar to one or more mine-exposed area (Appendix Figure D.1).

Concentrations of many PAHs were higher than the upper and/or lower WSQGs in sediment at all the sampled mine-exposed areas in 2021 (Appendix Table D.1; Appendix Figure D.14). In most cases, PAH concentrations were above the regional normal range (where available) and showed an increasing pattern from RG_FOUKI to a peak at RG_FOBCP before decreasing in the lower study area (RG_FRUPO and RG_FO22; Appendix Table D.1; Appendix Figure D.14). Recent findings from the Regional Sediment Toxicity Report identified toxicological effects in Hyalella and Hexagenia exposed to sediments from RG_FOUKI (survival and growth), however, effects were related to ammonia generation during sample storage and in the test system and were not representative of *in situ* ammonia concentrations (Golder 2022c).

3.3.2 Calcite

Calcite data will be interpreted to address Study Question #5 (see Section 4.5). Calcite was measured in riffle habitat (i.e., concurrent with BIC sampling) in September 2021 for the FRO LAEMP and tabulated along with calcite measurements from the Regional Calcite Monitoring program where available (Appendix Table D.2). Calcite index was reported using two methods in 2021 – Calcite Index based on a binary assessment of calcite presence (CI) and calcite index based on a proportional assessment of calcite presence (CI’). In both the Regional Calcite Monitoring Program and the FRO LAEMP in 2021, CI’ was lower than CI at all monitoring areas, and both CI’ and CI was higher from RG_FOBCP downstream to RG_FOUEW compared to areas upstream (Figure 3.4; Appendix Table D.2).

Consistent with previous years, CI values measured in the FRO LAEMP monitoring areas in 2021 were below the upper limit of the regional normal range (1.0) at all areas with very little concretion but were lower than CI values from the previous year in many areas (Appendix Table D.3). Calcite Index values at reference area RG_HENUP and RG_FO26 were 0.0 and 0.1, respectively, for all replicates. Consistent with previous years, Calcite Index associated with the Regional Calcite Monitoring Program were similar to those calculated in the LAEMP. Calcite Index was

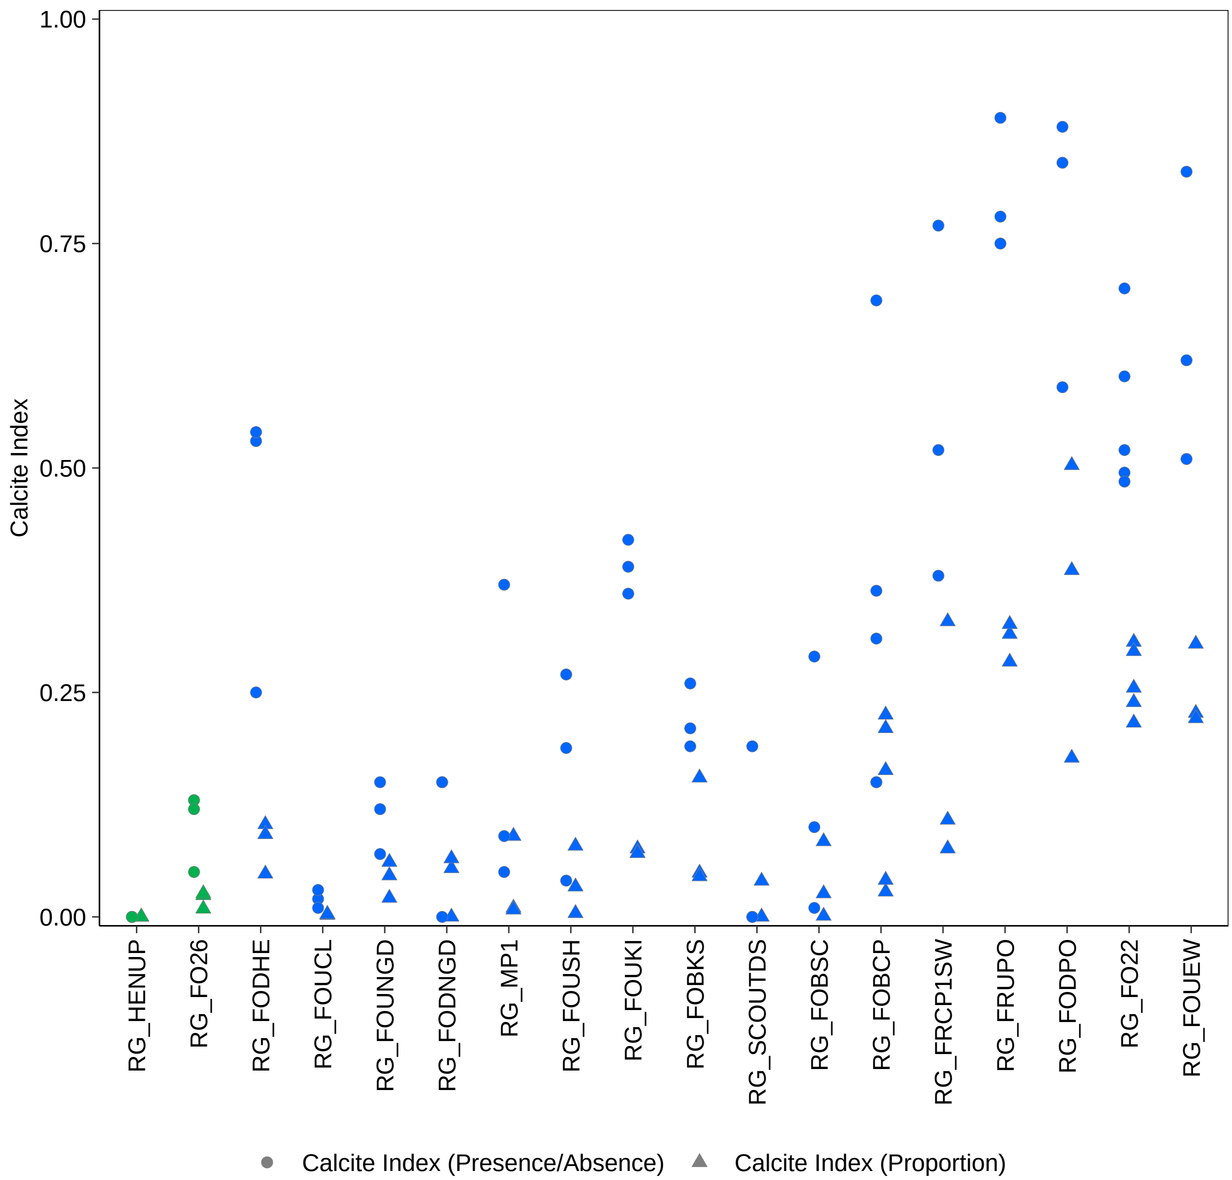

Figure 3.4: Calcite Index FRO LAEMP, 2021

Notes: Green symbols represent reference areas and blue symbols represent exposed areas. In 2021, calcite presence was measured using both a presence/absence and proportional method and both calculated indicies are presented.

below 1.0 at all reaches within the FRO LAEMP study area, except for the reach associated with FRO LAEMP monitoring area RG_FOUEW, where mean CI was 1.16 in the Regional program and 0.65 in the LAEMP (Appendix Tables D.2 and D.3). Calcite Index assessments have consistently been lower for the Regional Calcite Monitoring Program compared to CI measured within the FRO LAEMP (Appendix Table D.2). This can be attributed to differences in sampling methods, as the Regional Calcite Monitoring Program assesses 100-m-long reaches and containing a variety of habitat types (e.g., riffle, run, pool), whereas FRO LAEMP measurements are conducted within targeted riffle habitat in the immediate proximity of BIC sample collection (Lotic 2022).

3.4 Benthic Invertebrate

3.4.1 Biological Productivity

Benthic invertebrate productivity data will be interpreted to address Study Question #2 (see Section 4.2). Spatial variation in biomass and density of benthic invertebrates was observed in 2021 (Figure 3.5), but data within each monitoring area was consistent with previous years (Appendix Figures E.1 and E.2). Overall, density and biomass were lower in the middle part of the study area (RG_FOBKS, RG_SCOUTDS, and RG_FOBSC) compared to areas upstream and downstream (Figure 3.5).

Periphyton coverage scores (CABIN supporting measurement) are interpreted as a measure of primary productivity within the FRO LAEMP study area (Appendix Table G.11). Periphyton coverage ranged from a score of 1 (not slippery with no obvious coverage) to 3 (noticeably slippery with patches of thicker green to brown algae) with no areas exhibiting extensive algal growth. The highest scores (3) were observed at only several mine-exposed areas throughout the full study area (RG_FODNGD, RG_FOUKI, RG_FOBCP) as well as two reference areas (RG_HENUP and RG_FO26).

3.4.2 Benthic Invertebrate Tissue Chemistry

Benthic invertebrate tissue chemistry data will be interpreted to address Study Question #3 (see Section 4.3). Composite-taxa benthic invertebrate tissue samples were collected in June, September, and December 2021. Benthic invertebrate tissue selenium concentrations were within the reference normal range in 209 of 248 samples collected from mine-exposed areas in 2021, with the majority of samples having tissue selenium concentrations above normal ranges collected in September (Table 3.5). Tissue selenium concentrations were below the EVWQP Level 1 benchmarks for fish, benthic invertebrates, and birds throughout the FRO LAEMP study area, with some exceptions (Table 3.5; Figure 3.5). In June, one of three replicate samples

Value > EVWQP Level 2 benchmark of 20 mg/kg dw for effects to benthic invertebrates (Teck 2014).

Value > EVWQP Level 3 benchmark of 27 mg/kg dw for effects to benthic invertebrates (Teck 2014).

Value > EVWQP Level 1 benchmark of 15 mg/kg dw for dietary effects to juvenile birds (Teck 2014).

Value > EVWQP Level 2 benchmark of 22 mg/kg dw for dietary effects to juvenile birds (Teck 2014).

Value > EVWQP Level 3 benchmark of 41 mg/kg dw for dietary effects to juvenile birds (Teck 2014).

Value > upper limit of normal range of (8.74 mg/kg dw; Minnow 2020).

Note: '-' indicates sample that was not taken because it was not a part of the sampling design; 'x' indicates sample that was not taken because of drying and/or ice conditions.

[a] RG_UFR1 was used as a reference location in December when there was no access to RG_FO26 or RG_HENUP.

collected from the Fording River downstream of the Multiplate culvert (RG_MP1) and one of five replicate samples collected from the Fording River upstream of Chauncey Creek (RG_FO22) was above the Level 1 benchmark for juvenile fish. In September, one of three replicate samples collected from RG_FODHE and one of five replicate samples collected from RG_FOBCP was above the Level 1 benchmark for juvenile fish. Also in September, four of five replicates collected from RG_FOBSC had samples with selenium concentrations above one or more EVWQP benchmark: one of five replicate samples was above the Level 1 benchmark for juvenile birds, two of five replicates were above the Level 1 benchmark for benthic invertebrates, and one of five replicates was above the Level 1 benchmarks for juvenile fish. In addition, benthic invertebrate tissue selenium concentrations in the Greenhouse Side Channel (RG_FRGHSC) were elevated above EVWQP benchmarks in both September and December. In September, one of five replicates was above the Level 3 benchmarks for benthic invertebrates, one of five replicates was above the Level 2 benchmarks for juvenile fish, one of five replicates was above the Level 1 benchmarks for juvenile birds, and one of five replicates was above the Level 1 benchmarks for juvenile fish. In December, one of five replicates were each above the Level 1 benchmarks for juvenile birds, benthic invertebrates, and juvenile fish. All seven composite-taxa benthic invertebrate tissue samples collected at RG_FRGHSC with selenium concentrations above EVWQP benchmarks contained annelids. Benthic invertebrate tissue selenium concentrations have been consistent[19] at each monitoring area over time. Seasonal differences have been observed (i.e., highest concentrations observed in September compared to December and June) but have been consistent across the study area (Appendix Figure E.3).

Benthic invertebrate tissue selenium concentrations in June, September, and December 2021 were assessed against the biological triggers (see Appendix H). Biological triggers were evaluated for each replicate from FRO LAEMP monitoring areas with available water quality projections (i.e., six mine-exposed biological monitoring areas [RG_FODHE, RG_FOUKI, RG_FOBSC, RG_FOBCP, RG_FODPO, and RG_FO22] and one reference area [RG_FO26]; Appendix H). Except for two replicate samples at RG_FOBSC in September, no mine-exposed areas exceeded biological triggers for tissue selenium concentrations (above the 97.5th percentile of normal range and above the 95% prediction interval; Appendix H).

Biological monitoring areas (RG_FOUCL downstream to RG_FOUEW) having the highest concentrations of aqueous total selenium within the FRO LAEMP study area (Appendix Table E.2; Appendix Figure B.19), and detectible reduced forms of selenium (i.e., selenite; Appendix Table

[19] Exceptions were samples that contained annelids which differentially bioaccumulate selenium.

B.5; Appendix Figure B.20) were associated with the highest benthic invertebrate tissue selenium concentrations (Table 3.5; Figure 3.6). Paired aqueous total selenium concentrations and tissue selenium concentrations were plotted against predictions from the selenium bioaccumulation model (Golder 2020a) for 2021 only data (Figure 3.7) and for all data since 2012 (Appendix Table E.2; Appendix Figure E.4). In 2021, all values except for five replicates from RG_FRGHSC, two replicates from RG_FOBSC, and one replicate from RG_MP1 fell near or within the prediction limits, (Figure 3.7), suggesting that most tissue concentrations were expected based on the total selenium concentrations in the water. The selenium bioaccumulation tool ('B-tool;' Golder 2020b) was used to determine predicted benthic invertebrate tissue selenium concentrations based on concentrations of selenium species. The predicted benthic invertebrate tissue selenium concentrations were consistent with measured concentrations at all areas and sampling periods, except RG_FRGHSC in September and December, and RG_FODHE, RG_FOUCL, and RG_FOBSC in September (Appendix Table E.3).

3.4.3 Benthic Invertebrate Community

3.4.3.1 Spatial and Temporal BIC Endpoints

Spatial and temporal benthic invertebrate community data will be interpreted to address Study Questions #1, #5, and #6 (see Sections 4.1, 4.5, and 4.6). Benthic invertebrate community metrics calculated based on September 2021 data were plotted spatially and compared to regional normal ranges for all endpoints, and to site-specific normal ranges for total abundance, richness, and percent and total abundance for EPT and Ephemeroptera (Figures 3.8 to 3.17). Total benthic invertebrate abundance and LPL richness was within or above the regional and site-specific normal range at all FRO LAEMP areas in 2021, including areas with low % Ephemeroptera and/or % EPT (Figure 3.7).

Total Ephemeroptera abundance was within the regional and site-specific normal range throughout the study area in September 2021 (Figure 3.12), however, % Ephemeroptera was below the normal ranges in part of the middle study area and the lower study area (Figure 3.9). Percent Ephemeroptera values were below the regional normal range between RG_FOBCP and RG_FOUEW, and below site-specific normal ranges between downstream of RG_SCOUTDS and RG_FOUEW (Figure 3.9). Both Ephemeroptera abundance and % Ephemeroptera exhibited a similar spatial pattern showing an upstream to downstream decrease; the pattern was also observed in the abundance of two Ephemeroptera families: Heptageniidae and Ephemerellidae (Figures 3.14 and 3.15). Baetidae abundance, a third Ephemeroptera family within the study area, was more consistent throughout the FRO LAEMP study area (Figure 3.14).

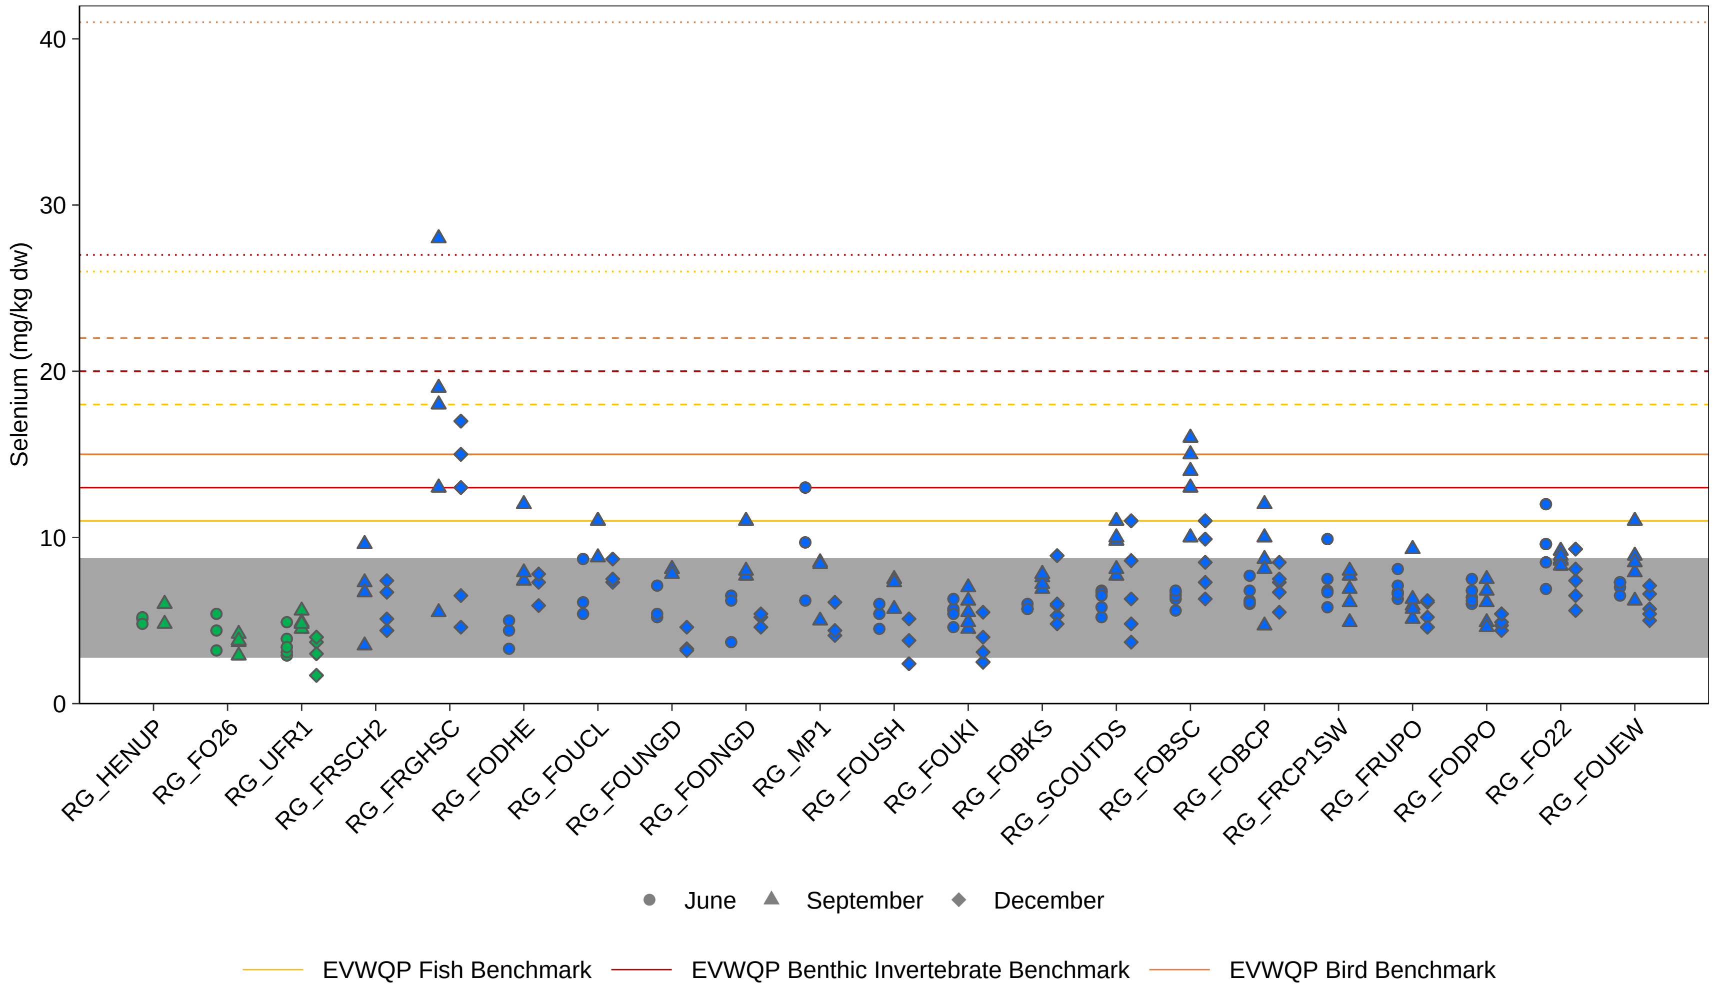

Figure 3.6: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

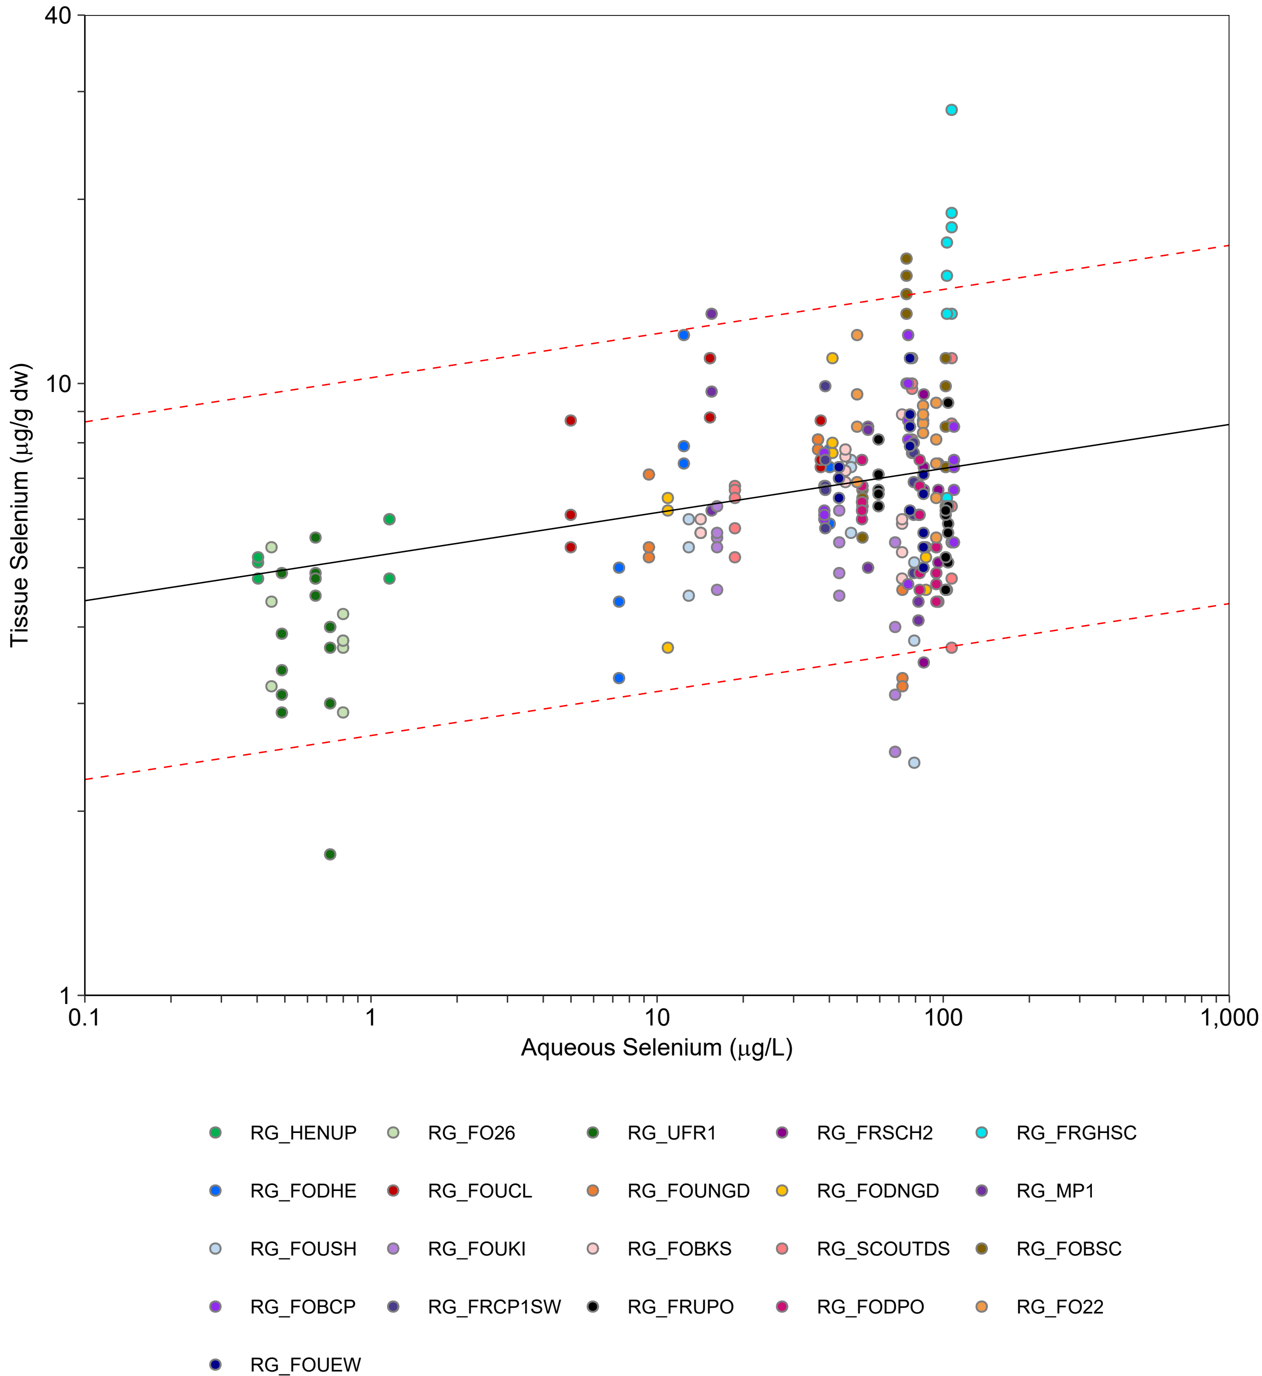

Figure 3.7: Observed and Modelled Selenium Concentrations in Benthic Invertebrate Composite-taxa Samples Relative to Aqueous Selenium Concentrations at Biological Monitoring Areas Upstream and Downstream of Fording River Operations, FRO LAEMP, 2021

Notes: Mean benthic invertebrate selenium concentrations (solid black line) were estimated using a one-step water to benthic invertebrate selenium accumulation model: log10[Se]benthic invertebrate=0.717+0.072 x log10[Se]aq (Golder 2020). The 95% prediction limits for a single value from the one-step water to benthic invertebrate selenium accumulation model are plotted as dashed red lines. Reference areas are shown in green.

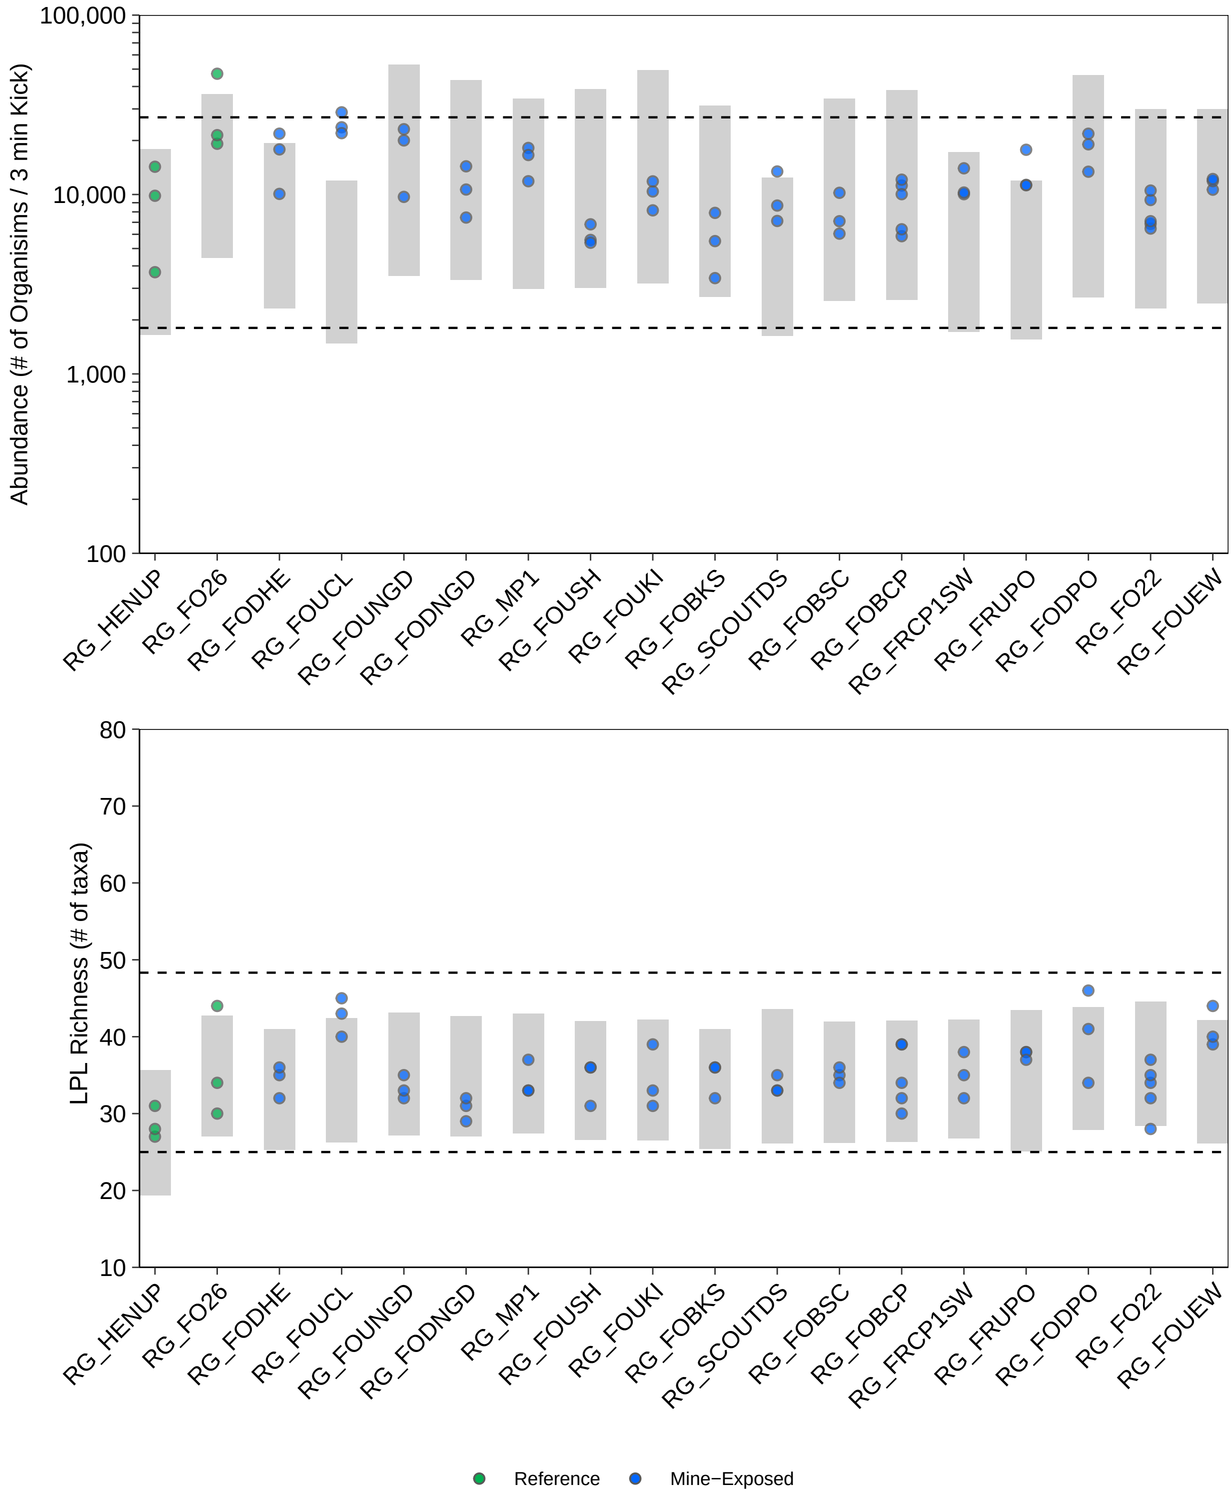

Figure 3.8: Benthic Invertebrate Abundance and Richness, FRO LAEMP, September 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

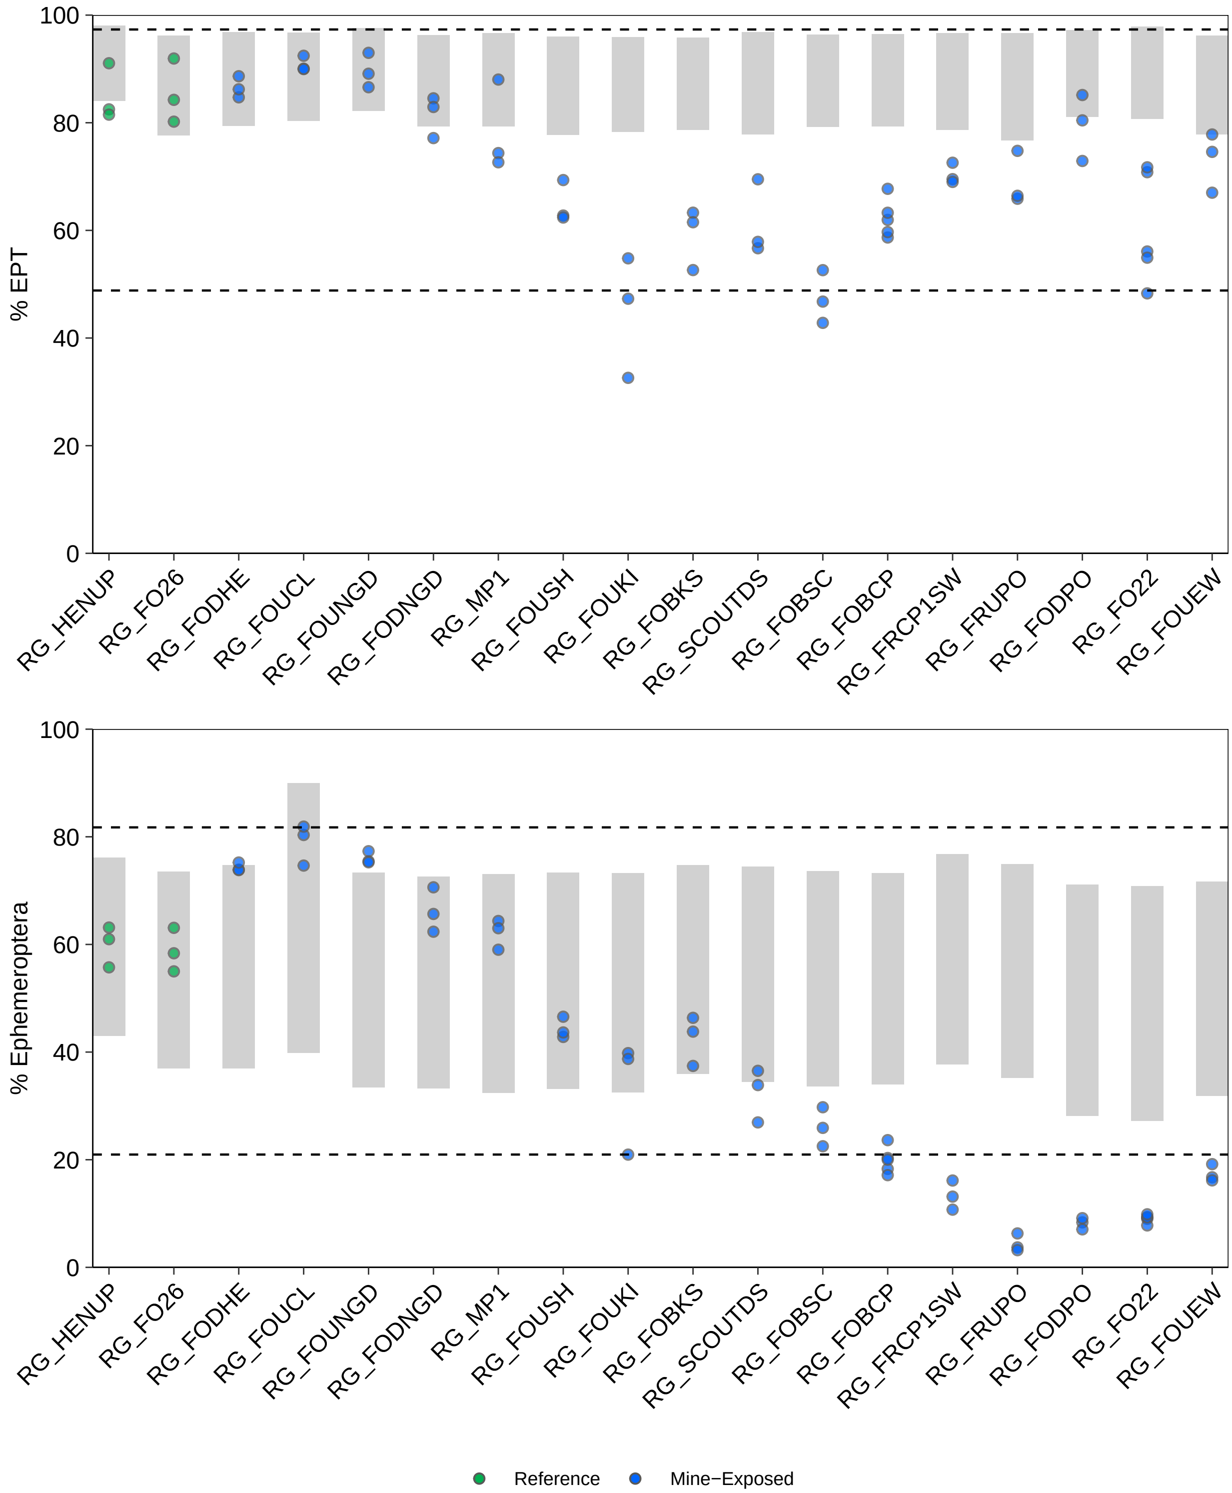

Figure 3.9: **Benthic Invertebrate % EPT and % Ephemeroptera, FRO LAEMP, September 2021**

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

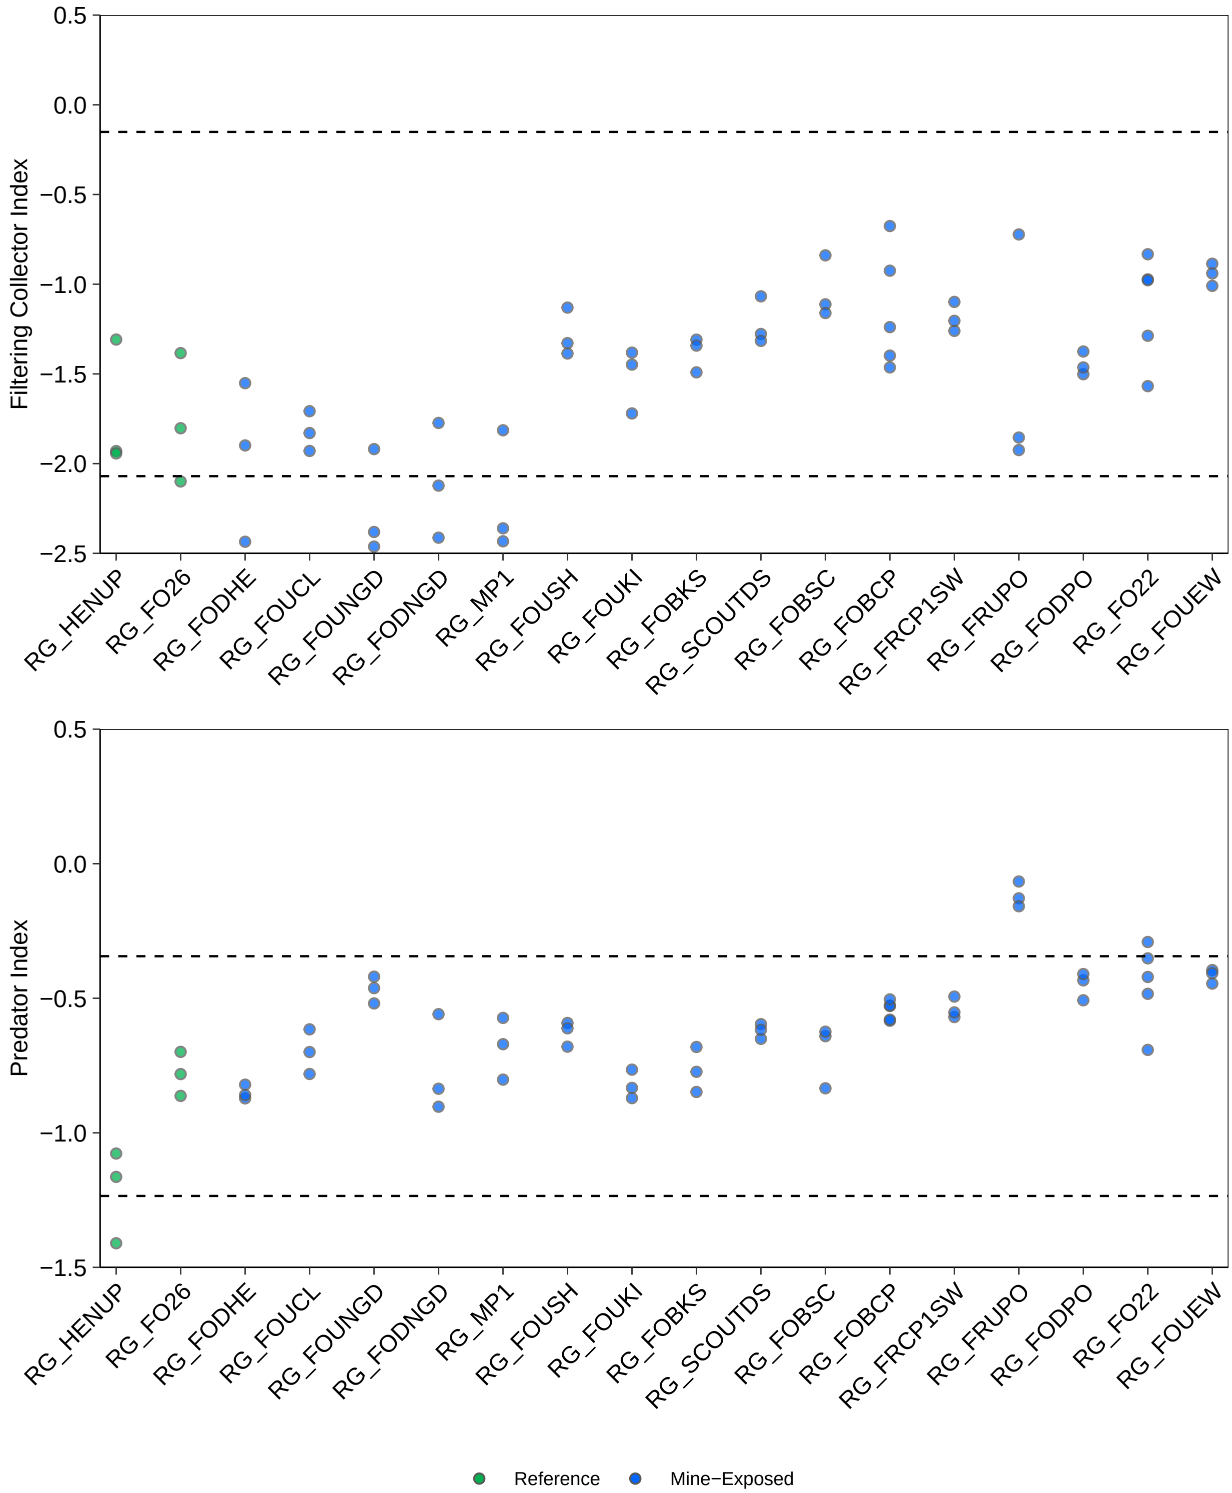

Figure 3.16: **Benthic Invertebrate Filtering Collector Index and Predator Index, FRO LAEMP, September 2021**

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

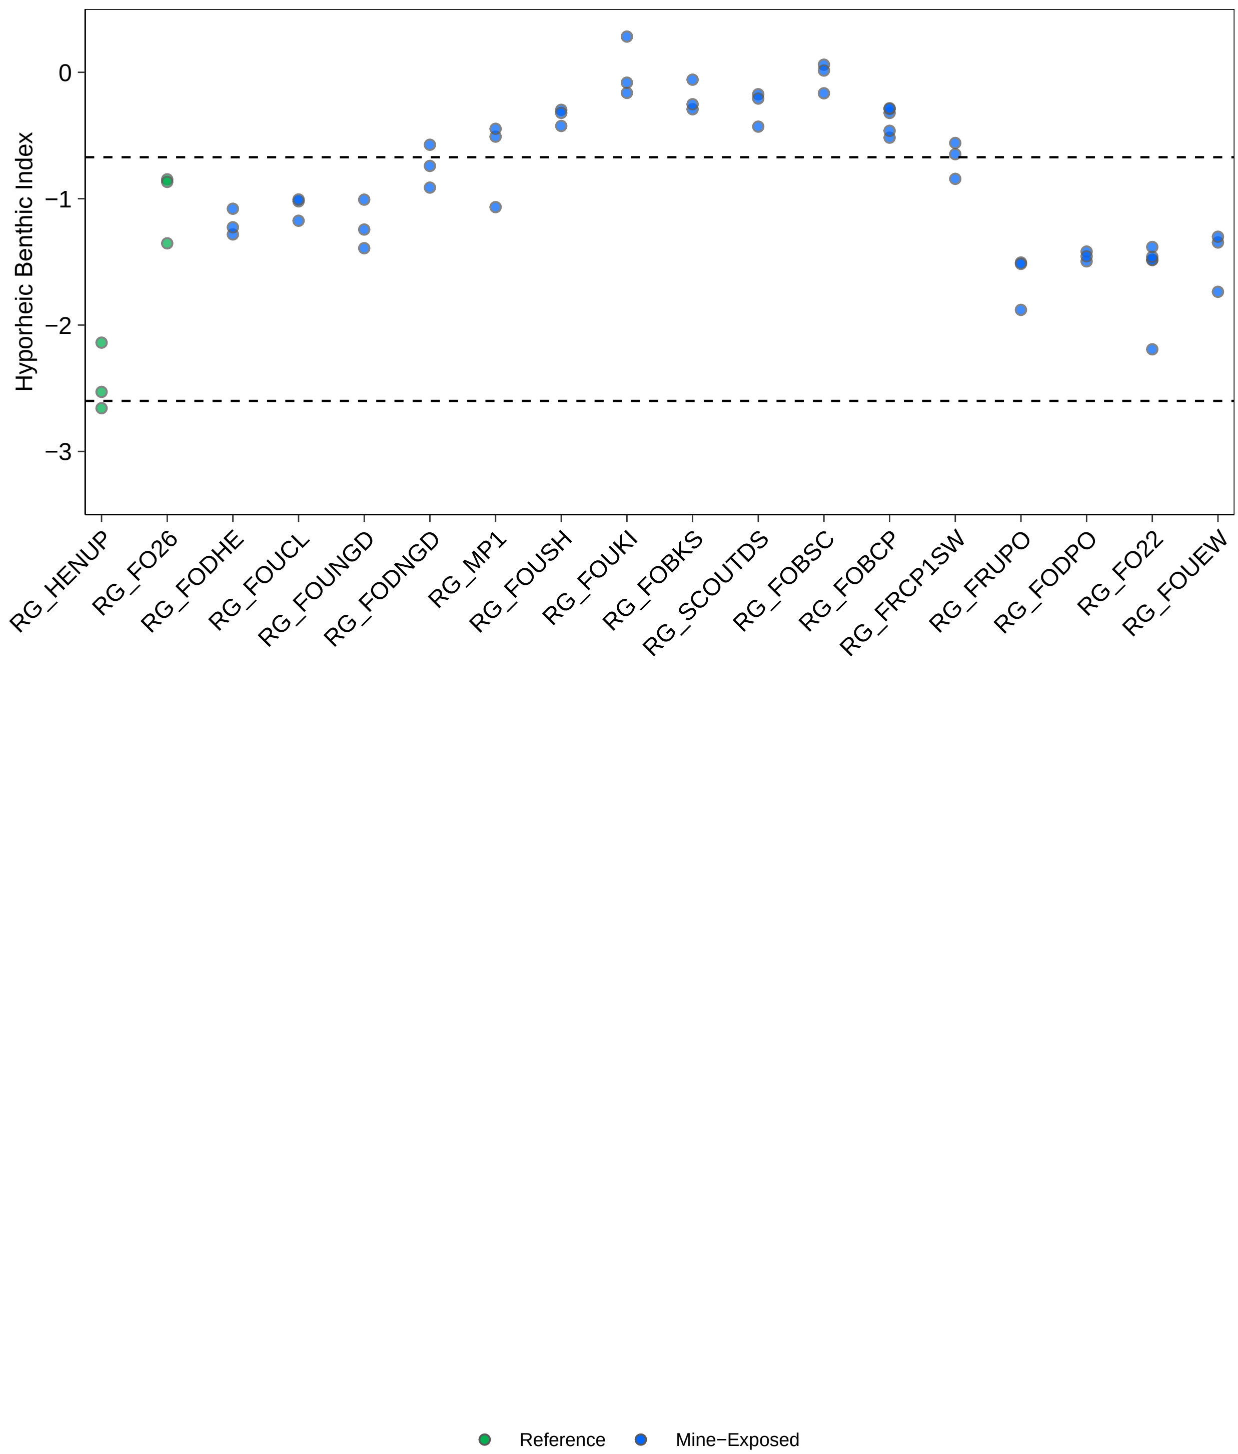

Figure 3.17: Benthic Invertebrate Benthic Hyporheic Index, FRO LAEMP, September 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Both total Plecoptera abundance and % Plecoptera were within or above the upper limit of the regional normal range in September 2021 and were relatively high at the areas where % Ephemeroptera was low (Figures 3.9, 3.10, and 3.12). In the middle and lower study (from RG_FOBCP to RG_FOUEW), % Plecoptera accounted for approximately 40% to 65% of all benthic invertebrates, but was lower in the upper study area where Ephemeroptera was dominant (Figures 3.9 and 3.10). Total Trichoptera abundance and % Trichoptera were within the regional normal range throughout the study area (Figures 3.10 and 3.13).

Percent EPT in September 2021 was within the regional normal range throughout most of the FRO LAEMP study area due to relatively high abundance of Plecoptera and, to a lesser extent Trichoptera, in areas where Ephemeroptera relative abundance was lower than the normal ranges (Figure 3.9, 3.12, and 3.13). However, with few exceptions % EPT was below the site-specific normal range throughout most of the FRO LAEMP study area from RG_MP1 to RG_FOUEW (Figure 3.9). The low relative abundance of EPT in 2021 was related to the high abundance of Diptera from the family Psychodidae and to some extent, Chironomidae (Figure 3.18). Total abundance of EPT was within the regional and site-specific normal range throughout the study area (Figure 3.11).

Except at RG_FO22, the Autotrophic to Heterotrophic Index in September 2021 was lowest from RG_SCOUTDS to RG_FOUEW (Figure 3.15), suggesting that organisms in these areas may utilize more food sources originating from terrestrial sources (heterotrophic energy) compared to those originating from within the river and its tributaries (autotrophic energy). Filtering Collector Index was highest in the middle and lower study area, with an increase observed between RG_FOUSH and RG_FOUEW (Figure 3.16). The proportion of predators was similar throughout the FRO LAEMP study area, except at RG_FRUPO where predators were dominant in the community, and the Predator index was greater than the normal range (Figure 3.16). The Hyporheic to Benthic Index was highest from RG_FODNGD downstream to RG_FRCP1SW and was lowest at the downstream areas (RG_FRUPO downstream to RG_FOUEW; Figure 3.17). Low Hyporheic to Benthic indices in the lower part of the study area (RG_FRUPO downstream to RG_FOUEW) was likely facilitated by the deeper, slower flowing water characteristic of these areas and that favor invertebrates who burrow under the substratum.

Correspondence analysis was conducted on September family-level relative abundance BIC data for all study years (2012 to 2021), with CA axis 1 (CA1) and CA axis 2 (CA2) accounting for 20.4% and 13.5% of the variability in the community, respectively (Appendix Tables E.4 and E.5; Appendix Figures E.5 and E.6). The four most downstream areas (i.e., the lower study area RG_FRUPO, RG_FODPO, RG_FO22, and RG_FOUEW) were separated from the rest of the areas along CA1, with RG_FO22 being the most divergent area (Appendix Figure E.5), which was

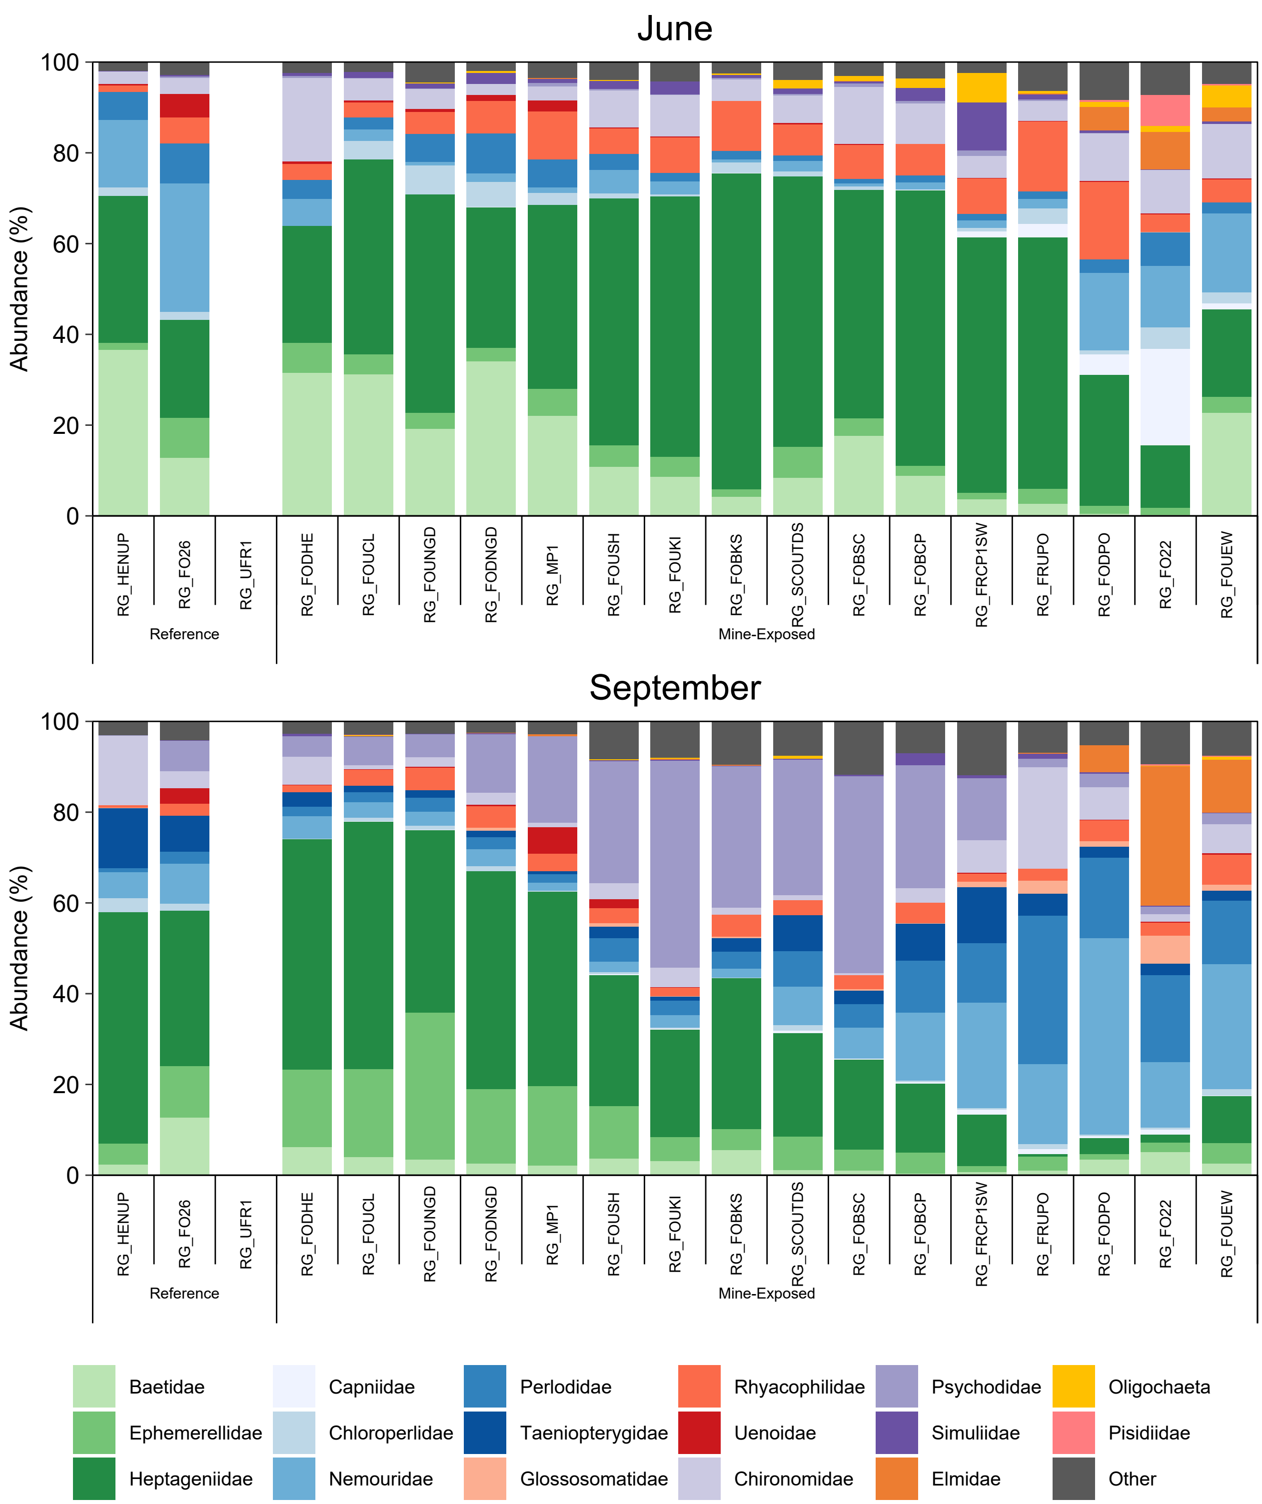

Figure 3.18: Benthic Invertebrate Community Percent Composition, FRO LAEMP, June to December 2021

Notes: Green colors represent Ephemeroptera taxa, blue colors represent Plectoptera taxa, red colors represent Tricoptera taxa, purple colors represent Chironomidae taxa, orange color represents Coleptera taxa (Elmidae), yellow color represents Oligochaeta taxa, pink color represents Bivalvia taxa (Pisidiidae) and grey color represents other remaining taxa.

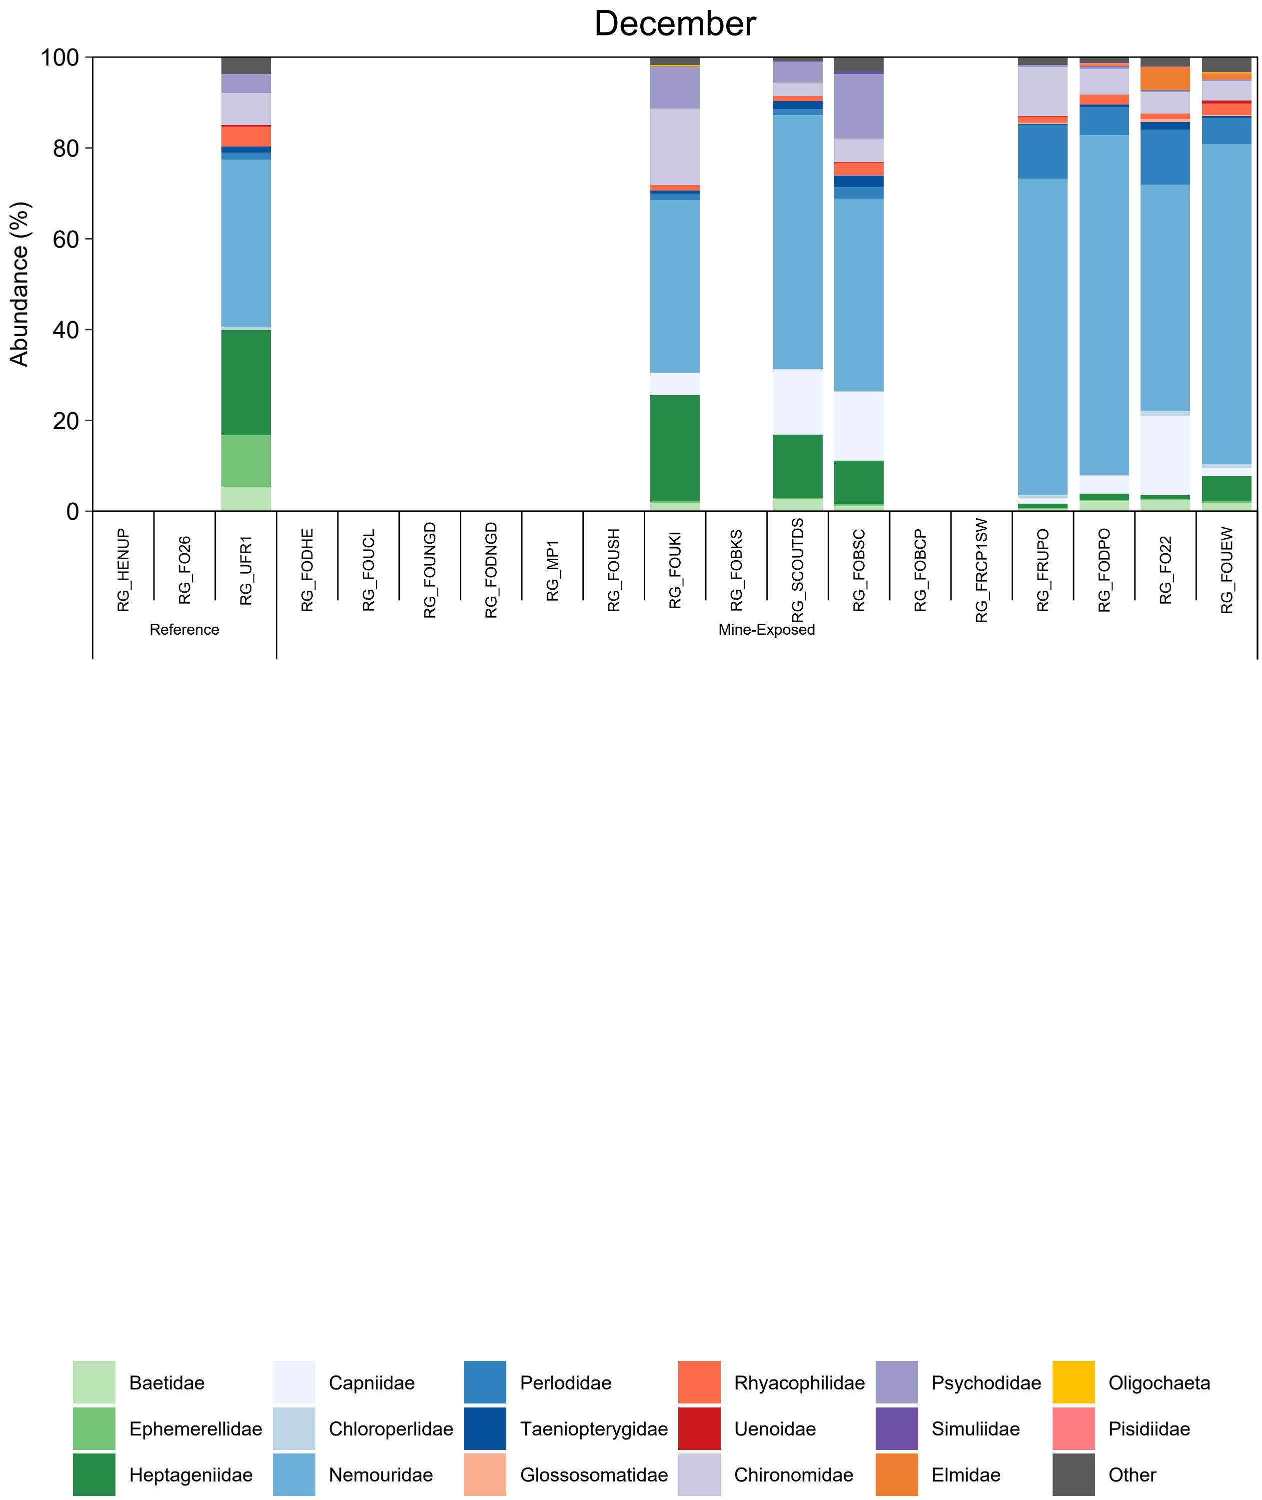

Figure 3.18: Benthic Invertebrate Community Percent Composition, FRO LAEMP, June to December 2021

Notes: Green colors represent Ephemeroptera taxa, blue colors represent Plectoptera taxa, red colors represent Tricoptera taxa, purple colors represent Chironomidae taxa, orange color represents Coleptera taxa (Elmidae), yellow color represents Oligochaeta taxa, pink color represents Bivalvia taxa (Pisidiidae) and grey color represents other remaining taxa.

similar to results from previous years (Minnow and Lotic 2019b, 2020b, 2021b). The primary taxon driving the separation in the positive direction on CA1 was the riffle beetle (Family Elmidae; Order Coleoptera), with significant influences from Limnephilidae and Glossosomatidae (Trichoptera), Capniidae (Plecoptera), and Tipulidae (Diptera; Appendix Table E.4; Appendix Figure E.5). Taxa driving CA1 in the negative direction were largely families of Ephemeroptera, such as Ameletidae, Ephemerellidae and Heptageniidae, with significant influences from Hydropsychidae and Brachycentridae (Trichoptera), Sperchontidae (Coleoptera), Psychodidae (Diptera), and Ceratopogonidae (Diptera; Appendix Table E.4; Appendix Figure E.5). Reference and mine-exposed areas were separated along CA2, which was strongly driven by Diptera (i.e, Simuliidae), Plecoptera (Capniidae and Perlidae), and Trichoptera (Brachycentridae) families in the negative direction (mine-exposed areas), and select Plecoptera (Chloroperlidae), Trichoptera (Limnephilidae) and Ephemeroptera families in the positive direction (reference areas).

Percent EPT in September 2021 was assessed against the biological trigger values (see Appendix H). This was completed for FRO LAEMP monitoring areas with available water quality projections (i.e., six mine-exposed areas [RG_FODHE, RG_FOUKI, RG_FOBSC, RG_FOBCP, RG_FODPO, and RG_FO22] and one reference area [RG_FO26]; see Appendix H for details). Except for RG_FODHE (3 of 3 replicates) and RG_FODPO (2 of 3 replicates), replicates from all mine-exposed areas had % EPT that were lower than the biological trigger. Percent EPT at these areas has previously been noted in past FRO LAEMP reports and the RAEMP based on benthic invertebrate community results (Minnow and Lotic 2020b, 2021b). Further information regarding the % EPT biological trigger as it pertains to the FRO LAEMP can be found in Appendix H and discussion of causes of lower % EPT in the study area is found in Section 4.5.

In 2021, total benthic invertebrate abundance was unchanged compared to previous years throughout the study area except at RG_FRCP1SW (increase from the base year [2017]) and RG_FO22 (decrease in 2021 compared to 2020; Appendix Table E.6; Appendix Figure E.7). Lowest practical level richness was similar in 2021 compared to previous years at all FRO LAEMP monitoring areas except at RG_MP1 (increase from the base year) and RG_FOBKS (increase from the base year; Appendix Table E.7; Appendix Figure E.8). In 2021, % EPT was significantly lower than the base year at RG_FOUKI and was significantly higher at RG_FODHE and RG_FOUSH in 2021 compared to 2020 (Appendix Table E.8; Appendix Figure E.9). Percent Ephemeroptera, however, was significantly lower than the base year at the majority of mine-exposed areas, particularly in the middle and lower study areas (Appendix Table E.9; Appendix Figure E.10). Decreases relative to the previous year (2020) were also observed in the middle and lower study areas between RG_FOBCP and RG_FOPDO, while increases were observed in the upper study area between RG_FODHE and RG_FOUSH (Appendix Table E.9; Appendix Figure E.10). Percent Plecoptera and Trichoptera have not changed over time throughout the FRO LAEMP study area, with few exceptions (i.e., Plecoptera was significantly higher than base year at RG_FOBCP but lower at RG_MP1 compared to 2020 [Appendix Table E.10; Appendix Figure E.11]; Trichoptera was higher than base year at RG_MP1, RG_FOUSH and RG_FO22 [Appendix Table E.11; Appendix Figure E.12]). Abundance and % Chironomids were significantly lower in 2021 compared to the base year and/or previous years at multiple monitoring areas throughout the full study area (Appendix Tables E.12 and E.20; Appendix Figures E.13 and E.18). Of the other endpoints evaluated, few significant differences were observed. Total abundance for key metrics (EPT, Ephemeroptera, Plecoptera, Trichoptera, Ephemeroptera families) have remained consistent over time in most areas, with significant changes occurring only intermittently throughout the study area and likely represent natural variation in benthic invertebrate communities (Appendix Tables E.13 to E.19; Appendix Figures E.14 to E.21). Benthic invertebrate community index endpoints were also plotted temporally to determine if changes in BIC represented a shift in the functional communities over time, and if they could explain differences in key BIC endpoints throughout the study area. Few changes of BIC indices were observed compared to previous years (Appendix Figures B.22 to B.25).

3.4.3.2 Seasonal

Seasonal benthic invertebrate community data will be interpreted to address Study Questions #1, #5, and #6 (see Sections 4.1, 4.5, and 4.6). Seasonal changes in BIC were visually compared using data collected in June, August, September and December 2018, February, June, September, and December 2019, and June, September, and December 2020 and 2021 to identify potential seasonal patterns. Only a subset of monitoring areas were sampled in the winter programs due to study design considerations and ice conditions (Minnow and Lotic 2019a, 2021a). Key BIC metrics were plotted over all sampling periods (Appendix Figures E.26 to E.44). Total abundance was the lowest in June and increased through September with a plateauing or decrease observed in December at most biological monitoring areas where data were available (Appendix Figure E.26). No consistent seasonal pattern in LPL richness was observed among the sampling areas (Appendix Figure E.27). Percent Ephemeroptera was lowest in September and December when % Plecoptera was highest (Appendix Figures E.29 and E.30), while % Trichoptera and % EPT showed no consistent seasonal pattern across monitoring areas (Appendix Figures E.28 and E.31). The abundance of EPT and Plecoptera was lowest in June and increased through September and December (Appendix Figures E.33 and E.35); however, the abundance of Ephemeroptera, including families within Ephemeroptera (i.e., Baetidae, Heptageniidae, and Ephemerellidae) and Trichoptera was similar or higher in

September compared to June, but lower in December at most monitoring areas (Appendix Figures E.34, E.36, and E.39 to E.40). Percent and abundance of Chironomids also showed no seasonal patterns among the monitoring areas (Appendix Figures E.32 and E.37).

Seasonal changes in BIC indices were also plotted to determine if changes in BIC represented a shift in the functional communities by season, and if they could explain differences in key BIC endpoints throughout the study area. No clear seasonal changes in BIC indices were observed (Appendix Figures E.41 to E.44).

Relative BIC composition was visually compared among the sampling periods, and across biological monitoring areas, to identify seasonal patterns (Figure 3.18). Consistent with previous years, except for the areas between Porter Creek and Chauncey Creek (RG_FODPO and RG_FO22), the FRO LAEMP study area had similar community composition in June, including areas where % Ephemeroptera has consistently been below normal ranges in September (Figure 3.18). Although families of Ephemeroptera varied in June, the relative abundance of Ephemeroptera was consistent across the study area, except between RG_FODPO and RG_FO22. In September, downstream areas having low % Ephemeroptera had relatively high proportions of Plecoptera, particularly species from the families Perlodidae and Nemouridae (Figure 3.18). Consistent with previous years, December had very low proportions of Ephemeroptera families in downstream areas (i.e., FR_FRUPO to RG_FOUEW) and were dominated by Plecoptera (i.e., Family Nemouridae) compared to upstream areas (Figure 3.18).

The relative proportion of organisms exhibiting different feeding and habitat groups were visually compared to identify patterns across areas and seasons (Appendix Figures E.45 and E.46). In September and December there was a higher proportion of shredders complimented by a lower proportion of collector-gatherers in downstream areas where % Ephemeroptera has consistently been below the normal range. The relative proportion of the different feeding groups were consistent across the study area in June, except in the Fording River between RG_FODPO and RG_FOUEW where proportions of shredders were higher compared to other areas (Appendix Figure E.45). In June, a higher proportion of swimmers were observed in the lower study area compared to upstream, while in September and December sprawlers comprised the dominant habitat group in the lower study area (Appendix Figure E.46). Burrowers were hardly present in the study area in June 2021; however, in the drier months of September and December they became more prominent, particularly in areas known to experience seasonal drying and/or low flows (see Section 4.6; Appendix Figure E.46). Sprawlers and clingers were the dominant BIC habitat groups in December (Appendix Figure E.46).

3.5 Integrated Analysis

3.5.1 Time Trend Analyses of Nitrate Concentrations and BIC

To further investigate Study Question #1, temporal comparisons of key BIC endpoints (total BIC abundance, richness, % EPT and % Ephemeroptera) and nitrate concentrations were explored. Total BIC abundance, richness, % Ephemeroptera and % EPT were plotted with nitrate concentrations across the study period to visually compare temporal patterns in BIC endpoints relative to changes in nitrate concentrations (Appendix Figures F.1 to F.4). No associations between LPL richness and changes in nitrate concentrations were observed between 2012 and 2021 (Appendix Figure F.2). Associations between decreases in the other BIC endpoints (total BIC abundance, % Ephemeroptera, and % EPT) and increases in aqueous nitrate concentrations were infrequent among monitoring areas and inconsistent over time (Appendix Figures F1, F.3, and F.4).

To statistically analyze how nitrate concentrations may have changed over time relative to BIC, a temporal trend analysis was conducted (Table 3.6). This analysis evaluated changes in nitrate concentrations and key BIC endpoints (total BIC abundance, richness, % EPT and % Ephemeroptera) at each FRO LAEMP biological monitoring area throughout the study period (2012 to 2021). Significant increases in nitrate concentrations were observed at reference location RG_FO26, RG_FOBSC, and overall (i.e., the full study area), while all other areas remained unchanged throughout the study period (i.e., 2012 to 2021; Table 3.6). The increases in nitrate concentrations at RG_FOBSC from 2012 to 2021 occurred together with increases in richness and decreases in % Ephemeroptera, however, total abundance and % EPT were unchanged. Although increases in nitrate concentrations occurred concurrently with increases in abundance and LPL richness and decreases in % EPT and % Ephemeroptera when considering the entire study area, individual monitoring areas having significantly decreased % EPT and % Ephemeroptera (i.e., a significant p-value and a negative slope) were not the same areas with significant increases in nitrate concentrations, except for % Ephemeroptera at RG_FOBSC (Table 3.6).

3.5.2 Correlation Analysis

To further investigate variations in BIC (Study Questions #1, #5, and #6; see Sections 4.1, 4.5, and 4.6), correlations between chemical and physical variables and BIC metrics were completed on the full study area, and on individual study areas (upper, middle, and lower study areas; Figure 3.19; Appendix Table F.1; Appendix Figures F.5 to F8). Annual mean water quality concentrations (2018 to 2021) calculated from four different seasons (described in Section 2.6) were used for the correlation analysis.

Table 3.6: Temporal Changes in Nitrate Concentrations and Benthic Invertebrate Community Endpoints in the FRO LAEMP, September 2012 to 2021

Station	Water Quality		Benthic Invertebrate Community

P-value < 0.1

Notes: Water quality parameters were analyzed with a Linear Model (LM) using log10-transformed Nitrate because there were no replicate samples taken. Benthic invertebrate communities were analyzed with Linear Mixed-Effects Models (LMM) using transformations (Abundance and Richness were log10- transformed, %EPT and %E were logit-transformed) to account for replicate samples taken for some years. Effect Sizes were calculated as regression slope coefficients (representing time) divided by the standard error of the regression coefficient from LM and LMM. P-values indicate if slopes are significantly different from zero. Only stations with a minimum of 4 years of data were included in the analysis.

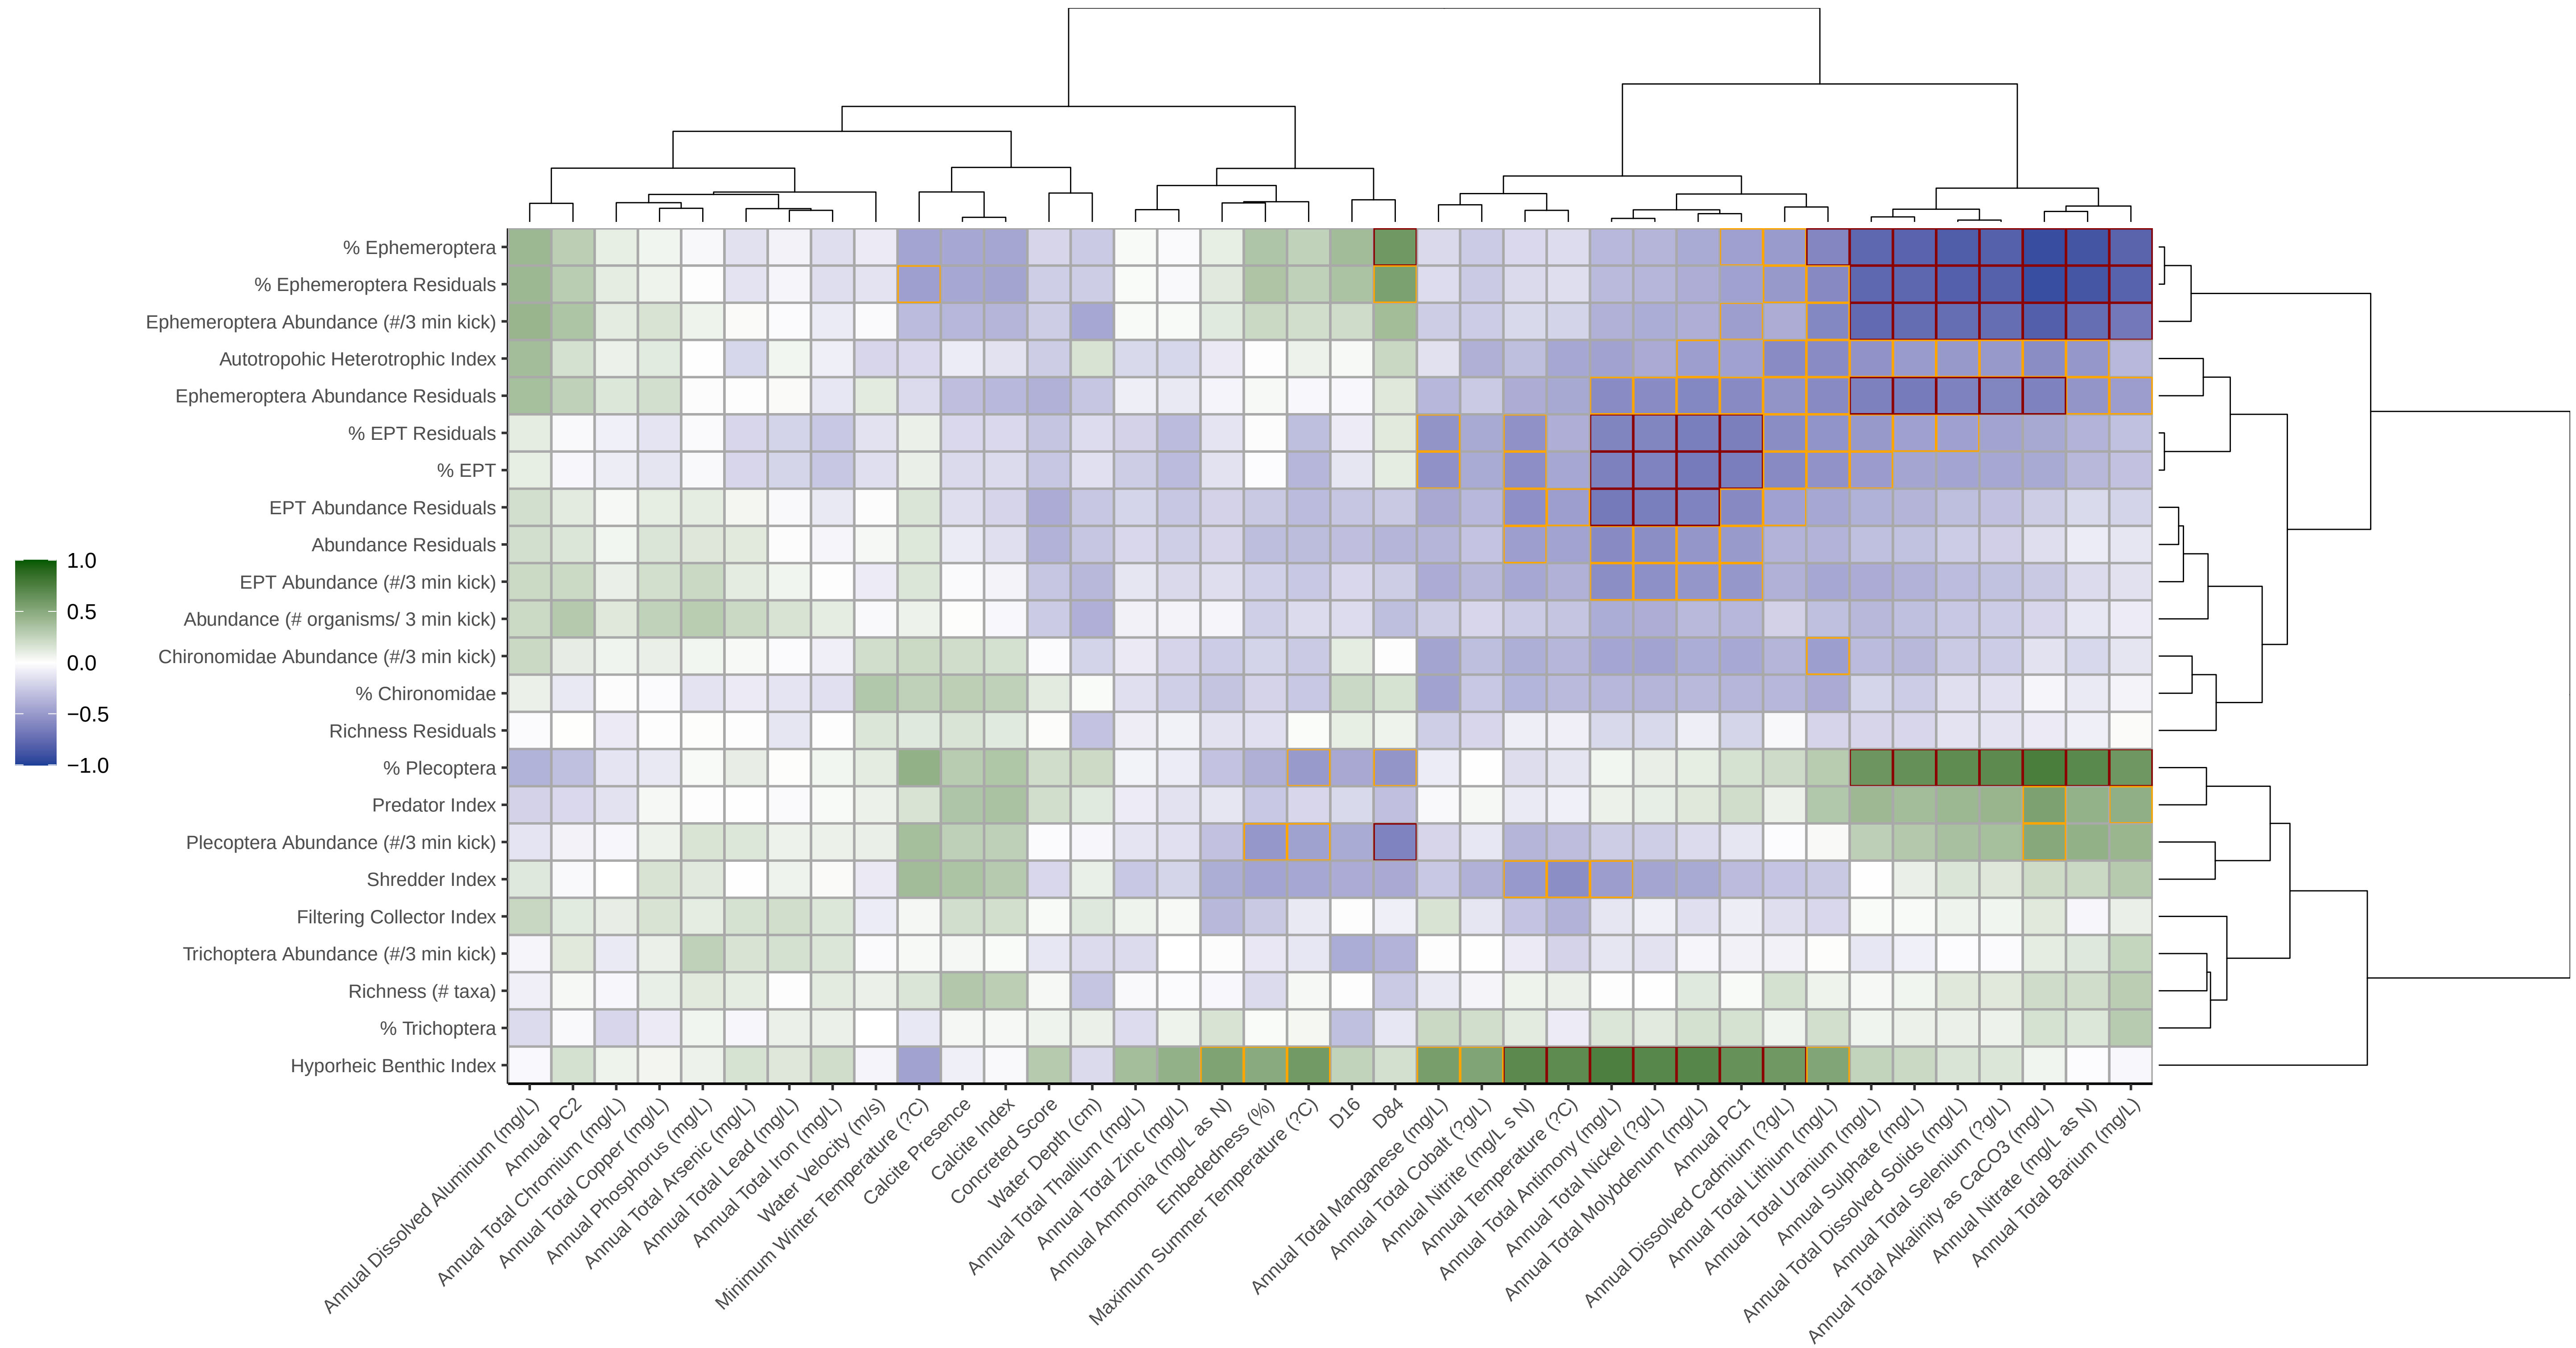

Figure 3.19: Heatmap of Spearman Correlation Coefficients of Benthic Invertebrate Community Endpoints against Physical and Chemical Parameters, Full Fording River, 2018 to 2021

Notes: Orange boxes show significant correlations (p−value < 0.05/38 for Bonferroni Correction), and red boxes show significant correlations with absolute coefficients > 0.6. Cluster diagrams on x− and y−axis represent similarities using Euclidean distances clustered according to Ward's minimum variance method.

Correlations between chemical and physical variables and BIC metrics were summarized in heatmaps of correlation coefficients for the full study area (Figure 3.19), and for the upper, middle, and lower study areas (Appendix Figure F.6 to F.8). Variables within each study area having strong ($r_s \geq |0.6|$) and significant correlations (p<0.00132; Bonforreni correction of 0.05/38 independent comparisons) were plotted (Appendix Figure F.5), and all correlations were summarized (Appendix Table F.1). For physical variables in the full study area, only D84 correlated strongly ($r_s \geq 0.6$) with BIC metrics (positively correlated with % Ephemeroptera and negatively correlated with Plecoptera abundance; Appendix Table F.1). Percent Plecoptera was positively correlated with calcite presence in the upper study area (Appendix Table F.1). In the middle study area, concretion score was the only physical parameters that had significant and strong correlations with any of the BIC metrics (positively correlated with % Plecoptera and negatively with benthic hyporheic index; Appendix Table F.1). Significant and strong positive correlations between minimum winter water temperature and abundances of Plecoptera and EPT were identified in the lower study area (Appendix Table F.1).

Many water quality constituents (alkalinity, nitrate, sulphate, TDS, total barium, total selenium, and total uranium) correlated strongly with key BIC metrics (i.e., negative correlations with % Ephemeroptera, Ephemeroptera abundance, as well as their residuals, and positive correlations with % Plecoptera) in the full study area (Appendix Table F.1; Appendix Figure F.5). In the upper study area, total nickel correlated significantly and strongly (negative) with Ephemeroptera abundance and its residuals, however, positive correlations were observed between total nickel and the benthic hyporheic index and between PC1 and % Trichoptera (Appendix Table F.1; Appendix Figure F.5). Multiple water quality constituents (alkalinity, total antimony, total molybdenum, and total nickel) correlated negatively with % Ephemeroptera, while others (alkalinity, sulphate, TDS, total antimony, total nickel, total selenium, and total uranium) correlated positively with % Plecoptera in the middle study area (Appendix Table F.1; Appendix Figure F.5). No water quality constituents correlated significantly and strongly with BIC endpoints in the lower study area (Appendix Table F.1; Appendix Figure F.5).

Hierarchical clustering showed groupings of variables that correlated similarly with BIC endpoints for each study area. Water quality constituents that clustered together and had the strongest correlations with key BIC metrics in the full study area were total barium, nitrate, total alkalinity, total selenium, TDS, sulphate, total uranium, and total lithium for one major cluster, and total antimony, total nickel, total molybdenum, and PC1 in another cluster (Figure 3.19). Percent Ephemeroptera, Ephemeroptera abundance, % EPT, and their residuals from the habitat model, as well as the autotrophic-heterotrophic index clustered together in the full study area (Figure 3.19). Although the upper, middle, and lower study areas clustered similarly to the full study area primarily based on water quality constituents, there were very few strong correlations

(Appendix Figures F.6 to F.8). Mine-related constituents including total selenium, alkalinity, TDS, total uranium, and sulphate clustered together in all three individual study areas, while nitrate, total nickel, dissolved cadmium, and PC1 clustered together in the upper and middle study areas, but less so in the lower study area (Appendix Figures F.6 to F.8). Some other notable variables that clustered with mine-related water quality constituents in individual study areas were calcite concretion score in the middle study area and minimum winter water temperature and annual water temperature in the lower study area (Appendix Figures F.7 and F.8).

3.5.3 Canonical Correspondence Analysis

Canonical Correspondence Analysis (CCA) will be interpreted to further address Study Questions #1, #5, and #6 (see Sections 4.1, 4.5, and 4.6). Benthic invertebrate community samples were collected at all FRO LAEMP monitoring areas in June and September (2018 to 2021) and were used to assess potential effects of habitat and water chemistry on BIC variation within each sampling period throughout the full study area and in individual study areas (upper, middle, lower; Figure 3.20; Appendix Table F.2; Appendix Figures F.9 to F.12).

The Correspondence Analysis (CA) showed an upstream to downstream gradient across the first axis, and a temporal separation of samples (primarily separating 2021 data) on the second axis (Appendix Figures F.9). This pattern was consistent in both June and September. The separation of 2021 data was quite distinct in September (driven largely by very high abundances of Cinygmula, a Heptageniidae). The separation was present in June as well, but was less distinct, and driven by a larger group of taxa. The CAs within individual study areas showed strong temporal patterns on the first axis in both June and September (Appendix Figures F.9). The CA of the upper study area showed an upstream to downstream gradient along the second CA axis in September, except at the monitoring area downstream of the North Tailings Pond (RG_FOUSH) which was more centralized in the plots than would be expected from its location along the Fording River within the upper study area. This pattern was less apparent in the June CA. The middle study area was more strongly temporally divided in both June and September (Appendix Figures F.9), with September showing a trend along the first axis from 2018 to 2021. The second axis approximately followed a gradient in water chemistry, with RG_FOUKI and RG_FOBKS in the upstream portion of the study area separated from the more impacted downstream areas. The CAs for the lower study areas showed a strong temporal separation in September along the first axis (primarily separating 2021 from other years), with an upstream to downstream gradient along the second axis; except RG_FO22 (Fording River upstream of Chauncey Creek) being most dissimilar from the upstream areas and RG_FOUEW being a bit more similar to the upstream areas. The June CA showed an even stronger spatial separation along the first axis, with temporal differences on the second axis. The arrangement of

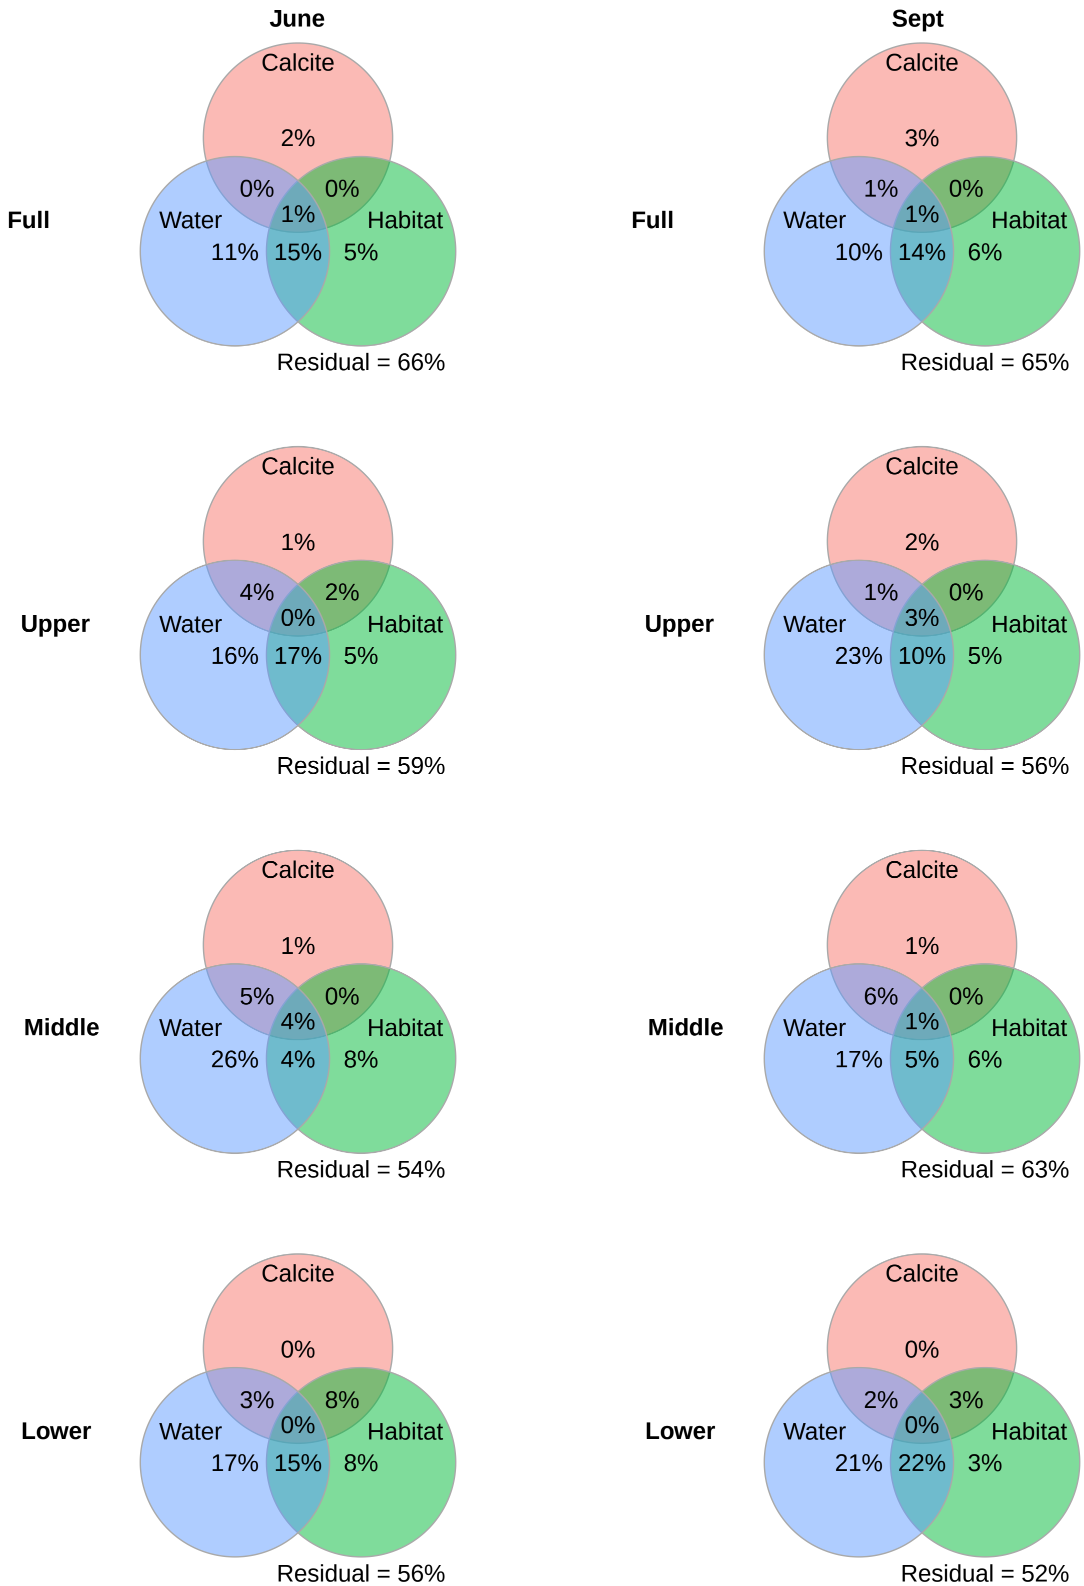

Figure 3.20: Variance Partitioning Between Habitat, Water and Calcite Using Partial Canonical Correspondence Analysis of Benthic Invertebrate Communities in June and September, FRO LAEMP, 2018 to 2021

Notes: Lowest Practical Level taxon abundances were ln(x+1) transformed prior to analysis. Taxa that made up less than 1% of total abundance (on the ln(x+1) scale) and occurred in fewer than 10% of samples were excluded from analysis. Mine−exposed areas included in the FRO LAEMP were divided into three sections from upstream to downstream: Upper Study Area, Middle Study Area, and Lower Study Area.

monitoring areas along the first axis of the June CA suggested the BIC at RG_FOUEW (Fording River upstream of Ewin Creek) was even more similar to the upstream RG_FRUPO then in September, suggesting potentially complex interactions among habitat and stressor gradients in this part of the study area.

Canonical Correspondence Analysis were used to explain variation in BIC using habitat, calcite and water chemistry predictors. Overall, habitat and water chemistry had more significant and stronger effects on BIC in September compared to June (Figure 3.20; Appendix Table F.2). Therefore, only the September results are summarized in detail. In September, within the full study area, 35% of variation in BIC was explained by habitat, water, and calcite predictor groups, but a relatively large percent (16%) was shared between the three predictor groups (Figure 3.20). After removing the shared variation, only 6%, 10%, and 3% was uniquely associated with habitat, water, and calcite, respectively. The unexplained residuals accounted for 65% of the overall variation in September BIC within the full study area. Sources of unexplained variation may include unexplored habitat predictors, natural temporal variability, annual climatic variation, and variation in organism life cycles. Separating the data into individual study areas (i.e., upper, middle, and lower) resulted in predictor variables explaining more variation in BIC (i.e., total explained variation in BIC ranged from 37% and 48% for individual study areas in September; Figure 3.20). Although the percent of variation in BIC explained by habitat and calcite remained relatively low (3% to 6%, and 0% to 2%, respectively) within individual study areas, the percent of variation in BIC explained by water increased (17% to 23%; Figure 3.20). Similar patterns of explained variance were observed in June BIC data (Figure 3.20).

Constraining the BIC data by habitat variables maintained the upstream to downstream gradient across the full study area in both June and September on the first axis (Appendix Figure F.10). This pattern was consistent with that observed in the unconstrained ordination, however the second axis of the habitat constrained CCA did not separate out 2021 samples as strongly as the unconstrained ordination (Appendix Figure F.9), indicating the overall differences in BIC observed in 2021 were not well predicted by the habitat alone. Catchment area was the most important habitat predictor (largest F-Statistic; Appendix Table F.2) followed by substrate sizes, then depth in both June and September. These were most important as both single (individual importance), and marginal (importance after all other habitat terms were included in the model) terms. The CCA for the upper study area separated 2021 data in both June and September (similar to unconstrained ordination), with the separation largely driven by smaller substrate sizes in 2021 (in both June and September) and wider stream widths (in September). This was confirmed by the importance of these habitat predictors in the ANOVA analysis (Appendix Table F.2). This may be the result of a smaller spring freshet (failing to move small substrates downstream) in 2021 compared to previous years, or fine sediments being deposited into the stream. The habitat constrained CCA of the middle study area also separated 2021 data, but along the second axis, suggesting it has weaker gradients than in the unconstrained ordination for this study area. The primary drivers separating 2021 in June and September were also smaller substrate sizes, as well as lower water velocities in June, and higher velocities in September. These patterns were also supported by ANOVA analysis (Appendix Table F.2), with these predictors having highest the F-Statistics. The habitat constrained CCA for the lower study area did not separate 2021 from other years in either June or September, unlike the unconstrained CA for this region. Instead, the first axis largely followed an upstream to downstream gradient, except the furthest downstream area (RG_FOUEW) which was pulled a little closer to the upstream areas due larger substrates. The most important habitat predictors identified by the ANOVA for this area was substrate sizes, slope, gradient, and catchment area (Appendix Table F.2). Overall, the habitat CCAs showed the observed patterns in BIC community variation can largely be explained by habitat features, including the unique communities overserved in 2021; however, the temporal patterns are clearer in the upper and middle study area than the lower study area, suggesting that the differences in the 2021 BIC at the lower study area were not explained by the habitat variables included in this study.

Constraining the BIC data by water chemistry and calcite (stressors) resulted in similar upstream to downstream patterns in June and September (Appendix Figure F.11) as those observed in the unconstrained and habitat constrained ordinations (Appendix Figure F.9 and F.10). The second axis strongly separated 2021 data in September, but not June in the full study area dataset. The BIC in the middle and lower study areas had higher concentrations of most water chemistry analytes. The September 2021 BIC are primarily separated from other years by having lower calcite presence than previous years. Most water chemistry predictors had a stronger effect on BIC in September than in June. Selenium and sulphate had the strongest effects in September and June, while uranium, alkalinity, TDS, and nitrate all had stronger effects in September (Appendix Table F.2). The stressor constrained CCA of the upper study area separated 2021 along the first axis in both June and September, with the second axis reflecting similar patterns as the unconstrained ordination (Appendix Figure F.11). Similar to the full study area, low calcite presence separated the 2021 samples from other years. The secondary gradient (second axis) across areas mainly separated RG_FODHE and RG_FOUCL from other upper study area sites by having lower concentrations of nearly all water chemistry constituents in both June and September. The ANOVA results suggested nitrate, selenium, sulphate, uranium and TDS are the strongest drivers of these separations, with September communities responding more strongly to these constituents than June communities (as shown by higher F-Statistics, both singly and marginally; Appendix Table F.2). The middle study area showed very similar patterns to the unconstrained ordination, separating 2021 across the first axis (Appendix Figure F.11).

Both RG_FOUKI and RG_FOBKS (located upstream and downstream of Kilmarnock Creek in the Fording River, respectively) separated from the more impacted downstream areas (i.e., downstream of the Swift-Cataract diversion) in September by having lower concentrations of most constituents. The September 2021 samples were associated with lower calcite (presence and concretion), lower barium, and higher manganese and the relationships between the BIC communities and water chemistry were less consistent in June than September. Overall, fewer water chemistry constituents had strong relationships with BIC in June in the middle study area (Appendix Table F.2), and the gradients of effects (vectors on the CCA plot) were less consistent. The stressor constrained CCA for the lower study area did not separate 2021 from other years in June but did in September (similar to unconstrained CA for this region). In June, RG_FO22 (Fording River upstream of Chauncey Creek) was separated from the remaining areas by a higher concentration of selenium, sulphate, TDS, barium and uranium, with the remaining areas higher in cadmium, molybdenum, and manganese. The BIC communities in September 2021 were separated by higher selenium, sulphate, TDS, cadmium, and nitrate concentrations compared to previous years. The remaining upstream to downstream gradient was driven by increases in manganese and calcite from upstream to downstream, but a drop in molybdenum. These patterns are supported by correspondingly high F-Statistics from ANOVAs on both single and marginal terms (Appendix Table F.2). Overall, the stressor constrained CCAs show the observed patterns in BIC community variation could largely be explained by stressor gradients, including the unique communities observed in 2021. The temporal patterns are stronger in the stressor constrained CCA than the habitat constrained one, especially in September. This suggests that the differences in the 2021 BIC at the lower study area was better explained by stressor variables than habitat alone.

Both stressor and habitat constrained CCAs were able to explain observed gradients in BIC, however, different predictor groups appeared to explain observed patterns slightly better in different study areas. The variance partition (Figure 3.20) identified a large degree of overlap in explained variation by these predictor datasets. This was verified with pCCA to understand the effects of water chemistry and calcite stressors on BIC variation after controlling for habitat (i.e., removing the shared variation of habitat and stressor variables; Appendix Table F.2; Appendix Figure F.12). After accounting for habitat, most water quality and calcite predictors still explained statistically significant amounts of variation in BIC in both June and September (though the magnitude of the F-Statistics are much smaller, indicating these predictors explained a smaller fraction). Among individual study areas, the upper and middle study areas had the most water quality stressors affecting residual BIC variation after accounting for habitat, and some of the highest effects (denoted by size of F-statistic value) were from total barium, nitrate, total selenium, and sulphate (Appendix Table F.1). The lower study area had the fewest number of stressors affecting BIC variation among the individual study areas (Appendix Table F.1), despite having some of the highest concentrations of mine-related constituents. The pCCA scatterplots (Appendix Figure F.12) did not separate BIC spatially within the full study area in June or September and spatial separation within individual study areas was also limited for both seasons. This resulted in few clear patterns of water quality and calcite stressors as they relate to variation in BIC (Appendix Figure F.12), indicating that the residual variation in the BIC that was being explained was minor and limited to differences in individual samples, and not large-scale patterns.

3.6 Fish Sampling in the Upper Fording River

3.6.1 Westslope Cutthroat Trout Tissue Chemistry

Westslope Cutthroat Trout tissue chemistry data will be interpreted to address Study Question #6 (see Section 4.6). Westslope Cutthroat Trout muscle tissue samples were collected from three reference (RG_MOYIE, RG_BULL, and RG_FH) and two mine-exposed (RG_MP1 and RG_FODGH) areas within the FRO LAEMP study area in 2018 and 2021 under the RAEMP (Figure 3.21; Appendix I.1). Tissue selenium concentrations were similar in 2018 and 2021 at both mine-exposed areas and the Bull River reference area (RG_BULL; Figure 3.21). Westslope Cutthroat Trout collected at the Multiplate culvert (RG_MP1) and between Chauncey Creek and Greenhills Creek (RG_FODGH) had muscle tissue selenium concentrations that were higher than the B.C. selenium guideline and the reference area normal range but were lower than the EVWQP muscle-equivalent benchmark for selenium concentrations in WCT muscle tissue (Figure 3.21).

Tissue (dorsal muscle and whole body) sampled due to incidental mortalities (i.e., opportunistic samples) were collected from Clode Creek (FR_CC1), the Lake Mountain Outfall (FR_NGD1), and the Fording River downstream of the Henretta confluence (FR_FRDSHC1), downstream of the Concrete Arch (RG_FOUNGD), and upstream of the FRO-S AWTF outfall (FR_FR3) in 2021 (Figure 3.22; Appendix Table I.2). Westslope Cutthroat Trout tissue selenium concentrations were highest in opportunistic samples collected from mortalities following a fish salvage at Clode Creek and lowest (i.e., below the B.C selenium guideline) in the Fording River downstream of the Henretta Creek confluence (FR_FRDSHC1; Figure 3.22). Selenium concentrations in the remaining opportunistic samples were higher than the reference normal range (Figure 3.22).

Muscle plugs were also collected from female WCT that were in spawning condition in June 2021 from Clode Flats (RG_CLFL) and from the Fording River S6 oxbow (RG_FROXB) within the FRO LAEMP study area to meet the Environment and Climate Change Canada (ECCC) direction (Figure 3.23; Appendix Table I.3). Although WCT tissue collected from both areas had

Notes: Green represents reference stations and blue represents mine−exposed stations. Muscle samples are plotted with an filled sample and whole body samples are plotted with an open symbol. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. M = Mainstem, T = Tributary.

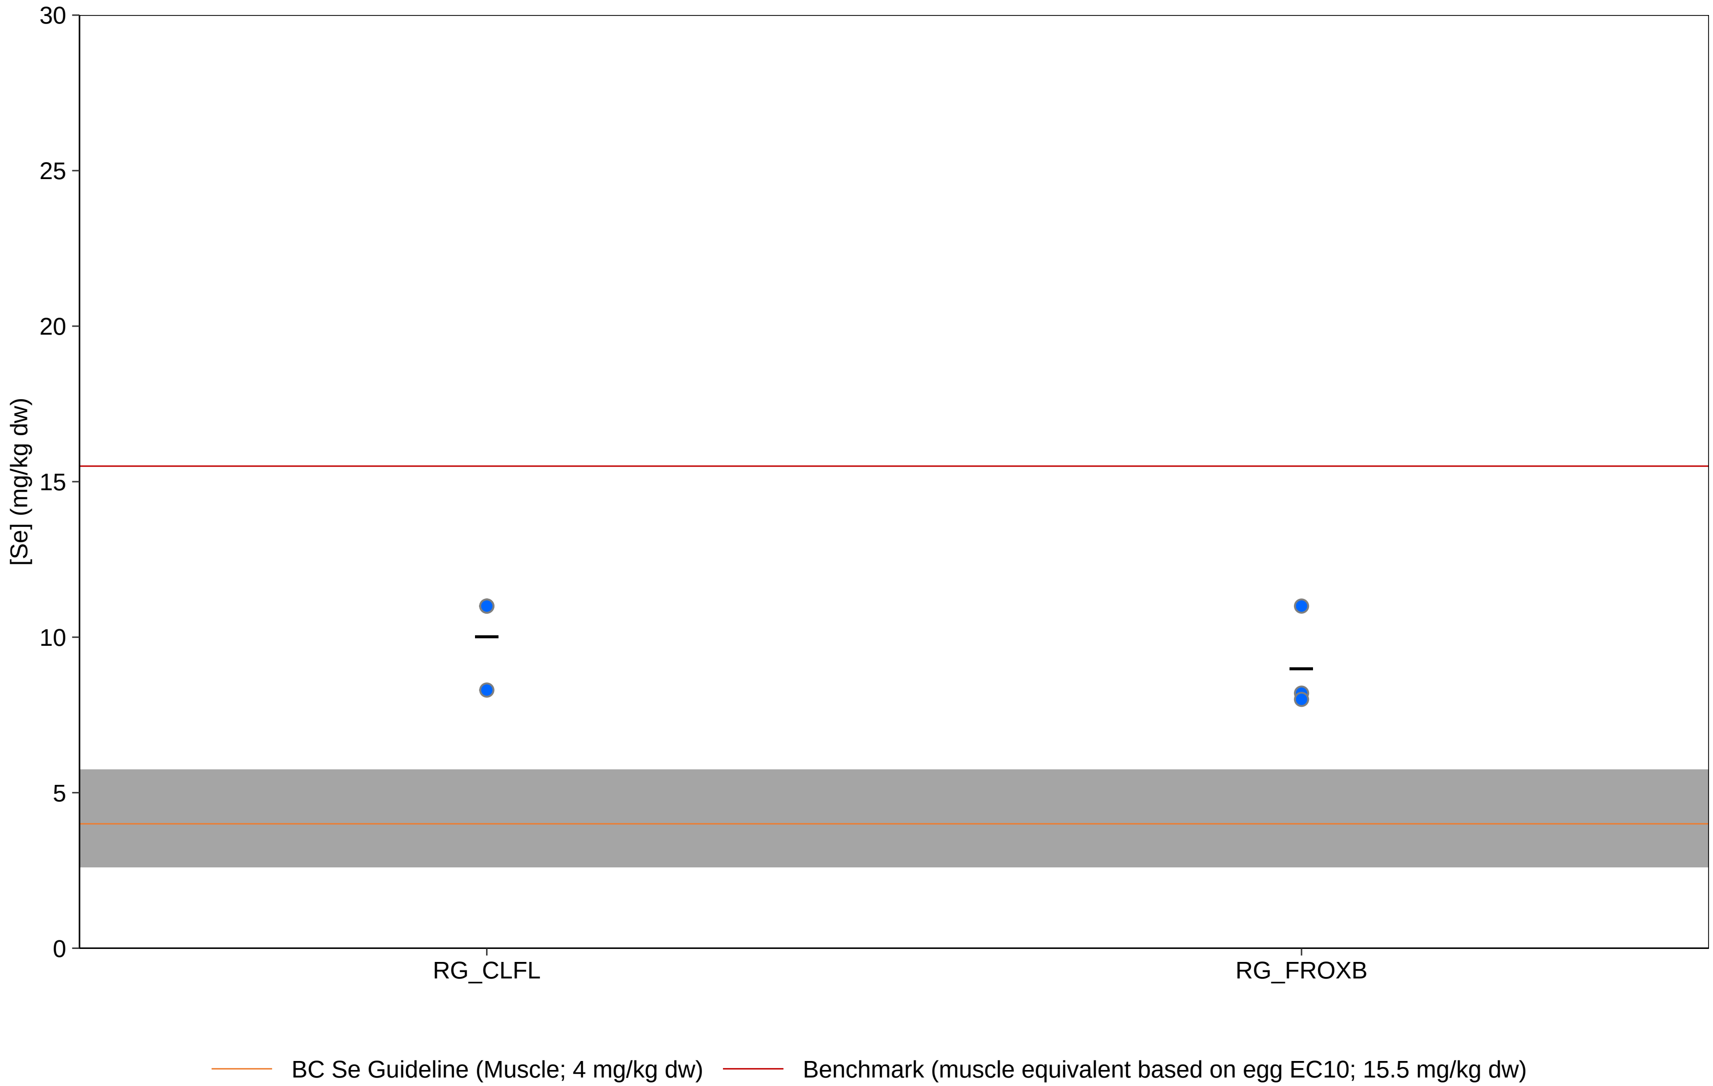

Figure 3.23: Selenium Concentration in Female West Slope Cutthroat Trout, Fording River, June 2021

Notes: Black horizontal bars indicate means. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP muscle selenium concentrations above the regional normal range and the B.C. selenium guideline, all samples were below the EVWQP WCT muscle-equivalent selenium benchmark (Figure 3.23).

3.6.2 Fish Condition Factor

Fish condition factor data will be interpreted to address Study Question #6 (see Section 4.6). Westslope Cutthroat Trout collected for tissue samples under the RAEMP, including ECCC requirements (see Section 3.6.1), were also assessed for meristics and anomalies (Appendix Tables I.1 and I.3). Of all the WCT captured within mine-exposed areas in the upper Fording River under the RAEMP in 2021 (22 total fish), only one fish at the Fording River S6 oxbow (RG_FROXB) had an anomaly (minor caudal fin erosion; Appendix Tables I.1 and I.3). Fulton's Condition Factor was calculated from meristics data for fish caught under the RAEMP, except for the fish caught for the ECCC requirement (Figure 3.24; Appendix Table I.1). Overall, fish condition was similar or higher at mine-exposed areas compared to reference areas (Figure 3.24; Appendix Table I.1). Anomalies and fish condition were not assessed for fish sampled opportunistically from incidental mortalities because of varying levels of deterioration when fish were found. Results of fish sampling in 2021 are summarized in this report as outlined in the 2021-2023 FRO LAEMP Study design. Additional alignment with Teck's regional fish monitoring framework approach will be further included in the 2022 FRO LAEMP reporting (including adjusting the assessment of fish condition to align with other fish monitoring programs).

Notes: Green represents reference stations and blue represents mine−exposed stations. M = Mainstem, T = Tributary.

4 DATA EVALUATION AND DISCUSSION

4.1 Study Question #1

4.1.1 Overview

Study Question #1 (Are nitrate concentrations increasing in the study area changing and do they have the potential for adverse effects on biota?) was developed because the EVWQP Regional Water Quality Model (RWQM) projected increases in nitrate concentrations throughout the FRO LAEMP study area over time (Teck 2014). Previous FRO LAEMP reports have demonstrated that, contrary to original projections (Teck 2014), nitrate concentrations have not increased significantly over time, although they are greater than EVWQP effects benchmarks in some areas (Minnow and Lotic 2019b, 2020b, 2021b). While nitrate concentrations have been at levels that may lead to effects on BIC, other water quality constituents as well as site-specific habitat conditions are also likely contributing to variations in BIC throughout the study area (Minnow and Lotic 2019b, 2020b, 2021b). To address Study Question #1, aqueous nitrate concentration and BIC data were collected throughout the FRO LAEMP study area in 2021. In addition, chronic toxicity testing completed under the Chronic Toxicity Program (Golder 2022b) on water from several locations within the FRO LAEMP study area has been considered in the context of Study Question #1.

4.1.2 Nitrate Concentrations

Updated model projections in 2022 identified an increasing pattern in projected nitrate concentrations between 2014 and 2021 at both the former (FR_FRCP1) and current (FR_FRABCH) FRO Compliance Point but decreasing concentrations at the Fording River Order Station (GH_FR1; Figure 3.1; Golder 2022b). Measured nitrate concentrations were similar to model predictions throughout the study period, except for seasonally low flow periods in the late fall and winter months when concentrations were above predictions (Figure 3.1; Golder 2022a). Although nitrate concentrations have remained consistent with previous years at most areas monitored under the FRO LAEMP, several areas, particularly from the FRO-S AWTF outfall location upstream to the Multiplate culvert, have increased significantly relative to historical values.

4.1.3 Biota in Relation to Nitrate Concentrations

Nitrate concentrations in the FRO LAEMP study area have increased relative to previous years from the Multiplate Culvert (RG_MP1) downstream to upstream of Kilmarnock Creek (RG_FOUKI), downstream of the FRO-S AWTF outfall location (RG_SCOUTDS), and the monitoring area located upstream of Chauncey Creek (RG_F022). Abundance and richness values, however, were within site-specific and regional normal ranges and have not changed over time. Relative proportion endpoints (% EPT, % Ephemeroptera) that have historically been below normal ranges, especially in the lower study area, were unchanged relative to recent years at monitoring areas where nitrate has increased. A statistical comparison[20] of temporal changes in BIC endpoints with temporal changes in nitrate concentrations did not identify any consistent associations between changes in nitrate concentrations and changes in BIC metrics for individual biological monitoring areas; however, strong negative correlations between nitrate and % Ephemeroptera, Ephemeroptera abundance, and % EPT were identified. In addition, constrained ordinations have suggested that spatial variations in BIC are partially explained by a number of water quality constituents including nitrate, but a large amount of shared variation exists among water quality, habitat, and calcite that remains difficult to tease apart (see Section 4.5).

Nitrate concentrations were not directly associated with adverse effects to biota in 2021 chronic toxicity testing, except for one test on rainbow trout survival with a possible adverse effect in water from FR_FRCP1 (former FRO Compliance point); however, the result was potentially confounded by microbial contamination (Golder 2022a) and occurred with water collected in Q4, which is not a season associated with early life stages of WCT in the upper Fording River (Evaluation of Cause Team 2021). Nitrate concentrations in the study area, however, are high enough to cause toxicity in invertebrates based on the EVWQP effects benchmarks (Teck 2014) and thresholds identified in the literature. Mean nitrate concentrations in 2021 at areas (RG_SCOUTDS to RG_FOUEW) exhibiting lower % Ephemeroptera and % EPT ranged from 15.4 to 27.6 mg/L, while maximum concentrations ranged from 29.4 to 48.9 mg/L. The EVWQP Level 1 benchmark was exceeded in 54% to 100% of samples, and the Level 2 benchmark was exceeded in 31%[21] to 79% of samples collected between RG_SCOUTDS and RG_FOUEW, with the highest proportion of samples exceeding benchmarks in the lower study area, particularly at RG_FRUPO. Level 1 and Level 2 benchmarks correspond to approximately 10% and 20% response effects to sensitive aquatic invertebrates (water flea and amphipod; Golder 2014b); however, the EVWQP benchmarks were not developed using toxicity data for specific benthic invertebrate taxa (e.g., Ephemeroptera, Plecoptera, Trichoptera, Diptera) present and abundant in the FRO LAEMP study area, which makes direct comparisons to benchmarks difficult. Although adverse effects of water collected in the upper Fording River were identified with water fleas and amphipods, nitrate was never identified as a leading contributing factor (Golder 2022a).

[20] Temporal model was designed to detect concurrent changes between the nitrate concentrations and BIC endpoints at individual biological monitoring areas and across the study areas but was not correlative.

[21] RG_FRCP1SW had 0% of samples exceeding EVWQP Level 2 benchmarks but only two samples were taken at this area in 2021 and one was taken during peak freshet.

Moreover, although many Ephemeroptera families, including families Ephemerellidae and Heptagenidae, have demonstrated some sensitivity to nitrate (Beketov 2004), covariation with other water quality and habitat variables affecting BIC makes the effect of nitrate difficult to separate.

4.1.4 Summary

Overall, although nitrate concentrations have increased at some areas within the study area in previous years, these changes were not commensurate with changes in BIC community at individual study areas. Taken together, while nitrate should not be considered the sole cause of observed effects to BIC endpoints, evidence suggests that nitrate is contributing to variations in benthic invertebrate community structure within the study area, and sensitive taxa (i.e., Ephemeroptera and EPT endpoints) are the lowest in areas where nitrate concentrations are the highest, supporting a link between nitrate concentrations and BIC structure based on monitoring data. Chronic toxicity testing has not demonstrated a link between nitrate concentrations and adverse responses to fish endpoints, particularly during early life stages of WCT. Water treatment was commissioned in the study area at the end of 2021 with the intent of significantly reducing nitrate and selenium loads into the upper Fording River. Evaluation of BIC following an improvement in water quality, as well as the use of BIC predictive modelling tools currently being developed under the RAEMP (Minnow 2021) will aid in the interpretation of monitoring data to support answering Study Question #1.

4.2 Study Question #2 (Current Condition)

4.2.1 Overview

Study Question #2 (Is water treatment affecting biological productivity downstream in the Fording River?) was developed to understand how water treatment may affect biological productivity downstream of the FRO-S AWTF and FRO-N SRF outfall locations as a result of potentially increased phosphorus loads into the upper Fording River due to treatment processes. To address the study question, aqueous nutrient (total phosphorus and orthophosphate) concentrations and benthic invertebrate biomass and density data were collected within the study area. Benthic invertebrate biomass and density were utilized as the proxy for primary productivity because they are less variable compared to periphyton (Minnow 2018). Results from 2021 represent the conditions prior to commissioning.

4.2.2 Nutrient Concentrations and Benthic Invertebrate Biomass and Density

Measurements of productivity (nutrient concentrations and biological productivity) have been consistent over time in the study area prior to commissioning of the FRO-S AWTF and FRO-N SRF. Total phosphorus and orthophosphate concentrations were similar across years

(2012 to 2021) at all mine-exposed biological monitoring areas included in the FRO LAEMP, and no clear spatial patterns were identified. Benthic invertebrate biomass and density has remained consistent within each biological monitoring area throughout the study period (2017 to 2021 for most locations).

4.3 Study Question #3 (Current Condition)

4.3.1 Overview

Study Question #3 (Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent within predictions, and if not, why?) was developed to understand how FRO-S AWTF and FRO-N SRF commissioning and operation may affect benthic invertebrate tissue selenium concentrations downstream of water treatment. The FRO-S AWTF and the FRO-N SRF were designed to remove up to 50% and 26% of total selenium downstream in the Fording River, respectively (Teck 2019c; Teck 2022c), which should result in reduced tissue selenium concentrations downstream (Golder 2020a). Although the AWTF was designed to mitigate generation of reduced selenium with the addition of Advanced Oxidation Process to the treatment process (Teck 2019c; Teck 2022c), there remains a possibility that water treatment from both the FRO-S AWTF and the FRO-N SRF may increase concentrations of the more bioavailable selenium species. Study Question #3 was developed to assess changes in selenium concentrations downstream of treatment, and aqueous selenium (total selenium, dissolved selenium and speciated selenium) concentrations and composite-taxa benthic invertebrate tissue selenium data were collected pre-commissioning of the FRO AWTF- S and the FRO-N SRF.

4.3.2 Benthic Invertebrate Tissue Selenium Concentrations

Benthic invertebrate tissue selenium concentrations were highest in areas that had the highest aqueous total and reduced selenium concentrations. In particular, benthic invertebrate tissue samples from areas located directly downstream from the Swift-Cataract diversion had among the highest selenium concentrations in the study area, but concentrations decreased quickly with distance downstream. Water entering the Fording River through the diversion is influenced by Swift Ponds, and current understanding of selenium speciation in sedimentation ponds suggests that concentrations are the highest immediately downstream, but as smaller tributaries enter larger main stem areas, dilution occurs quickly and the spatial extent is small (ADEPT 2022). Water from the Swift-Cataract diversion, as well as Kilmarnock Creek, will be treated by the FRO-S AWTF, and is expected to result in decreases in both aqueous selenium and benthic invertebrate tissue selenium concentrations in 2022.

Benthic invertebrate tissue selenium concentrations were within the prediction limits of the selenium bioaccumulation model (Golder 2020a) throughout most of the study area in 2021, with the exception of five replicates from the Greenhouse Side Channel (RG_FRGHSC), two replicates from RG_FOBSC (downstream of the Swift-Cataract diversion, upstream of the old Cataract Creek channel), and one replicate from the Multiplate Culvert (RG_MP1). The five replicates above prediction limits at RG_FRGHSC were a result of the presence of annelid worms within the composite-taxa samples (i.e., common in the Greenhouse side-channel), as annelids have been identified as bioaccumulating more selenium than other taxa typically present in composite samples from lotic areas in the Elk River watershed (Luoma 2021). Annelids were present in seven of ten tissue samples (four in September and three in December) collected from RG_FRGHSC in 2021. The Greenhouse Side Channel is groundwater-fed with no upstream surface water connection to the Fording River, and has a semi-lentic habitat (i.e., slower flowing waters with relatively small substrate) known to be more favorable to annelids (Pan et al 2012) compared to the erosional habitat more typical to lotic areas within the FRO LAEMP study area. The two replicates (in September) above prediction limits at RG_FOBSC did not contain annelids and the B-tool, which predicts tissue selenium concentrations from concentrations of reduced aqueous selenium species, predicted lower tissue selenium concentrations than what was observed at RG_FOBSC in September 2021. This suggested aqueous reduced selenium concentrations may have had a limited role in concentrations observed in these replicates; however, selenium speciation can be temporally variable, so it is possible that the concurrent sampling did not reflect typical exposure conditions at that area. Nevertheless, most replicates from RG_FOBSC in 2021 and previous years have been within bioaccumulation model prediction limits and below EVWQP benchmarks. The single replicate (of fifteen replicates total for 2021) above the upper prediction limit at RG_MP1 in June 2021 was likely a result of natural variation in selenium concentrations, as total and reduced aqueous selenium concentrations were relatively low in this area of the Fording River and all other replicates from RG_MP1 were well below prediction limits and EVWQP benchmarks. The remaining 2021 samples throughout the FRO LAEMP study area were within prediction limits for the bioaccumulation model, and most were below EVWQP benchmarks.

4.3.3 Summary

Benthic invertebrate tissue selenium concentrations within the FRO LAEMP study area were as expected based on water chemistry in most areas in 2021, except in the Greenhouse Side Channel, downstream of the Swift-Cataract diversion, and the Multiplate Culvert. Elevated tissue selenium concentrations at RG_FRGHSC were explained by the presence of annelids in composite-taxa samples; however, the cause of elevated tissue selenium concentrations at RG_FOBSC and RG_MP1 are not clearly understood. Tissue selenium concentrations were highest at monitoring areas where total and bioavailable (reduced) selenium species were detected at the highest concentrations. Overall, few samples had selenium concentrations greater than EVWQP effects benchmarks in 2021. Future sampling will continue to monitor tissue selenium concentrations in the study area, and current data will be used as a basis for comparison post commissioning of the FRO AWTF- S in Q4 2021.

4.4 Study Question #4 (Current Condition)

4.4.1 Overview

Study Question #4 (How is temperature changing over time in the FRO LAEMP study area? 4a. Is water temperature measurably different (greater than 1 degree Celsius) downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition? 4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF)? was developed to understand how water temperatures may change throughout the study area over time, particularly in relation to water treatment. To address the study question, continuous water temperature data has been collected at locations throughout the study area upstream and downstream of the FRO-S AWTF and FRO-N SRF outfall locations. Results from 2021 represent conditions prior to commissioning.

4.4.2 Water Temperature

Water temperature in the Fording River was similar to previous years and continued to be influenced by groundwater in the lower study area (i.e., downstream of the Greenhouse Side Channel [FR_FRRD] to upstream of the Porter Creek confluence [GH_PC2; SNC Lavalin 2021]), which led to higher temperatures compared to areas upstream in the winter (i.e., temperatures remained greater than zero), and lower compared to areas upstream in the summer. Water temperatures upstream (both the upper and middle study areas) have larger seasonal ranges as they have significantly less groundwater influences and are therefore largely affected by ambient temperatures. Temperature data gathered prior to treatment will be used as a basis for comparison following the commissioning of the FRO-S AWTF and FRO-N SRF and will also be used to track potential changes in temperature in the study area not related to treatment.

4.5 Study Question #5

4.5.1 Overview

Study Question #5 (What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP?) was developed to address variations in BIC observed throughout the FRO LAEMP study area (Minnow 2017a, Minnow and Lotic 2018, 2019b, 2020b, 2021b). Previous FRO LAEMP reports identified that decreases in % Ephemeroptera have not been associated with losses in taxa but a shift in community structure, whereby areas with low % Ephemeroptera compared to normal ranges have had correspondingly higher abundances of Plecoptera and Trichoptera, resulting in fewer effects on % EPT (Minnow and Lotic 2018, 2019b, 2020b, 2021b). Correlation analyses conducted in previous FRO LAEMP reports found that several water quality parameters correlated negatively with abundance and % Ephemeroptera and positively with % Plecoptera (Minnow and Lotic 2019b, 2020b, 2021b). Additional analyses (multivariate constrained ordinations) found significant covariation among habitat variables and water quality stressors, and after removing the variation in BIC shared by both habitat and water quality (i.e., the variation that could not be separated), the water stressors alone could not fully explain BIC differences among monitoring areas (Minnow and Lotic 2020b, 2021b).

Analysis and interpretation of data collected in 2021 has furthered the understanding of the BIC in the upper Fording River at monitoring areas included in the FRO LAEMP. Data has indicated that multiple factors are influencing the variation in BIC in the study area (i.e., changes in BIC are due to both mine-related water quality stressors and habitat differences among monitoring areas), and the variability attributed to each change throughout the study area but overall is difficult to separate based on current understanding, but interpretive ability may improve with the addition of treatment as well as the finalization of the BIC predictive models. Work to date has highlighted that the factors affecting the BIC vary depending on the location within the study area, and as such, each area (full and individual [upper, middle, and lower] study area, which were defined by spatial differences of habitat and water quality) were analyzed and discussed separately. The following sections interpret the BIC data as it relates to habitat and water quality in the study area.

4.5.2 Upper Study Area

The upper study area extends from downstream of the Henretta Creek confluence (RG_FODHE) to upstream of Shandley Creek and the South Tailings Pond (RG_FOUSH) and is generally characterized by steep gradients (Ecofish 2022) facilitating shallow, fast flowing water with relatively coarse substrate compared to other areas, resulting in a low proportion of benthic invertebrates that burrow in the substrate. Water temperatures in the upper study area are typically lower in the winter and higher in the summer compared to the lower study area as a result of the shallower water depths and minimal groundwater influence (SNC Lavalin 2021). Habitat characteristics in the upper study area help facilitate growth of periphyton and other autochthonous energy sources (Vannote et al. 1980; Cummins 2019) utilized by obligate and facultative scrapers such as Heptageniidae and Ephemerellidae (Cummins 2019) and supports the high abundance of these Ephemeropteran families and high autotrophic to heterotrophic index in the upper study area. Moreover, the relatively large substrate in the upper study area likely has a significant influence on BIC structure (Peckarsky 1979; Kaller and Harman 2003;

Leszczynska et al. 2017), potentially favoring Ephemeroptera. Recent drying surveys (see Section 3.2) have determined that the northern part of the upper study area is prone to seasonal drying, which may temporarily affect BIC through reduced habitat diversity (Dewson et al. 2007; Herbst et al. 2019).

Concentrations of mine-related water quality constituents are consistently lower throughout the upper study area compared to downstream study areas, but increase from upstream to downstream as additional mine inputs (e.g., Clode Creek, Grassy Creek, Lake Mountain Creek) are added to the system. Although concentrations of nitrate were frequently (13% to 78% of samples) above EVWQP benchmarks throughout the upper study area in 2021, concentrations of other Order constituents were infrequently (total selenium and sulphate) or never (dissolved cadmium) above EVWQP benchmarks. Comparison to EVWQP benchmarks helps identify potential responses of sensitive aquatic organisms (water flea and amphipod) to each benchmark threshold (e.g., Level 1 benchmark equates to a 10% response effect); however, the benchmarks have limitations as they were developed for organisms (water flea and amphipod) not related to benthic invertebrate taxa (e.g., Ephemeroptera, Plecoptera, Trichoptera, Diptera) present and abundant in the FRO LAEMP study area.

Benthic invertebrate communities, including % Ephemeroptera, in the upper study area have consistently been within both the site-specific and regional normal range with a few exceptions. Community shifts towards relatively low % EPT with subsequent increases in % Chironomids occurred at RG_FODHE (Fording River downstream of Henretta Creek) and RG_FOUSH (Fording River upstream of Shandley Creek) in 2019 and 2020; however, community structure returned to within historic levels in 2021 at both areas. The decreases in % EPT at RG_FODHE has likely been related to habitat changes associated with increased braiding following recent freshets (Minnow and Lotic 2021b), which has changed the channel making it shallower, more dispersed, and more prone to temperature swings (i.e., less thermal mass) compared to previous years, leading to changes in BIC (Dewson et al. 2007; Herbst et al. 2019). These habitat changes may have also influenced the duration and spatial extent of seasonal drying around RG_FODHE as the area was observed dry during December 2020 sampling, and the spatial extent of drying was larger in winter 2020/2021 compared to winter 2019/2020. Water chemistry at RG_FODHE has remained consistent throughout this period. The cause of reduced % EPT at RG_FOUSH during in 2019 and 2020 is currently unknown as habitat has remained relatively unchanged, and visual inspection of water chemistry data did not suggest changes in concentrations of key constituents in 2019 to 2021 compared to previous years. However, water chemistry data is limited to concurrent biological monitoring prior to 2020, except for 2018 when sampling was monthly.

4.5.3 Middle Study Area

The middle study area begins upstream of Kilmarnock Creek (RG_FOUKI) and extends downstream of the former FRO Compliance Point (RG_FRCP1SW). This area is generally characterized by shallower gradients (Ecofish 2022) facilitating more slow flowing and deeper water compared to the upper study area, which supports finer substrate and higher proportions of burrowing benthic invertebrates. The middle study areas, however, is also prone to extensive season drying, particularly between upstream of RG_FRCP1SW downstream to the Greenhouse Channel confluence, where river gradients become more level (Ecofish 2022) and subsurface flows (SNC Lavalin 2021) and braiding causes water depths to become shallow, particularly during low flow seasons. The upstream Side Channel #2 confluence with the Fording River begins in the lower extent of the middle study area and reconnects with the Fording River in the lower study area upstream of Porter Creek. It has habitat that transitions from relatively shallow riffle habitat that also dries seasonally to deeper waters and pools consistent with habitat in the lower study area. Like the upper study area, seasonal water temperatures in the middle study area fluctuate compared to the lower study area. Concentrations of mine-related water quality constituents (e.g., total selenium, sulphate, total nickel, dissolved cadmium) are the highest within the middle study area compared to the rest of the FRO LAEMP study area, particularly in the area downstream of the Swift-Cataract diversion (i.e., FRO-S AWTF outfall [uncommissioned in the present report]; Minnow and Lotic 2019b, 2020b).

Habitat and water quality vary considerably from upstream to downstream through the middle study area and are associated with gradual changes in BIC structure. Fewer differences in BIC structure among monitoring areas were observed in June compared to September, suggesting that effects of habitat and water quality on BIC differed by season. This was supported by more limited (fewer and weaker) significant effects of habitat and water chemistry on BIC in June compared to September identified in the CCA. In September, however, while abundance metrics (EPT, Ephemeroptera, Plecoptera, Trichoptera, Chironomidae) were within regional and site-specific (where available) normal ranges, % EPT was below the site-specific normal ranges through most of the middle study area. A spatial pattern of decreasing % Ephemeroptera, and to a lesser extent Ephemeroptera abundance, particularly families Heptageniidae and Ephemerellidae, from upstream to downstream was also identified, with values at the monitoring areas in the lower portion of the middle study area (i.e., RG_SCOUTDS, RG_FOBSC, RG_FOBCP, RG_FRCP1SW) below the site-specific normal ranges for % Ephemeroptera. Abundance and relative abundances of Plecoptera, on the other hand, followed an opposite spatial pattern, with the lowest values observed in the upper portion of the middle study area, and the highest values observed in the lower portion of the middle study area.

While a single cause of the shift in community within the middle study area cannot clearly be identified, changes in riverbed topography coupled with higher concentrations of mine-related constituents are likely influencing BIC structure, particularly in the areas downstream of the FRO-S AWTF outfall location (RG_SCOUTDS). Both water quality and habitat variables influenced the separation of monitoring areas between the FRO-S AWTF outfall (RG_SCOUTDS) and the lower extent of the middle study area (RG_FRCP1SW) from upstream areas in the CCA. Changes in topography can influence habitat variables such as water depth and velocity, substrate size, and station gradients, all of which have been identified as contributing significantly to BIC variation within the middle study area, which is consistent with other studies (Dewson et al. 2007; Kuchapski and Rasmussen 2015; Alvarez-Cabria et al. 2017; Leszczynska et al. 2017; Herbst et al. 2019). In addition, concentrations of mine-related constituents (e.g., nitrate, selenium, sulphate, total nickel) have historically been elevated relative to EVWQP benchmarks (and interim screening values for nickel; Teck 2017) in areas downstream of the future FRO-S AWTF outfall location (RG_SCOUTDS) as a result of inputs from Cataract Creek and from the Fording River upstream. These constituents and others (nitrate, sulphate, total selenium, total uranium, and dissolved cadmium) have also been identified as correlating significantly with key BIC endpoints and may be contributing to BIC variation within the middle study area. In particular, Ephemeroptera families present in the middle study area (Heptageniidae and Ephemerellidae) are known to be sensitive to anthropogenic contamination, including metals (Clements et al. 2000; Clements 2004; Pond et al. 2008; Cormier et al. 2013). Plecopterans tended to be more abundant in the middle study area and may be more tolerant to elevated concentrations of mine-related water quality constituents than Ephemeropterans (Clements 1999; Clements 2004; Boehme et al. 20016) and have a preference for the smaller substrate (Peckarsky 1979) in the middle study area, particularly downstream of the former Compliance Point (RG_FRCP1SW). Moreover, the highly abundant and predaceous stonefly family Perlodidae may opportunistically consume Ephemeroptera in these areas, contributing to the lower abundance of Ephemeroptera (Peckarsky 1979; Kiffney 1996; Cummins 2019). Overall, consistent with results from previous FRO LAEMP reports, both habitat variables and water chemistry have been identified as important contributors to BIC variation in the middle study area, indicating that no one single causal factor is responsible for observed effects on BIC in this area.

4.5.4 Lower Study Area

The lower study area begins downstream of the Greenhouse Side Channel (upstream of Porter Creek; RG_FRUPO) and extends downstream to Ewin Creek (RG_FOUEW) in the Fording River and has habitat characteristics markedly different from the upper and middle study areas. Most of the lower study area (areas upstream of Chauncey Creek) is influenced by the Chauncey Creek alluvial fan, and is characterized by slow flowing, deep water, and small substrate as a result of an upward sloping riverbed gradient at the confluence of Chauncey Creek in the Fording River, slowing water down and allowing for more deposition upstream (Ecofish 2022). As a result, the habitat conditions within the lower study area support a different BIC structure with a higher proportion of sprawlers compared to upstream study areas. These areas also tend to have more allochthonous food sources (i.e., leaves, woody debris, particulate organic matter from upstream) ideal for shredders common to Plecopteran families (Cummins 2019). The lower study area is also characterized by water temperatures that have smaller seasonal fluctuations that typically result from ambient cold and warm temperatures in the winter and summer, respectively, leading to a distinct temperature regime compared to the upper and middle study areas. These unique water temperatures are a result of groundwater influences (SNC Lavalin 2021) and overall water depths of the lower study area. Groundwater influences in the lower study area (SNC Lavalin 2021) have consistently maintained warmer (up to 4°C) winter water temperatures and cooler summer temperatures compared to areas upstream.

Abundance endpoints (EPT, Ephemeroptera, Trichoptera, Chironomidae) were within the site-specific (where available) and/or regional normal range throughout the lower study area; however, the relative abundances of EPT and Ephemeroptera remained below the site-specific and/or the regional normal range in September, while abundances and relative abundances of Plecoptera were high (Minnow 2017a, Minnow and Lotic 2018, Minnow and Lotic 2019b, 2020b, 2021b). High relative abundances of the riffle beetle from the family Elmidae have also consistently been elevated in the lower study area compared to areas upstream (Minnow and Lotic 2019b, 2020b, 2021b). Low % Ephemeroptera in the study area was related to lower abundances of two Ephemeroptera families, Heptageniidae and Ephemerellidae, compared to other areas within the FRO LAEMP study area, particularly in September (Minnow and Lotic 2020b, 2021b).

There are a number of factors that may be contributing to the different BIC structure in the lower study area. Relatively cool waters throughout the summer in the lower study compared to the upper and middle study areas may hinder an abundant Ephemeroptera community, as many species have a preference for warmer summer temperature (Brittain and Saltveit 1989; Pritchard et al. 1996; Haidekker and Hering 2008). Plecopterans tend to prefer cooler summer temperatures and warmer winter temperatures such as those observed in the lower study area (Haidekker and Hering 2008). In addition, the two families of Ephemeroptera showing a decline in the lower study area are particularly sensitive to high concentrations of metals (Clements et al. 2000; Clements 2004; Pond et al. 2008) and nitrate (Beketov 2004). Similar to the middle study area, elevated concentrations of mine-related constituents, especially nitrate in this area, are potentially influencing BIC structure. Ephemeroptera in particular are known to be sensitive to nitrate, and % Ephemeroptera and Ephemeroptera abundance correlate negatively with concentrations of nitrate. Plecopterans, however, seem to be less sensitive to elevated concentrations of mine-related constituents (Clements 1999; Clements 2004; Boehme et al. 2016), so, coupled with favorable habitat conditions (e.g., smaller substrate, deeper water, cooler summer temperatures, warmer winter temperatures; Peckarsky 1979, Haidekker and Hering 2008), may be better suited to thrive in the lower study area. In addition, of the Plecoptera community in the lower study area, a large proportion are from the family Perlodidae. Family Perlodidae is primarily composed of obligate predators that prey on the smaller Ephemeropterans (Cummins 2019); this dynamic may also be contributing to lower Ephemeroptera abundance in the lower study (Peckarsky 1979; Kiffney 1996; Clements 1999).

Together, water chemistry, habitat, and predator-prey dynamics are likely simultaneously suppressing populations of Ephemeroptera but increasing Plecoptera populations in the lower study area. Especially in the lower study area, covariability between mine-related water quality constituents and habitat variables continues to make it difficult to separate the individual contributions of factors affecting BIC variation.

4.5.5 Full Study Area

The full study area encompasses the simultaneous effects of changes to habitat and water quality on BIC structure observed from upstream to downstream throughout the FRO LAEMP study area and described above for individual study areas. Overall, larger data gradients for BIC endpoints and habitat and water quality variables in the full study area resulted in more significant and strong correlations and effects on BIC variation in the CCA when compared with individual study areas. In the CCA, almost every habitat and water quality variable effected BIC variation and was likely related to higher relative abundances of Ephemeroptera in upstream portions of the FRO LAEMP study area and higher relative abundances of Plecoptera in lower portions. This result highlighted the difficulty in separating the individual contributions of important variables on BIC structure over a large habitat and water quality gradient. Results from chronic toxicity testing at various locations throughout the study area have demonstrated adverse effects of water chemistry on water flea reproduction and amphipod dry weights, particularly during lower flow seasons, with nickel concentrations showing the greatest evidence as a potential contributor to effects (Golder 2022b); however, these tests do not consider habitat variables or community dynamics within the study area, nor are they conducted on benthic invertebrate taxa (e.g., Ephemeroptera, Plecoptera, Trichoptera, Diptera) present and abundant in the FRO LAEMP study area.

4.5.6 Summary

It is clear through the evaluation of the BIC data in the FRO LAEMP study area that both habitat and water quality factors are affecting variation in BIC communities, and although it remains difficult to separate the effect of individual contributions of each variable to the observed effects on BIC, the weight of evidence suggests that the key factors influencing shifts in BIC in the middle and lower study areas are elevated nitrate concentrations (middle and lower study area) and total nickel concentrations (middle study area), changes in substrate size and station gradient related to the Chauncey Creek alluvial fan (lower study area), and seasonal differences in water temperature and other habitat variables related to groundwater influence among areas. Abundance metrics (total, EPT, Ephemeroptera, Plecoptera, Trichoptera, Chironomidae) were within the normal ranges and have remained consisted over time. Percent EPT was below the site-specific normal ranges throughout the middle and lower study areas, while % Ephemeroptera exhibited a decreasing spatial pattern from upstream to downstream, with values within the normal ranges in the upper study area, below the site-specific normal ranges but within the regional normal range for most of the middle study area, and below both the site-specific and regional normal ranges in the lower study area. Several key habitat variables were identified as significantly contributing to the variation in BIC, including water velocity, water depth, water temperature, substrate size, embeddedness, station gradient, watershed slope, and watershed area. Variations in these habitat characteristics were apparent from upstream to downstream and occurred simultaneous with increases in the aqueous concentrations of mine-related constituents, making it difficult to identify the contribution of individual variables to the variation in BIC. Benthic invertebrate communities in the middle study area are simultaneously impacted by concentrations of mine-related constituents as well as dynamic changes in water flow related to subsurface flow and riverbed gradients that effect habitat characteristics, especially at and downstream from the former Compliance point (associated with RG_FOBCP). The lower study area is also largely affected by riverbed gradients that affect habitat characteristics (water depth, velocity, temperature, station gradient, watershed slope, substrate size), which, together with elevated levels of mine-related constituents, influence BIC. Specifically, from RG_FOBCP downstream to the lower extent of the full study area, low abundances and relative abundance of Ephemeroptera corresponded with high abundances and relative abundances of Plecoptera, which was a result of habitat preferences, potential water quality tolerance, and potential predator-prey dynamics. Continued evaluation of BIC following an improvement in water quality related to the commissioning of the FRO-S AWTF, as well as the use of BIC predictive modelling tools currently being developed under the RAEMP (Minnow 2021a) will aid in the interpretation of monitoring data to support answering Study Question #5.

4.6 Study Question #6

4.6.1 Overview

Study Question #6 (What are the factors influencing fish health and population in the upper Fording River?) was added to the FRO LAEMP in 2021 as a way to summarize key findings collected under different fish monitoring programs in response to the observation of a significant decline in the upper Fording River WCT population in 2019 compared to population estimates from 2017. Following the detailed Evaluation of Cause, the decline was attributed to an "interaction of extreme ice conditions (due to extreme, prolonged, cold air, temperatures; seasonal, winter low flows, and lower winter snowpack), sparse overwintering habitats, and restrictive fish passage conditions during the preceding migration period in fall 2019" (Evaluation of Cause Team 2021). To address Study Question #6, key findings from fish studies in the upper Fording River (i.e., UFR WCT Population Monitoring Program, FRO-S AWTF Flow Related Monitoring and Assessment Plan) were summarized, as applicable, with relevant data (seasonal drying, benthic invertebrate tissue chemistry, and water chemistry) from the FRO LAEMP and the RAEMP (WCT muscle selenium concentrations, condition factor, and observations of external anomalies) to bring together a summary of WCT monitoring data within the FRO LAEMP study area.

4.6.2 WCT Monitoring Data

Routine monitoring under the RAEMP evaluates fish health in the upper Fording River on a three-year cycle. Westslope Cutthroat Trout health endpoints assessed under the RAEMP included tissue selenium concentration, external anomalies such as deformities, erosions, lesions, tumours, injuries, infections, and/or parasites, and Fulton's condition factor as a general measure of fitness.

Measurement of selenium in eggs or ripening ovaries is the most direct way to evaluate potential effects of selenium on fish reproduction compared to measurement of selenium in water or other tissue types (Janz et al. 2010; Golder 2014; USEPA 2016). For this reason, a site-specific benchmark was derived based on the EC10 for fish egg/ovary concentrations (25 mg/kg dw; Nautilus and Interior Reforestation, 2011). Non-lethal expression of eggs is not always possible, therefore, monitoring of selenium in fish has often involved non-lethal collection of muscle plugs for selenium analysis and compared to the site-specific benchmark converted to a muscle-equivalent based on the muscle:egg selenium concentration ratio of 1:1.6 in WCT (Nautilus and Interior Reforestation 2011). Typically, non-lethal muscle sampling is conducted during the same timeframe just prior to spawning, however, a comparison of WCT muscle selenium concentrations from May (i.e., prior to spawning) and late August/September (i.e., post-spawning) in 2015 under the RAEMP showed no differences among seasons (Minnow 2018a).

In 2021, WCT were sampled (non-lethal muscle plug) prior to spawning in the upper (Clode Flats [RG_CLFL]) and lower (Fording River Oxbow S6 [RG_FROXB]) parts of the upper Fording River in accordance with direction from ECCC under the RAEMP (Minnow 2021, Minnow 2022). All tissue selenium concentrations (8.2 to 11 mg/kg dw) of pre-spawning WCT were below the site-specific benchmark (15.5 mg/kg dw) indicating low potential risk of effects to WCT egg and embryo development.

Selenium concentrations in muscle samples from WCT captured at mine exposed areas for the RAEMP at the Multiplate culvert (RG_MP1) and the Fording River between Chauncey Creek and Greenhills Creek (RG_FODGH) in 2018 and 2021 were consistently below (4.7 to 12 mg/kg dw) the EVWQP benchmark (15.5 mg/kg dw; muscle equivalent based on egg EC10; Nautilus and Interior Reforestation 2011), except for one replicate at RG_MP1 (29 mg/kg dw) in 2021. The cause of the elevated tissue selenium concentrations in the replicate at the Multiplate culvert is unknown (i.e., selenium concentrations in water and benthic invertebrate tissue could not explain the elevated selenium concentration in fish muscle) but could be a result of fish migration from an area having higher selenium concentrations.

Incidental mortalities of Westslope Cutthroat Trout found during routine monitoring or fish salvage programs within the FRO LAEMP study area in 2021 were opportunistically sampled. If fish were in good condition, dorsal muscle or whole-body tissue was analyzed for selenium concentrations. Fish sampled from incidental mortalities generally had tissue selenium concentrations similar to or less than those sampled under the RAEMP, except for three fish from Clode Creek with selenium concentrations ranging from 15 to 26 mg/kg dw. The WCT sampled from Clode Creek were associated with mortalities occurring during a fish salvage immediately downstream of the Clode Sedimentation Pond. Aqueous concentrations of mine-related constituents (including selenite and methylseleninic acid) are elevated in Clode Creek, and selenium concentrations in benthic invertebrate tissue samples ranged from 13 to 25 µg/g dw in September 2021 (Minnow 2022).

Westslope Cutthroat Trout caught for the RAEMP in June and September were assessed for external anomalies. No anomalies were observed in WCT caught at mine-exposed areas (RG_MP1 and RG_FODGH) in September 2021, while one fish caught in June had minor caudal fin erosion; however, caudal fin erosion can naturally occur with fish as a result of physical trauma and is not likely a mine effect. Overall, only one of twenty-two WCT captured in mine-exposed areas had anomalies in 2021, suggesting good overall health.

Fish condition factor in WCT captured under the RAEMP indicated that fish in the upper Fording River were in good health (condition factor was similar to or higher than in fish from reference areas). Similar results were observed in the UFR WCT Population Monitoring study, which indicated body condition "has been near or above average in the past three years of monitoring" but that increases in body condition may be associated with less density dependent pressure on fish (Thorley et al. 2022 in preparation).

Chronic toxicity of water collected from stations throughout the upper Fording River indicated that concentrations of mine-related constituents were unlikely to cause toxicity to fish. No adverse effects were observed for rainbow trout survival, viability, length, and weight in Q2 or Q4 with water from all stations in the upper Fording River (Golder 2022a), with one exception for survival in water in Q4 from the former Compliance point (FR_FRCP1). Further assessments determined that the possible adverse effect may have been a result of nitrate concentrations; however, results may have been confounded by microbial contamination. No adverse effects were observed for fathead minnow hatch, survival, biomass, length, or development in Q3, and while there were likely adverse effects to fathead minnow survival in water from FR_F2 and FR_FRCP1 in Q1, no water quality constituent was associated with these effects. Adverse effects to both rainbow trout and fathead minnow were only observed in Q1 and Q4 which do not align with seasons when WCT early life stages are expected to be present in the upper Fording River (Evaluation of Cause Team 2021). Chronic toxicity testing was conducted on 30-d early life stage rainbow trout and fathead minnow, and observed adverse effects are not expected to translate to other life stages present during Q1 and Q4.

4.6.3 Fish Population

Since the WCT population decline in 2019, additional work has been completed to identify the key fish population metrics that should be quantified for the UFR WCT population monitoring design. A regional approach to fish population monitoring has been designed to answer 14 secondary questions to guide monitoring approach, provide inter-watershed consistency, and improve interpretation of population dynamics to guide recovery efforts. Detailed approaches and 2021 results will be reported in detail in the 2021 UFR WCT Population Report and UFR Population Study Design (Thorley et al. 2022 in preparation).

In the two years of focused monitoring since the decrease in subadult and adult abundance, (sub)adult populations of WCT have increased at a rate of about 125% per year, and data suggests densities of (sub)adult populations may have increased locally as a result of habitat offsetting measures to improve degraded habitat from mining operations (Thorley et al. 2022 in preparation). "Overall, the available fish monitoring data is consistent with a relatively large, diverse, productive population of genetically pure WCT with a range that currently includes about

52 km of the mainstem upper Fording River and 36 km of connected tributaries" (Thorley et al. 2022 in preparation).

Fish abundance and distribution monitoring was completed for the FRO-S AWTF Flow Related Monitoring and Assessment Plan (Suzanne et al. 2021) from September 2021 until April 2022. The objective of the surveys was to monitor whether FRO-S AWTF operations cause fish to hold or aggregate in the vicinity of the AWTF outfall during the fall or overwintering period to support assessment of the potential for the FRO-S AWTF to adversely affect fish due to alterations to fish behaviour. Results of surveys in 2021 will be reported in the FRO-S AWTF Flow Related Monitoring and Assessment Plan annual report and summarized in the 2022 FRO LAEMP report.

The Evaluation of Cause determined that sparse overwintering habitats combined with restrictive fish passage from seasonal drying and extreme ice conditions were the primary reasons for WCT population declines (Evaluation of Cause Team 2021). Primary overwintering habitats have been identified as the pools around the Greenhills confluence with the Fording River, Segment 6 pools upstream of Chauncey Creek, the Multiplate culvert/Clode Flats area and Henretta Lake, although fish may overwinter in other areas as well (Cope et al. 2016). As such, monthly drying surveys are being used to identify potential limitations to fish migration, particularly during fall migration to overwintering habitat in September and October (Cope et al. 2016). Drying survey results indicated that drying in the southern survey area disconnected the Fording River in the third week of December in 2021. In the northern survey drying occurred in early October in 2021, which may have impacted overwintering migration in that section of the upper Fording River.

4.6.4 Summary

Westslope Cutthroat Trout in the FRO LAEMP study area were in good condition and had a general absence of external anomalies based on the 2021 fishing efforts under the RAEMP. Data on anomalies from the UFR Population study in 2021 are being compiled and will be incorporated into future FRO LAEMP reports. Muscle selenium concentrations were lower than the site-specific effects benchmark for WCT in all fish caught in the Fording River mainstem in 2021 except one (i.e., at the Multiplate culvert) and concentrations were consistent with previous years. Fish sampled opportunistically from Clode Creek, which received mine-influenced water from Clode Sedimentation Ponds, however, did have higher muscle selenium concentrations compared to other areas. Drying in the study area has varied spatially and temporally but annual drying usually occurs in the northern and southern drying sections between early October and late December each year, respectively, and may represent barriers to fish migration to key overwintering areas in the northern survey area. The WCT population appears to be recovering rapidly from the steep population decline in winter 2018/2019 and annual population monitoring will continue to track recovery. .

5 CONCLUSIONS

The current report represents pre-commissioning (existing) conditions within the FRO LAEMP study area[22]. Data was collected in 2021 to assess current productivity and water temperature conditions prior to commissioning (Study Questions #2 and #4), and to evaluate study questions related to nitrate concentrations (Study Question #1), benthic invertebrate tissue selenium concentrations (Study Question #3), variability in BIC (Study Question #5), and WCT health and population (Study Question #6; Table 5.1).

Nitrate concentrations in the FRO LAEMP study area have increased at some areas compared to previous years, but these changes have not been commensurate with changes in BIC community. Results have indicted that nitrate concentrations are strongly associated with patterns in BIC endpoints in general, but the individual contribution of nitrate to the observed effects in BIC (i.e., Ephemeroptera and Plecoptera endpoints) continues to be confounded by the covariation of nitrate concentrations with other mine-related constituents and habitat variables within the FRO LAEMP study area.

Benthic invertebrate tissue selenium concentrations were highest in areas where aqueous total and reduced selenium concentrations were elevated. Most benthic invertebrate tissue samples taken in 2021 were within prediction limits of the selenium bioaccumulation model and the majority of samples above predictions (i.e., in the Greenhouse Side Channel) contained annelids. Of the few samples above predictions that could not be explained by sample composition, the cause could not be conclusively determined (i.e., selenium speciation did not explain the variation)

Spatial decreases in % Ephemeroptera from upstream to downstream, between downstream of the historical Cataract Creek confluence and upstream of Ewin Creek, were commensurate with increases in abundance and relative abundance of Plecoptera. The gradual shift in community structure throughout the middle study area and continuing downstream to Ewin Creek in the lower study area can be attributed in part to simultaneous increases in water quality from upstream to downstream (with a peak for most constituents in the middle study area), but habitat variation within the study area also plays an important role in the BIC structure. This was especially apparent in the shift from a river dominated by Ephemeroptera to a river dominated by Plecoptera, which was likely related to gradient and habitat (water velocity and depths, substrate size, seasonal differences in water temperature) changes associated with the Chauncey Creek alluvial fan in the lower study area. The weight of evidence suggests that the key factors influencing shifts in BIC in the middle and lower study areas are elevated nitrate concentrations (middle and

[22] The FRO-S AWTF was commissioned in December 2021, so the current report summarizes the final year of baseline data prior to commissioning. The FRO-N SRF is scheduled to be commissioned in Q4 2022.

Table 5.1: Summary of Results (Study Questions #1, #3, #5, and #6), FRO LAEMP, 2021

Evaluation	Assessment Endpoint	Indicator Type	Measurement Endpoint	Evaluation Criteria	Results	Conclusion
Are nitrate concentrations in the study area changing and do they have the potential for adverse effects on biota?	Benthic invertebrate abundance and assemblage	Direct	Benthic invertebrate community (BIC) endpoints	Benthic invertebrate community relative to nitrate concentrations in the upper Fording River	BIC endpoints did not change concurrently with changes in nitrate concentrations when analyzed with a temporal trend model designed to detect concurrent changes between the two measures. Strong negative correlations of key BIC endpoints (% and abundance of Ephemeroptera, residuals of % Ephemeroptera) occurred with nitrate; however, significant covariation among water quality constituents and habitat variables make the effects of nitrate concentrations on BIC hard to elucidate.	Nitrate concentrations have increased over time in parts of the FRO LAEMP study area, and were higher than EVWQP benchmarks in most areas where %Ephemeroptera was below normal ranges; however, temporal increase in nitrate have not been observed in in areas with decteasing trends in BIC endpoints. Nitrate concentrations likely contribute to observed BIC variation but is not the only factor. Covariation among water quality and habitat variables makes contributions from nitrate alone difficult to determine.
		Semi-indirect	Chronic Toxicity Testing	*Ceriodaphnia dubia, Hyalella azteca, Oncorhynchus mykiss,* and *Pimephales promelas* relative to water samples at FR_MULTIPLATE, FR_FR2, FR_FR4, the former Compliance Point (FR_FRCP1), FR_FRRD, and the current Compliance Point (FR_FRABCH).	Chronic toxicity tests only identified nitrate as causing possible adverse effects to Rainbow Trout survival in Q4 at the former Compliance Point (FR_FRCP1) but results were confounded by microbial contamination.	
		Indirect	Surface water nitrate concentrations	Evaluate nitrate concentrations relative to predictions in the EVWQP, benchmarks, and past observations	Nitrate concentrations were consistent with predictions from EVWQP modelling and updated models show increasing concentrations since 2014 at both the former (FR_FRCP1) and current (FR_FRABCH) Compliance points but decreasing concentrations at the Fording River Order Station (GH_FR1). Nitrate concentrations were higher than EVWQP benchmark(s) at most mine-exposed areas.	
Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?	Benthic invertebrate tissue selenium concentrations	Direct	Benthic invertebrate tissue selenium concentrations	Benthic Invertebrate tissue selenium concentrations relative to selenium bioaccumulation model predictions	Tissue selenium concentrations were above the prediction limits of the selenium bioaccumulation model in five replicates from the Greenhouse Side Channel (RG_FRGHSC), two replicates from RG_FOBSC, and one replicate from RG_MP1	Benthic invertebrate tissue selenium concentrations were above predictions in the Greenhouse Side Channel (RG_FRGHSC) because the composite-taxa samples contained annelids. Replicate samples at RG_FOBSC (two of fifteen replicates) and RG_MP1 (one of nine) were also greater than predictions but the cause could not be attributed to composition of the sample or selenium speciation.
		Indirect	Aqueous total and reduced selenium concentrations	Benthic Invertebrate tissue selenium concentrations relative to selenium Bioaccumulation Tool (B-tool) predictions	Benthic invertebrate tissue selenium concentrations that were above predictions from the selenium bioaccumulation model could not be explained by the B-tool (i.e., selenium speciation), as B-tool predicted benthic invertebrate tissue selenium concentrations were lower than those measured.	
What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?	Benthic invertebrate abundance and assemblage	Direct	Benthic invertebrate community endpoints (abundance, richness [LPL taxonomy], percent [%] and total abundance of Ephemeroptera-Plecoptera-Trichoptera [EPT], Ephemeroptera, Plecoptera, Trichoptera, and Chironomidae, total abundance of key Ephemeroptera families [Baetidae, Heptageniidaie, Ephemerellidae])	Spatial and temporal comparisons to site-specific and regional normal ranges for September, and seasonal assessments for June, September, and December.	% Ephemeroptera was below the regional normal range from RG_FOBCP downstream to RG_FOUEW, and below the site-specific normal range from RG_SCOUTDS downstream to RG_FOUEW. Ephemeroptera abundance was within the regional normal range throughout the study area, but a decrease from upstream to downstream was observed which was driven by decreases in families Heptageniidae and Ephemerellidae, similar to previous years. Plecoptera (% and abundance) was higher where Ephemeroptera was low, keeping % EPT within regional normal ranges but below site-specific normal ranges at most monitoring areas. Downstream areas having low % Ephemeroptera were dominated by two Plectoptera families (Perlodidae and Nemouridae) in September.	Consistent with previous years, % Ephemeroptera was below normal ranges in the lower study area as a result of lower abundances of Heptageniidae and Ephemerillidae families. Gradual shifts from Ephemeroptera dominated communities to ones having high abundances and relative abundances of Plecoptera begin in the mid-portion of the middle study area (i.e., downstream of the FRO AWTF-S outfall location) and continue downstream to Ewin Creek. These shifts in community were associated with simultaneous changes in habitat and water quality, which was supported by correlations and constrained multivariate ordination (CCA) as well as the literature.
			Benthic invertebrate community feeding and habitat indices	Spatial and temporal comparisons to site-specific and regional normal ranges for September, and seasonal assessments for June, September, and December.	Benthic invertebrate community feeding and habitat index patterns were not consistent with patterns of high and low % Ephemeroptera but helped explain differences in BIC as a result of habitat differences throughout the study area.	
			Community Composition	Correspondence analysis (CA) to assess difference in community structure among areas from 2012 to 2021.	Similar to previous years, CA1 identified a clear difference in community composition in areas experiencing low % Ephemeroptera related to higher proportions of taxa other than Ephemeroptera (e.g., Elmidae, Limnephilidae, Glossosomatidae, Tipulidae, and Capniidae). CA2 separated reference from mine-exposed areas.	

Note: NR = Normal Range. BIC = Benthic Invertebrate Community. CA = Correspondence Analysis. CI = Calcite Index. EPT = Ephemeroptera,-Plecoptera-Trichoptera. EVWQP = Elk Valley Water Quality Plan. FRO = Fording River Operations. LPL = Lowest Practical Level. PCA = Principal Component Analysis. TDS = Total Dissolved Solids. CCA = canonical correspondence analysis. WCT = Westslope Cutthroat Trout.
Study Questions #2 and #4 were not included in the summary table because the FRO AWTF-S was not commissioned in 2021.

Table 5.1: Summary of Results (Study Questions #1, #3, #5, and #6), FRO LAEMP, 2021

Evaluation	Assessment Endpoint	Indicator Type	Measurement Endpoint	Evaluation Criteria	Results	Conclusion
What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?	Benthic invertebrate abundance and assemblage	Semi-indirect	Chronic Toxicity Testing	*Ceriodaphnia dubia, Hyalella azteca, Oncorhynchus mykiss,* and *Pimephales promelas* relative to water samples at FR_MULTIPLATE, FR_FR2, FR_FR4, the former Compliance Point (FR_FRCP1), FR_FRRD, and the current Compliance Point (FR_FRABCH).	Chronic toxicity tests identified nickel as causing possible or likely adverse effects to *C. dubia* reproduction and *H. azteca* dry weight at several station in the study area, mostly in low flow seasons (Q3 and Q4).	Consistent with previous years, % Ephemeroptera was below normal ranges in the lower study area as a result of lower abundances of Heptageniidae and Ephemerillidae families. Gradual shifts from Ephemeroptera dominated communities to ones having high abundances and relative abundances of Plecoptera begin in the mid-portion of the middle study area (i.e., downstream of the FRO AWTF-S outfall location) and continue downstream to Ewin Creek. These shifts in community were associated with simultaneous changes in habitat and water quality, which was supported by correlations and multivariate analyses (CCA) as well as the literature.
		Indirect	Tissue selenium concentrations	Concentrations relative to normal ranges, EVWQP effect benchmarks, past observations, and models.	Most benthic invertebrate tissue samples were below regional normal ranges and EVWQP benchmarks in June and December. Four of five benthic invertebrate tissue samples were above EVWQP benchmarks in the Greenhouse Side Channel (RG_FRGHSC) and the area upstream of the old Cataract Creek channel and downstream of the future FRO AWTF-S outfall location (RG_FOBSC), but all four samples taken within the Greenhouse Side Channel contained annelids, which disproportionately bioaccumulate selenium.	
			Surface water chemistry	Concentrations of mine-related constituents relative to EVWQP effect benchmarks, interim screening values, and past observations.	Concentrations of water quality constituents were highest in winter months. Nitrate concentrations exceeded Level 2 benchmark at most stations in the study area and have increased from FR_MULTIPLATE downstream to FR_SCOUTDS, relative to historical values. Sulphate concentrations were above the EVWQP Level 1 benchmark from FR_FRABEC1 downstream to FR_FRRD. Total selenium was above the Level 1 benchmark at all stations downstream of FR_FR1. Total nickel was above the Level 1 interim screening value from FR_FRABEC1 downstream to FR_FRRD. Total dissolved solids were above the Level 1 screening value at FR_SCOUTDS downstream to GH_PC2. Concentrations of sulphate, total selenium, total nickel, and total dissolved solids were similar to previous years at most stations, with increases that varied spatially for each constituent and no real overall pattern.	
				Principal component analysis (PCA) to assess contributions of various water quality variables to PCA1 and PCA2	The majority of variability in water quality was explained by PC1 (50%) and PC2 (26%) and PC1 had strong positive correlations with all mine-related constituents.	
			Temperature and Flow	Continuous Monitoring of temperature and discharge at FR_UFR1, FR_FR1, FR_FRDSSC1, FR_FR2, FR_FR3, FR_SCOUTDS, FR_FR4, FR_FRCP1, FR_FRCP1SW, FR_FRRD, GH_PC2, FR_FRABC evaluated over time	The lower study are (FR_FRRD and GH_PC2) were warmer in the winter and cooler in the summer compared to areas upstream. Flow velocities were lowest in the lower study area as a result of changing river bottom gradients from the Chauncey Creek alluvial fan.	

Note: NR = Normal Range. BIC = Benthic Invertebrate Community. CA = Correspondence Analysis. CI = Calcite Index. EPT = Ephemeroptera,-Plecoptera-Trichoptera. EVWQP = Elk Valley Water Quality Plan. FRO = Fording River Operations. LPL = Lowest Practical Level. PCA = Principal Component Analysis. TDS = Total Dissolved Solids. CCA = canonical correspondence analysis. WCT = Westslope Cutthroat Trout.
Study Questions #2 and #4 were not included in the summary table because the FRO AWTF-S was not commissioned in 2021.

Table 5.1: Summary of Results (Study Questions #1, #3, #5, and #6), FRO LAEMP, 2021

Evaluation	Assessment Endpoint	Indicator Type	Measurement Endpoint	Evaluation Criteria	Results	Conclusion
What are the factors contributing to the variations in percent Ephemeroptera?	Benthic invertebrate abundance and assemblage	Indirect	Calcite	Calcite index relative to known or suspected effect levels and past observations	Calcite indices varied throughout the study area but were generally similar to or lower than the previous year and below 1.0 at each area.	Consistent with previous years, % Ephemeroptera was below normal ranges in the lower study area as a result of lower abundances of Heptageniidae and Ephemerillidae families. Gradual shifts from Ephemeroptera dominated communities to ones having high abundances and relative abundances of Plecoptera begin in the mid-portion of the middle study area (i.e., downstream of the FRO AWTF-S outfall location) and continue downstream to Ewin Creek. These shifts in community were associated with simultaneous changes in habitat and water quality, which was supported by correlations and multivariate analyses (CCA) as well as the literature.
			Correlations between physical and chemical factors, and BIC metrics	Physical: CI, Calcite %, Concretion Score, embeddedness, pebble size, water velocity, water depth, minimum winter temperature, maximum summer temperature; Chemical: PC1, PC2, individual constituents; BIC metrics: total abundance, richness, % Ephemeroptera, Plecoptera, Trichoptera, EPT, and Chironomidae, Abundance Ephemeroptera, Plecoptera, Trichoptera, EPT, and Chironomidae, Habitat Model Residuals for Abundance, Richness, % Ephemeroptera, and % EPT, Feeding and Habitat Indices	Full study area water correlations: % Ephemeroptera and % Ephemeroptera residuals were negatively correlated with alkalinity, nitrate, selenium, sulphate, total dissolved solids, uranium, barium, while % Plecoptera was positively correlated; Ephemeroptera abundance was negatively correlated with selenium, total dissolved solids sulphate, uranium and alkalinity; Individual study area water correlations: few correlations in upper and lower study areas, but correlations were similar in middle study area and full study area Full study area habtitat correlations: % Ephemeroptera and % Plecoptera were positively and negatively correlated with D84, respectively; upper study area calcite presence positively correlated with % Plecoptera; middle study area concretion score positively correlated with % Plecoptera, lower study area Plecoptera and EPT abundance positively correlated with minimum winter water temperature	
			Canonical Correspondence Analysis	Habitat Variables: bankfull width, mean depth, mean velocity, embeddedness, substrate size D16, D84, % Watershed greater than 30% slope, watershed area, station gradient; Stressor Variables: calcite presence, calcite concretion, total barium, total manganese, total molybdenum, nitrate, total selenium, sulphate, alkalinity, total dissolved solids, total uranium, dissolved cadmium	Habitat and water quality parameters, along with calcite, explained 35% of the BIC variation in September but 16% was shared by all three predictor groups. Predictor variables had more significant and strong effects on BIC variation in September compared to June. Almost every habitat and water quality stressor affected BIC variation in the full study area because of larger data gradients. Habitat and water quality stressors affected BIC variation differently within individual study areas, but after removing the shared variation of both habitat and water quality stressors, most mine-related constituents affected BIC variation the most in the middle study area.	
What are the factors influencing fish health and population in the upper Fording River?	WCT health and population	Direct	WCT population	WCT populations within the study area, including rates of population increase or decrease (Thorley 2022)	Westslope Cutthroat Trout (sub)adult population are estimated to have increased at a rate of ~125% per year since the population decline of 2019. Habitat offsetting measures to improve degraded habitat may have increased local (sub)adult densities.	Westslope Cutthroat Trout captured within the study area show signs of good health, indicated by low observations of external anomalies and condition factor similar or higher than that of reference areas. The WCT population is recovering since the steep population decline of 2019 (currently increasing at a rate of ~125% per yea)r. Evidence suggests that habitat offsetting measures to restore degraded habitat may have increased local (sub)adult densities. Fall migrations to overwintering habitat has not been inhibited in the southern drying survey area over the past two years, however, there may be some limitations to fall migrations to Henretta Lake overwintering habitat as a result of drying in the northern survey area.
		Indirect	Seasonal drying	Determination of timing and spatial extent of drying within the Fording River	Seasonal drying varies temporally and spatially and surveys from recent years suggest that drying in the southern survey area has occurred from mid-October to late December, which would not inhibit WCT fall migrations to overwintering habitat. In the northern survey area, there are two areas that dry seasonally, one in the downstream portion of the survey area and one more upstream. The downstream area has been connected year round via a side channel, despite seasonal drying in the mainstem Fording River; however, the area upstream that dries annually became dry in mid-October in 2020 but early October in 2021. This upstream area of the northern survey area was disconnected during the last couple of weeks of the fall migration, which could prevent upstream migration of WCT to Henretta Lake overwintering habitat.	
		Direct	WCT anomalies	Observation of external anomalies on WCT captured for muscle tissue sampling	Only one of twenty two fish captured in the study area in 2021 had anomalies.	
		Indirect	WCT condition factor	Observation of overall fitness in WCT caught for muscle tissue sampling	WCT condition at mine-exposed areas was similar or higher than those caught at reference areas in 2018 and 2021.	
		Indirect	WCT tissue selenium concentrations	Muscle selenium concentrations of WCT caught at mine-exposed areas within the upper Fording River	Muscle selenium concentrations in WCT sampled in 2021 under the RAEMP were below the site-specific effects benchmark	

Note: NR = Normal Range. BIC = Benthic Invertebrate Community. CA = Correspondence Analysis. CI = Calcite Index. EPT = Ephemeroptera,-Plecoptera-Trichoptera. EVWQP = Elk Valley Water Quality Plan. FRO = Fording River Operations. LPL = Lowest Practical Level. PCA = Principal Component Analysis. TDS = Total Dissolved Solids. CCA = canonical correspondence analysis. WCT = Westslope Cutthroat Trout.
Study Questions #2 and #4 were not included in the summary table because the FRO AWTF-S was not commissioned in 2021.

lower study area) and total nickel concentrations (middle study area), changes in substrate size and station gradient (lower study area), and seasonal differences in water temperature and other habitat variables related to groundwater influence among areas. Improvement in water quality from commissioning of water treatment, as well as the BIC predictive modelling tool being developed under the RAEMP, will likely provide an opportunity to better separate the covariation in the factors contributing to BIC structure throughout the study area.

Assessment of health metrics in WCT from the upper Fording River have indicated that fish in the mainstem are in good condition with respect to muscle selenium concentrations below the effects benchmark, body condition, and the presence of external anomalies. Seasonal drying occurred in early October in the northern survey area and may represent a possible barrier to overwintering migration. Drying did not occur until December in the southern survey area. The WCT population appears to be rapidly recovering since the population decline in 2019, and habitat offsetting measures to improve degraded habitat may been contributing to locally increased (sub)adult densities.

The results from the FRO LAEMP were summarized (Table 5.2) to support Teck's Adaptive Management Program (Teck 2018). The results from this study also supported the evaluation of biological triggers which are intended to identify unexpected monitoring results that may lead to responses under the AMP response framework. Of the areas within the FRO LAEMP assessed for biological triggers, only the monitoring areas downstream of Henretta Creek (RG_FODHE) and downstream of Porter Creek (RG_FODPO) in the Fording River had replicates not reach biological triggers for % EPT (Table 5.3; Appendix H). Uncertainty remains around the cause of biological responses associated with the change in % EPT at the areas identified by the biological triggers, so this trigger, along with other BIC endpoints, will continue to be monitored as part of the 2022 FRO LAEMP and the RAEMP. Other efforts are also currently underway (i.e., BIC predictive modeling) to resolve uncertainty around effects of mine-related stressors on BIC endpoints (further information regarding the response for these biological triggers can be found in Appendix H). Except for two of five replicates at the monitoring area located upstream of the old Cataract Creek channel and downstream of the future FRO-S AWTF outfall location (RG_FOBSC), benthic invertebrate tissue selenium concentrations did not exceed the biological triggers (Table 5.3; Appendix H). The two benthic invertebrate samples exceeding biological triggers at RG_FOBSC may be a result of natural variation in data as the thirteen other replicates from 2021 were below triggers; monitoring in 2022 will be conducted post-commissioning of the AWTF. Overall, results of the biological trigger evaluation were consistent with the findings of the data evaluation conducted under the 2021 FRO LAEMP. Given that current biological triggers were sufficient to identify monitoring areas where biological responses are occurring, no additional biological triggers are recommended at this time.

Table 5.2: Summary of Findings, Responses and Adjustments Related to the FRO LAEMP in 2021

Program Name	Study Question(s)	Data Evaluation Process	Outcome(s)	Responses & Adjustments in 2021	EMC Engagement
FRO LAEMP	1. Are nitrate concentrations in the study area changing and do they have the potential for adverse effects on biota?	Evaluate nitrate concentrations relative to projections in the EVWQP.	Nitrate concentrations have increased over time in parts of the FRO LAEMP study area, and were higher than EVWQP benchmarks in most areas where %Ephemeroptera was below normal ranges; however, temporal increases in nitrate have not been observed in in areas with decreasing trends in BIC endpoints. Nitrate concentrations likely contribute to observed BIC variation but is not the only factor. Covariation among water quality and habitat variables makes contributions from nitrate alone difficult to determine.	There were no responses and adjustments in 2021	- Draft data package of 2017 results submitted to EMC Feb 15, 2018; Additional results for early 2018 presented May 3 and submitted October 23, 2018 - Report of 2017 results submitted to ENV/EMC May 31, 2018 - 2018 Study design submitted to ENV/EMC May 31, 2018 - In-person meetings on Feb 22 and May 2; and conference call on March 27, 2018 - Written input from EMC received between June 1 and July 18, 2018 - Draft data package of additional 2018 results submitted to EMC March 22, 2019 and discussed at in-person meeting March February 22, 2019 -Report of 2018 results submitted to ENV/EMC May 31, 2019 -Second FRO LAEMP study design (2019-2020) submitted May 31, 2019 -Written input from 2018 FRO LAEMP report received July 2019 -Draft data package of 2019 FRO LAEMP report data submitted March 3, 2020 -Written input from 2019 FRO LAEMP data package received March 17, 2020 -Report of 2019 results submitted to ENV/EMC May 31, 2020 -Study design amendment letter for the 2019-2020 FRO LAEMP Study Design submitted to ENV/EMC June 1, 2020 -Conference call December 3, 2020 to discuss study question and study design updates for next FRO LAEMP cycle -Written input from EMC about study question and study design updates received December 17, 2020 -Conference call February 3, 2021 to discuss study question and study design updates for next FRO LAEMP cycle -Written input from EMC about study question and study design updates received February 18, 2021 -Conference call February 23, 2021 to discuss study question and study design updates for next FRO LAEMP cycle -Third FRO LAEMP study design (2021-2023) submitted April 1, 2021 -Draft data package data package of 2020 FRO LAEMP report data submitted April 8, 2021 -Written input from 2020 FRO LAEMP data package received April 22, 2021 -Report of 2020 results submitted to ENV/EMC May 31, 2021 -Draft data package of 2021 FRO LAEMP report data submitted April 6, 2022 -Follow up call to discuss FRO LAEMP data package April 12, 2022 -Written input from 2021 FRO LAEMP data package received April 20, 2022
		Determine if benthic invertebrate community endpoints are outside of site specific and regional normal ranges or moving away from normal ranges in accordance with observed nitrate concentrations.			
		Determine if benthic invertebrate community results correspond with expectations based on nitrate concentrations in water relative to the site-specific benchmark for nitrate.			
	2. Is water treatment affecting biological productivity downstream in the Fording River?	FRO AWTF-S and FRO-N SRF have not yet been commissioned. Data collection in 2021 continues to represent pre-water treatment conditions so they can be compared to post-commissioning conditions.	Data were summarized and reported.	There were no responses and adjustments in 2021	

Notes: ATWF = Active Water Treatment Facility; LAEMP = Local Aquatic Effects Monitoring Program; EMC = Environmental Monitoring Committee; ENV = Ministry of Environment and Climate Change Strategy; FRO = Fording River Operation; EVWQP = Elk Valley Water Quality Plan; BIC = Benthic Invertebrate Community; CCA = Canonical Correspondence Analysis; EPT = Ephemeroptera-Plectoptera-Trichoptera; WCT = Westslope Cutthroat Trout

Table 5.2: **Summary of Findings, Responses and Adjustments Related to the FRO LAEMP in 2021**

Program Name	Study Question(s)	Data Evaluation Process	Outcome(s)	Responses & Adjustments in 2021	EMC Engagement
FRO LAEMP	3. Are benthic invertebrate tissue selenium concentrations downstream of FRO water treatment consistent with predictions, and if not, why?	Evaluate benthic invertebrate tissue selenium concentrations relative to selenium bioaccumulation model and the selenium bioaccumulation tool (B-tool).	Benthic invertebrate tissue selenium concentrations were above predictions in the Greenhouse Side Channel (RG_FRGHSC) because the composite-taxa samples contained annelids. Replicate samples at RG_FOBSC (two of fifteen replicates) and RG_MP1 (one of nine) were also greater than predictions but the cause could not be attributed to composition of the sample or selenium speciation.	There were no responses and adjustments in 2021	-
	4. How is temperature changing over time in the FRO LAEMP study area? 4a. Is water temperature measurably different (greater than 1 degree Celsius) downstream of the AWTF and/or SRF effluent discharge relative to the upstream baseline condition? 4b. If changes in water temperature are observed, are these changes attributed to mitigations (i.e., AWTF and/or SRF)?	FRO AWTF-S and FRO-N SRF have not yet been commissioned. Data collection in 2021 continues to represent pre-water treatment conditions so they can be compared to post-commissioning conditions.		There were no responses and adjustments in 2021	
	5. What are the factors contributing to the variations in benthic invertebrate communities in the FRO LAEMP study area?	Determine if benthic invertebrate community endpoints, particularly Ephemeroptera and associated families, are outside of site-specific and regional normal ranges or moving away from the normal ranges.	Consistent with previous years, % Ephemeroptera was below normal ranges in the lower study area as a result of lower abundances of Heptageniidae and Ephemerellidae families. Gradual shifts from Ephemeroptera dominated communities to ones having high abundances and relative abundances of Plecoptera begin in the mid-portion of the middle study area (i.e., downstream of the FRO AWTF-S outfall location) and continue downstream to Ewin Creek. These shifts in community were associated with simultaneous changes in habitat and water quality, which was supported by correlations and constrained multivariate ordination (CCA) as well as the literature.	-analyzed data for full study area, upper study area, middle study area, and lower study area separately for correlations analysis; Included additional BIC endpoints in correlation analysis	
		Investigate connection between benthic invertebrate community variation and water chemistry and habitat within the study area.		-analyzed data for full study area, upper study area, middle study area, and lower study area separately for Canonical Correspondence Analysis (CCA); adjusted CCA to remove shared variation of habitat and water quality on BIC variation to further develop the integrated analysis	

Notes: ATWF = Active Water Treatment Facility; LAEMP = Local Aquatic Effects Monitoring Program; EMC = Environmental Monitoring Committee; ENV = Ministry of Environment and Climate Change Strategy; FRO = Fording River Operation; EVWQP = Elk Valley Water Quality Plan; BIC = Benthic Invertebrate Community; CCA = Canonical Correspondence Analysis; EPT = Ephemeroptera-Plectoptera-Trichoptera; WCT = Westslope Cutthroat Trout

Table 5.2: Summary of Findings, Responses and Adjustments Related to the FRO LAEMP in 2021

Program Name	Study Question(s)	Data Evaluation Process	Outcome(s)	Responses & Adjustments in 2021	EMC Engagement
FRO LAEMP	6. What are the factors influencing fish health and population in the upper Fording River?	Evaluate WCT health through tissue selenium concentrations, observed external abnormalities and condition factor of fish caught.	Westslope Cutthroat Trout captured within the study area show signs of good health, indicated by low observations of external anomalies and condition factor similar or higher than that of reference areas. The WCT population is recovering since the steep population decline of 2019 (currently increasing at a rate of ~125% per year). Evidence suggests that habitat offsetting measures to restore degraded habitat may have increased local (sub)adult densities. Fall migrations to overwintering habitat has not been inhibited in the southern drying survey area over the past two years, however, there may be some limitations to fall migrations to Henretta Lake overwintering habitat as a result of drying in the northern survey area.	There were no responses and adjustments in 2021 under the FRO LAEMP. Responses and adjustments under other programs are reported therein.	-
		Determine potential limitations to overwintering habitat during fall migration as a result of seasonal drying.			
		Estimate any changes in WCT population, including population densities.			

Notes: ATWF = Active Water Treatment Facility; LAEMP = Local Aquatic Effects Monitoring Program; EMC = Environmental Monitoring Committee; ENV = Ministry of Environment and Climate Change Strategy; FRO = Fording River Operation; EVWQP = Elk Valley Water Quality Plan; BIC = Benthic Invertebrate Community; CCA = Canonical Correspondence Analysis; EPT = Ephemeroptera-Plectoptera-Trichoptera; WCT = Westslope Cutthroat Trout

Table 5.3: Summary of Biological Trigger Analysis for Percent EPT and Selenium Benthic Invertebrate Tissue, FRO LAEMP, 2021

Waterbody	Area		% EPT [a]		Selenium BIT [b]	
			Number Replicates Evaluated	Number of Replicates Reaching Biological Trigger [c]	Number Replicates Evaluated	Number of Replicates Reaching Biological Trigger [d]
Fording River	RG_FO26	Reference	3	0	8	0
	RG_FODHE	Mine-exposed	3	0	9	0
	RG_FOUKI		3	3	15	0
	RG_FOBSC[e]		3	3	20	0
	RG_FOBCP		5	5	15	2
	RG_FODPO		3	1	15	0
	RG_FO22		5	5	15	0

Notes: % EPT = Percent EPT (Ephemeroptera ([mayflies], Plecoptera [stoneflies], and Trichoptera [caddisflies]); Selenium BIT = Selenium concentrations in benthic invertebrate tissue (mg/kg dw).

[a] Biological Trigger analysis for %EPT was for the September sampling event.

[b] Biological Trigger analysis for Selenium BIT was for the June, September, and December sampling events.

[c] Number of Replicates Reaching Biological Trigger for % EPT refers to those replicates which were below both triggering steps (i.e., below the lower 2.5th percentile of the habitat-adjusted normal range and expectations [as based on predicted ADIT Scores]. See section H.2.2 for more details.

[d] Number of Replicates Reaching Biological Trigger for Selenium BIT refers to those replicates which were above both triggering steps (i.e., above the upper 97.5th percentile prediction limit of the regional normal range and expectations [as based on the predicted 95% percentile from the water to benthic invertebrate selenium bioaccumulation model]). See section H.2.3 for more details.

[e] BIT samples were collected at this location in November 2020 to support a scope outside the FRO LAEMP, however, BIT samples were screened against biological trigger values.

6 UPDATES TO 2021 TO 2023 FRO LAEMP STUDY DESIGN

Permit 107517 was amended in March 2021 to include the third cycle of FRO LAEMP monitoring, and Section 8.3.2 outlines the LAEMP requirements for any changes to the approved 2021 to 2023 study design as follows:

> 8.3.2: The permittee must complete to the satisfaction of the director a study design for a LAEMP which will focus on the upper Fording River for 2021 to 2023 by April 1, 2021. The study design must be reviewed by the EMC and be designed to an appropriate temporal scale to capture short term, local effects to the immediate receiving environment. Any changes to the approved study design must be reported in the annual LAEMP report.

1. Several adjustments to the approved FRO LAEMP 2021 to 2023 study design have been made based on learnings from the LAEMP, input from the EMC, and monitoring needs associated with the future commissioning of the FRO-N SRF Benthic invertebrate community will no longer be sampled in June and December (Table 6.1); data has shown that the largest variations in BIC occur in September across the largest spatial extent, In addition, a large historical and reference dataset is available for September and thus provides the most information for evaluating FRO LAEMP study questions.
2. Benthic invertebrate community sampling will be added at the monitoring area in the Fording River Side Channel #2 (RG_FRSCH2) in September because this side channel is becoming an important flow path in this section of the Fording River (Table 6.1).
3. The FRO-N SRF commissioning sampling plan (Table 6.2) will be added to the study design for 2022 and 2023 monitoring to help understand any potential changes to water and tissue chemistry as a result of commissioning, which is scheduled for Q4 2022 (Teck 2022).
4. Replicates of five benthic invertebrate tissue samples will be collected at areas associated with the FRO-N SRF commissioning sampling plan to provide additional pre-commissioning data for greater statistical power (Tables 6.1 and 6.2).

The above updates to the 2021 to 2023 FRO LAEMP study design reflect agreements between the study team and the EMC during the April 6, 2022, EMC meeting and the subsequent advice table provided to the study team from the EMC.

Table 6.1: Summary of Sampling Plan for the FRO LAEMP, 2022

Biological Monitoring Area (Associated Teck Water Station)[dg]		Area Description	Biological Monitoring Area UTM Coordinates		Water Quality						Sediment Quality			Benthic Invertebrates								
														Hess			Kick and Sweep					
					Water Chemistry			Selenium						Biomass/Density (# of samples)			Community (# of samples)			Composite-taxon Selenium (# of samples)[b]

Notes: '-' indicates sample that was not a part of the sampling design
[a] RG_UFR1 will be used as a reference area in winter months when there is no access to RG_FO26 or RG_HENUP.
[b] n=5 for composite-taxon tissue samples in areas associated with the FRO AWTF-S Sampling Commissioning Plan.
[c] The water quality monitoring station is the same for biological monitoring stations RG_FO26 and RG_UFR1
[d] Routine water quality monitoring stations associated with biological monitoring areas are outlined in brackets
[e] RG_FRSCH2 and RG_FRGHSCH will continue to be monitored for water and benthic invertebrate tissue chemistry for post-FRO AWTF-S commissioning monitoring.
[f] Triplicate samples of periphyton for both ash free dry mass and chlorophyll-a analysis
[g] Periphyton scores of n=5 will be taken at each biological monitoring area in September.

Table 6.2: FRO-N SRF Commissioning Sampling Plan, 2022[fg]

	Biological Monitoring Area (Associated Teck Water Station)[d]	Area Description	Biological Monitoring Area UTM Coordinates		Sampling Design											
					Water Chemistry				Water Selenium Speciation				Composite-taxon Selenium			
			Easting	Northing	0 Weeks[c]	4 Weeks	12 Weeks	20 Weeks	0 Weeks[c]	4 Weeks	12 Weeks	20 Weeks	0 Weeks[c]	4 Weeks	12 Weeks	20 Weeks
Ref	RG_UFR1[a] (FR_UFR1)	Fording River u/s Henretta at Teck WQ station	651376	5566758	1	1	1	1	1	1	1	1	5	5	5	5
Exposed	RG_CLODE (FR_CC1)	Clode Cr. near mouth	650871	5564287	1	1	1	1	1	1	1	1	5	5	5	5
	RG_GRASSY[b]	Grassy Creek u/s of Fording River confluence	650944	5563681	1	1	1	1	1	1	1	1	5	5	5	5
	RG_FOUCL (FR_FOUCL)	Fording River u/s of Clode Creek	650787	5564445	1	1	1	1	1	1	1	1	5	5	5	5
	RG_FRDSCC1[e] (FR_FRDSCC1)	Fording River d/s of Clode Creek	TBD	TBD	1	1	1	1	1	1	1	1	5	5	5	5
	RG_FOUNGD	Fording River u/s of Lake Mountain Creek and d/s of Grassy Creek	650870	5563476	1	1	1	1	1	1	1	1	5	5	5	5
	RG_FODNGD (FR_FRABEC1)	Fording River d/s Lake Mountain Creek/ North Greenhills Diversion	650972	5563162	1	1	1	1	1	1	1	1	5	5	5	5
	RG_MP1 (FR_MULTIPLATE)	Fording River d/s Multiplate d/s Eagle Ponds	651143	5562400	1	1	1	1	1	1	1	1	5	5	5	5

Notes: the FRO-N SRF primary outfall of Clode Creek will be located downstream of RG_FOUCL and upstream of RG_FRDSCC1.

[a] RG_UFR1 will be used as the reference location because of limited access to RG_FO26 or RG_HENUP during winter months.

[b] Riffles within tributaries to Fording River may be frozen during winter months.

[c] Week zero sampling may be conducted several weeks before FRO-N SRF commences water discharge from phase 2 operations.

[d] Routine water quality monitoring stations associated with biological monitoring areas are outlined in brackets

[e] Locations of riffles need to be determined during the first sampling campaign

[f] RG_WED was removed from the sampling plan because two years of studies has demonstrated that the West Exfiltration Ditch is not affected by Clode Pond and Clode Creek

[g] More frequent sampling may occur if benthic invertebrate tissue selenium concentrations appear to be rapidly changing. Following the adaptive management framework, if results of the current FRO-N SRF commissioning sampling plan indicate a need to continue sampling past 20 weeks the study plan for 2023 will be updated.

A1 INTRODUCTION

A1.1 Background

A variety of factors can influence the physical, chemical, and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Depending on their magnitude, inaccuracy or imprecision have the potential to affect the reliability of conclusions made from data. Therefore, it is important to ensure that programs incorporate appropriate steps to control non-natural sources of data variability (i.e., minimize variability that does not reflect authentic spatial and temporal variability in the environment) and thus assure the quality of the data. Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. A Data Quality Review (DQR) involves the comparison of field and laboratory measurement performance to Data Quality Objectives (DQOs) established for a particular study, such as evaluation of Laboratory Reporting Limits (LRLs), blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials). Trusted analytical laboratories certified by Canadian Association for Laboratory Accreditation (CALA) or the National Environmental Laboratory Accreditation Program (NELAP) with a rigorous internal quality assurance program were selected to ensure the highest possible data quality. Data Quality Objectives were established *a priori* to reflect reasonable and achievable performance expectations (Table A.1). Programs involving many samples and analytes usually yield some results that exceed DQOs. This is particularly so for multi-element scans, as the analytical conditions are not necessarily optimal for every element included in the scan. Generally, scan results may be considered acceptable if no more than 20% of the parameters fail to meet DQOs. Overall, the intent of a DQR is not to reject any measurement that did not meet a DQO, but to ensure that any questionable data received more scrutiny to determine what effect, if any, this had on interpretation of results within the context of the project.

A1.2 Quality Control Samples

A DQR was conducted on all laboratory data collected as part of the 2021 Fording River Operations Local Aquatic Effects Monitoring Program (FRO LAEMP). The objective of a DQR is to define the overall quality of the data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions. A DQR involves the examination of analytical results associated with several types of Quality Control (QC)

Table A.1: Laboratory Data Quality Objectives for the FRO LAEMP, 2021

Quality Control Measure	Quality Control Sample Type	Study Component				
		Water Chemistry	Selenium Speciation	Sediment Chemistry	Benthic Invertebrate Community	Benthic Invertebrate Tissue Chemistry
		ALS Environmental	Brooks Applied Labs	ALS	Cordillera Consulting	TrichAnalytics
Analytical Laboratory LRLs	Comparison of actual LRL versus target LRL	LRL for each parameter should be at least as low as applicable guidelines, benchmarks, and screening values	LRL for each parameter should be at least as low as applicable guidelines, benchmarks, and screening values	LRL for each parameter should be at least as low as applicable guidelines and benchmarks	-	LRL for each parameter should be at least as low as applicable guidelines and benchmarks
Blank Analysis	Field, Trip, or Laboratory Blank	Concentrations measured in blank samples should be < LRL	Concentrations measured in blank samples should be < LRL	Concentrations measured in blank samples should be < LRL	-	-
Laboratory Precision	Laboratory Duplicates	< 4% (pH) <10% (conductivity) ≤15% RPD or <2x LRL (ORP, turbidity) ≤20% RPD or <2x LRL (all remaining analytes)	≤25% RPD (selenium species) ≤20% RPD (total selenium)	0.2 (pH) ≤5% to 25% RPD (particle size) ≤20% RPD (inorganic and total carbon, moisture) ≤30% RPD (all remaining analytes) ≤40% RPD (aluminum, barium, lead, mercury, molybdenum, potassium, silver, sodium, strontium, tin, titanium) ≤50% RPD (PAHs)	-	≤60% RPD (calcium and strontium) ≤40% RPD (all remaining analytes)
	Organism Sorting Efficiency	-	-	-	≥ 95%	-
	Organism Sub-Sampling Precision and Accuracy	-	-	-	<20% between subsamples	-
Accuracy	Recovery of Blank Spike	-	75% to 125% (methylseleninic acid, selenate, selenite, selenocyanate, selenomethionine, total selenium)	-	-	-
	Recovery of Matrix Spike	70% to 130% (TKN, orthophosphate, phosphorus, TOC, DOC, total and dissolved metals) 75% to 125% (ammonia, bromide, chloride, fluoride, nitrate, nitrite, sulphate)	75% to 125% (selenate, selenite, selenocyanate, selenomethionine, total selenium)	-	-	-
	Matrix Spike Duplicate	-	75% to 125% (selenate, selenite, selenocyanate, selenomethionine, total selenium)		-	-
	Recovery of Certified Reference Material	-	75% to 125% (total selenium)	0.15 mg/kg to 0.55 mg/kg (Se) 0.16 mg/kg to 0.36 mg/kg (Ag) 0.2 mg/kg to 4.2 mg/kg (Sn) 1 mg/kg to 2 mg/kg (W) 70 mg/kg to 130% (all other metals) 7.7 mg/kg to 8.3 pH units (pH) 50% to 130% (Naphthalene) 80% to 120% (Inorganic Carbon, Total Carbon) 60% to 130% (all other PAHs) 0% to 26.5% (particle size)		60% to 140% (antimony, barium, boron, silver, tin, titanium) 90% to 110% (selenium) 70% to 130% (all remaining analytes)
	Laboratory Control Sample	6.9 to 7.1 (pH) 75% to 125% (TKN) 80% to 120% (orthophosphate, phosphorus, DOC, TOC, total and dissolved metals) 85% to 115% (acidity, alkalinity, ammonia, bromide, TDS, TSS, turbidity) 90% to 110% (conductivity, chloride, fluoride, nitrate, nitrite, sulphate) 95.4% to 104% (ORP)	-	0% to 26.5% (particle size) 60% to 130% (PAHs) 80% to 120% (inorganic carbon, total carbon) 7.4 to 8 (pH 1:2 soil:water)	-	-
	Taxonomic Accuracy	-	-	-	<5% TIR	-

Notes: LRL = Laboratory Reporting Limit; "-" = not applicable; < = less than; ≤ = less than or equal to; % = percent; RPD = Relative Percent Difference; ORP = oxidation-reduction potential; TKN = Total Kjeldahl Nitrogen; TOC = total organic carbon; DOC = dissolved organic carbon; TSS = total suspended solids; TDS = total dissolved solids; mg/kg dw = milligrams per kilogram dry weight; TIR = total identification error rate.

samples collected or prepared in the field and laboratory. General QC samples collected for this project include the following:

- **Blanks** are samples of de-ionized water and/or appropriate reagent(s) that are handled and analyzed in the same way as regular samples. These samples will reflect any contamination of samples occurring in the field (in the case of field or travel blanks) or in the laboratory (in the case of laboratory or method blanks). Analyte concentrations should be below detection.
- **Laboratory Duplicates** are replicate sub-samples created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.
- **Field Duplicates** are samples collected from a randomly selected field station that are homogenized to the extent possible, split and analyzed separately in the laboratory. The duplicate samples are handled and analyzed in an identical manner in the laboratory.
- **Spike Recovery Samples** are created in the laboratory by adding a known amount/concentration of a given analyte (or mixture of analytes) to a randomly selected test sample previously divided to create two sub-samples. The spiked and regular sub-samples are then analyzed in an identical manner. The spike recovery represents the difference between the measured spike amount (total amount in the spiked sample minus the amount in the original sample) relative to the known spike amount (as a percentage). Two types of spike recovery samples are commonly analyzed: spiked blanks (or blank spikes) are created using laboratory control materials whereas matrix spikes (MS) are created using field-collected samples. The analysis of spiked samples provides an indication of the accuracy of analytical results.
- **Certified Reference Materials (CRM) or Reference Materials (RM)** are commercially prepared (or commercially homogenized) samples containing known chemical concentrations that are processed and analyzed along with batches of environmental samples. The sample results are then compared to the known concentrations to provide a measure of analytical accuracy. The results are reported as the percent of the known concentration that was recovered in the analysis.
- **Laboratory Control Samples** are created in the laboratory to have a known analyte concentration in a matrix free of interferences, such as deionized water or reference sand. The sample results are compared to the target results to confirm that

the analytical method is accurate in a purified reference sample. The results are reported as the percent of the known concentration that was recovered in the analysis.

- **Laboratory Sorting Duplicates** are randomly selected grabs of the initially sorted community material. These samples are recounted and the number of invertebrates that were not recovered during the initial sort was determined. In order to reduce bias, recounting is conducted by an analyst uninvolved in the initial sample processing. This check is performed on 10% of samples and determines the accuracy through assessment of recovery (sorting) efficiency and quantifies any under-estimation of organism enumeration.

- **Taxonomic Quality Control Samples** are a randomly selected portion of a benthic invertebrate community field sample to be assessed by the laboratory using an internal quality control audit. A blind re-enumeration and re-identification of random samples is performed by an analyst uninvolved in the original sample processing. This assessment quantifies taxonomic misidentification among laboratory analysts and ensures accurate organism identities are reported.

- **Laboratory Subsamples** are community samples prepared by the laboratory to ensure that the fraction of the total sample examined was an accurate representation of the total number of organisms. By comparing the amount recovered between at least two sub-samples, one can assess the analytical precision. In addition, comparisons of the sub-samples from the whole community sample allows for an evaluation of sub-sampling accuracy.

A2 WATER CHEMISTRY

A2.1 Laboratory Reporting Limits

The analytical reports for water chemistry from ALS Environmental (ALS; Appendix K) and Brooks Applied Labs (BAL; Appendix K) were examined to assess Laboratory Reporting Limits (LRLs) relative to analyte concentrations and applicable guidelines (Tables A.2 and A.3). Water quality data from 2021 were entered directly into Teck's EQuIS database and thus were assessed as part of Teck's annual water quality reporting for 2021. The LRLs for water quality analytes were assessed relative to British Columbia Water Quality Guidelines (BC WQG; BCMOECCS 2021a, 2021b) for the protection of freshwater aquatic life, Elk Valley Water Quality Plan (EVWQP) benchmarks, screening values for water quality (Teck 2014), and relevant site-specific benchmarks. Several analytes were reported at concentrations below the LRL in 100% of samples (Tables A.2 and A.3). For those analytes with one or more result(s) below the LRL, achieved LRLs were consistently lower than the BC WQG, EVWQP benchmarks, and screening values for water quality, if relevant guidelines exist. Therefore, the achieved LRLs were appropriate for this study.

A2.2 Laboratory and Field Blanks

A total of 293 method blank (MB) samples were analyzed in the ALS laboratory reports (Appendix K). Of the 1,343 reported method blank results, only two results did not meet the laboratory DQO (one result for total arsenic, see laboratory report CG2104189, and one result for dissolved magnesium, see laboratory report CG2102041). The above MB result for total arsenic caused the LRL to be adjusted in total arsenic samples that were below five-times the MB result concentration. The above MB result for dissolved magnesium did not result in any adjusted LRLs for dissolved magnesium. Overall, these two results only represent 0.15% of MB samples and do not suggest significant laboratory contamination.

A total of 44 method blank (MB) samples were analyzed in the BAL laboratory reports (Appendix K). Of the 172 reported method blank results, 12 had detectable concentrations: total selenium in nine blank samples (see laboratory reports 2112275, 2106283, and 2109234 in Appendix K) and selenite in three blank samples (see laboratory report 2109234 in Appendix K). For all 12 of the above results, concentrations were below the LRL despite exceeding the method detection limit, and so met the DQO. Therefore, all BAL MB samples met the laboratory DQO.

As the overall number of DQO exceedances was low (ALS: 0.14%; BAL: 0%), the impacted results were considered to have a negligible impact on data interpretability and laboratory

Table A.2: Laboratory Reporting Limit (LRL) Evaluation for Water Chemistry Analyses, FRO LAEMP, 2021

Parameter	Units	BC WQG[a]		EVWQP Level 1 Benchmarks/ Relevant Screening Values[b]	Range of LRLs	No. LRLs > Guideline[c]	No. Sample Results < LRL
		Long-term	Short-term

Thallium	mg/L	-	-	-	0.00001	-	54 (83.1%)
Tin	mg/L	-	-	-	0.0001	-	65 (100%)
Titanium	mg/L	-	-	-	0.0003	-	63 (96.9%)
Vanadium	mg/L	-	-	-	0.0005	-	65 (100%)
Zinc	mg/L	-	-	-	0.001	-	7 (10.8%)

Notes: Only analytes with at least one result < Laboratory Reporting Limit (LRL) or LRL were above guidelines were displayed. The total number of samples in 2021 (n) was 65, which included six field duplicate samples. EVWQP = Elk Valley Water Quality Plan; "-" = no applicable guideline exists.

[a] British Columbia Water Quality Guidelines for the protection of Aquatic Life (BCMOECCS 2021a, BCMOECCS 2021b).

[b] Where more than one EVWQP Level 1 Benchmark or screening value was applicable, the most conservative (lowest) value was used.

[c] The LRLs for all analytes were consistently less than the applicable EVWQP Level 1 benchmarks (Teck 2014) or screening values (Golder 2014; Teck 2020).

[d] Guideline is the most conservative (lowest), based on estimates of a maximum temperature of 20°C and a minimum pH of 8.04.

[e] Minimum water quality guidelines for Nitrite (as N) reported in BCMOECCS (2021a) for chloride concentrations < 2 mg/L.

[f] Guideline for Chromium VI (0.001 mg/L) was selected, as this is the principal species found in surface waters.

[g] Hardness-based guidelines calculated using the minimum hardness observed for all samples (402 mg/L).

[h] The most conservative guideline (0.125 µg/L) was applied.

[i] Guideline based on minimum field pH (8.04).

Notes: Only analytes with at least one result < LRL or an LRL above guidelines were displayed. The total number of samples in 2021 (n) was 65 including six field duplicate samples. EVWQP = Elk Valley Water Quality Plan; LRL = Laboratory Reporting Limit, "-"= no applicable guideline exists.

[a] British Columbia Water Quality Guidelines for the protection of Aquatic Life (BCMOECCS 2021a,b).

[b] Where more than one EVWQP Level 1 Benchmark or screening value was applicable, the most conservative (lowest) value was used.

precision was considered excellent. Six field blank samples and five trip blank samples were submitted to ALS for water chemistry analyses to assess the potential for field sampling contamination (Table A.4). Out of 582 individual analyte results for field blanks, 92.3% were below detection and therefore met the DQO (Table A.1). Out of 335 individual analyte results for trip blanks, 96.2% were below detection and therefore met the DQO (Table A.1). However, several analytes of primary concern did not meet the laboratory DQO in the field blank sample. In one field blank sample (RG_FBLANK_WS_2021-06-17_1330, see laboratory report CG2102104 in Appendix K), the laboratory DQOs for conductivity, hardness, alkalinity, Total Kjeldahl Nitrogen, total and dissolved aluminum, antimony, arsenic, barium, chromium, copper, lead, manganese, strontium, tin, total mercury, and dissolved zinc were not met, indicating substantial field contamination associated with this sample. Additionally, laboratory DQOs for ammonia and dissolved zinc were not met in one other field blank sample (RG_FBLANK_WS_LAEMP_FRO_2021-12_NP, see laboratory report CG2106911) and the DQO for total mercury was not met in another (RG_FBLANK_WS_2021-06-18_1300, see laboratory report CG2102104). In trip blank samples, the laboratory DQO was not met in two samples (RG_TRIP_WS_2021-06-18_1300 and RG_TRIP_WS_2021-06-17_1330, see laboratory report CG2102104) for acidity, total ammonia, Total Kjeldahl Nitrogen (TKN), and total zinc, of which the latter three are analytes of interest within the FRO LAEMP. This suggests a minor degree of contamination was associated with these trip blank samples. As several analytes of concern did not meet the laboratory DQO in both field and trip blanks, potential contamination will be taken into consideration during data interpretation. Field and trip blanks were not collected for selenium speciation.

A2.3 Data Precision

A total of 47 laboratory duplicate samples were used to evaluate precision within the ALS laboratory reports (Appendix K). One TKN result was flagged by ALS as it was biased low due to interference from high nitrate in the parent sample that was used, which caused a negative bias in TKN (see laboratory report CG2104008 in Appendix K); however, this result still met the laboratory DQO. As all 1,444 individual analyte results met the laboratory DQO, ALS laboratory analytical precision was considered excellent.

A total of 13 laboratory duplicate samples were used to evaluate precision within the BAL laboratory reports (Appendix K). Out of the 45 individual analyte results, all met the laboratory DQO. Therefore, BAL laboratory analytical precision was considered excellent.

Six sets of field duplicate samples were collected to assess field sampling precision for water chemistry analyzed by ALS (Table A.5). Several relative percent differences (RPDs) could not

Table A.4: **Field Blank and Trip Blank Evaluation for Water Chemistry Analyses, FRO LAEMP, 2021**

Zinc	mg/L	0.001	2 (33.3%)	-

Notes: LRL = Laboratory Reporting Limit. Six field blank samples and five trip blank sample were collected in 2021. Only analytes with at least one blank results > LRL were displayed. Calcium, magnesium, potassium, and sodium are the only dissolved metals measured in trip blank samples.

Indicates RPD exceeded 30%

Notes: RPD = relative percent difference; "-"= no data/not calculated; LRL = Laboratory Reporting Limit. The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were < LRL. Turbidity was not analyzed in duplicate samples.

Indicates RPD exceeded 30%

Notes: RPD = relative percent difference; "-"= no data/not calculated; LRL = Laboratory Reporting Limit. The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were < LRL. Turbidity was not analyzed in duplicate samples.

Indicates RPD exceeded 30%

Notes: RPD = relative percent difference; "-"= no data/not calculated; LRL = Laboratory Reporting Limit. The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were < LRL. Turbidity was not analyzed in duplicate samples.

be calculated as analyte concentrations in both samples were below the LRL. Of the 385 RPDs that could be calculated, 34 analyte results had RPDs greater than 30% (8.8% of all pairs; Table A.5). Of the comparisons with RPDs greater than 30%, 10 RPDs resulted from analyte concentrations near and below the LRL, where greater variability is expected. RPDs for analytes of primary concern that exceeded the DQO included one RPD for carbonate alkalinity as $CaCO_3$. Relative percent differences for analytes that are not of primary concern that exceeded the DQO included one RPD for total organic carbon, total aluminum, arsenic, and copper, total and dissolved iron, and dissolved manganese and titanium, two RPDs for TKN and total chromium, and three RPDs for total ammonia, total suspended solids (TSS), and dissolved aluminum and zinc. Overall, as only 8.8% of calculable RPDs exceeded the DQO, the data were considered to have adequate field precision and reproducibility. Field duplicate samples were not collected for selenium speciation.

A2.4 Data Accuracy

A total of 45 matrix spike (MS) samples were used to evaluate precision within the ALS laboratory reports (Appendix K). Of the 1,267 individual analyte results, one result was flagged by ALS was it was biased low due to interference from high nitrate in the parent sample that was used, which causes a negative bias in TKN (see laboratory report CG2104008 in Appendix K). Recovery could not be calculated in numerous MS samples as background levels were greater than or equal to one-times spike levels. However, as several other QC tests were successful and do not imply uncertainties as to ALS data accuracy, MS recovery not being calculable in several MS samples does not present concern as to the reliability of the data. Overall, ALS laboratory analytical precision was considered excellent.

Data accuracy within the BAL laboratory reports was evaluated based on results of 26 LCS, 13 MS samples, 13 Matrix Spike Duplicate (MSD) samples, and 22 Reference Material (RM) samples (Appendix K). All 42 LCS results, 25 MS results, 25 MSD results, and 22 RM results met the laboratory DQO; therefore, BAL laboratory analytical precision was considered excellent.

A2.5 Hold Times

The recommended hold times for pH and ORP analyses (0.25 to 0.34 hrs) were exceeded in all samples collected. As *in situ* pH and ORP were used for data interpretation, these hold time exceedances had no impact on data interpretability. The hold times for nitrite, nitrate, and turbidity were exceeded by one day in eight samples each (see laboratory reports CG2106911 and CG2104067 in Appendix K). The hold times for nitrite and nitrate were also exceeded by less than one day in one sample each (see laboratory report CG2104149) and by four days in four samples each (see laboratory report CG2104110). The hold time for nitrate was exceeded by two days in two samples (see laboratory report CG2104213). The hold time for turbidity was also exceeded by less than one day in one sample (see laboratory report CG2104008). The hold time for dissolved orthophosphate was exceeded by one day in 17 samples (see laboratory reports CG2104213 and CG2106911). The only analytes of primary concern for which hold times were exceeded were nitrate and nitrite, and these hold time exceedances will be taken into consideration during data interpretation. All hold times were met for selenium speciation samples.

A2.6 Other Concerns

Samples for dissolved organic carbon (DOC), dissolved metals, and dissolved mercury were not submitted for the trip blank sample submitted to ALS in September. Additionally, a total mercury sample was not submitted from RG_FOBCP in June. Therefore, data for these analytes were not available for these samples. The sample for dissolved mercury from RG_FO26 in June was not preserved in the field; therefore, dissolved mercury results from this sample may be biased low and should be treated with caution in analyses. Total selenium samples submitted to BAL for RG_FOUCL and RG_FRUPO in December arrived in broken containers but were still contained in the plastic bags used for secondary containment. There was minimal risk of cross-contamination and measurements of total selenium from these samples were flagged as estimates. Additionally, total selenium sample for RG_FOBKS in December was not submitted to Brooks; however, total selenium concentrations are taken from ALS reports, so the above estimates and absences of total selenium concentrations from BAL did not affect the resultant data. Additionally, 13 results for selenosulfate were flagged as estimates by BAL (see laboratory reports 2106283 and 2109306 in Appendix K). These results were affected by chromatic interference, as indicated by elevated baselines or co-eluting peaks.

A2.7 Data Quality Statement

Water chemistry data collected for the 2021 FRO LAEMP were of acceptable quality as characterized by appropriate LRLs, negligible analyte concentrations in method blanks, excellent laboratory precision and accuracy, adequate field precision and reproducibility, and few hold time exceedances. Field and trip blank analyses indicated potential contamination that will be taken into consideration during data interpretation. Overall, the associated data can be used with a high level of confidence in the derivation of conclusions.

A3 SEDIMENT CHEMISTRY

A3.1 Laboratory Reporting Limits

The analytical reports for sediment chemistry from ALS (Appendix K) were examined to assess LRLs relative to analyte concentrations and applicable guidelines (Table A.6). The LRLs for these analytes were assessed relative to existing British Columbia Working Sediment Quality Guidelines (BC WSQG; BCMOECCS 2021). Five analytes were reported at concentrations below the LRL in 100% of samples (bismuth, tin, tungsten, zirconium, and quinoline; Table A.6); however, no relevant guidelines exist for these analytes. All LRLs for metals were above relevant guidelines, but several LRLs for polycyclic aromatic hydrocarbons (PAHs) including acenaphthene, acenaphthylene, chrysene, and dibenz(a,h)anthracene exceeded the lower BC WSQG (i.e., Interim Sediment Quality Guideline) in 26.7% to 87.5% of samples. The LRLs for acenaphthene also exceeded the upper BC WSQG (i.e., Probable Effect Limit) in 27.8% of samples. The reason for these high LRLs was due to a combination of chromatographic interference due to PAH co-elution effects and high moisture content (resulting in low sample volume) in specific sediment samples. High LRLs for PAHs will be considered during data interpretation, but as only five LRLs for one analyte (acenaphthene) exceeded relevant guidelines, LRLs were ultimately considered appropriate for this study.

A3.2 Laboratory Blanks

A total of 35 MB samples were analyzed in the ALS laboratory reports (Appendix K). All 580 individual analyte results met the laboratory DQO, indicating no inadvertent contamination of sediment samples during analysis. Therefore, laboratory precision as determined by laboratory blanks was considered excellent.

A3.3 Data Precision

A total of 10 laboratory duplicate samples were used to evaluate precision within the ALS laboratory reports (Appendix K). All 135 individual analyte results met the laboratory DQO (Table A.1). Therefore, ALS laboratory analytical precision was considered excellent.

One set of field duplicate samples was collected to assess field sampling precision for sediment chemistry (Table A.7). Samples were collected as split samples (i.e., a larger sample was homogenized and then split into two duplicate sub-samples), and some variability was expected based on the inherent heterogeneity of sediments. Several RPDs could not be calculated as both analyte concentrations in the pair were below the LRL. Of the 58 RPDs that could be calculated, only two were greater than 30% (benzo(g,h,i)perylene and perylene;

Indicates RPD exceeded 30%

Notes: RPD = relative percent difference; "-"= no data/not calculated; LRL = Laboratory Reporting Limit. The RPD was calculated using < LRL results at the LRL if one result in a duplicate pair was below the LRL. The RPD was not calculated if both results were < LRL.

3.4% of all pairs; Table A.7). The RPD for benzo(g,h,i)perylene resulted from an analyte concentration below the LRL, where greater variability is expected. The greater variability observed for polycyclic aromatic hydrocarbons (PAHs) is likely attributed to residual heterogeneity in the samples. Subtle differences in the distribution of fine particulate matter and associated PAHs amongst split samples may exist even after homogenization in the field. Since only 3.4% of calculable RPDs exceeded the DQO, the data were considered to have excellent field precision and reproducibility.

A3.4 Data Accuracy

Data accuracy for sediment chemistry analyses completed by ALS was evaluated based on the analysis of 39 LCS, five CRM samples, and 32 Internal Reference Material (IRM) samples. All 503 LCS, 165 CRM, and 344 IRM individual analyte results met the laboratory DQO (Table A.1). Therefore, the accuracy achieved by the laboratory was considered excellent.

A3.5 Hold Times

All recommended hold times were met for all samples.

A3.6 Data Quality Statement

Sediment chemistry data collected for the 2021 FRO LAEMP were of acceptable quality as characterized by appropriate LRLs, excellent laboratory precision and accuracy, good field precision and reproducibility, and no hold time exceedances. Overall, the associated data were considered acceptable for this study.

A4 BENTHIC INVERTEBRATE COMMUNITY

A4.1 Organism Sorting Efficiency

The analytical reports from Cordillera Consulting Inc. (benthic invertebrate community structure; see Appendix K for laboratory reports) were examined to assess sub-sampling accuracy. Canadian Aquatic Biomonitoring Network (CABIN) protocols were followed for sub-sampling (i.e., identification of a minimum 300 invertebrates), with a minimum of 5% of a sample being assessed. Of the 139 benthic invertebrate community samples analyzed, only one sample was processed in its entirety (Table A.8). The proportion of sub-sampled material ranged from 5% to 90% of the total sample material (Table A.8). Both the precision and accuracy of the subsamples randomly chosen for subsample assessment (approximately 10% of samples that were subsampled; n = 13) met the DQO in all subsamples (Table A.9). Thus, the precision and accuracy for sub-sampling of the benthic invertebrate community samples was considered excellent.

A4.2 Subsampling Accuracy and Accuracy

To measure the effectiveness of the sorters, at least 10% of samples were selected at random for resorting analysis by a different sorter. Sorting efficiency (i.e., percent recovery) of benthic invertebrate samples was excellent, achieving an average of 99.4% for the samples evaluated (Table A.10). As recovery in quality control samples was above the laboratory's DQO (95%), organism sorting efficiency was considered excellent.

A4.3 Taxonomic Identification Accuracy

Cordillera Consulting Inc. performed an internal audit of taxonomic identification for approximately 10% of all community structure samples (n = 13; Table A.11). The analysts reported total identification error rate (TIR) of 0%, percent difference in enumeration (PDE) of 0% to 0.75%, percent taxonomic disagreement (PTD) of 0.402% to 1.79%, and Bray Curtis Dissimilarity Index (BCDI, a measure of the differences in identifications between different analysts) of 0.002 to 0.012 (Table A.11). The laboratory DQO was based on TIR as per CABIN laboratory methods (< 5% TIR; Environment Canada 2014). As TIR was below 5% for all samples examined, the taxonomic accuracy of the analysis was considered excellent.

A4.4 Data Quality Statement

Benthic community data collected for the 2021 FRO LAEMP and analyzed by Cordillera Consulting Inc. were of good quality as characterized by excellent sorting efficiency, subsampling precision and accuracy, and taxonomic identification accuracy. Therefore, the

Notes: TIR = Total Identification Error Rate, PDE = Percent Difference in Enumeration, PTD = Percent Taxonomic Disagreement, BCDI = Bray Curtis Dissimilarity Index to quantify differences in identifications.

[a] For error rationale and calculations, refer to Cordillera Consulting laboratory report (Appendix X).

associated data can be used with a high level of confidence in the derivation of conclusions. Quality control procedures were not conducted on benthic invertebrate community structure and density data analyzed by Zeas.

A5 BENTHIC INVERTEBRATE TISSUE CHEMISTRY

A5.1 Laboratory Reporting Limits

Analytical reports of benthic invertebrate tissue metal concentrations from TrichAnalytics (see laboratory reports in Appendix K) were examined to provide an inventory of analyte results below the LRL and to compare the LRLs for these analytes to available benchmarks (Table A.12). Arsenic and mercury were the only analytes that had at least one result below the LRL (Table A.12); however, the sole focus of interpretation of benthic invertebrate tissue chemistry results for the FRO LAEMP was selenium. Selenium was detectable (i.e., above the LRL) in all benthic invertebrate samples, therefore comparison of the selenium LRL to the applicable guidelines was not necessary to assess whether adequate detectability was achieved. Overall, the detectability of selenium in all samples (i.e., below the LRL) indicates that the achieved LRLs were suitable for the study.

A5.2 Data Accuracy and Precision

Data accuracy and precision were evaluated based on the analysis of 25 CRM samples (see laboratory reports in Appendix K). As all 750 CRM results met the laboratory DQO, laboratory accuracy and precision as determined by CRM analyses were considered excellent. Laboratory precision was also evaluated by duplicate analysis of 27 benthic invertebrate tissue samples (Appendix K). As all 810 duplicate results met the laboratory DQO, laboratory accuracy and precision as determined by duplicate analyses were considered excellent.

A5.3 Data Quality Statement

Benthic invertebrate tissue data collected for the 2021 FRO LAEMP were of good quality as characterized by appropriate LRLs and excellent laboratory precision and accuracy. Therefore, the associated data can be used with a good level of confidence in the derivation of conclusions for this study.

Table A.12: Laboratory Reporting Limit (LRL) Evaluation for Benthic Invertebrate Tissue Chemistry Analyses, FRO LAEMP, 2021

Parameter	Units	Range of LRLs	No. Sample Results < LRL
Arsenic	mg/kg dw	0.425 to 0.471	38 (15.2%)
Mercury	mg/kg dw	0.033 to 0.034	63 (25.2%)

Notes: "-" = no applicable guideline exists; LRL = Laboratory Reporting Limit; dw = dry weight. Only analytes with at least one sample results < LRL are displayed. Total number of samples was 250. The only guidelines that exist for benthic invertebrate tissue are for selenium, and LRLs for selenium were below the applicable guidelines.

[a] British Columbia Water Quality Guidelines for the protection of Aquatic Life (BCMOECCS 2021a, BCMOECCS 2021b).

[b] Level 1 EVWQP benchmark for benthic invertebrates.

A6 DATA QUALITY REVIEW SUMMARY

Overall, the quality of the data collected for this project was considered acceptable for the derivation of conclusions associated with the objectives of the 2021 FRO LAEMP. Several results were above detection in field and trip blanks, including for some analytes of primary concern, suggest possible field contamination of water samples that will be taken into consideration during data interpretation.

Figure B.1: Time Series Plots for Total Antimony Concentrations from FRO LAEMP Sampling Areas, 2012 to 2021

Notes: Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Constituent was plotted because it was identified as a mine−related constituent in the Adaptive Management Plan and an early warning trigger was defined (Azimuth 2018). When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

Notes: Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Constituent was plotted because it was identified as a mine−related constituent in the Adaptive Management Plan and an early warning trigger was defined (Azimuth 2018). When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

Figure B.17: Time Series Plots for Total Uranium Concentrations from FRO LAEMP Sampling Areas, 2012 to 2021

Notes: Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Constituent was plotted because it was identified as a mine−related constituent in the Adaptive Management Plan and an early warning trigger was defined (Azimuth 2018). When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

Figure B.18: Time Series Plots for Total Zinc Concentrations from FRO LAEMP Sampling Areas, 2012 to 2021

Notes: Concentrations reported below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Guidelines are dependent on water hardness. Constituent was plotted because it was identified as a mine−related constituent in the Adaptive Management Plan and an early warning trigger was defined (Azimuth 2018). When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and plotted together with the biological monitoring area depicted in parenthesis.

Figure B.19: Seasonal Means for Select Water Quality Parameters, FRO LAEMP, 2021

Notes: Winter is comprised of December 2020 to March 2021. Only annual means are depicted with a black bar and are only presented when data is avalable from all four seasons. Reference areas are shown in green and mine−exposed areas are shown in blue. Censored values are shown with hollow shapes.

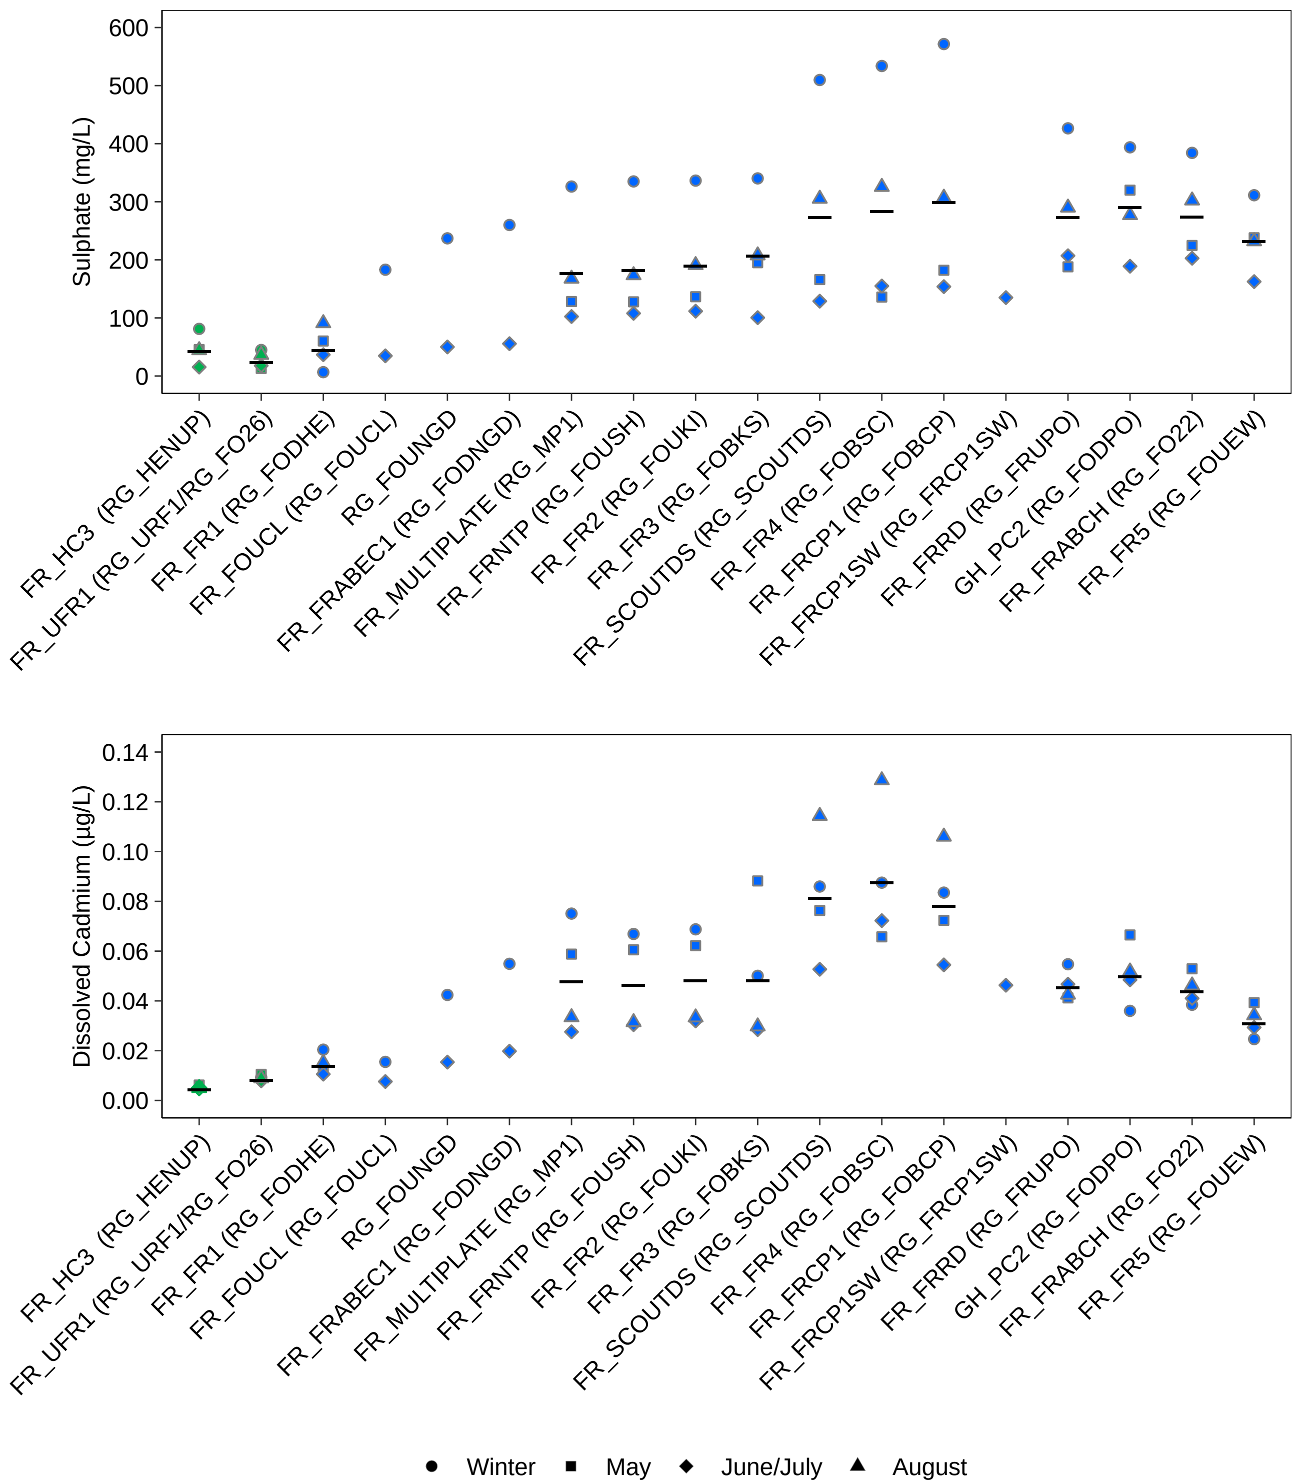

Figure B.19: Seasonal Means for Select Water Quality Parameters, FRO LAEMP, 2021

Notes: Winter is comprised of December 2020 to March 2021. Only annual means are depicted with a black bar and are only presented when data is avalable from all four seasons. Reference areas are shown in green and mine−exposed areas are shown in blue. Censored values are shown with hollow shapes.

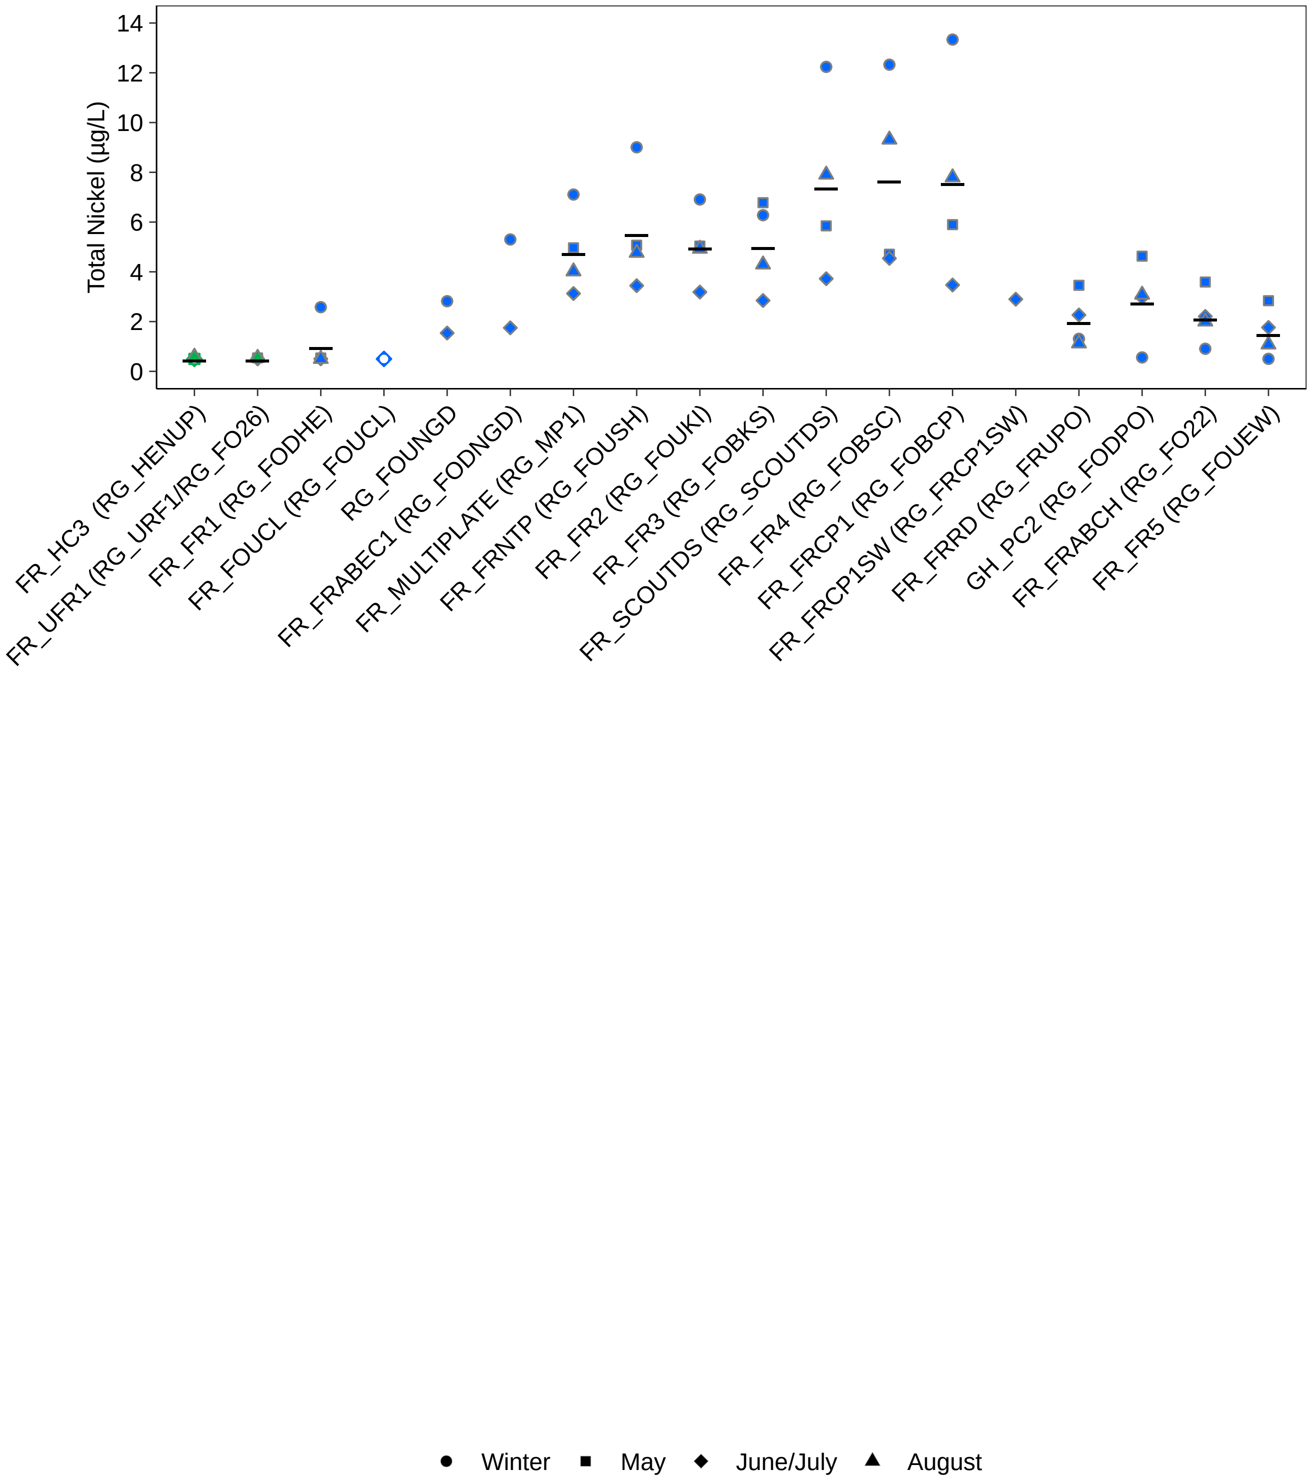

Figure B.19: Seasonal Means for Select Water Quality Parameters, FRO LAEMP, 2021

Notes: Winter is comprised of December 2020 to March 2021. Only annual means are depicted with a black bar and are only presented when data is avalable from all four seasons. Reference areas are shown in green and mine−exposed areas are shown in blue. Censored values are shown with hollow shapes.

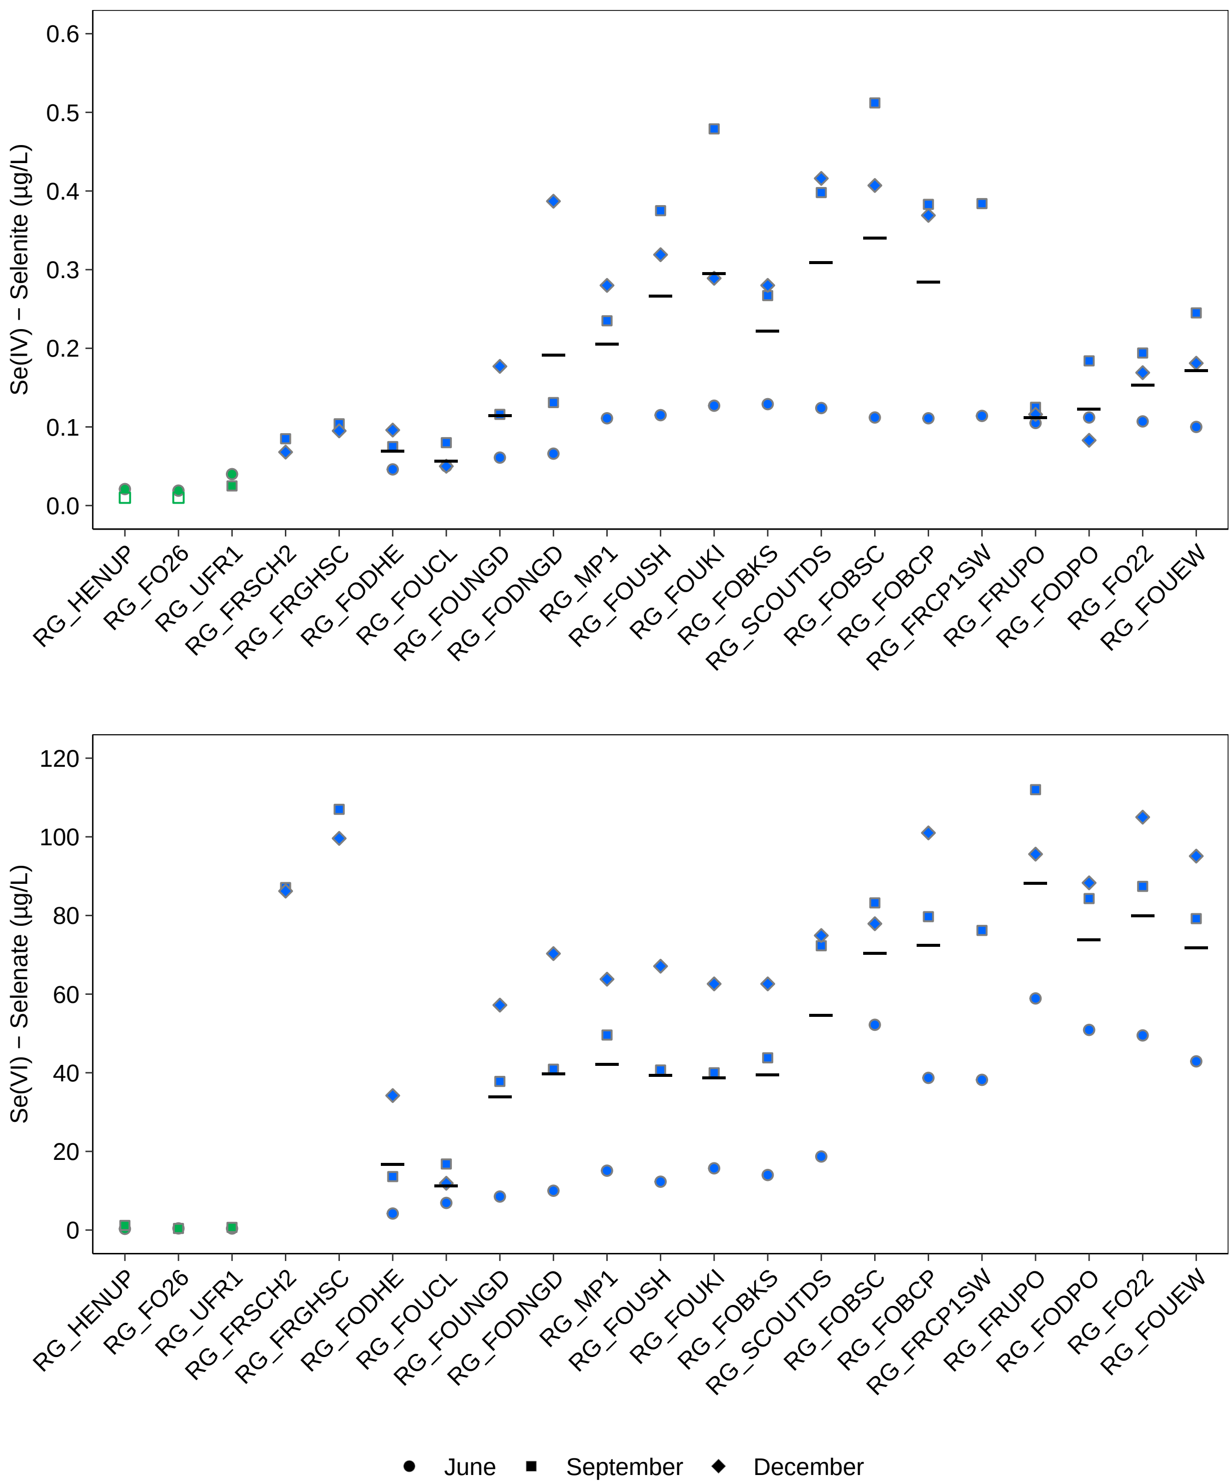

Figure B.20: Concentrations of Selenium Species in June, September, and December, FRO LAEMP, 2021

Notes: Only annual means are depicted with a black bar and are only presented when data is avalable from June, September, and December. Reference areas are shown in green and mine−exposed areas are shown in blue. Censored values are shown with hollow shapes. Selenium species with values below the laboratory detection limit were not plotted.

> 5% of samples exceed the guideline or benchmark.
> 50% of samples exceed the guideline or benchmark.
> 95% of samples exceed the guideline or benchmark.

Notes: "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline

[a] Long-term average BCQWG for the Protection of Aquatic Life.

[b] Short-term maximum BCQWG for the Protection of Aquatic Life. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures.

[c] Total Dissolved Solids was screened again one screening value. Nickel was screened against Levels 1, 2, and 3 interim screening values.

> 5% of samples exceed the guideline or benchmark.
> 50% of samples exceed the guideline or benchmark.
> 95% of samples exceed the guideline or benchmark.

Notes: "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline

[a] Long-term average BCQWG for the Protection of Aquatic Life.

[b] Short-term maximum BCQWG for the Protection of Aquatic Life. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures.

[c] Total Dissolved Solids was screened again one screening value. Nickel was screened against Levels 1, 2, and 3 interim screening values.

> 5% of samples exceed the guideline or benchmark.

> 50% of samples exceed the guideline or benchmark.

> 95% of samples exceed the guideline or benchmark.

Notes: "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline

[a] Long-term average BCQWG for the Protection of Aquatic Life.

[b] Short-term maximum BCQWG for the Protection of Aquatic Life. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures.

[c] Total Dissolved Solids was screened again one screening value. Nickel was screened against Levels 1, 2, and 3 interim screening values.

Table B.1: Summary of Water Chemistry Data for Key Constituents at Monitoring Stations Monitoring Stations, FRO LAEMP, 2021

> 5% of samples exceed the guideline or benchmark.
> 50% of samples exceed the guideline or benchmark.
> 95% of samples exceed the guideline or benchmark.

Notes: "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline

[a] Long-term average BCQWG for the Protection of Aquatic Life.

[b] Short-term maximum BCQWG for the Protection of Aquatic Life. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures.

[c] Total Dissolved Solids was screened again one screening value. Nickel was screened against Levels 1, 2, and 3 interim screening values.

> 95% of samples exceed the guideline or benchmark.

Notes: "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline

[a] Long-term average BCQWG for the Protection of Aquatic Life.

[b] Short-term maximum BCQWG for the Protection of Aquatic Life. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures.

[c] Total Dissolved Solids was screened again one screening value. Nickel was screened against Levels 1, 2, and 3 interim screening values.

> 5% of samples exceed the guideline or benchmark.
> 50% of samples exceed the guideline or benchmark.
> 95% of samples exceed the guideline or benchmark.

Notes: "LRL" = laboratory reporting limit. "BCWQG" = British Columbia Working or Accepted Water Quality Guideline

[a] Long-term average BCQWG for the Protection of Aquatic Life.

[b] Short-term maximum BCQWG for the Protection of Aquatic Life. For guidelines dependent on other analytes (e.g., hardness or chloride), guidelines were screened using concurrent concentrations. When concurrent hardness or chloride concentrations were not measured, the most conservative concentration observed for that station was used to estimate the guidelines or benchmark. All summary statistics are reported to 3 significant figures.

[c] Total Dissolved Solids was screened again one screening value. Nickel was screened against Levels 1, 2, and 3 interim screening values.

Non-Metals	Total Alkalinity	mg/L	For dissolved calcium = < 4mg/L, WQG = <10 For dissolved calcium = 4 to 8 mg/L, WQG = 10 to 20 For dissolved calcium = > 8 mg/L, WQG = > 20	-	2015	Working	-
	Unionized Ammonia [c]	mg/L	pH and Temperature dependent (tabular)	pH and Temperature dependent (tabular)	2009	Approved	-
	Chloride	mg/L	150	600	2003	Approved	-
	Fluoride	mg/L	-	For hardness ≤ 10 mg/L, WQG = 0.4 For hardness > 10 mg/L, WQG = [-51.73 + 92.57 × $\log_{10}$(hardness)]×0.01 Maximum applicable hardness = 385 mg/L	1990	Approved	-
	Nitrate-N	mg/L	3	33	2009	Approved	Level 1 EVWQP benchmark= $10^{1.0003[\log(\text{hardness})]-1.52}$ Maximum applicable hardness = 500 mg/L Level 2 EVWQP benchmark= $10^{1.0003[\log(\text{hardness})]-1.38}$ Maximum applicable hardness = 500 mg/L
	Nitrite-N [d]	mg/L	0.02 to 0.20	0.06 to 0.60	2009	Approved	-
	Dissolved oxygen [e]	mg/L	For buried embryo/alevin life stages, WQG (water column) = 11 WQG (interstitial) = 8 For other life stages, WQG (water column) = 8	For buried embryo/alevin life stages, WQG (water column) = 9 WQG (interstitial) = 6 For other life stages, WQG (water column) = 5	1997	Approved	-
	pH [f]	pH units	6.5 - 9.0		1991	Approved	-
	Sulphate [g]	mg/L	128 to 429 Maximum applicable hardness = 250 mg/L	-	2013	Approved	Level 1 EVWQP Benchmark = BCWQG = 429
	Total Dissolved Solids	mg/L	-	-	-	-	Level 1 Screening Value = 1000

[a] British Columbia Working (BCMOE 2017) or Accepted (BCMOE 2019) Water Quality Guidelines for the Protection of Aquatic Life. For guidelines dependent on other analytes (e.g., hardness), guidelines were screened using concurrent values.

[b] When appropriate, site-specific Elk Valley Water Quality Plan Benchmarks (EVWQP; Teck 2014) or interim screening values were applied in addition to or instead of BC water quality guidelines. Interim screening values are displayed for nickel (Golder 2017; Coal Mountain Operations Aquatic Health Assessment Report).

[c] Temperature and pH dependent; range of minimum and maximum values.

[d] Dependent on concurrent chloride, range of values reported (BCMOE 2019)

[e] Dissolved oxygen guidelines represent a minimum value, and so exceedances were quantified below this guideline.

[f] Unrestricted change permitted within this pH range.

[g] For hardness-based guidelines, concurrent hardness values were used for calculating guidelines. If hardness values exceeding the maximum applicable hardness, then guidelines were determined using the maximum applicable hardness. If hardness values is lower than the minimum hardness, then guidelines were determined using the minimum hardness.

[h] Chromium(VI) is the dominant oxidation state in oxygenated environments, and so its guideline was applied.

[i] The most conservative guideline (0.00000125 mg/L) was applied.

Table B.2: British Columbia Water Quality Guidelines, Site-Specific Elk Valley Water Quality Plan (EVWQP) Benchmarks, and Interim Screening Values for Constituents Assessed, FRO LAEMP, 2021

		Variable	Units	British Columbia Water Quality Guidelines [a]				Site-Specific Benchmark [b]
				Long-term Average	Short-term Maximum	Year	Status

Table B.3. Temporal Changes in Water Chemistry Constituents at Stations, FRO LAEMP, 2012 to 2021

Constituents	Status	Station	Annual Variation [a]		Q1. Is there a positive or negative change in concentrations since the base year (b) of monitoring? Magnitude of Difference (MOD)[b] and Significance (bolded) from Base Year (b) [c]										Q2. Is the 2021 annual mean greater or less than all annual historical means (2012 to 2020) and the previous year (2020)?[c]											
			DF	P-Value	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2021 vs. 2012-2020	2021 vs. 2020

> 33% Decrease in concentration.
> 43% Decrease in concentration.
> 50% Decrease in concentration.
> 25% Increase in concentration.
> 50% Increase in concentration.
> 75% Increase in concentration.
> 100% Increase in concentration.
***Bold** **Significant increase or decrease from base year.**

Notes: Temporal trends were only conducted for areas that have a complete routine water quality monitoring dataset. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and analyzed together with the biological monitoring area depicted in parenthesis. Only constituents considered mine-related under the Adaptive Management Plan (AMP) and that have early warning triggers, and orthophosphate and total phosphorus were analyzed for temporal trends.

[a] The presence of annual variation was determined by a significant Year term (α = 0.05) using an ANOVA with factors Year and Month.

[b] Magnitude of Difference (MOD) was calculated as the concentrations in each year minus the concentration in the first year divided by the concentration in the fist year × 100.

[c] Significance between each year determined using all pairwise comparisons with Tukey correction.

[d] "ns" = not significant year term so no post-hoc comparison tested; "-" insufficient data for comparison, where insufficient data is less than 6 months of recorded data.

Table B.4: Pearson Correlations of Annual Water Analytes and PCA Axis Scores, FRO LAEMP, 2018 to 2021

$r_s \geq 0.6$ or ≤ -0.6.

Significant correlation (p-value < 0.05).

Notes: Annual water summary calculated as the average of seasonal means (Winter, Spring, Summer, and Fall). Stations without data for all four seasons in a given year were excluded.

Table B.5: Concentrations of Selenium Species Measured in Water Samples from Fording River, June to December, FRO LAEMP, 2021

P-value < 0.05 (annual variation).
\> 20% Decrease in concentration.
\> 33% Decrease in concentration.
\> 43% Decrease in concentration.
\> 50% Decrease in concentration.
\> 25% Increase in concentration.
\> 50% Increase in concentration.
\> 75% Increase in concentration.
\> 100% Increase in concentration.
***Bold** Significant increase or decrease from base year.

Notes: Temporal trends were only conducted for areas that have a complete routine water quality monitoring dataset. When biological monitoring areas and routine water quality stations were in close proximity to each other and with no additional inputs between them, data collected at the biological monitoring area were combined with routine data and analyzed together with the biological monitoring area depicted in parenthesis. Only constituents considered mine-related under the Adaptive Management Plan (AMP) and that have early warning triggers, and orthophosphate and total phosphorus were analyzed for temporal trends.

[a] The presence of annual variation was determined by a significant Year term (α = 0.05) using an ANOVA with factors Year and Month.

[b] Magnitude of Difference (MOD) was calculated as the concentrations in each year minus the concentration in the first year divided by the concentration in the fist year × 100.

[c] Significance between each year determined using all pairwise comparisons with Tukey correction.

[d] "ns" = not significant year term so no post-hoc comparison tested; "-" insufficient data for comparison, where insufficient data is less than 6 months of recorded data.

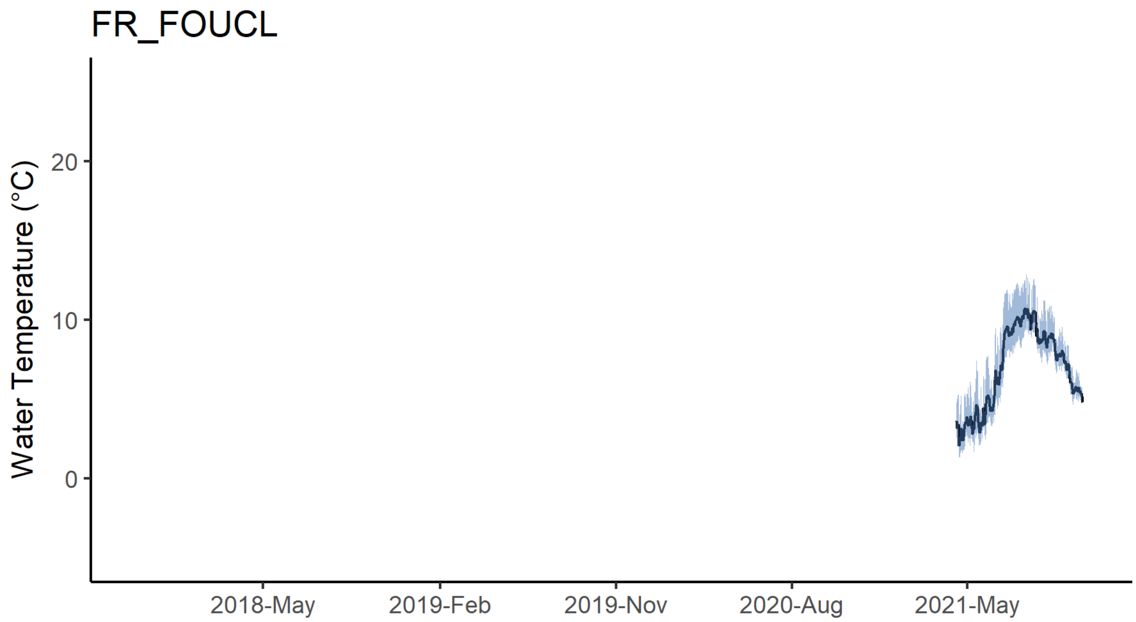
Figure C.10: Continuous Water Temperature Logging in the Fording River, 2021

Notes: Black line represents average daily water temperature. Blue line represents maximum and minimum daily water temperature. Gray highlighted area represents average daily water temperature below 0°C. Gaps in data are due to logger corruption or loss of logger due to environmental conditions. Areas with a constant temperature of ~0°C during the winter represent periods where the loggers were entombed in ice. Data loggers were installed at FR_UFR1, FR_FR1, FR_FRDSCC1, and FR_SCOUTDS in summer of 2020 and the data logger at FR_FOUCL was installed in the spring of 2021.



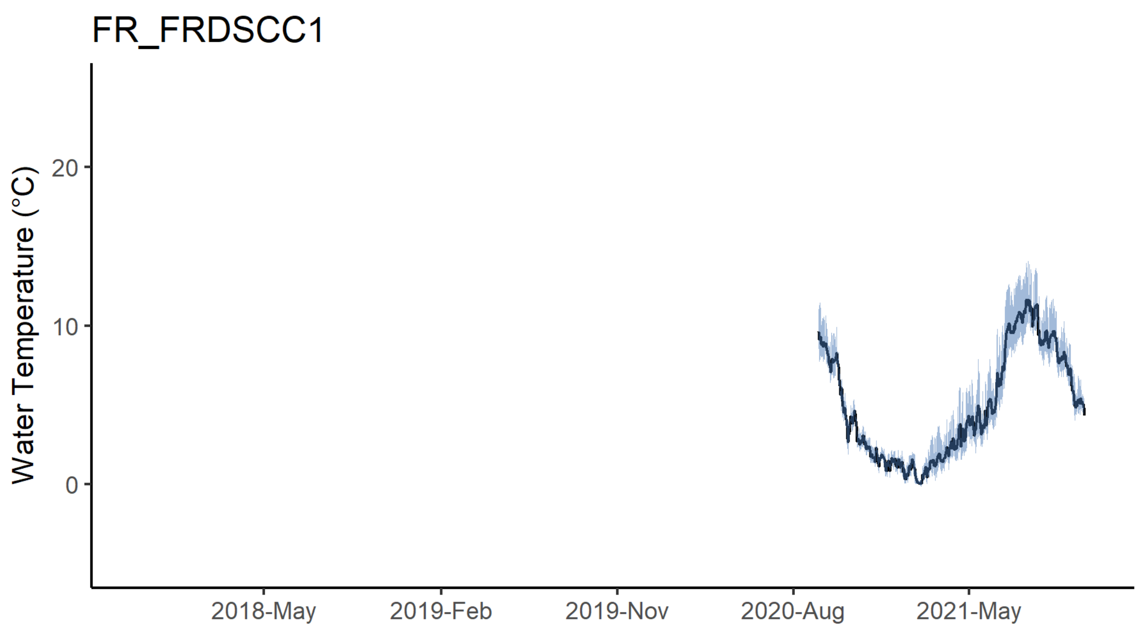


Figure C.10: Continuous Water Temperature Logging in the Fording River, 2021

APPENDIX D
SUBSTRATE QUALITY

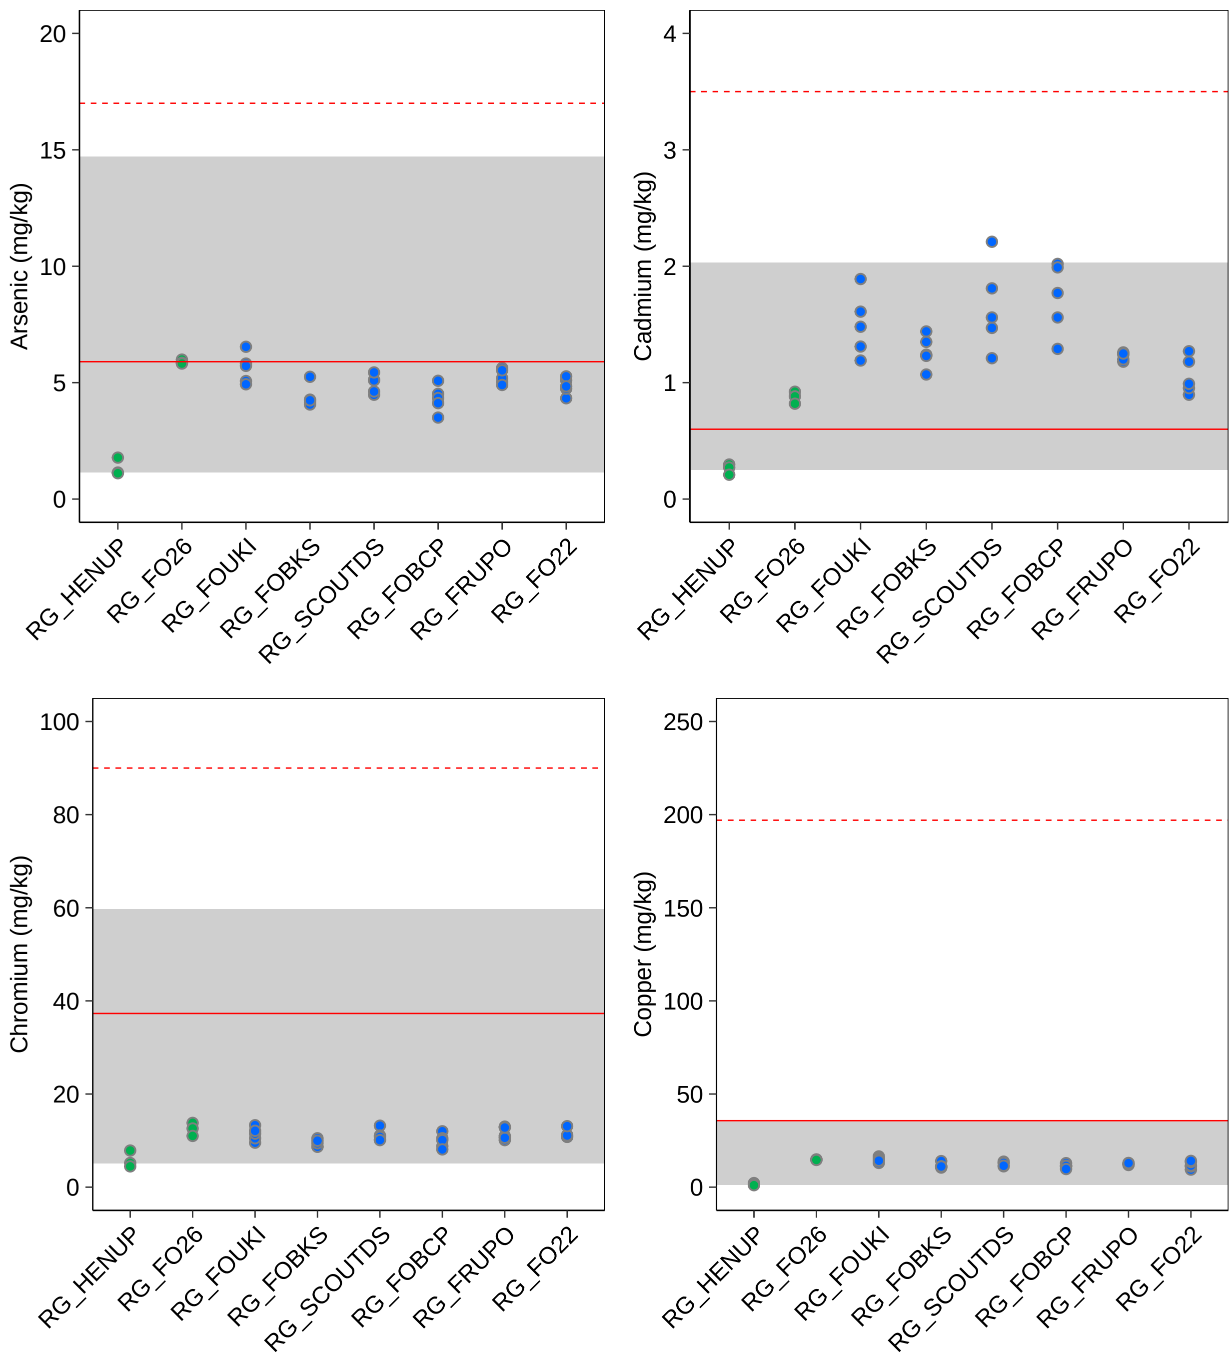

Figure D.1: Sediment Metal Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, September 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

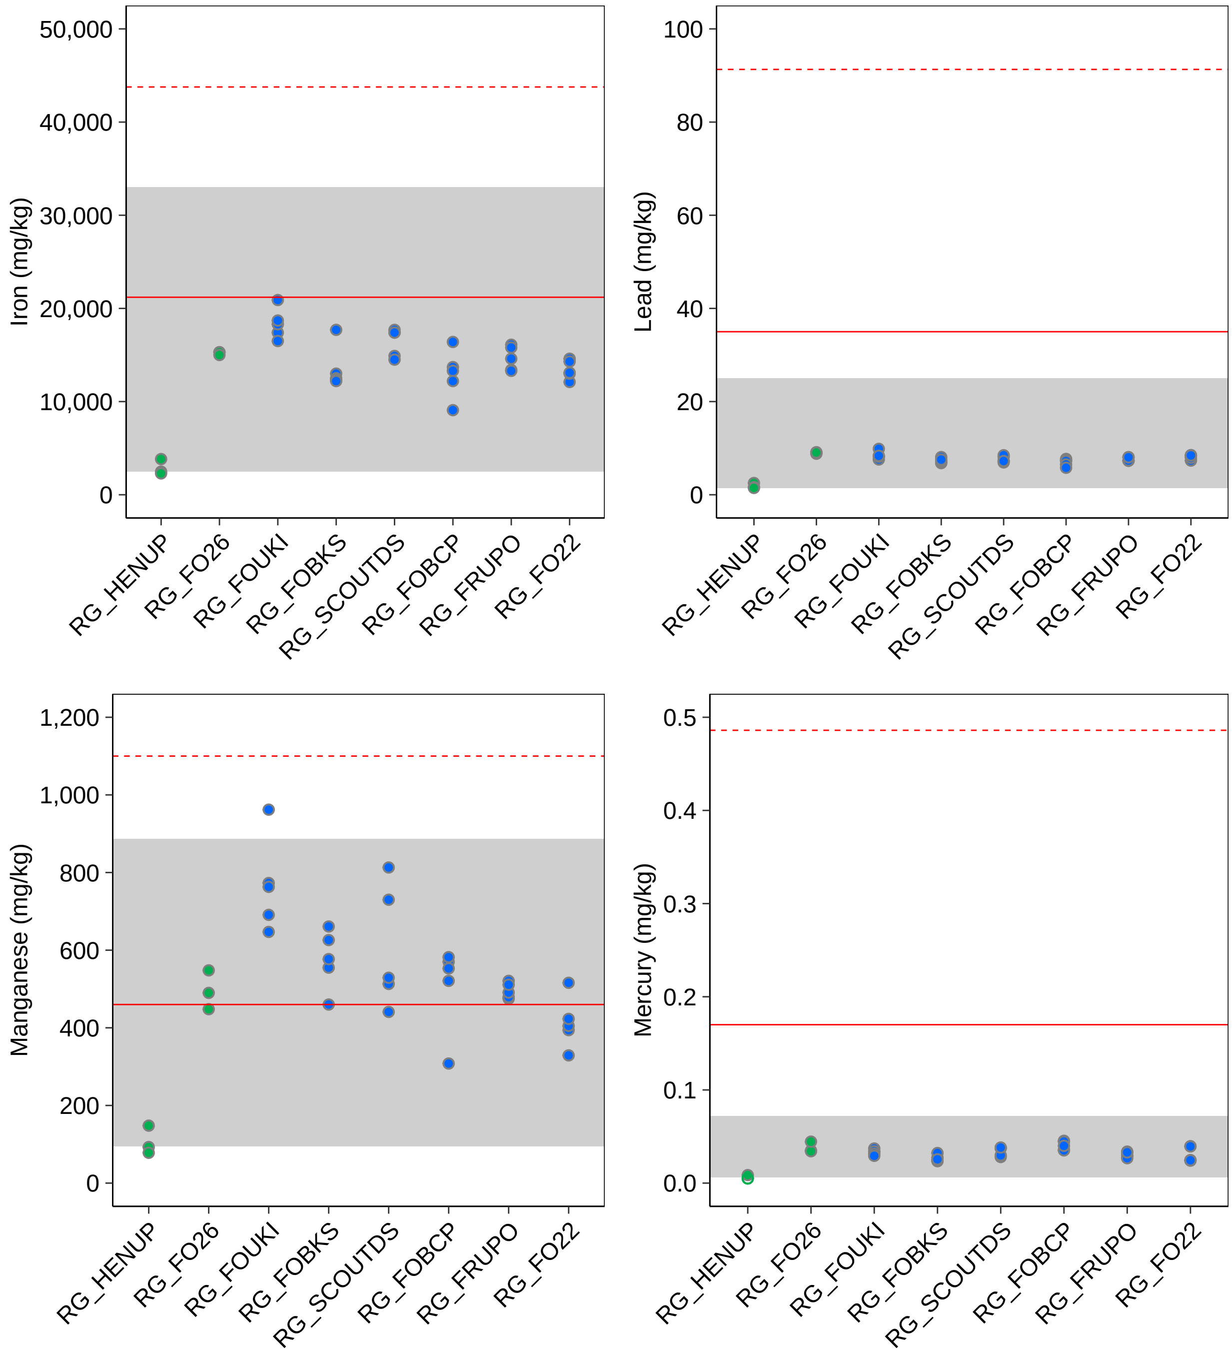

Figure D.1: Sediment Metal Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, September 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

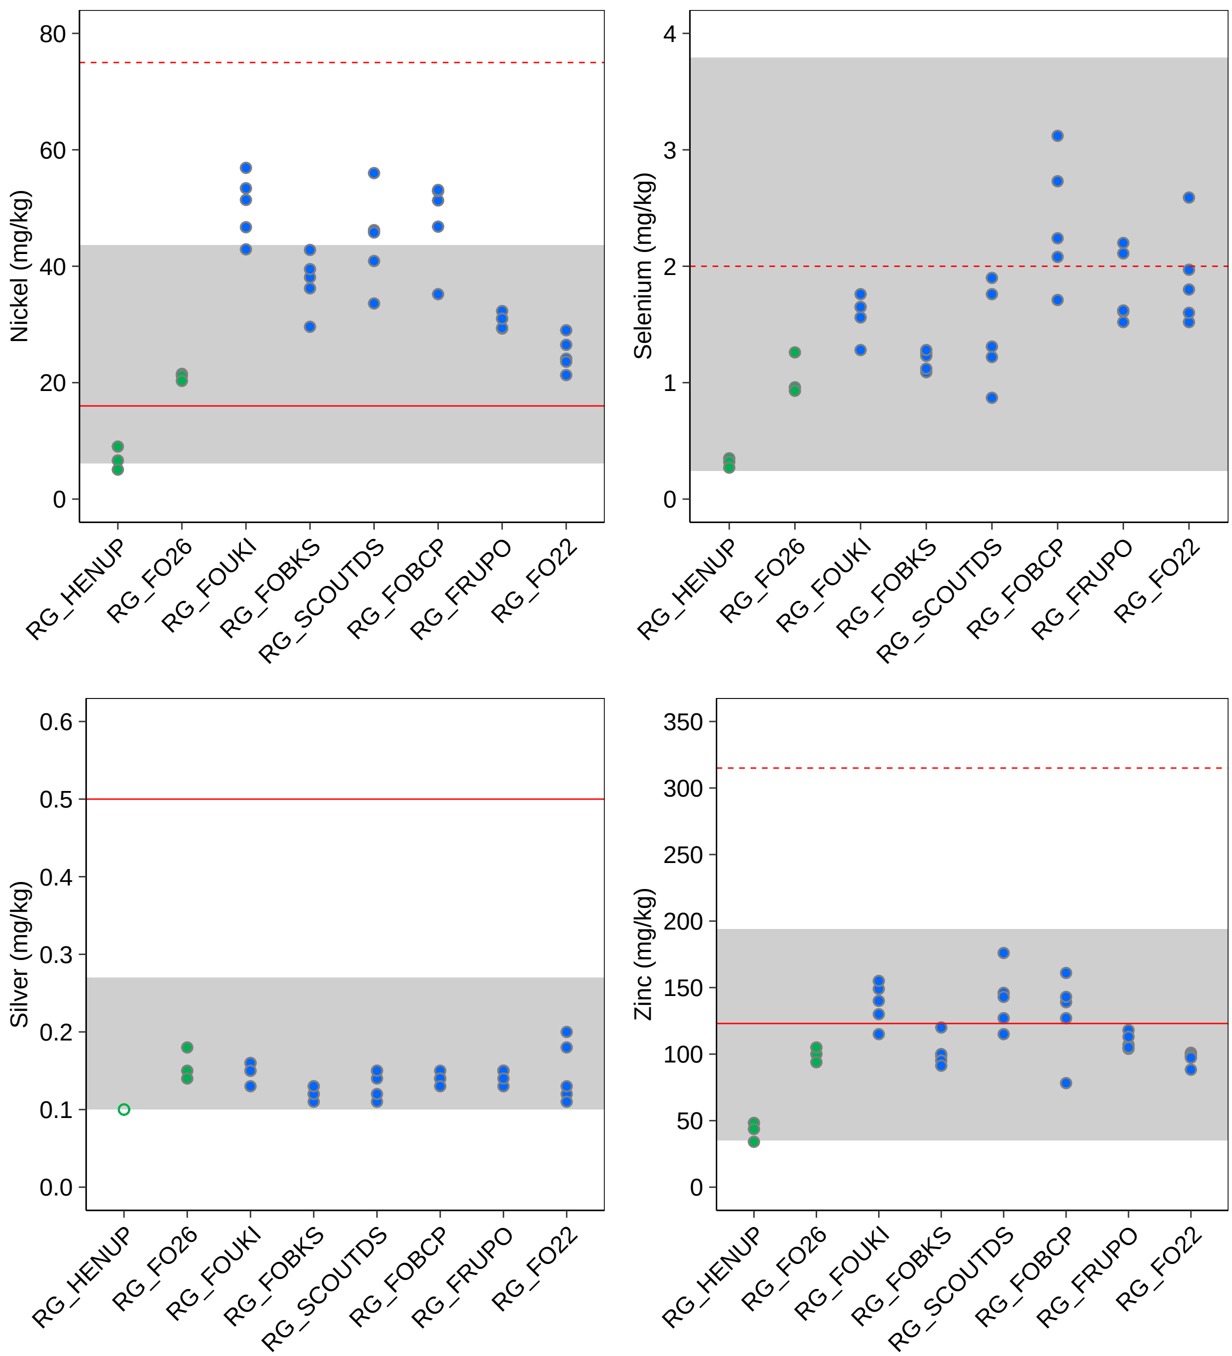

Figure D.1: Sediment Metal Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, September 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Figure D.2: Arsenic Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

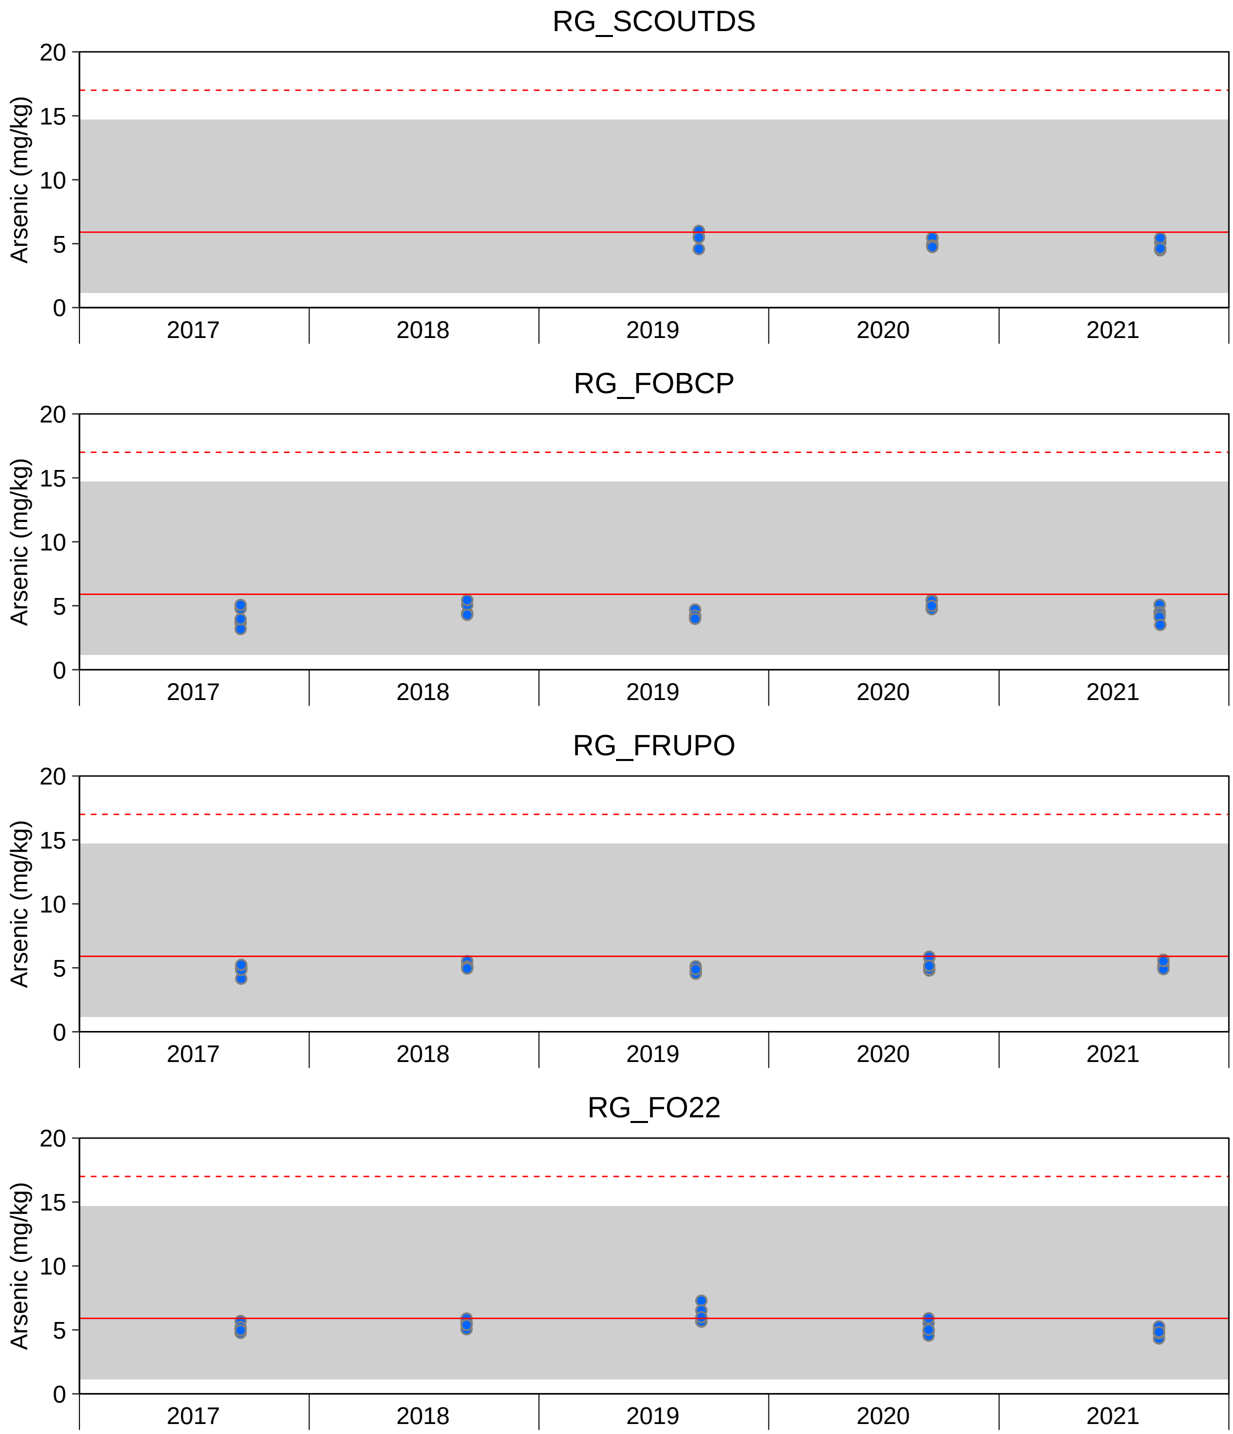

Figure D.2: Arsenic Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

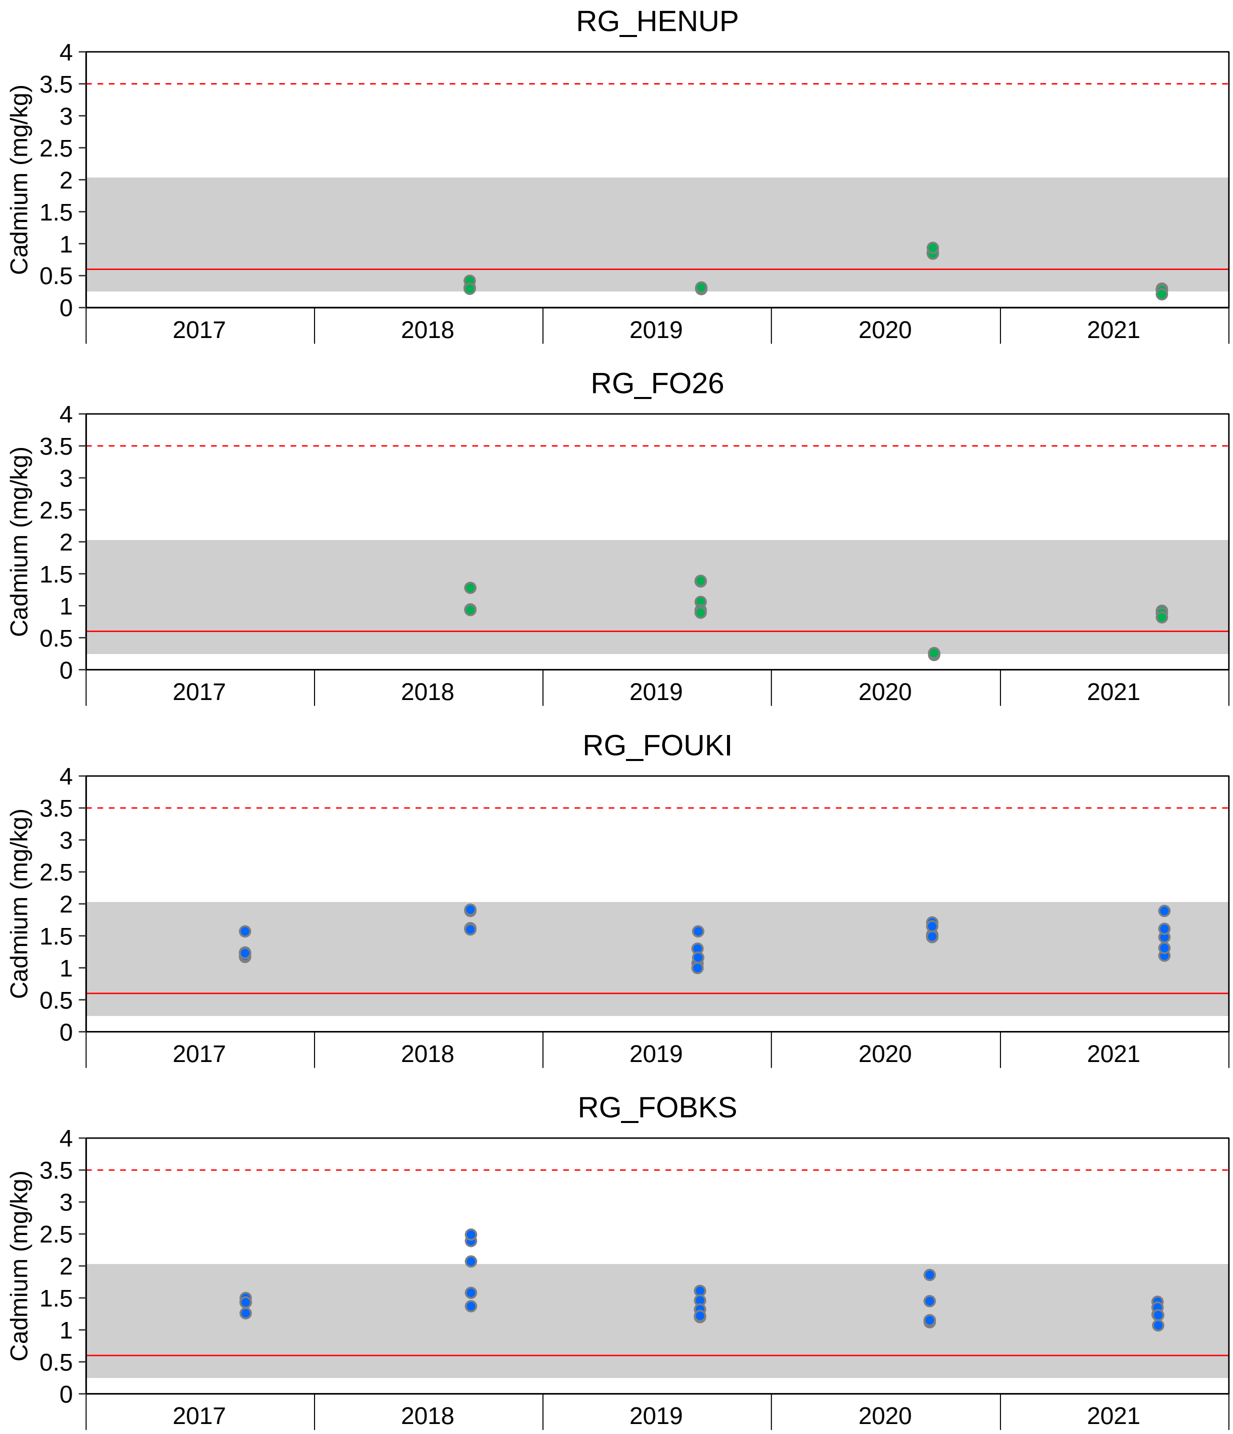

Figure D.3: Cadmium Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

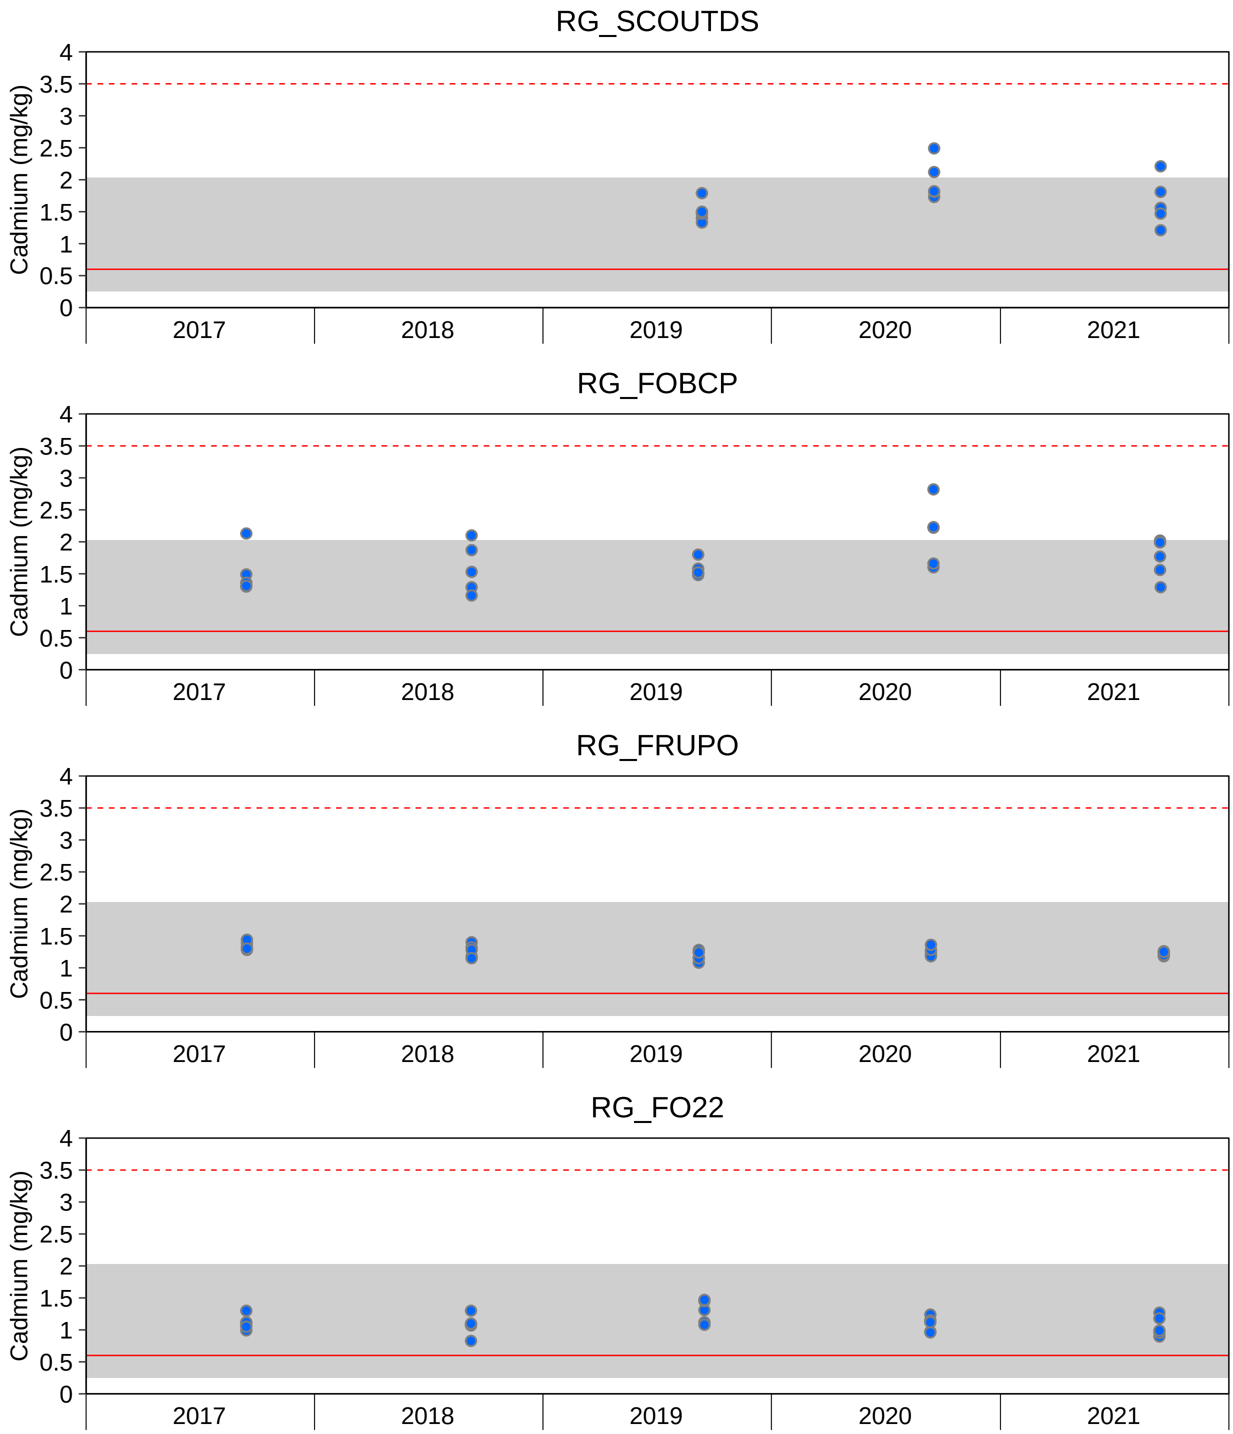

Figure D.3: Cadmium Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

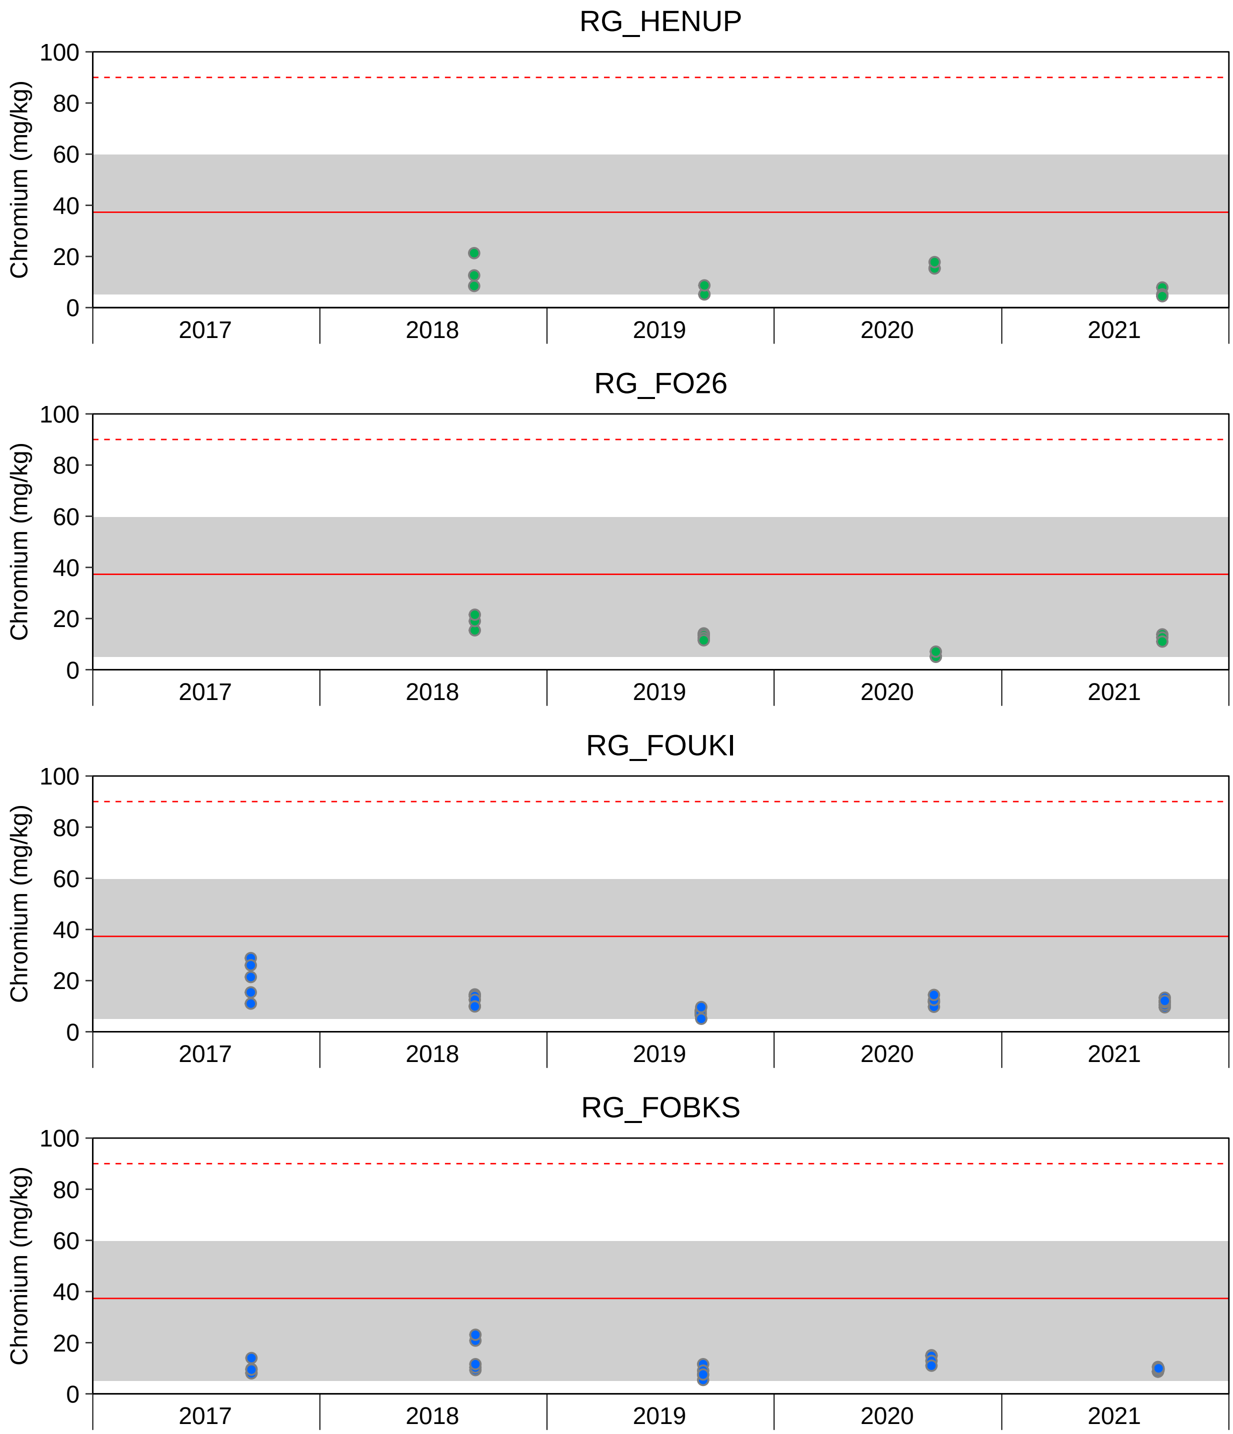

Figure D.4: Chromium Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

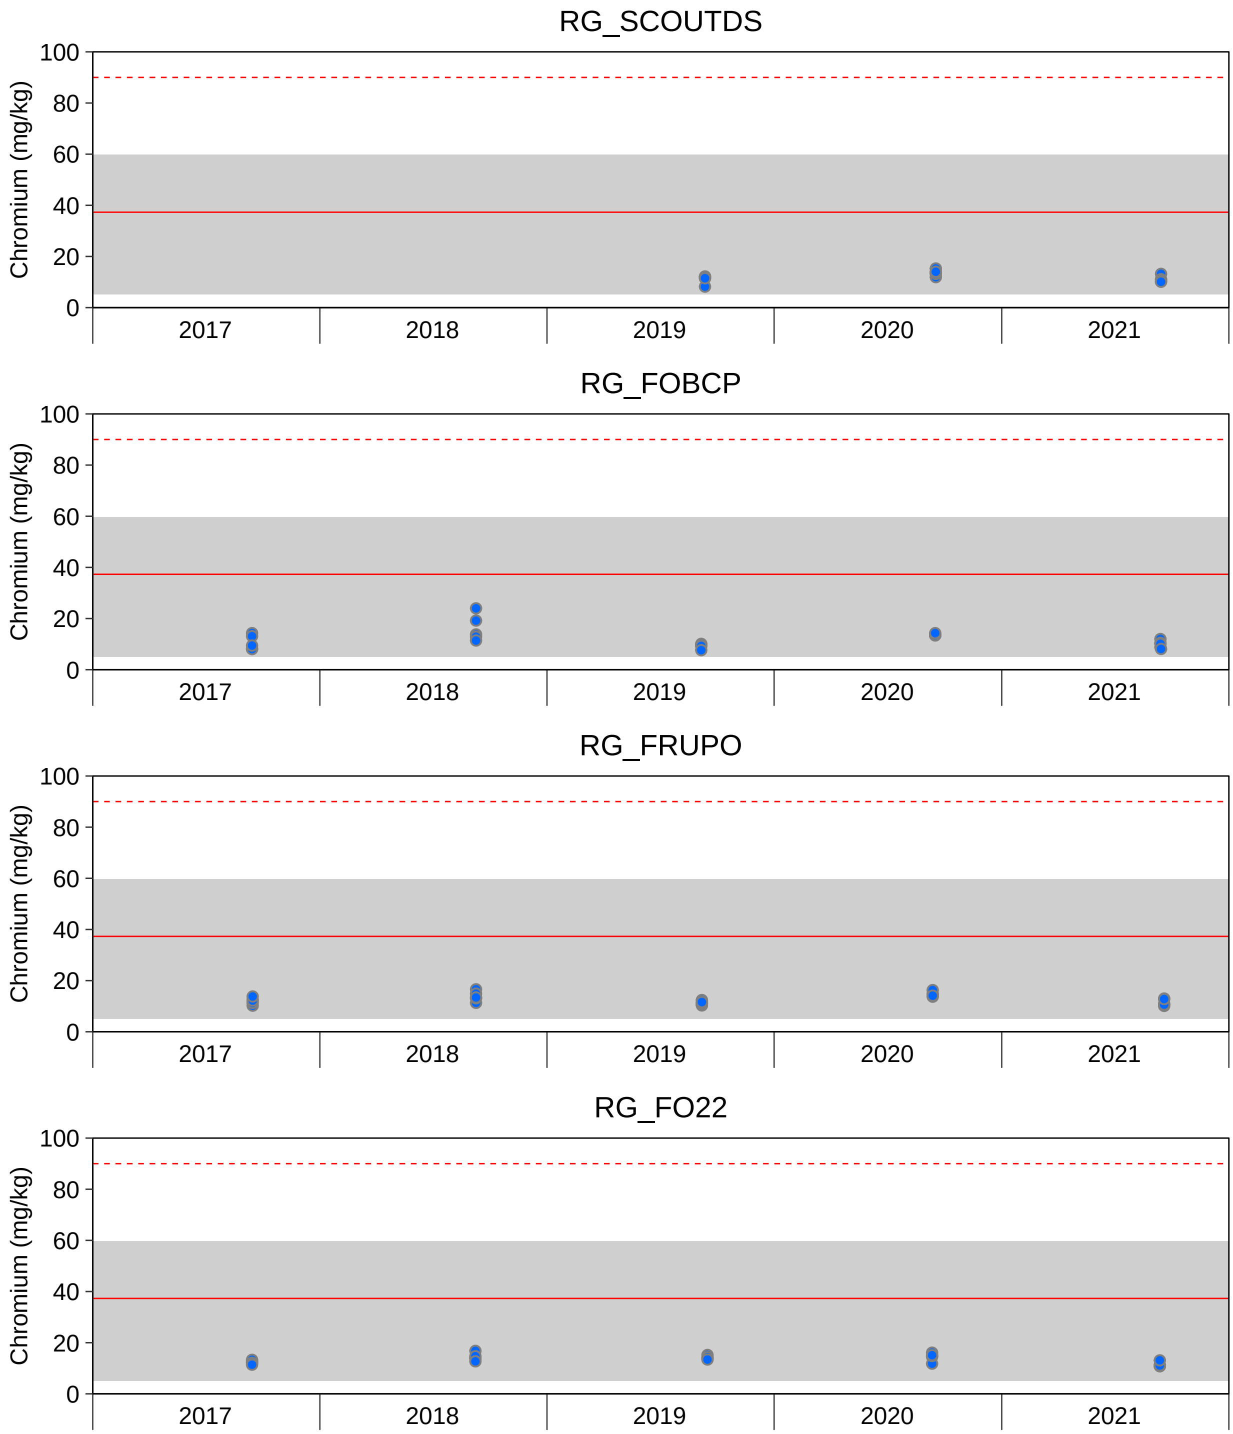

Figure D.4: Chromium Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

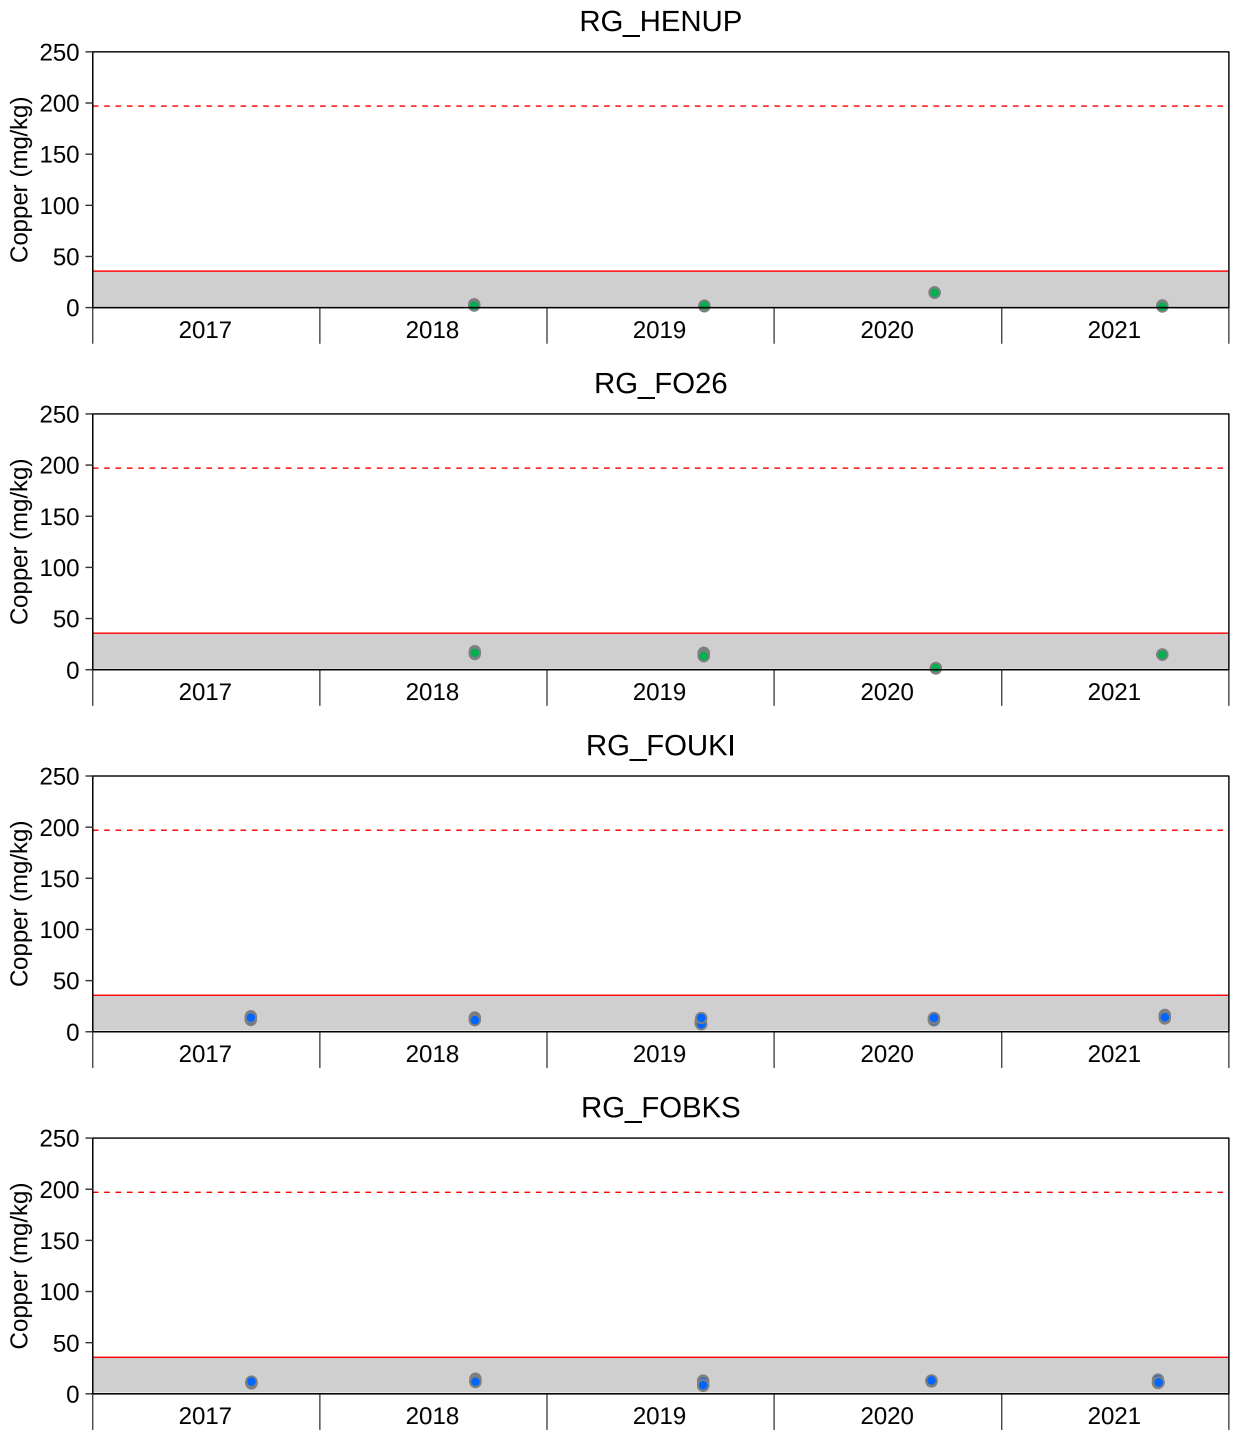

Figure D.5: Copper Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

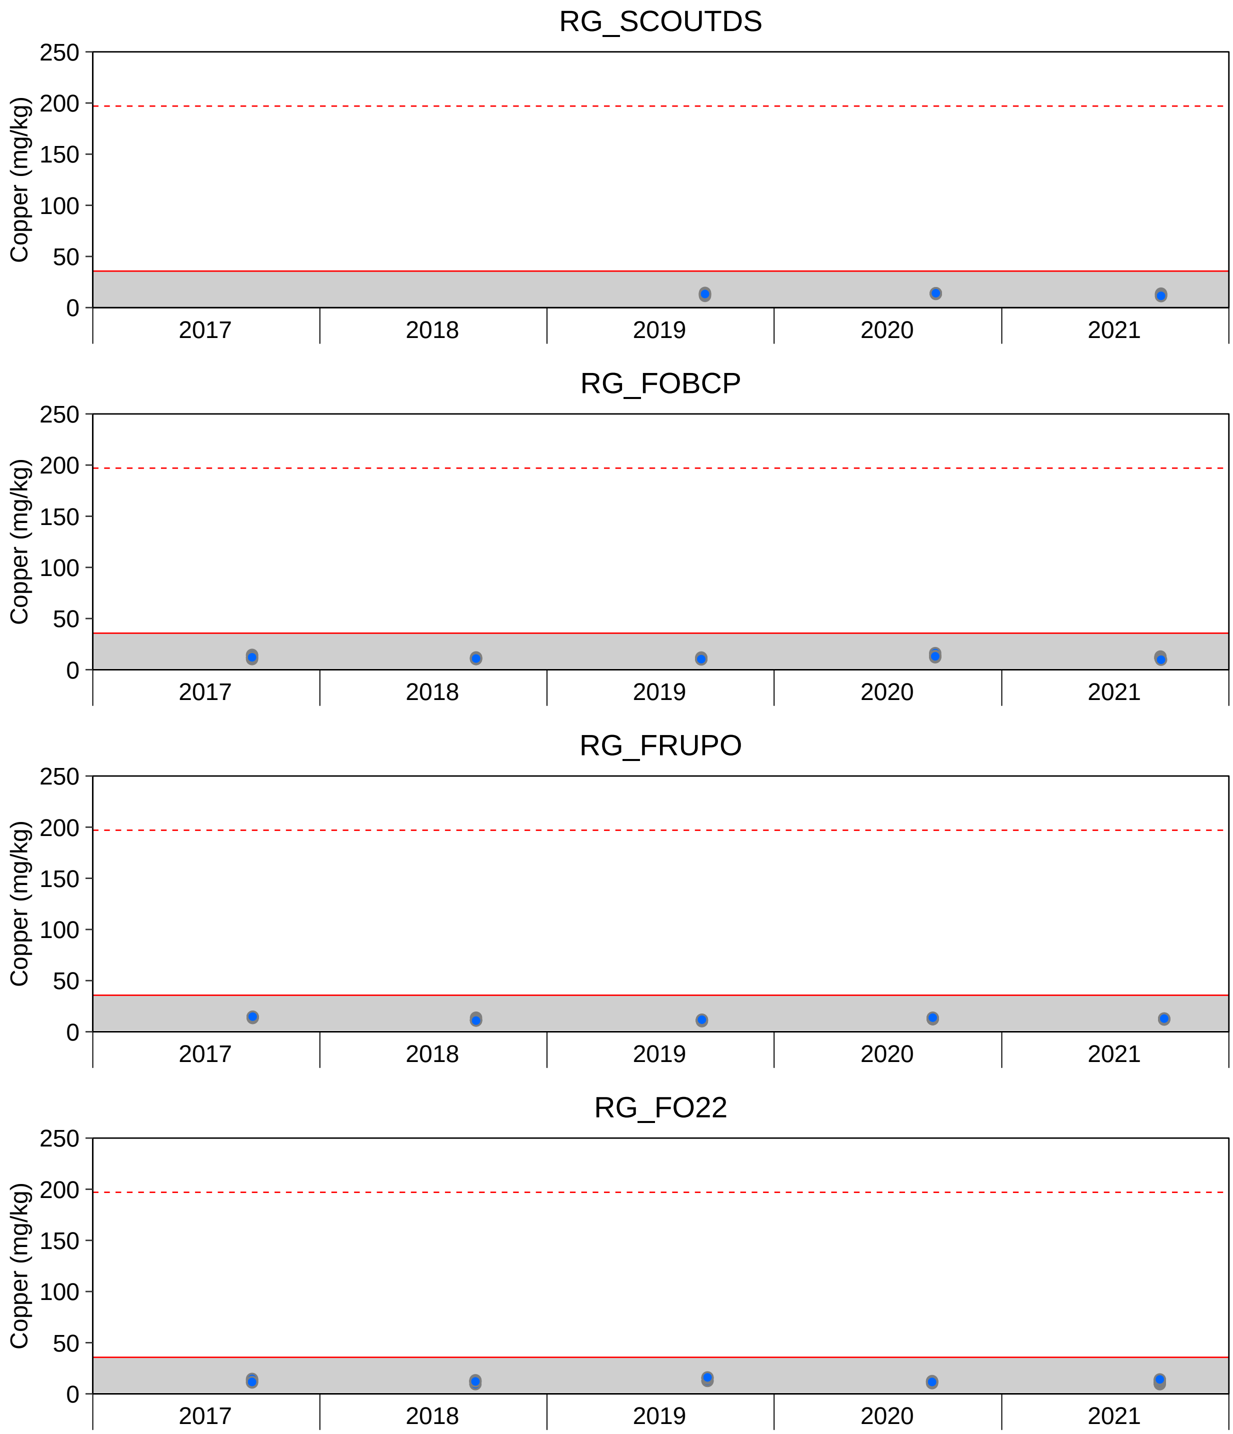

Figure D.5: Copper Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

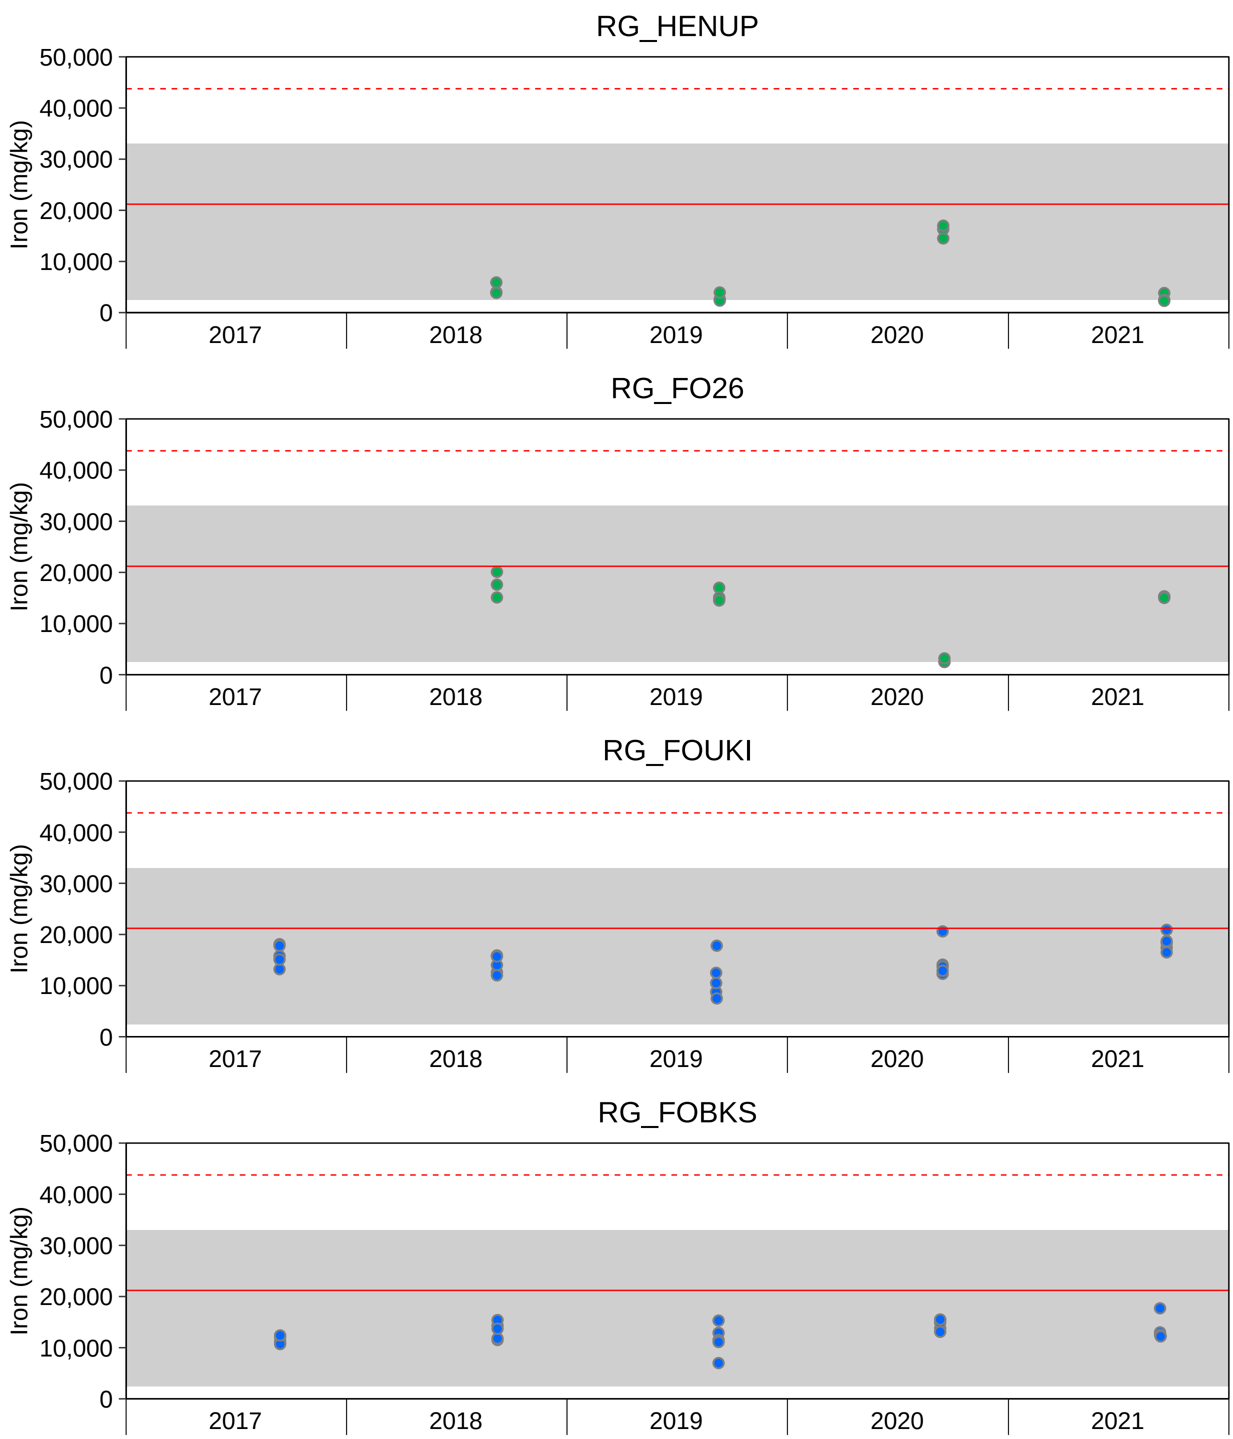

Figure D.6: Iron Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

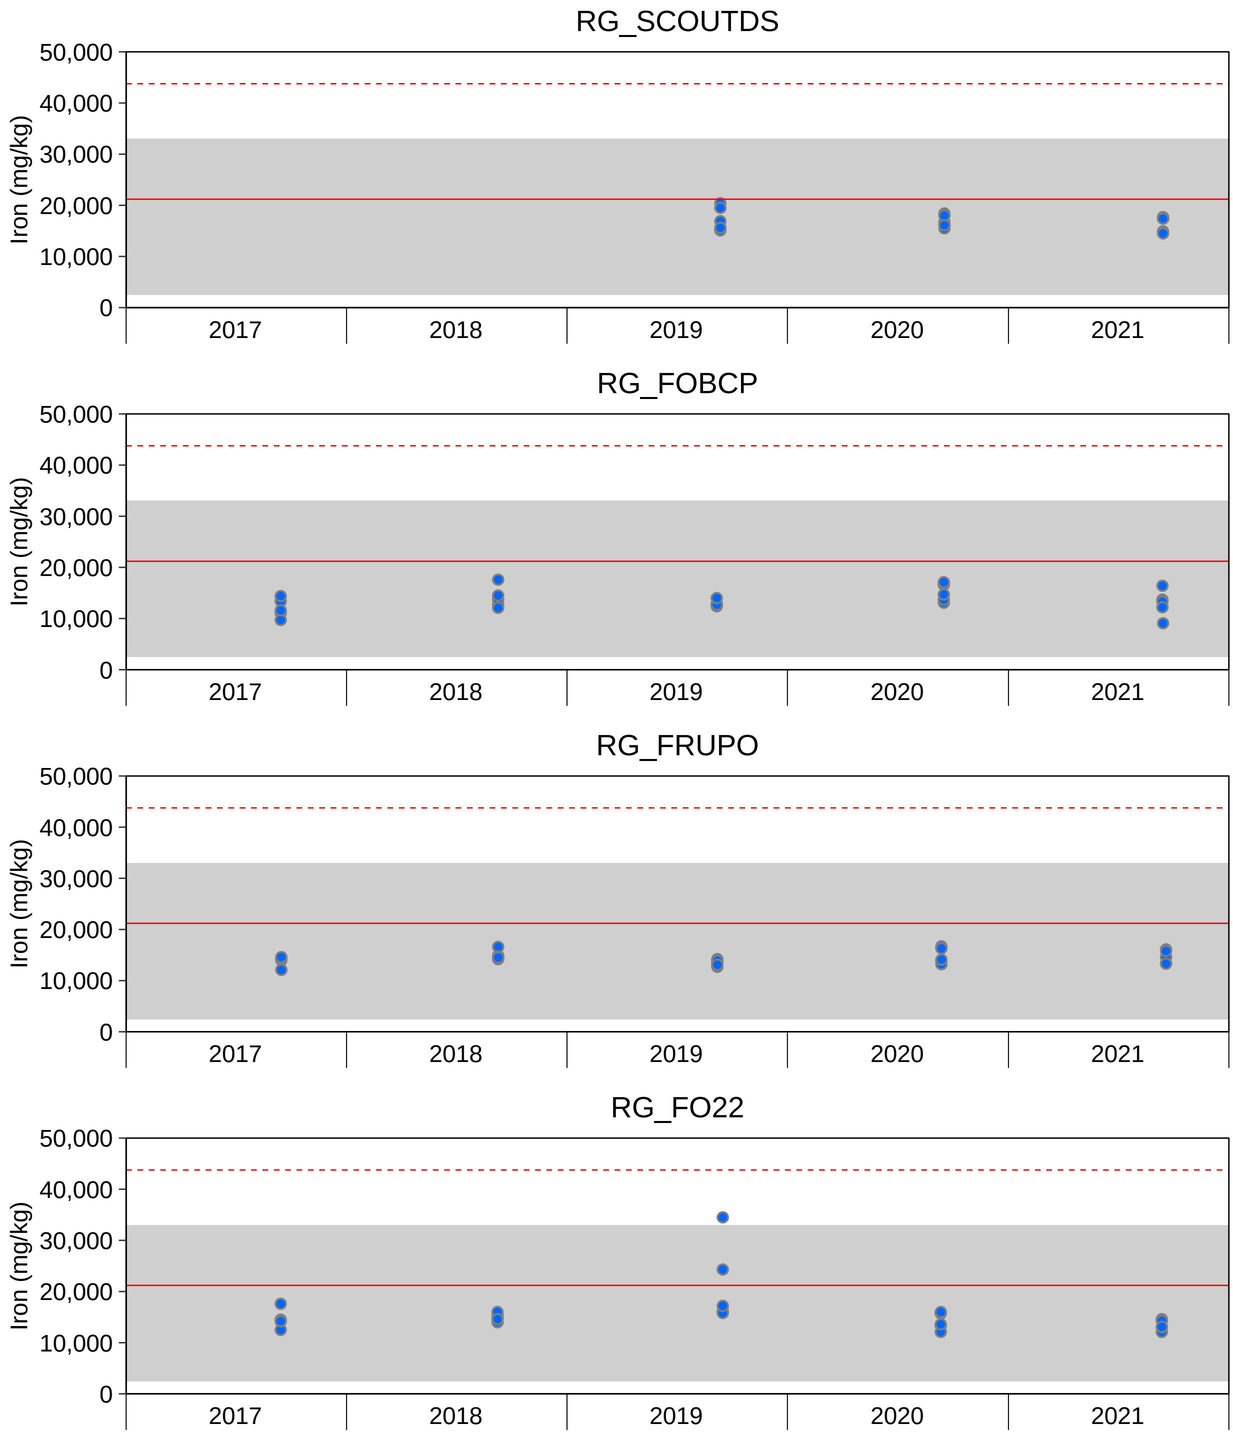

Figure D.6: Iron Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Figure D.7: Lead Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

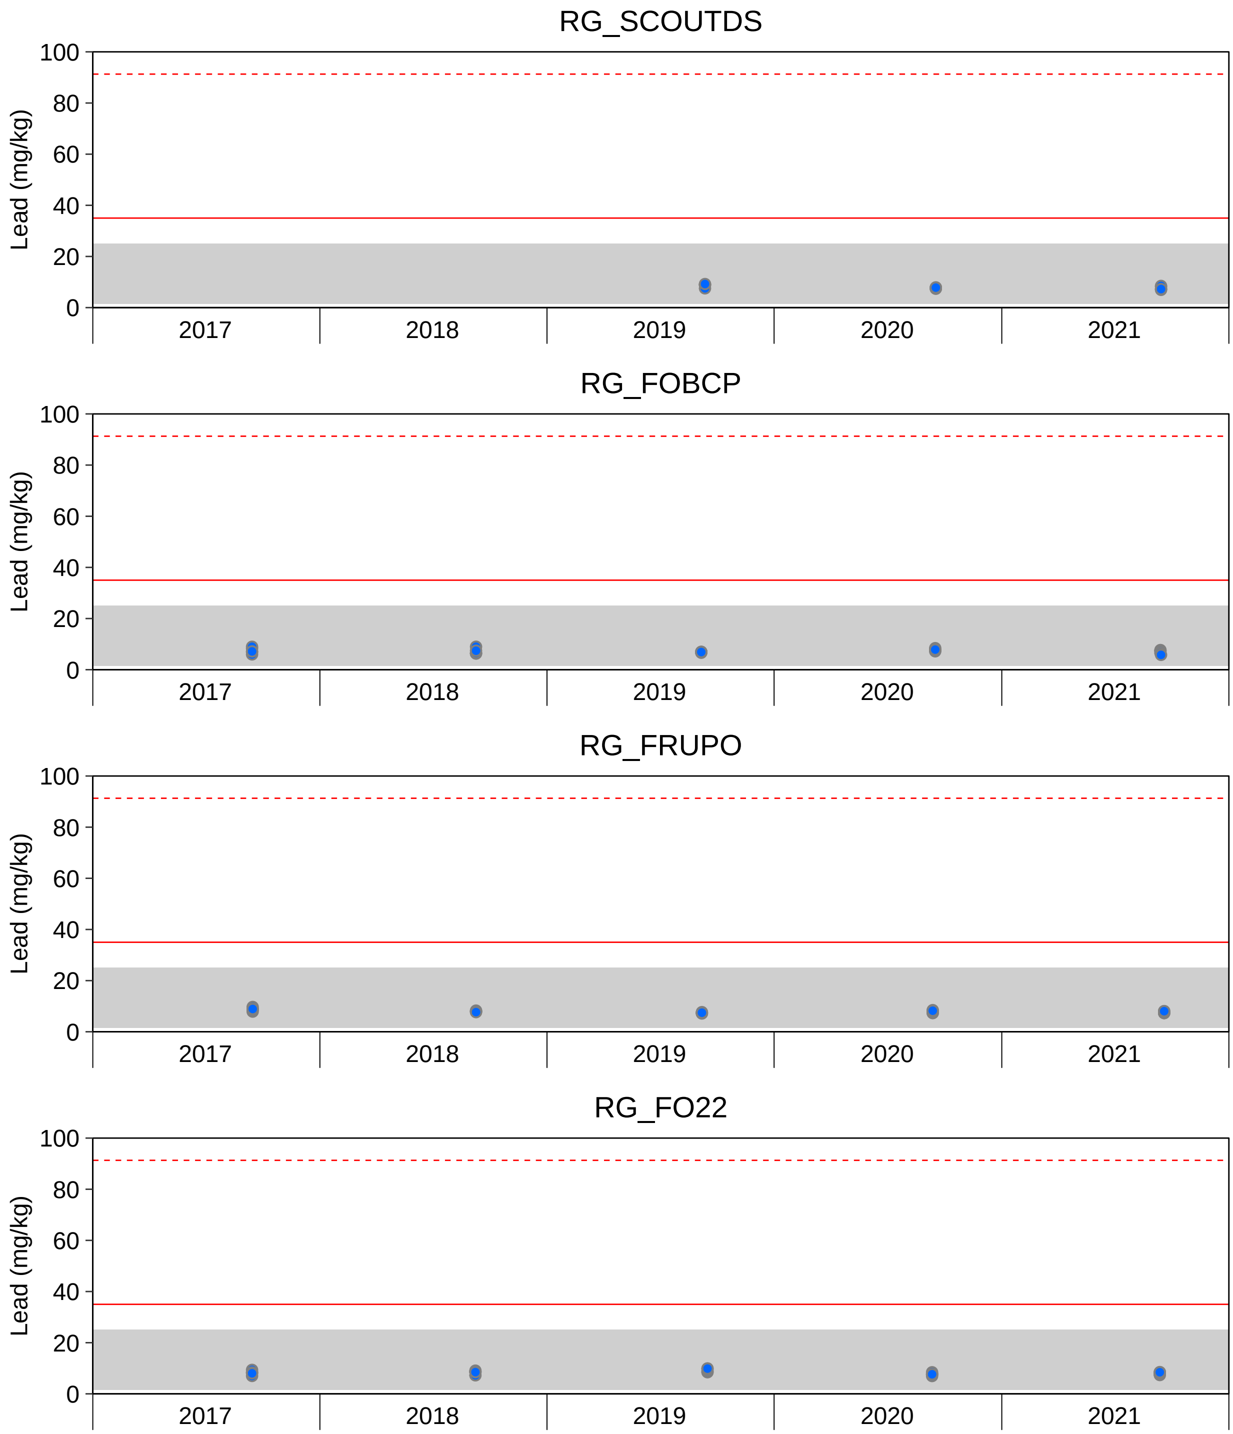

Figure D.7: Lead Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

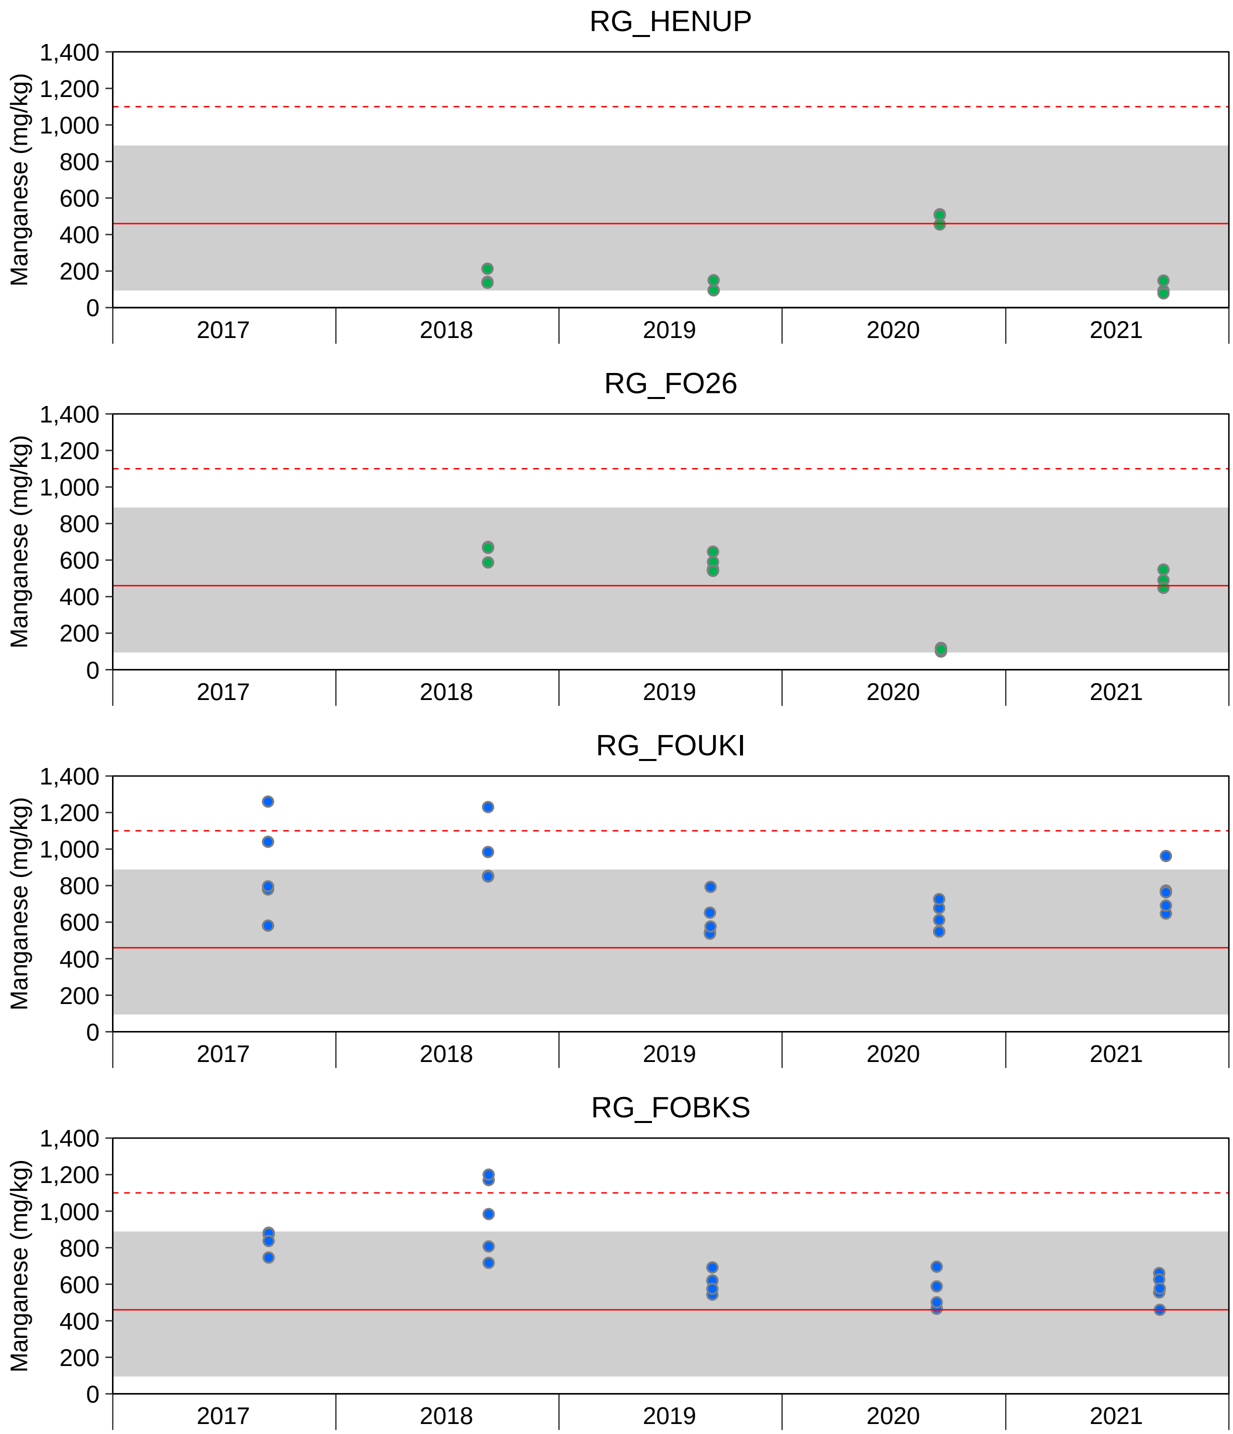

Figure D.8: Manganese Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

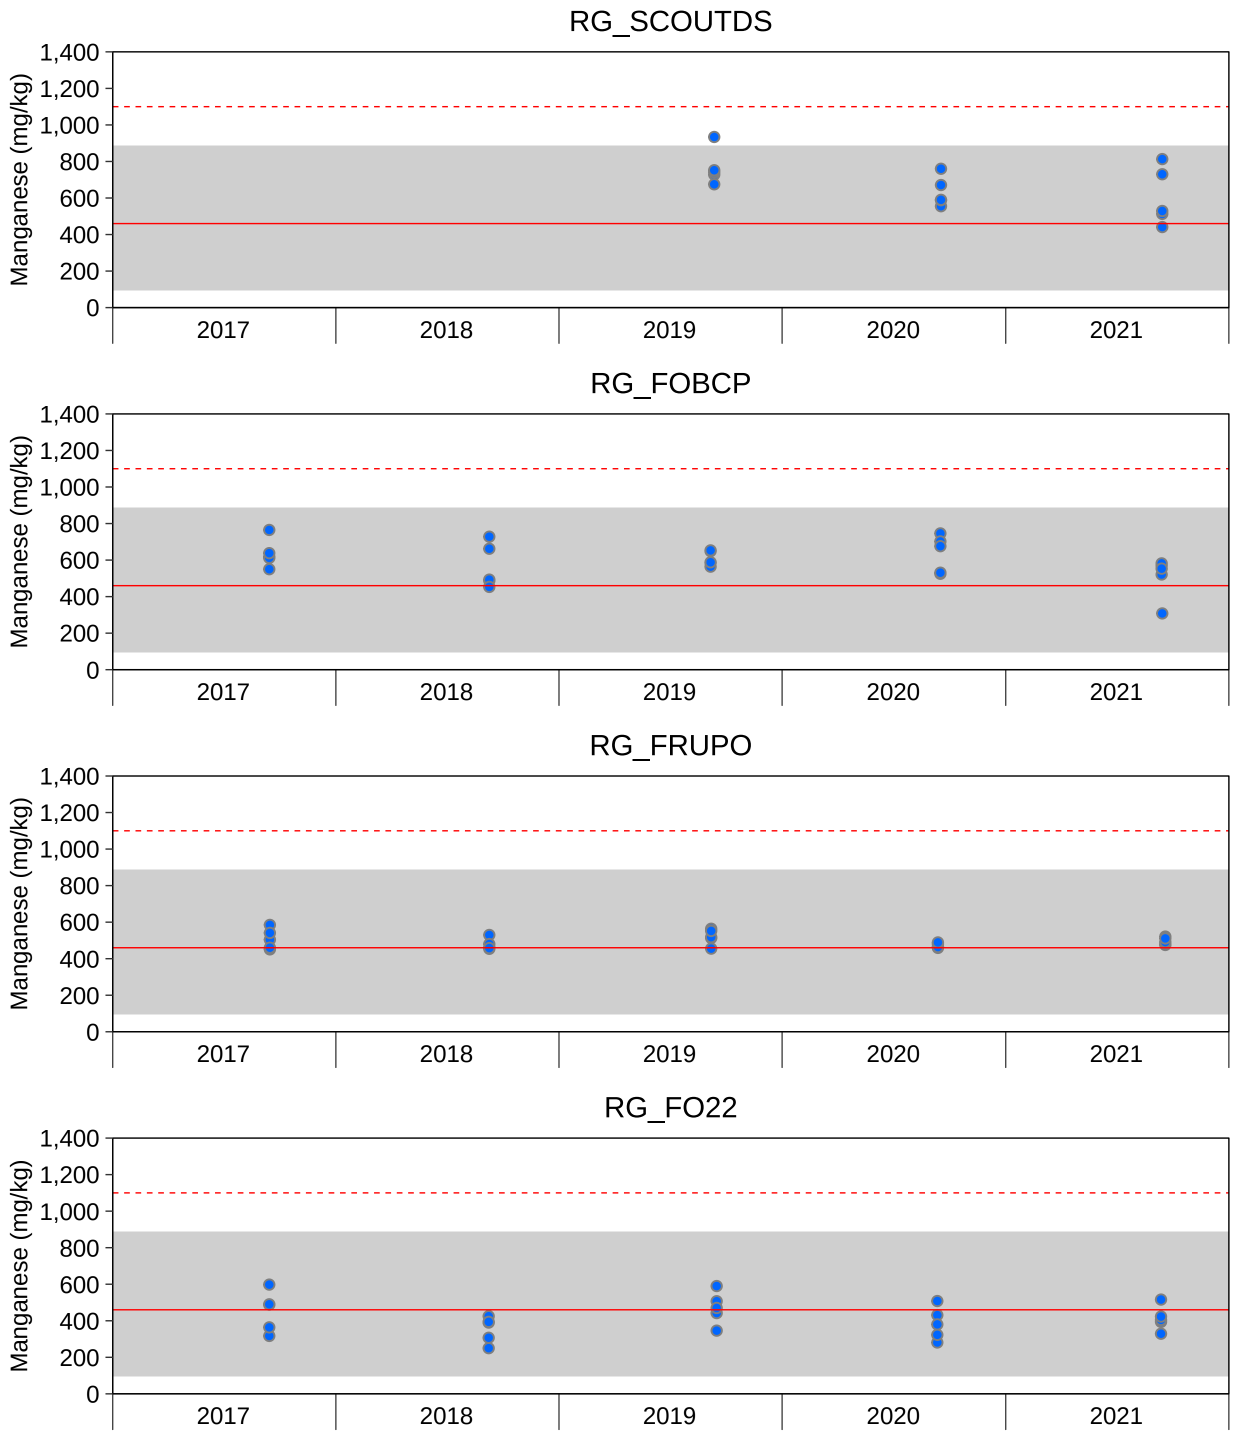

Figure D.8: Manganese Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

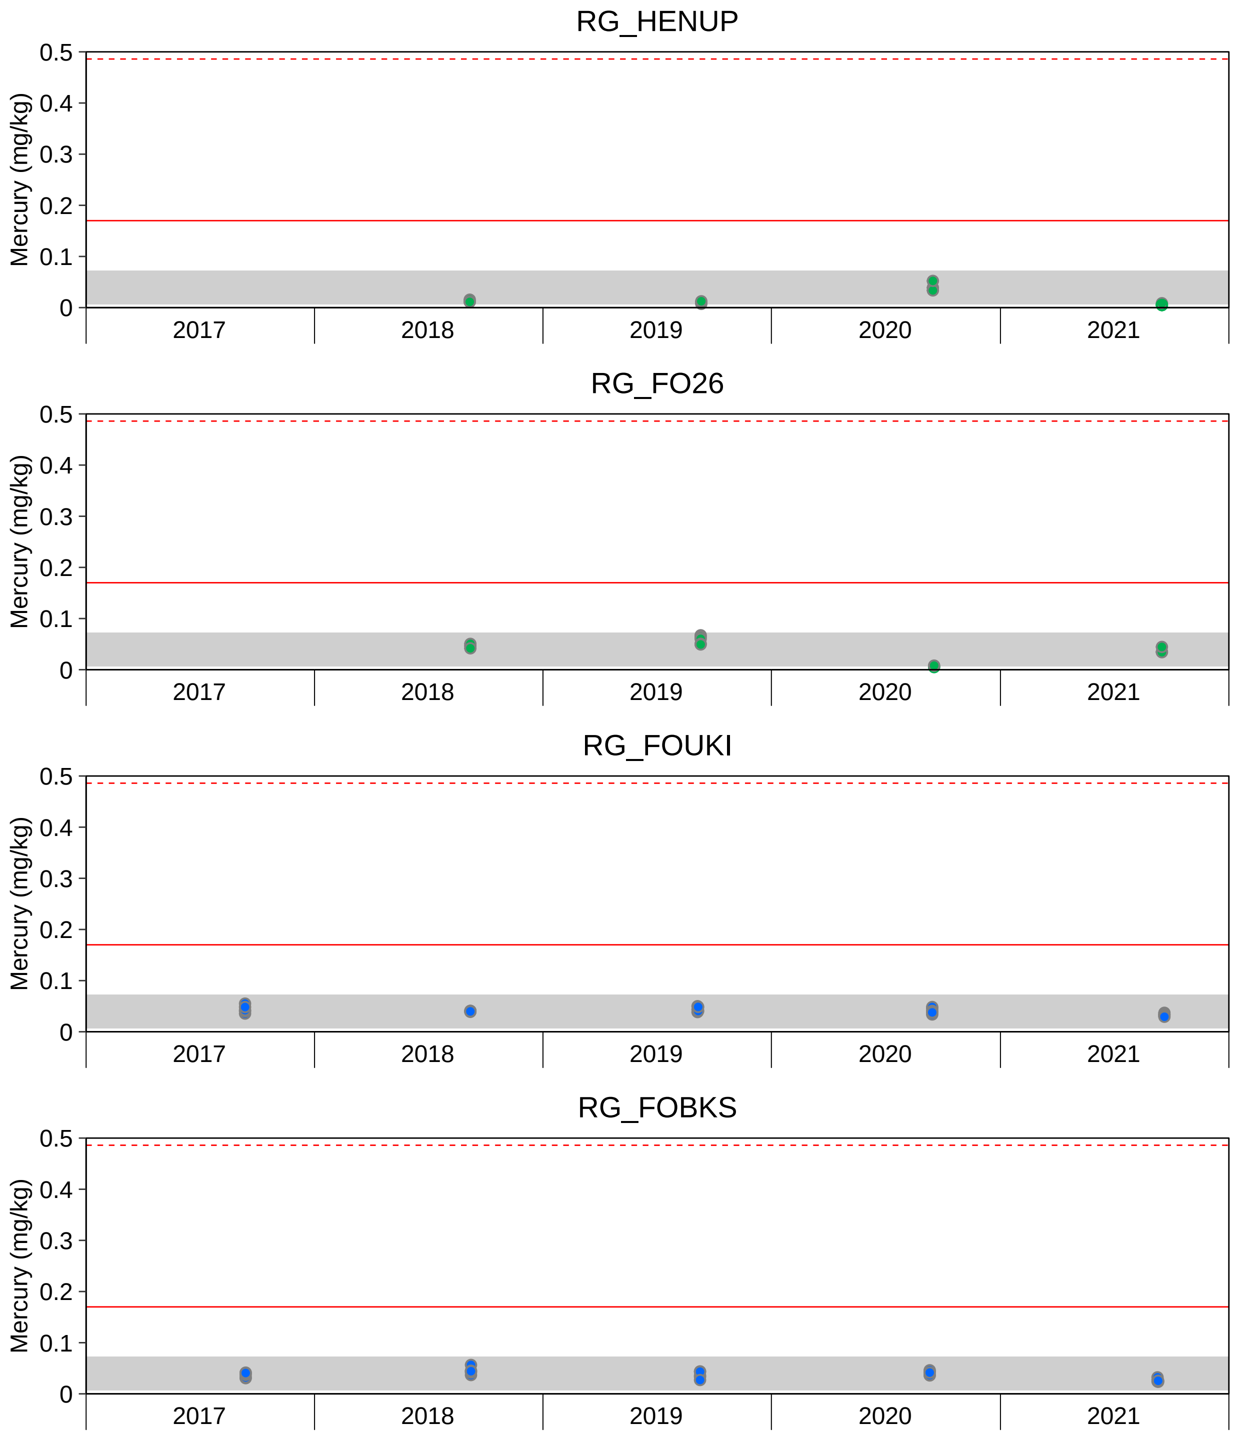

Figure D.9: Mercury Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

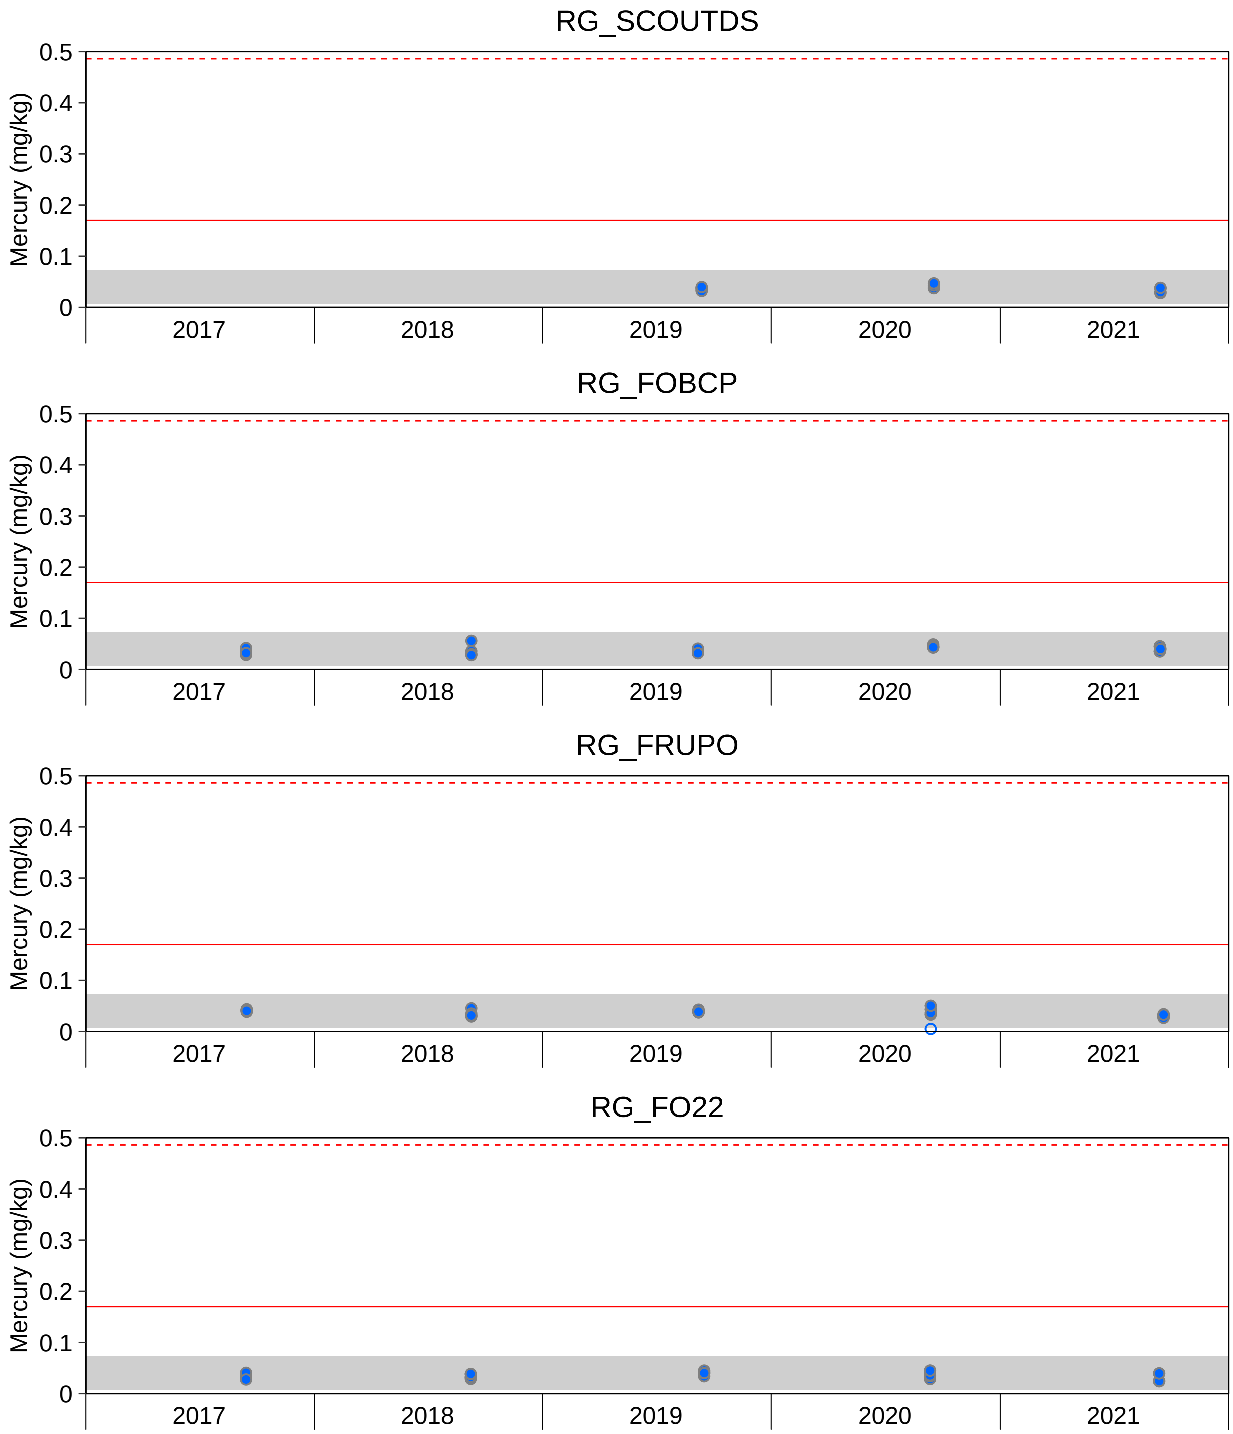

Figure D.9: Mercury Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

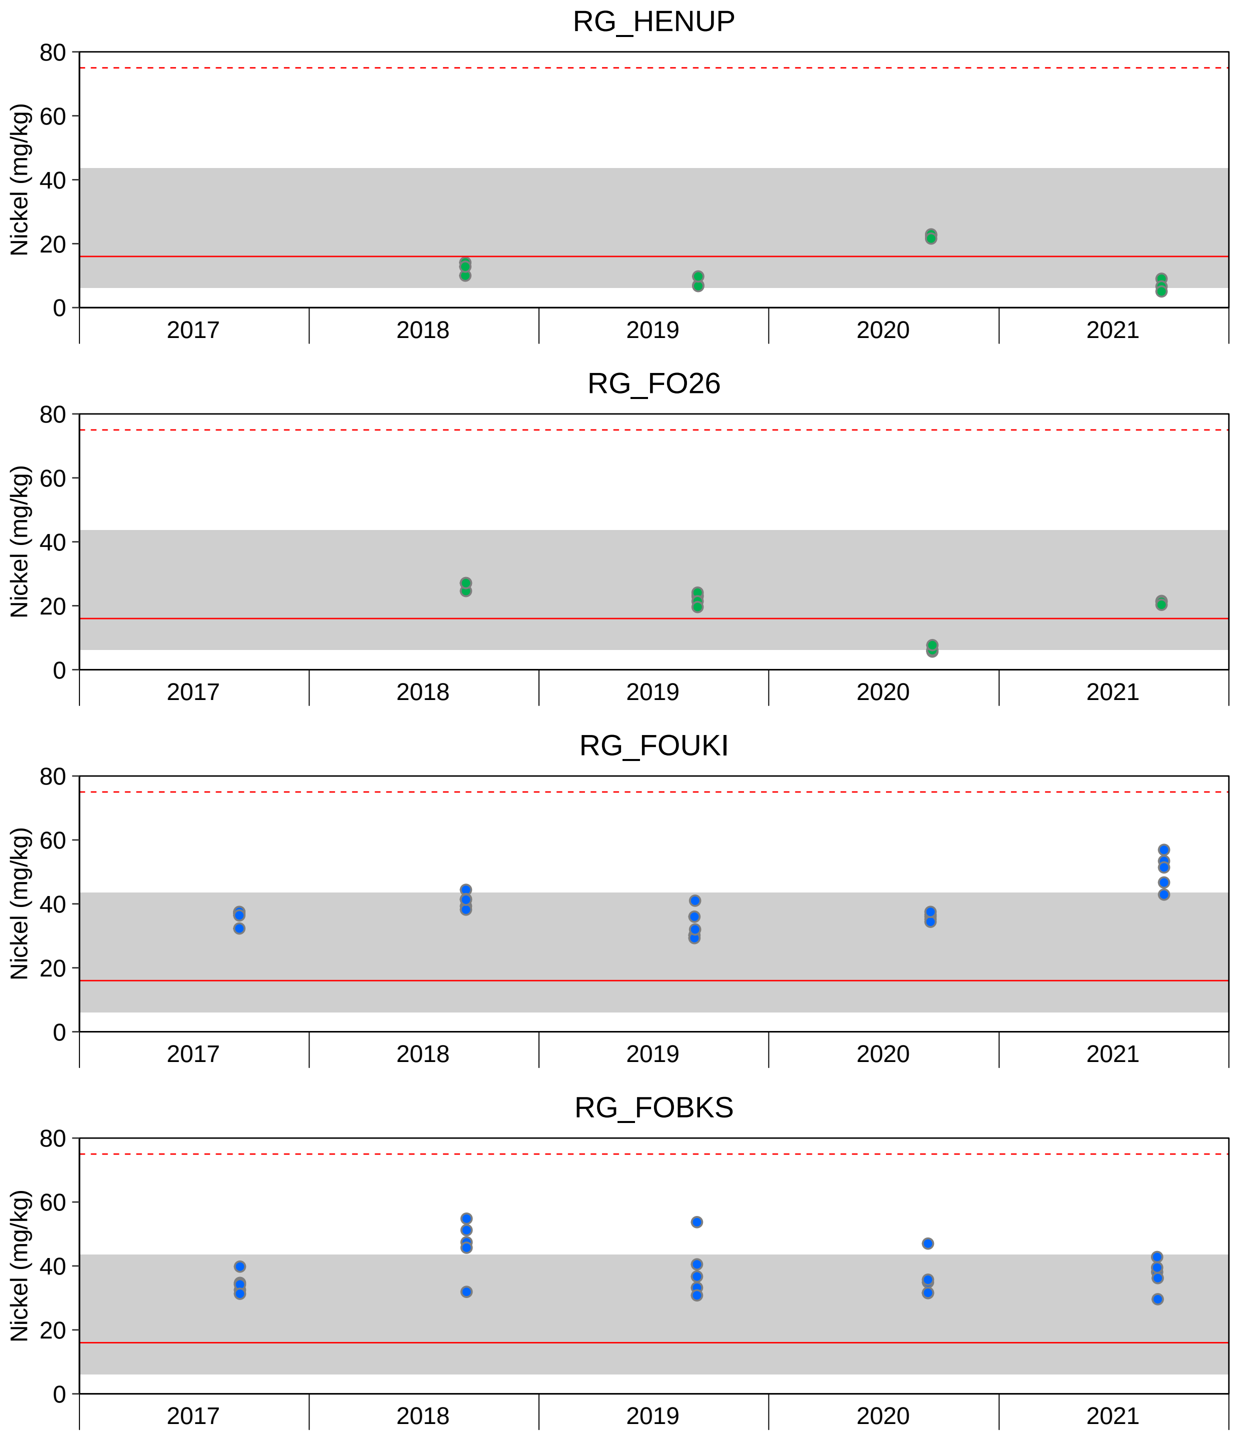

Figure D.10: Nickel Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

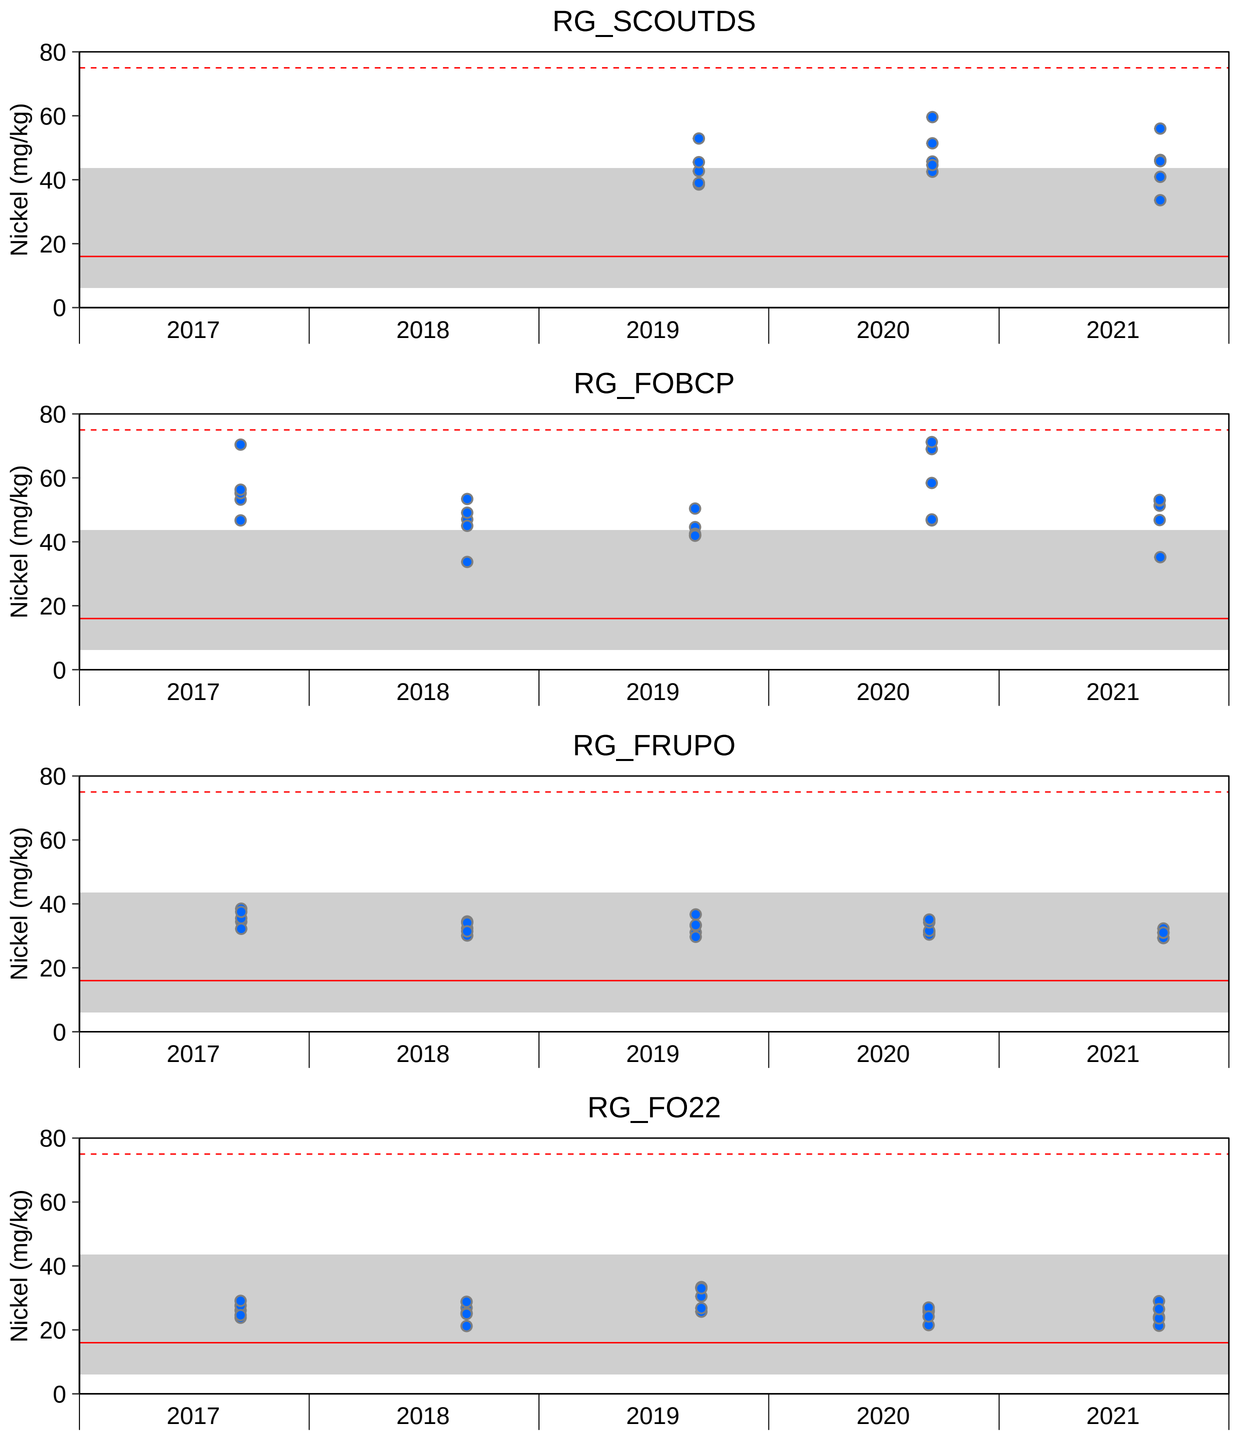

Figure D.10: Nickel Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

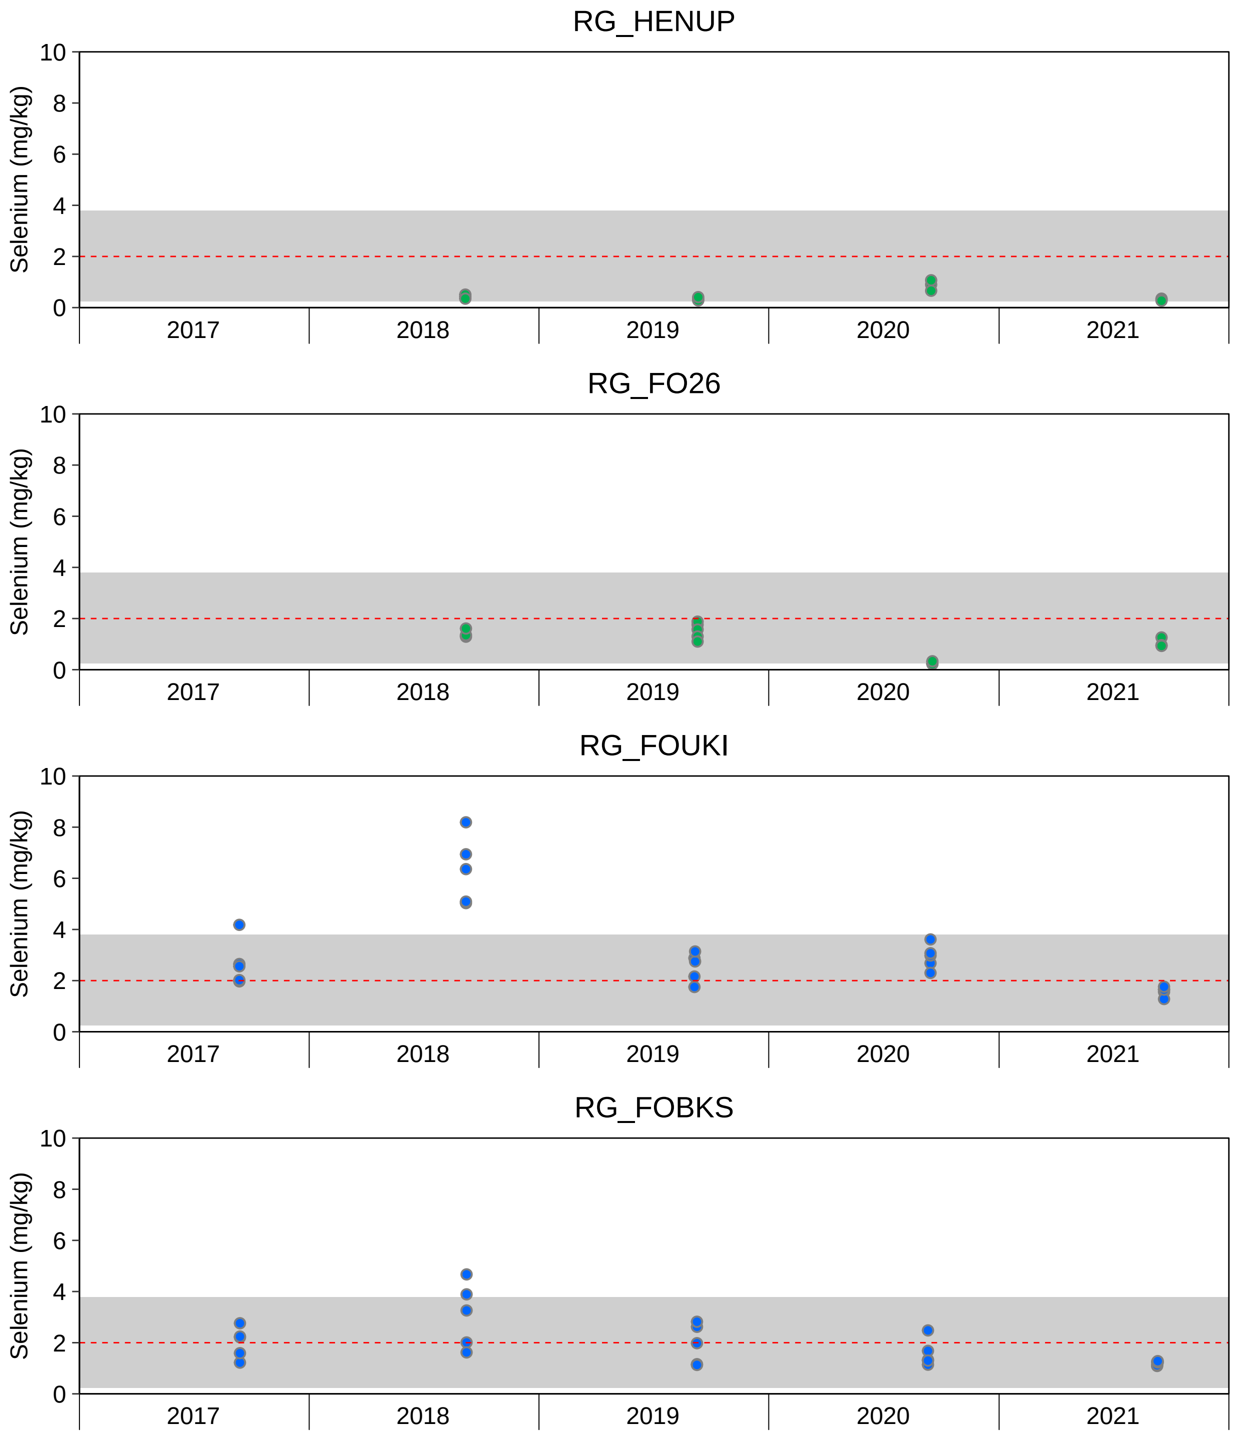

Figure D.11: Selenium Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

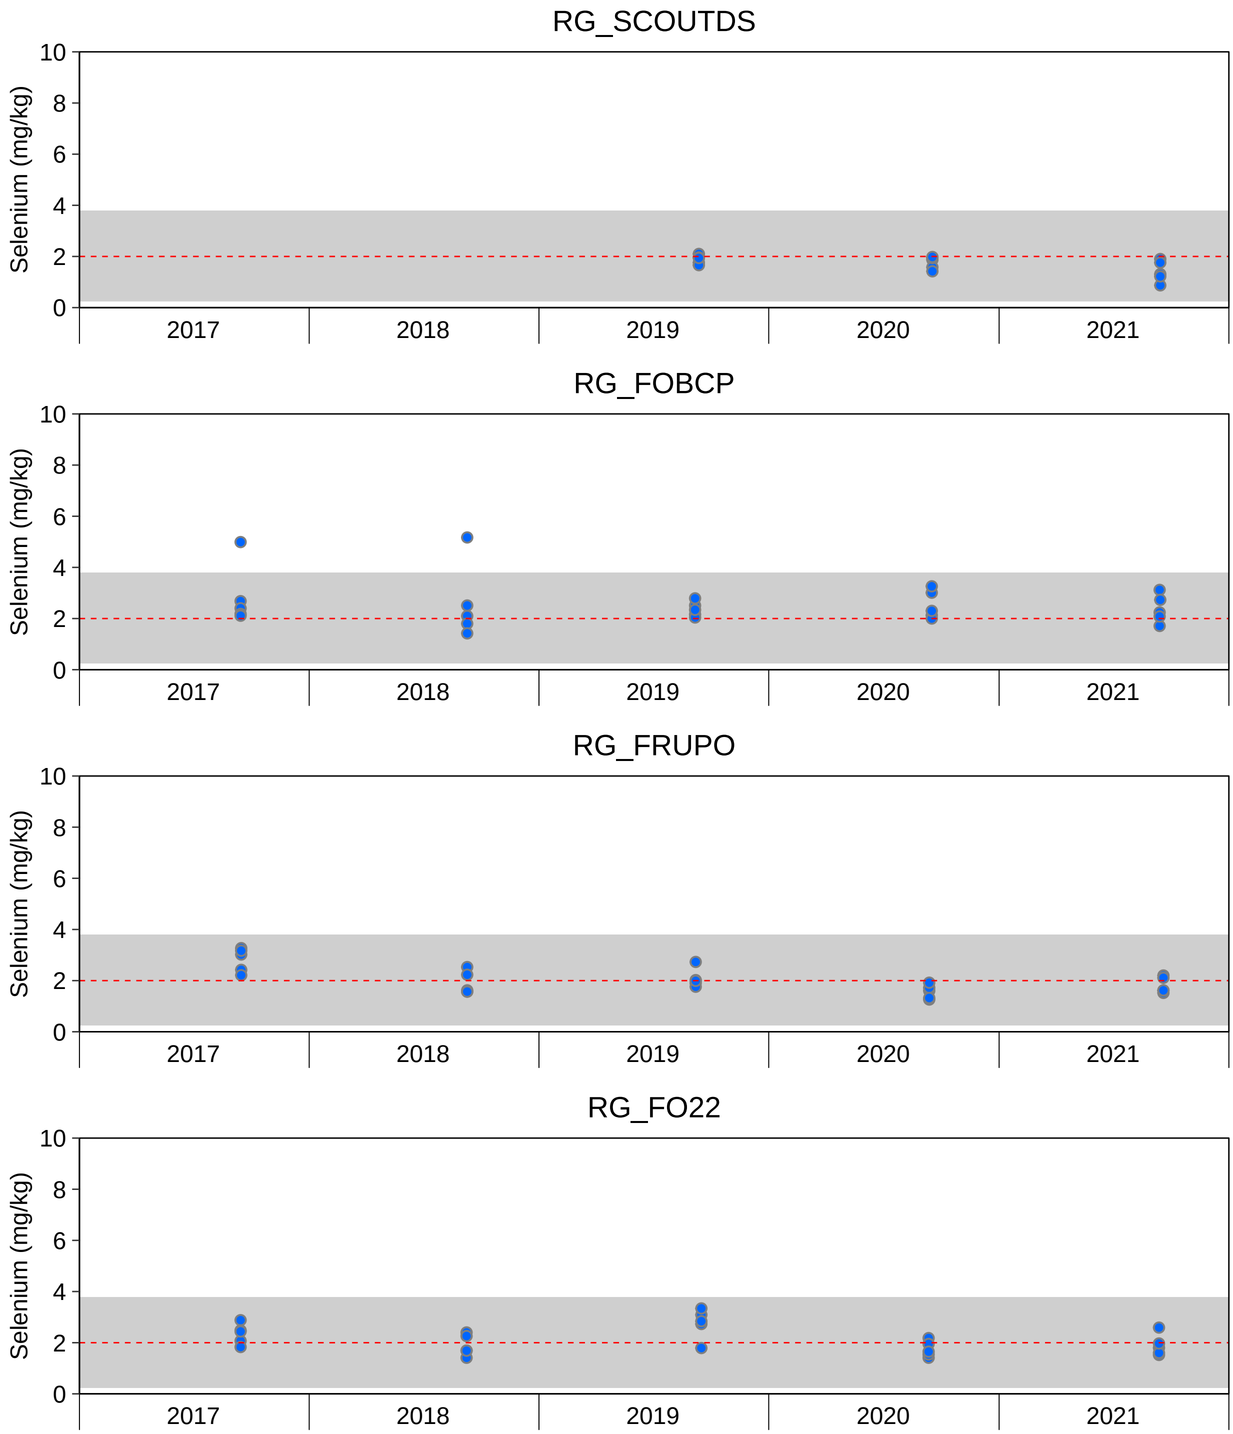

Figure D.11: Selenium Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

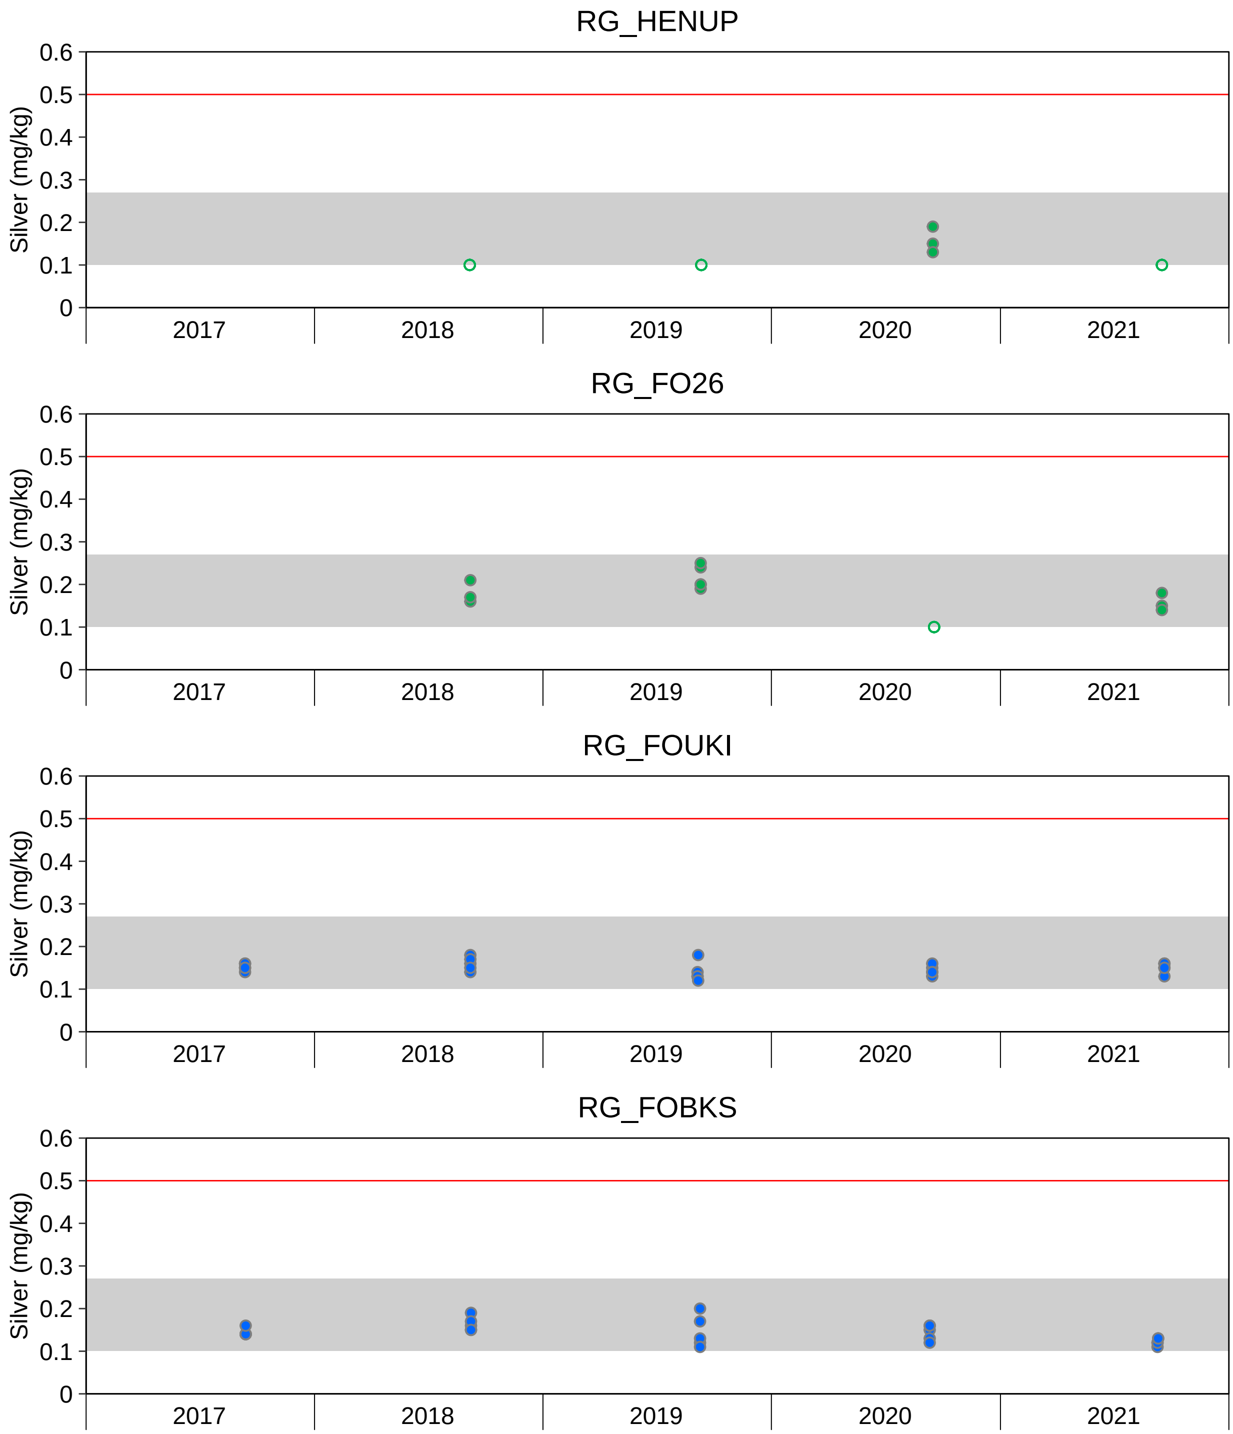

Figure D.12: Silver Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

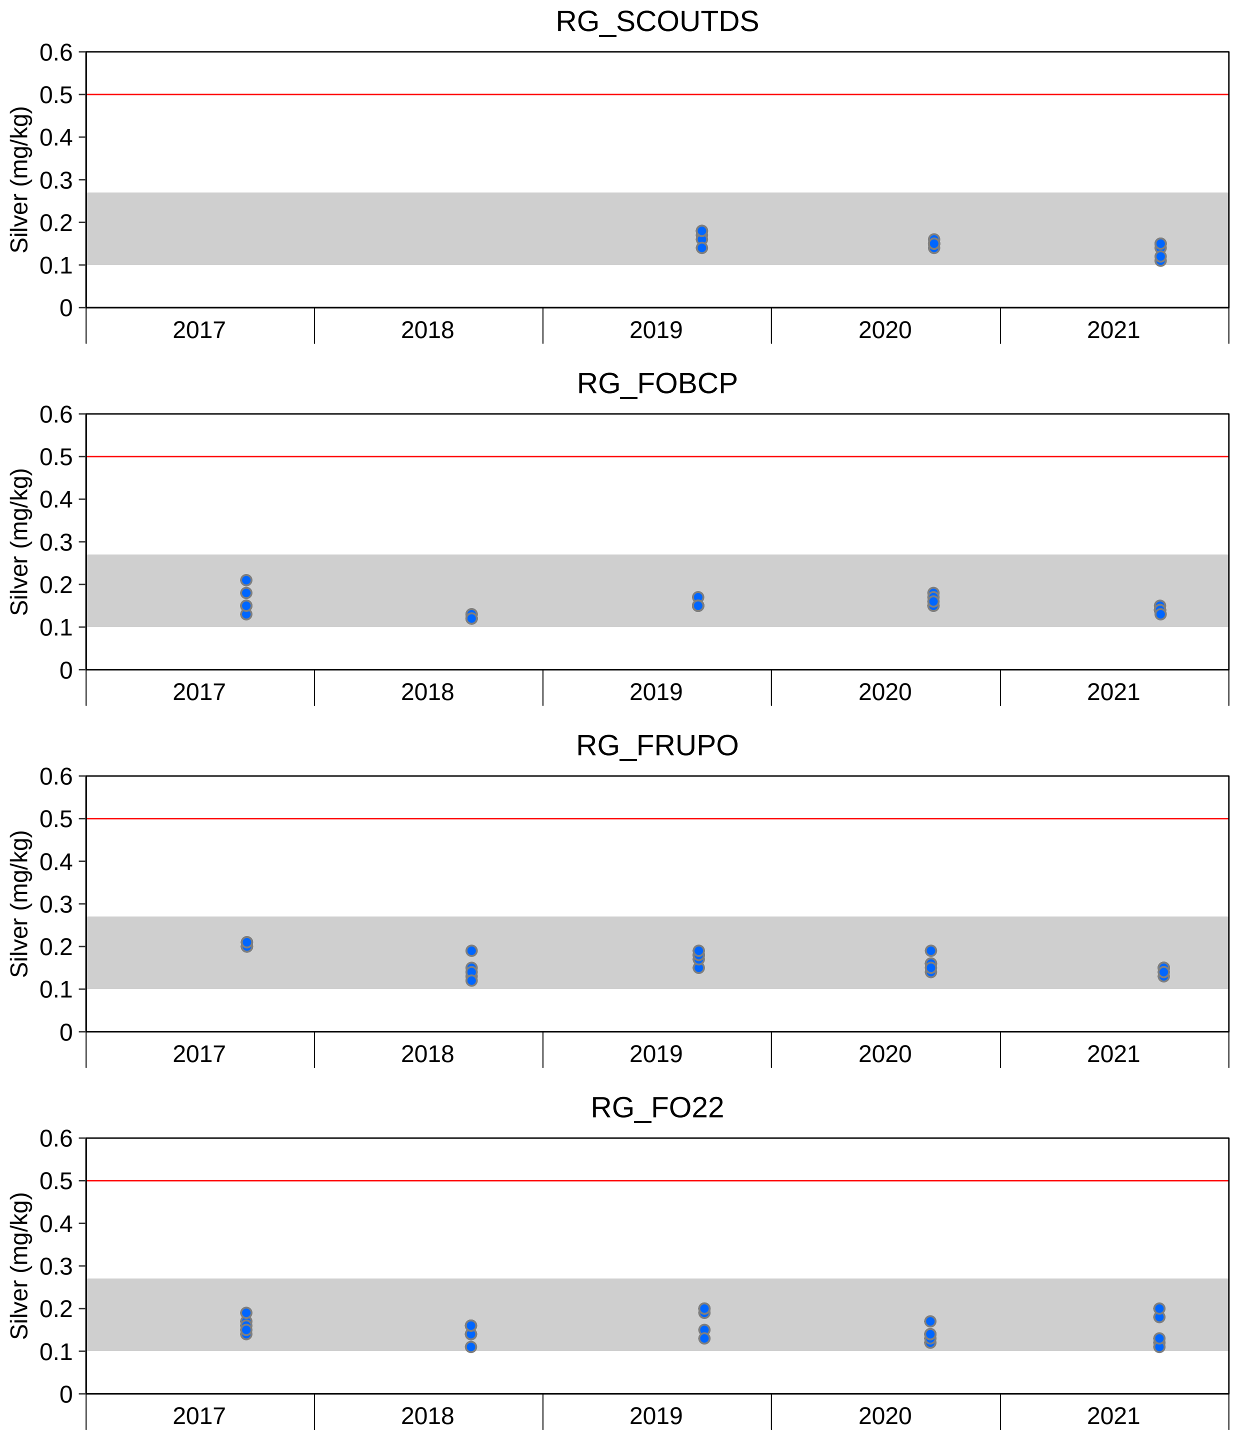

Figure D.12: Silver Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

Figure D.13: Zinc Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

Figure D.13: Zinc Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAEMP, 2017 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG (or alert concentration in the case of selenium). Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

Figure D.14: Sediment Polycyclic Aromatic Hydrocarbons Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAMEP, September 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG. Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

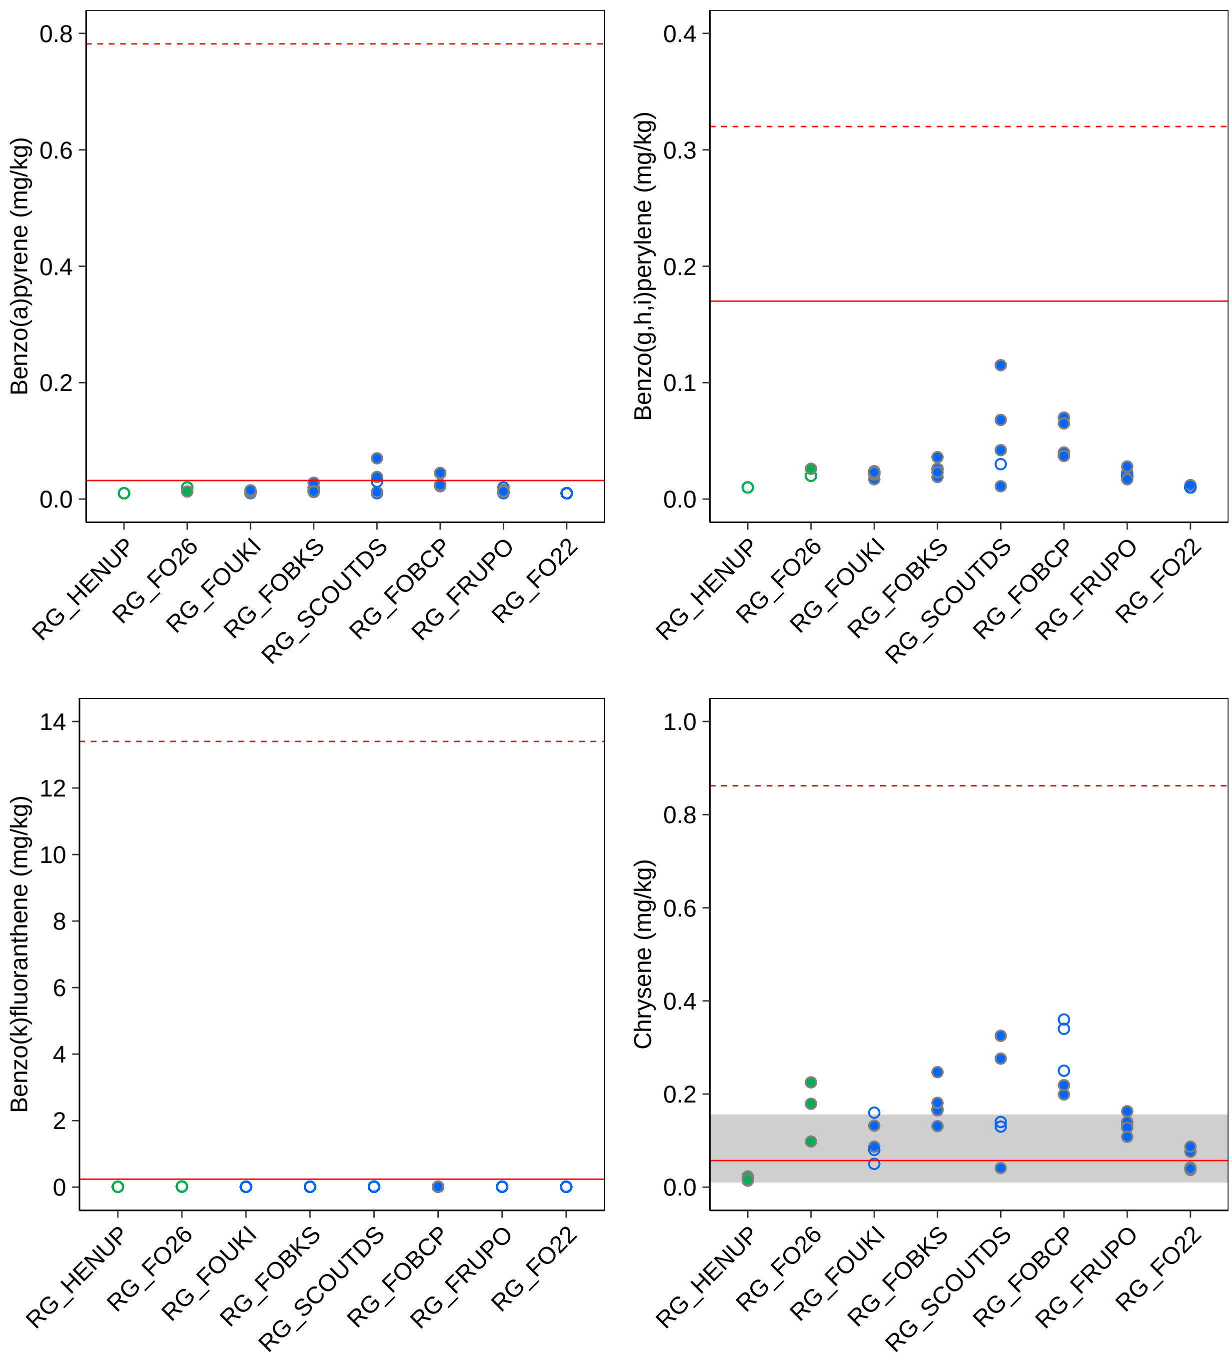

Figure D.14: Sediment Polycyclic Aromatic Hydrocarbons Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAMEP, September 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG. Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

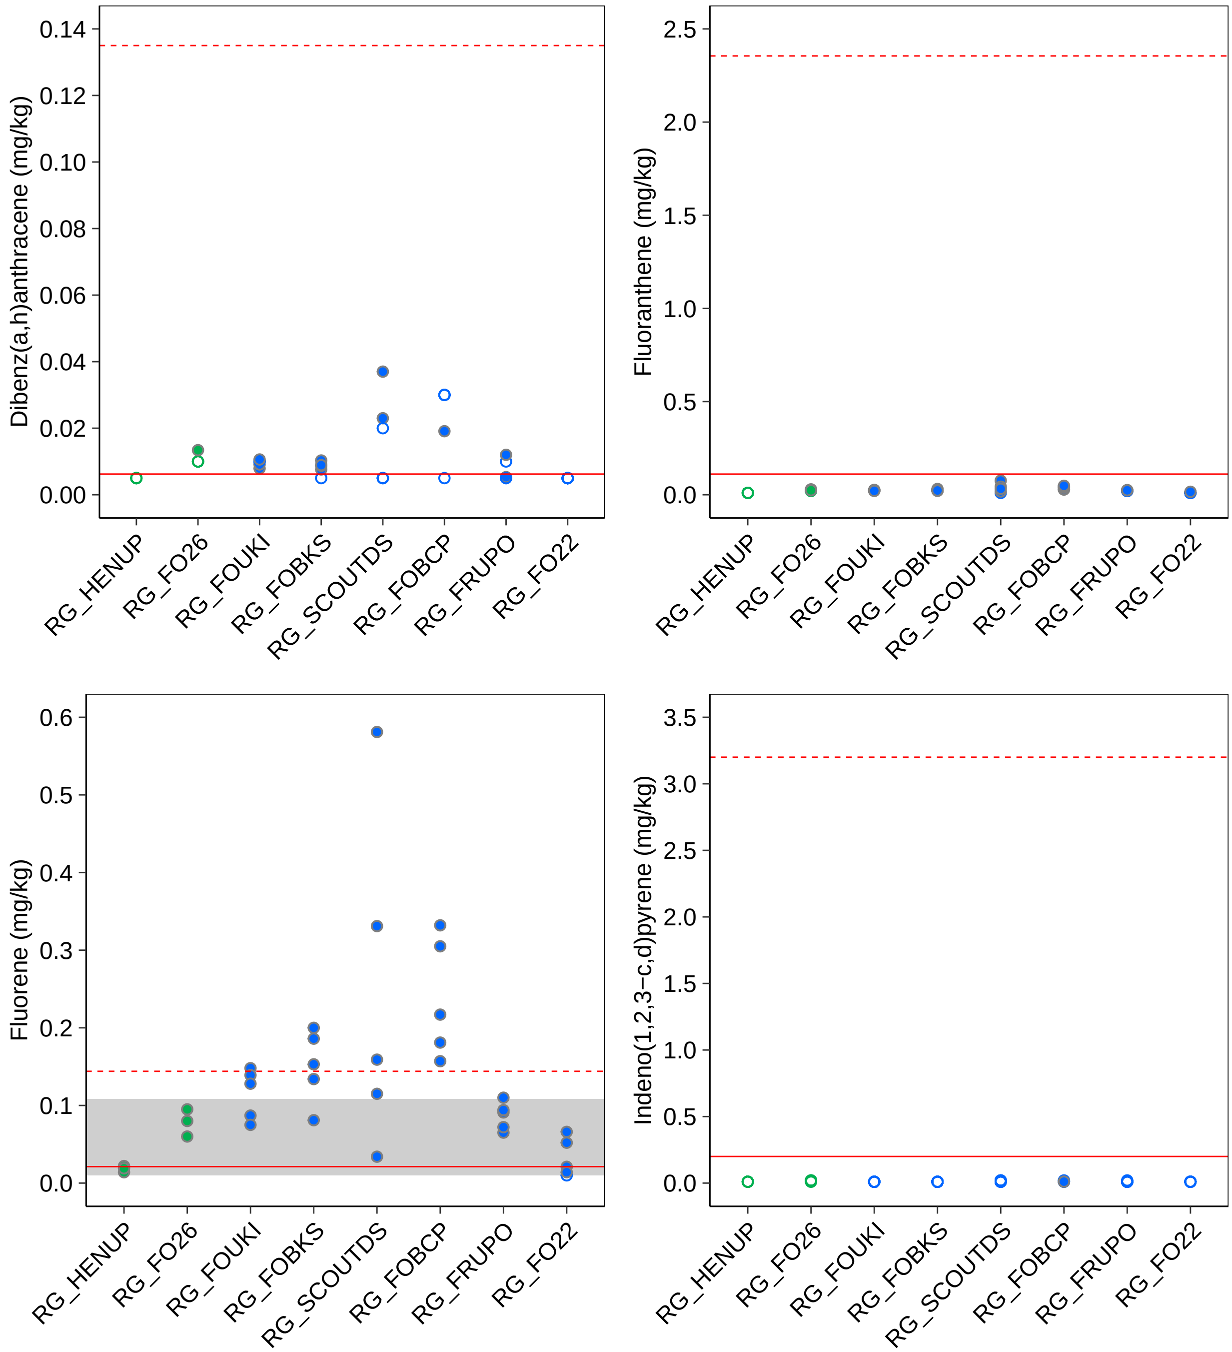

Figure D.14: Sediment Polycyclic Aromatic Hydrocarbons Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAMEP, September 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG. Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

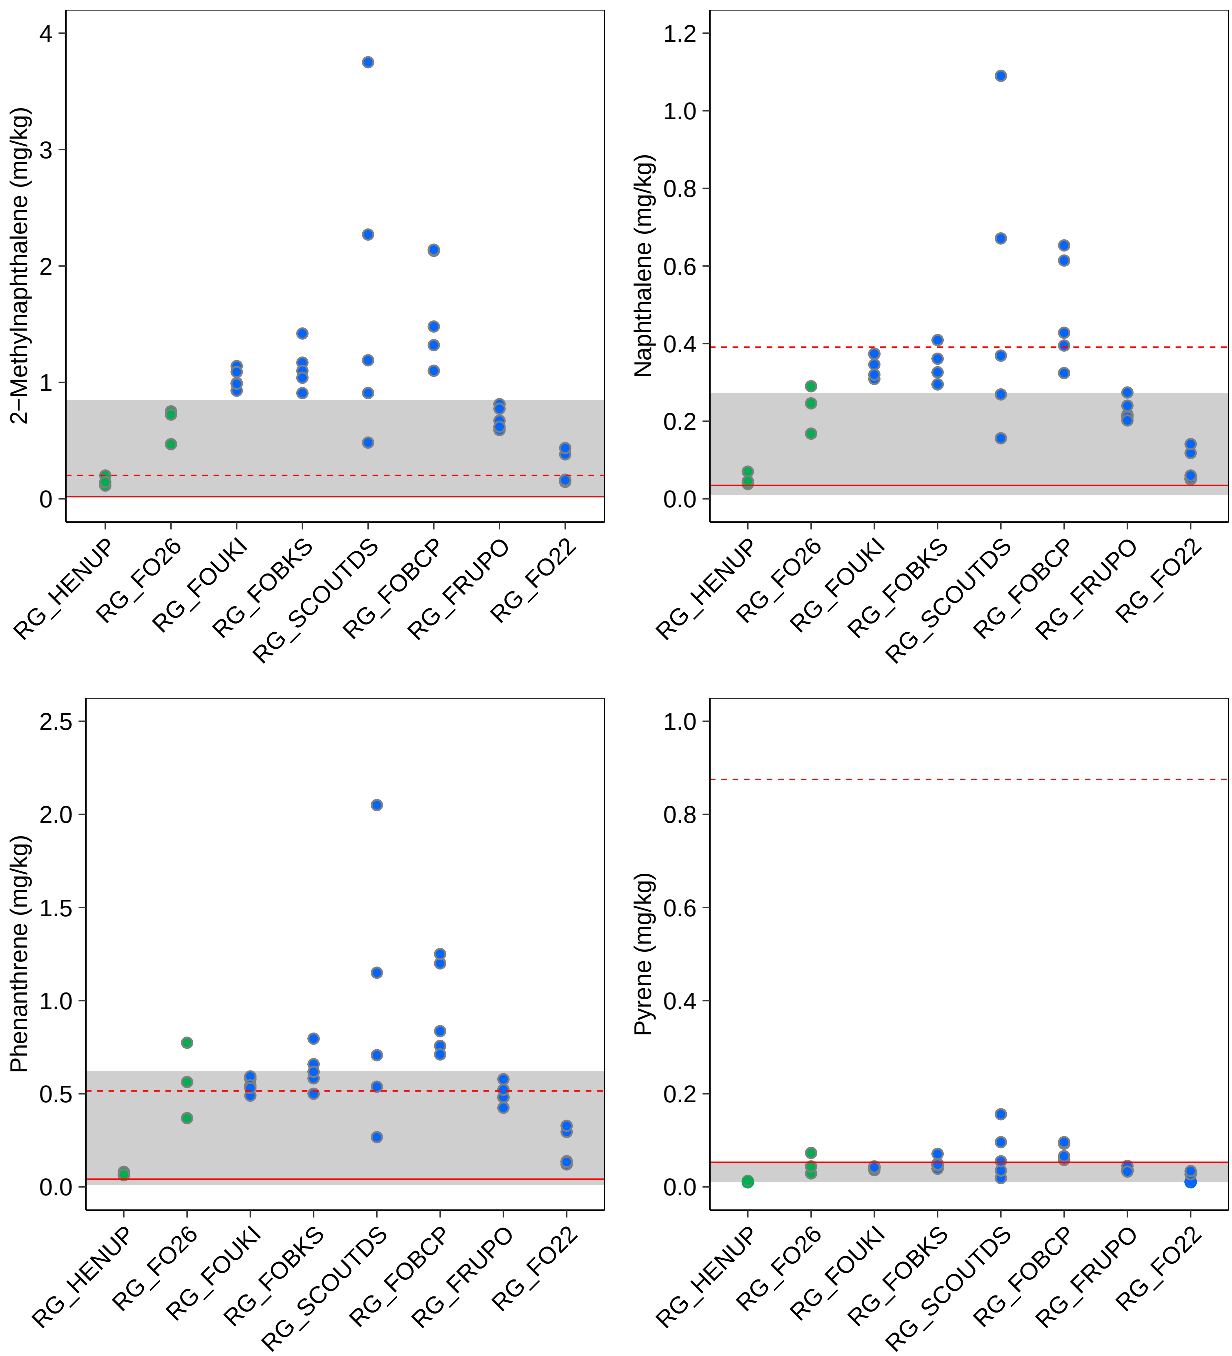

Figure D.14: Sediment Polycyclic Aromatic Hydrocarbons Concentrations Relative to British Columbia Working Sediment Quality Guidelines, FRO LAMEP, September 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL value. Solid red line represents Lower Working Sediment Quality Guideline (WSQG). Hashed red line represents Upper WSQG. Grey shading represents the reference area normal range (2.5th and 97.5th percentiles of 2017 to 2020 pooled reference area data, Minnow 2020).

Notes: "-" indicates that no calcite monitoring was completed. Calcite Index (CI) was calculated using binary presence/absence scoring to allow for comparisons over time. See table X.x for Calculated using the proportional calcite presence scoring method (CI').

APPENDIX E
BENTHIC INVERTEBRATES

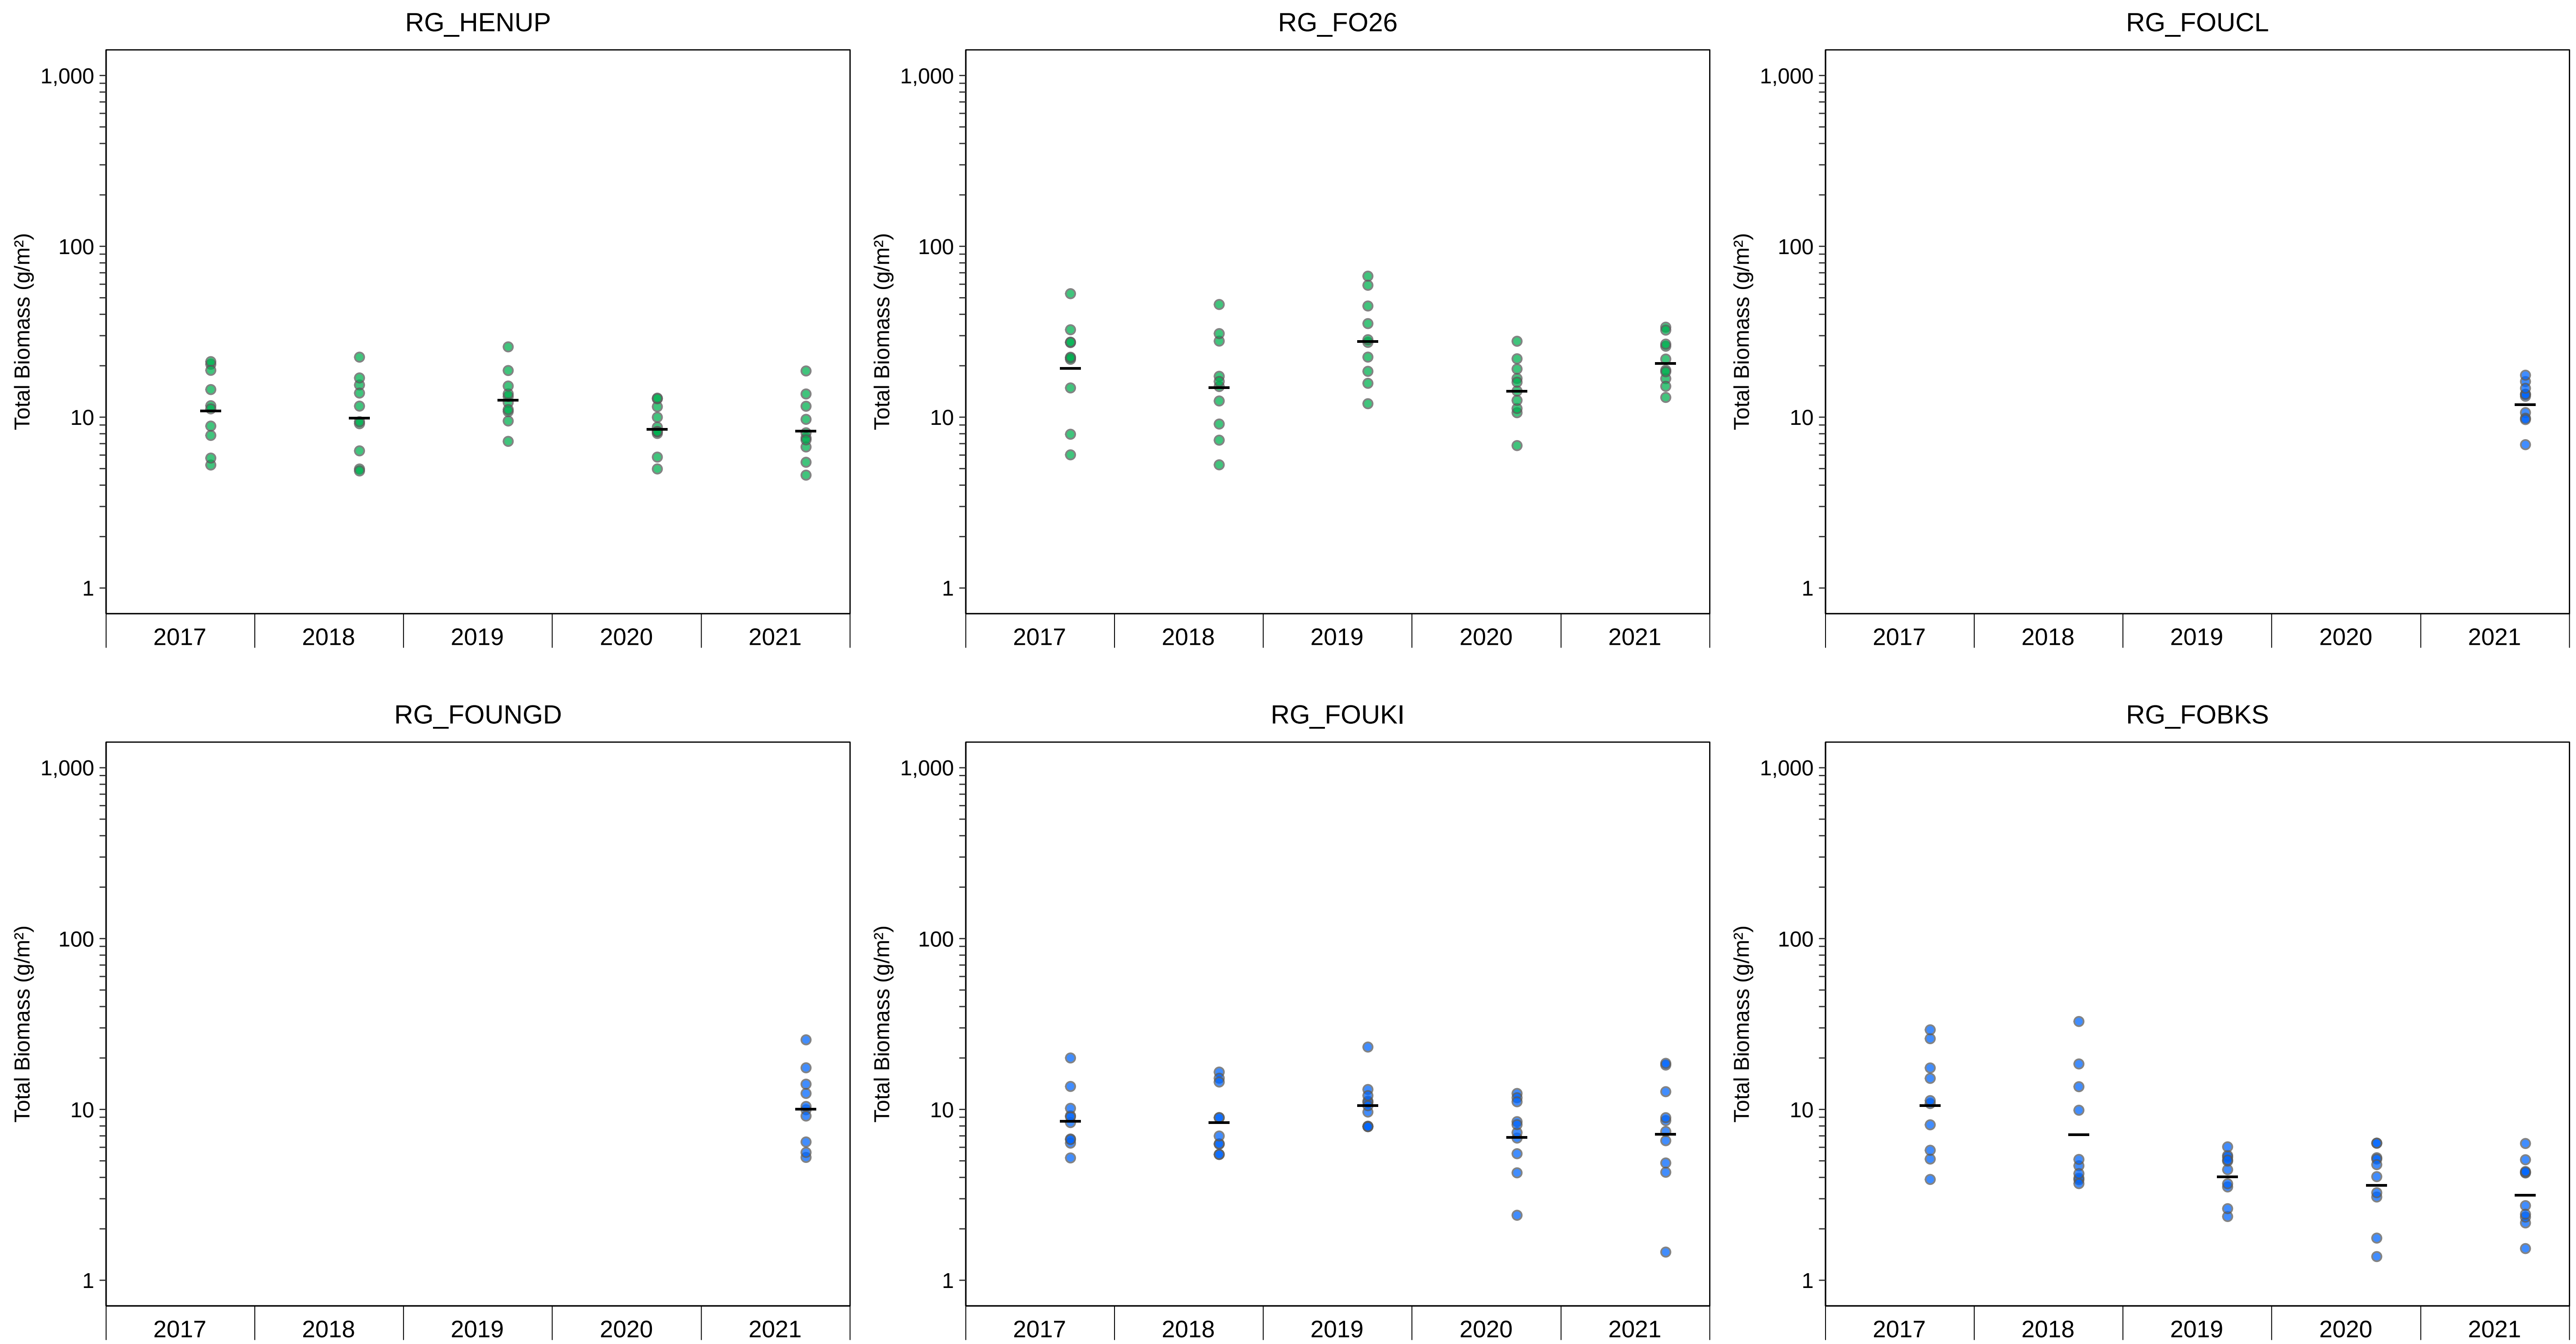

Figure E.1: Total Benthic Invertebrate Biomass (Hess Sampling) by Year, FRO LAEMP, September 2012 to 2021

Note: Green represents reference areas and blue represents exposed areas. Black lines denote the geometric means.

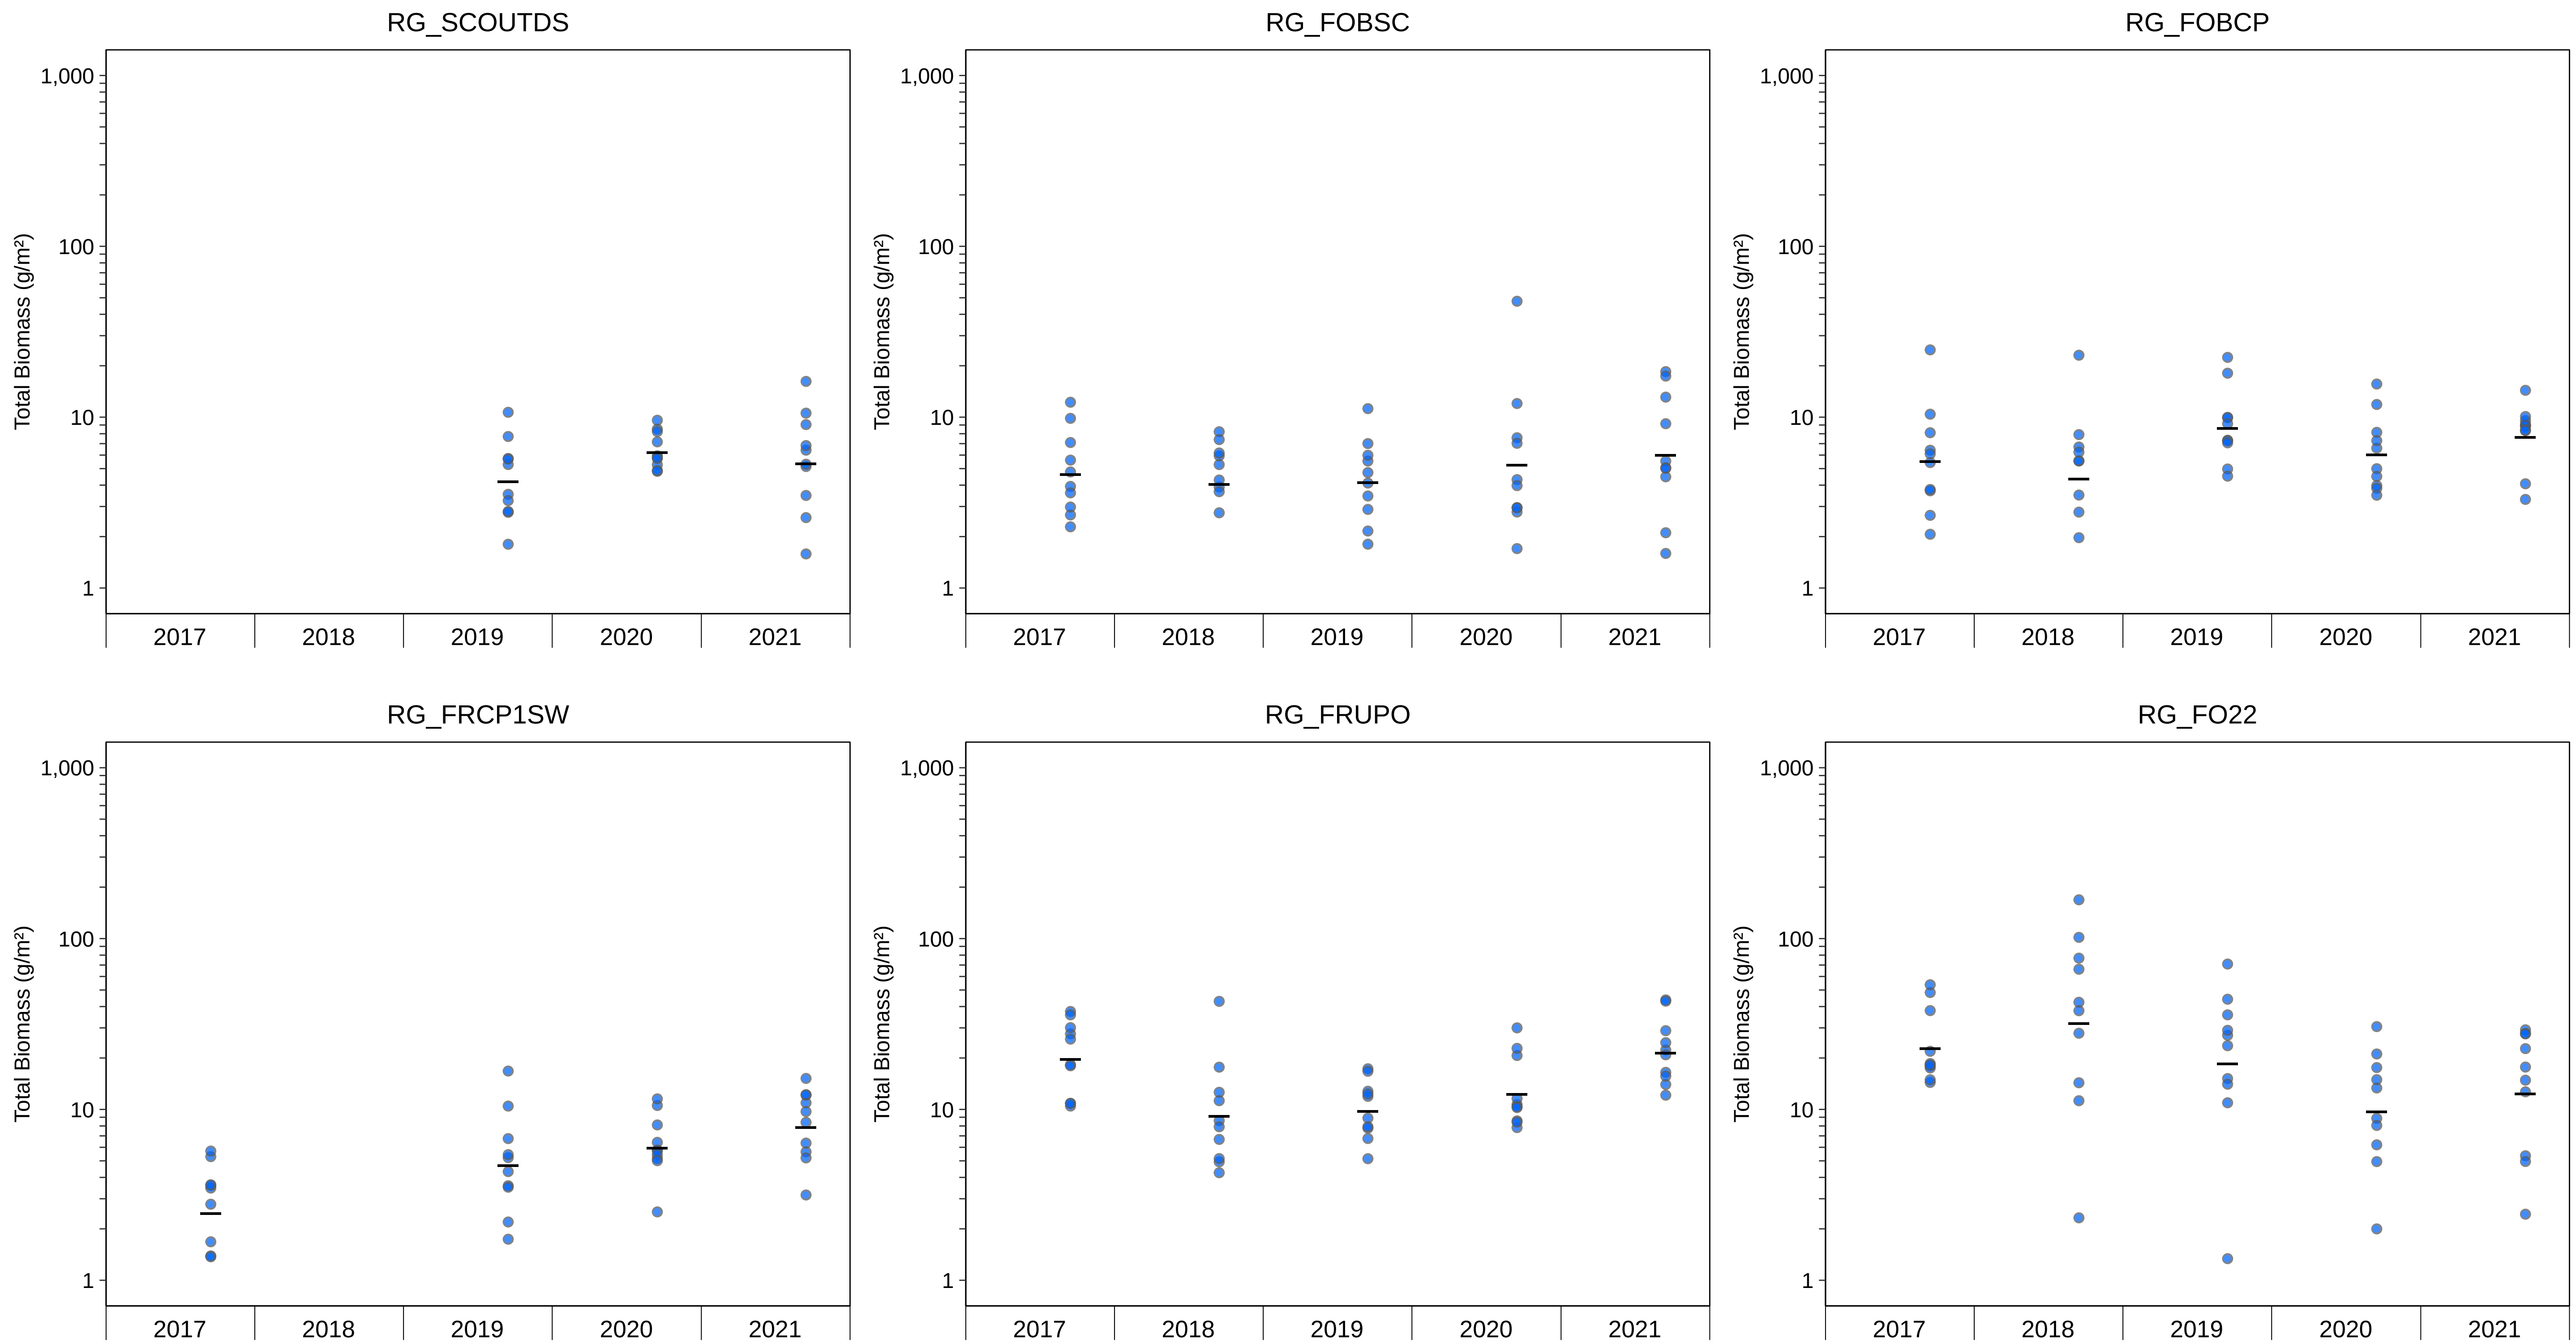

Figure E.1: Total Benthic Invertebrate Biomass (Hess Sampling) by Year, FRO LAEMP, September 2012 to 2021

Note: Green represents reference areas and blue represents exposed areas. Black lines denote the geometric means.

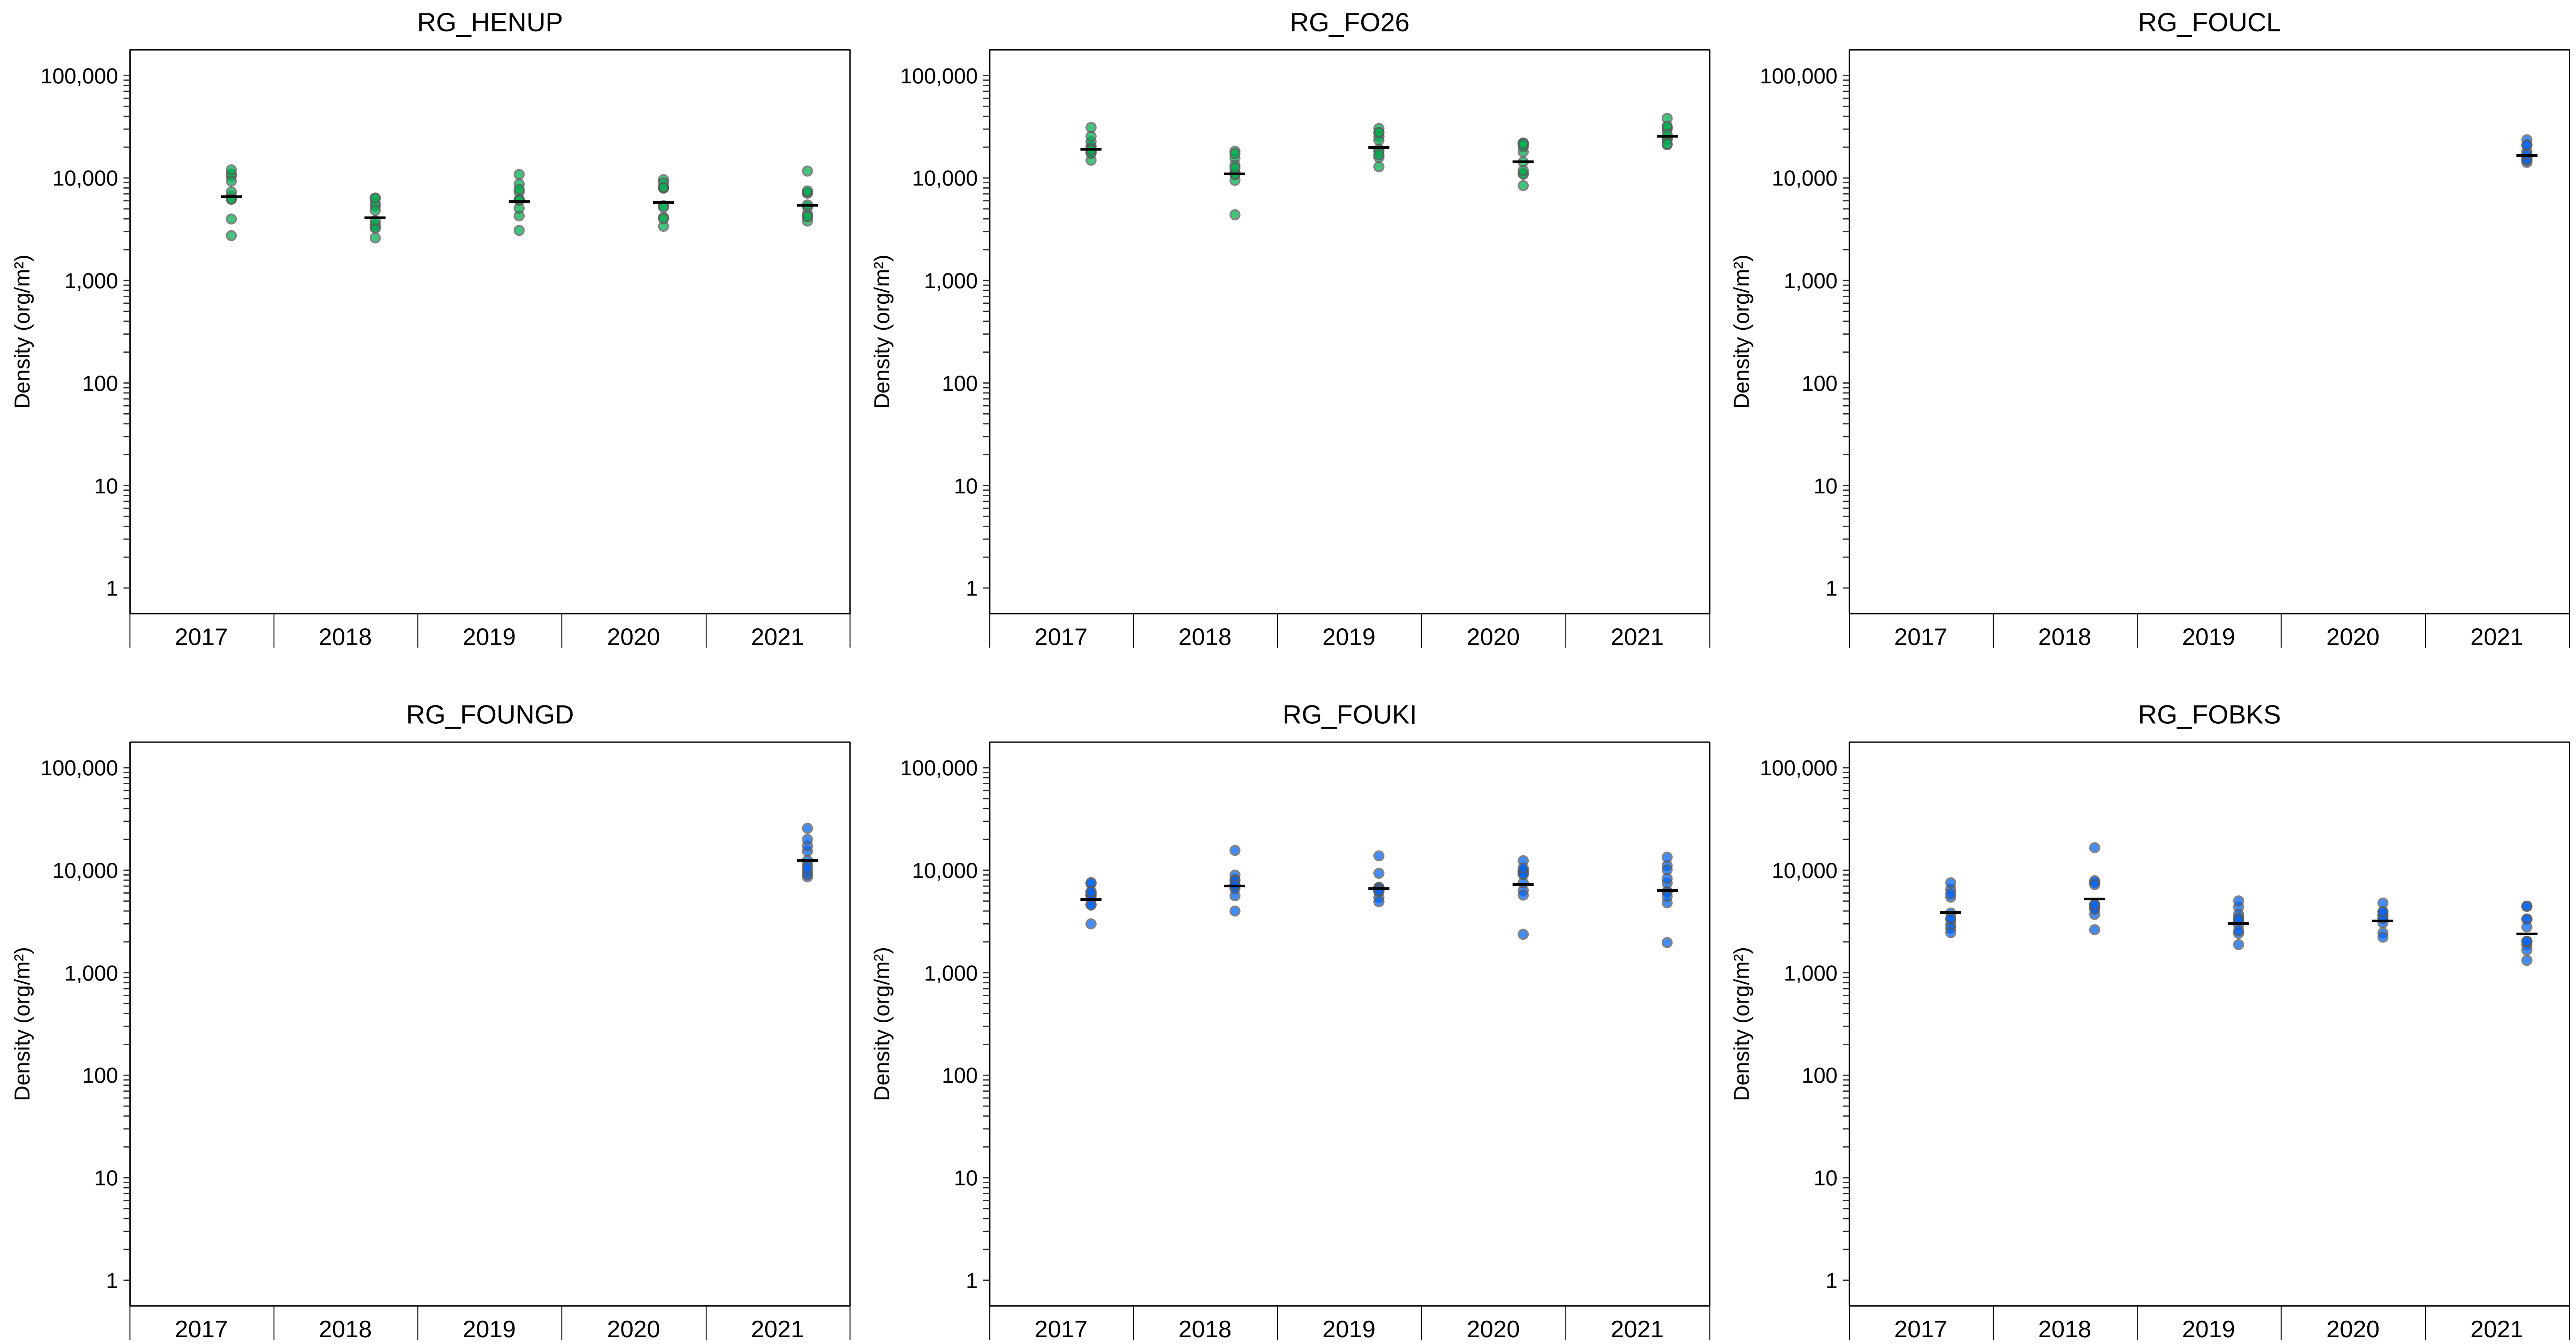

Figure E.2: Total Benthic Invertebrate Density (Hess Sampling) by Year, FRO LAEMP, September 2012 to 2021

Note: Green represents reference areas and blue represents exposed areas. Black lines denote the geometric means.

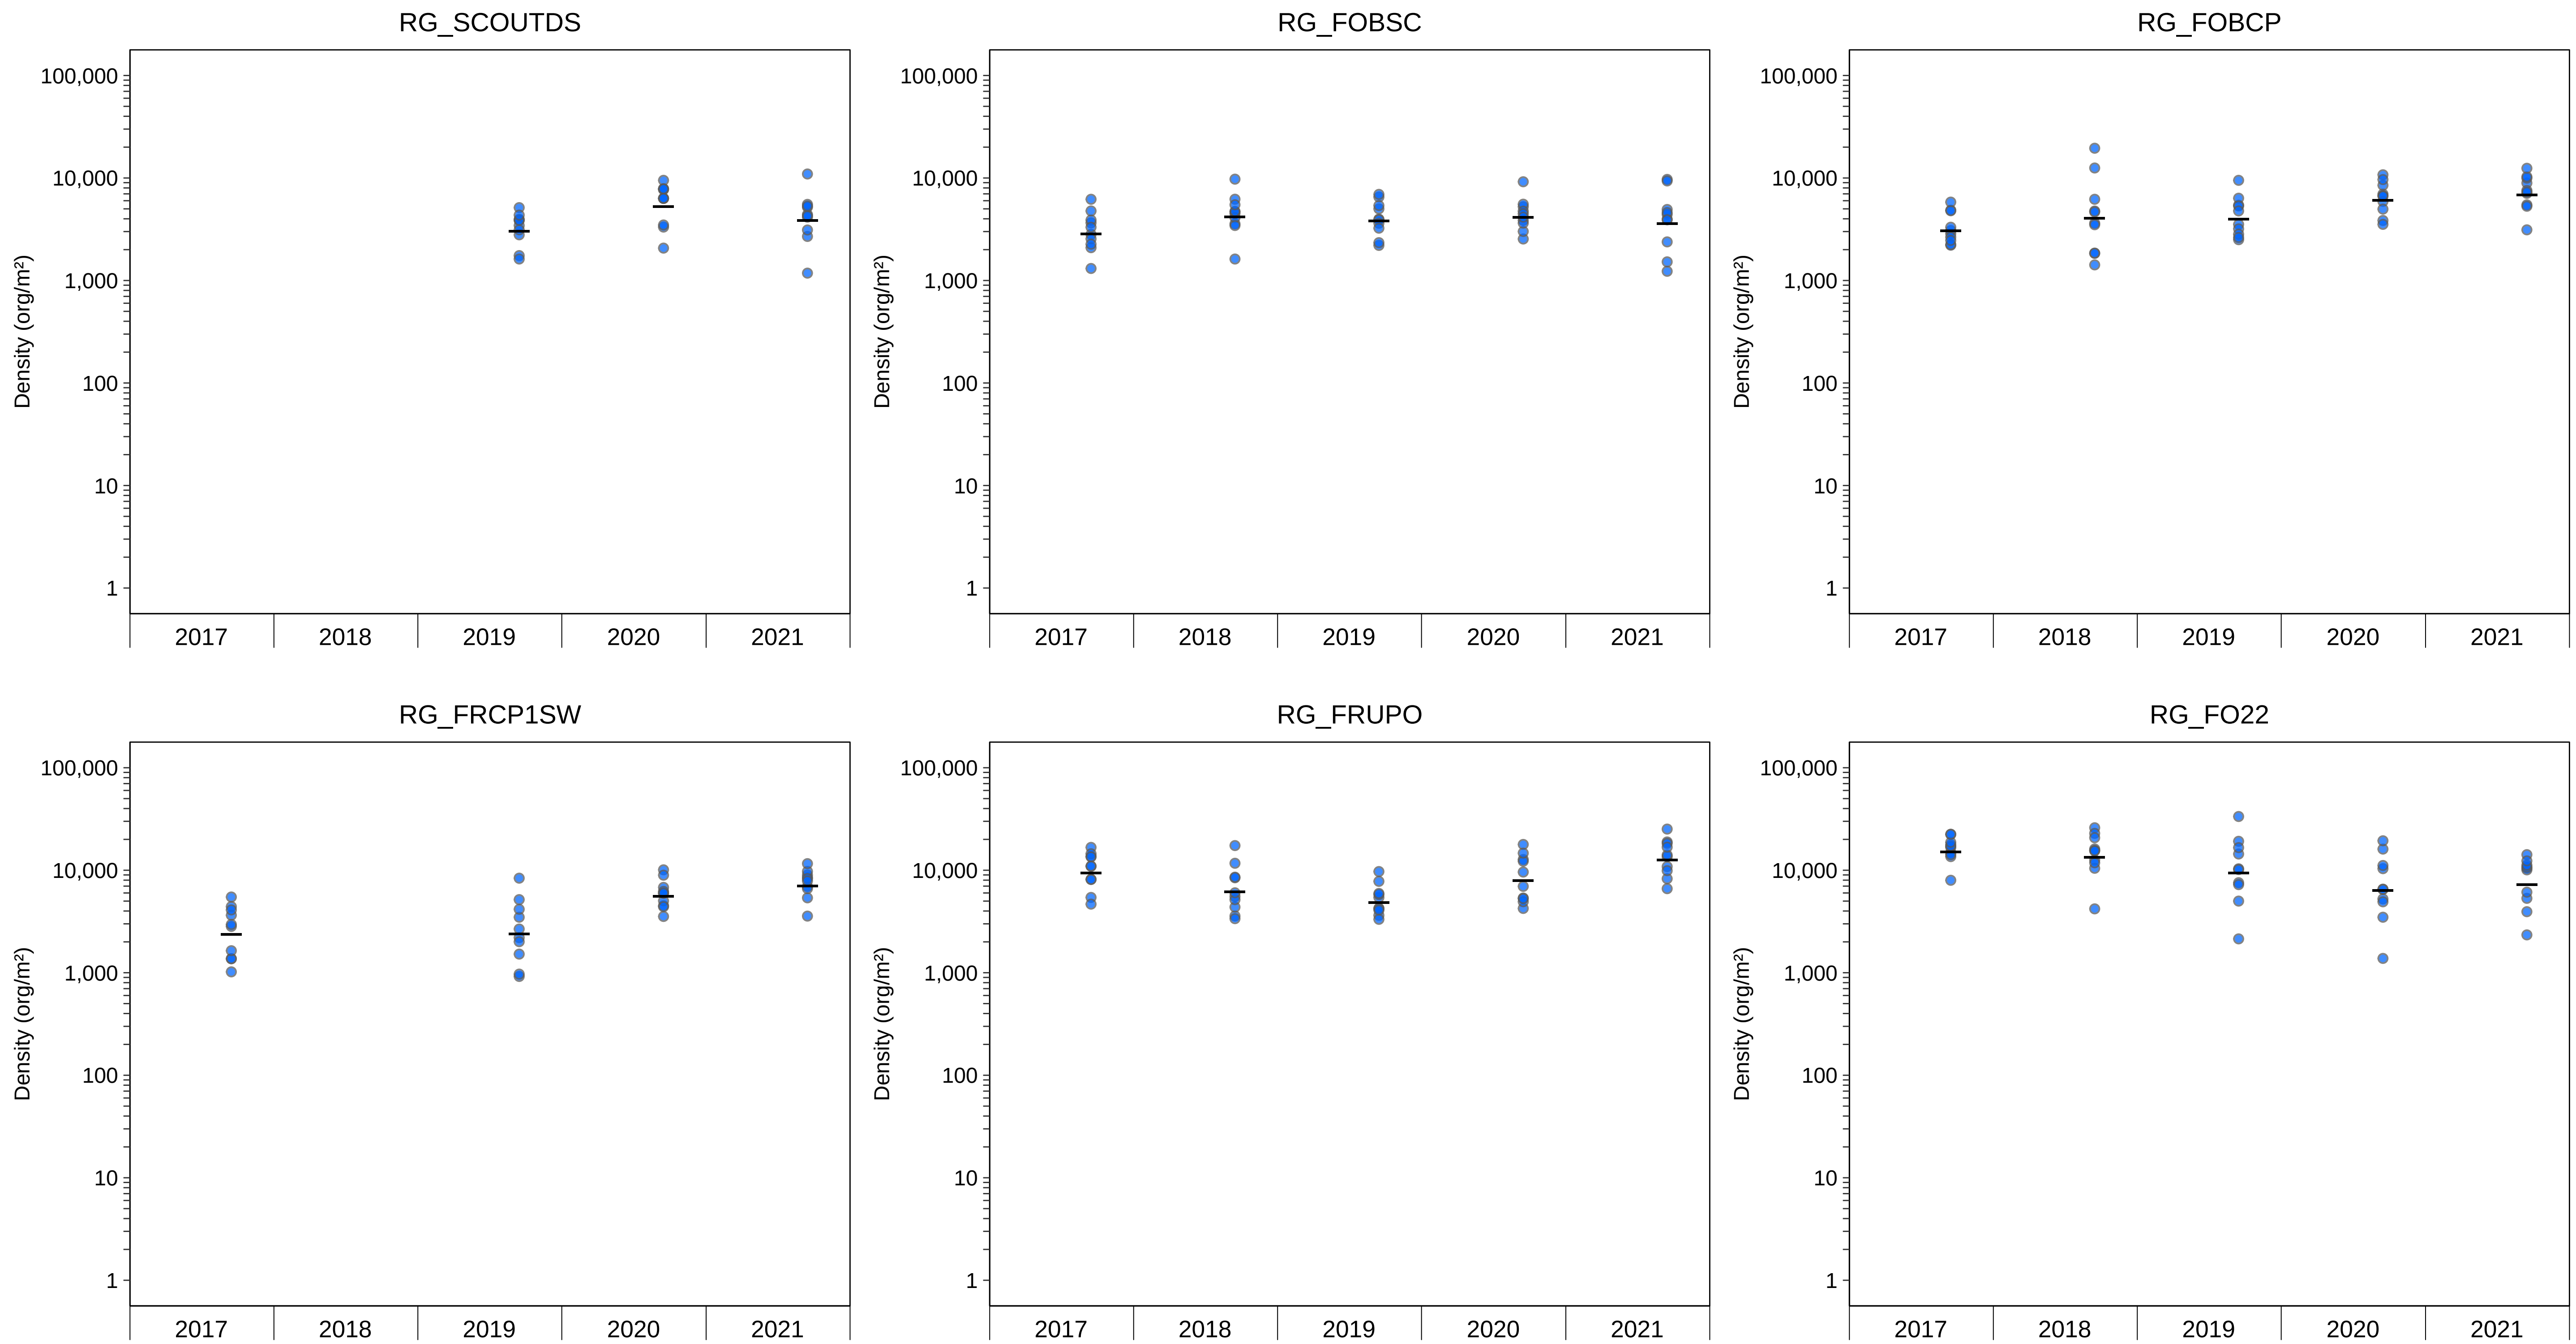

Figure E.2: Total Benthic Invertebrate Density (Hess Sampling) by Year, FRO LAEMP, September 2012 to 2021

Note: Green represents reference areas and blue represents exposed areas. Black lines denote the geometric means.

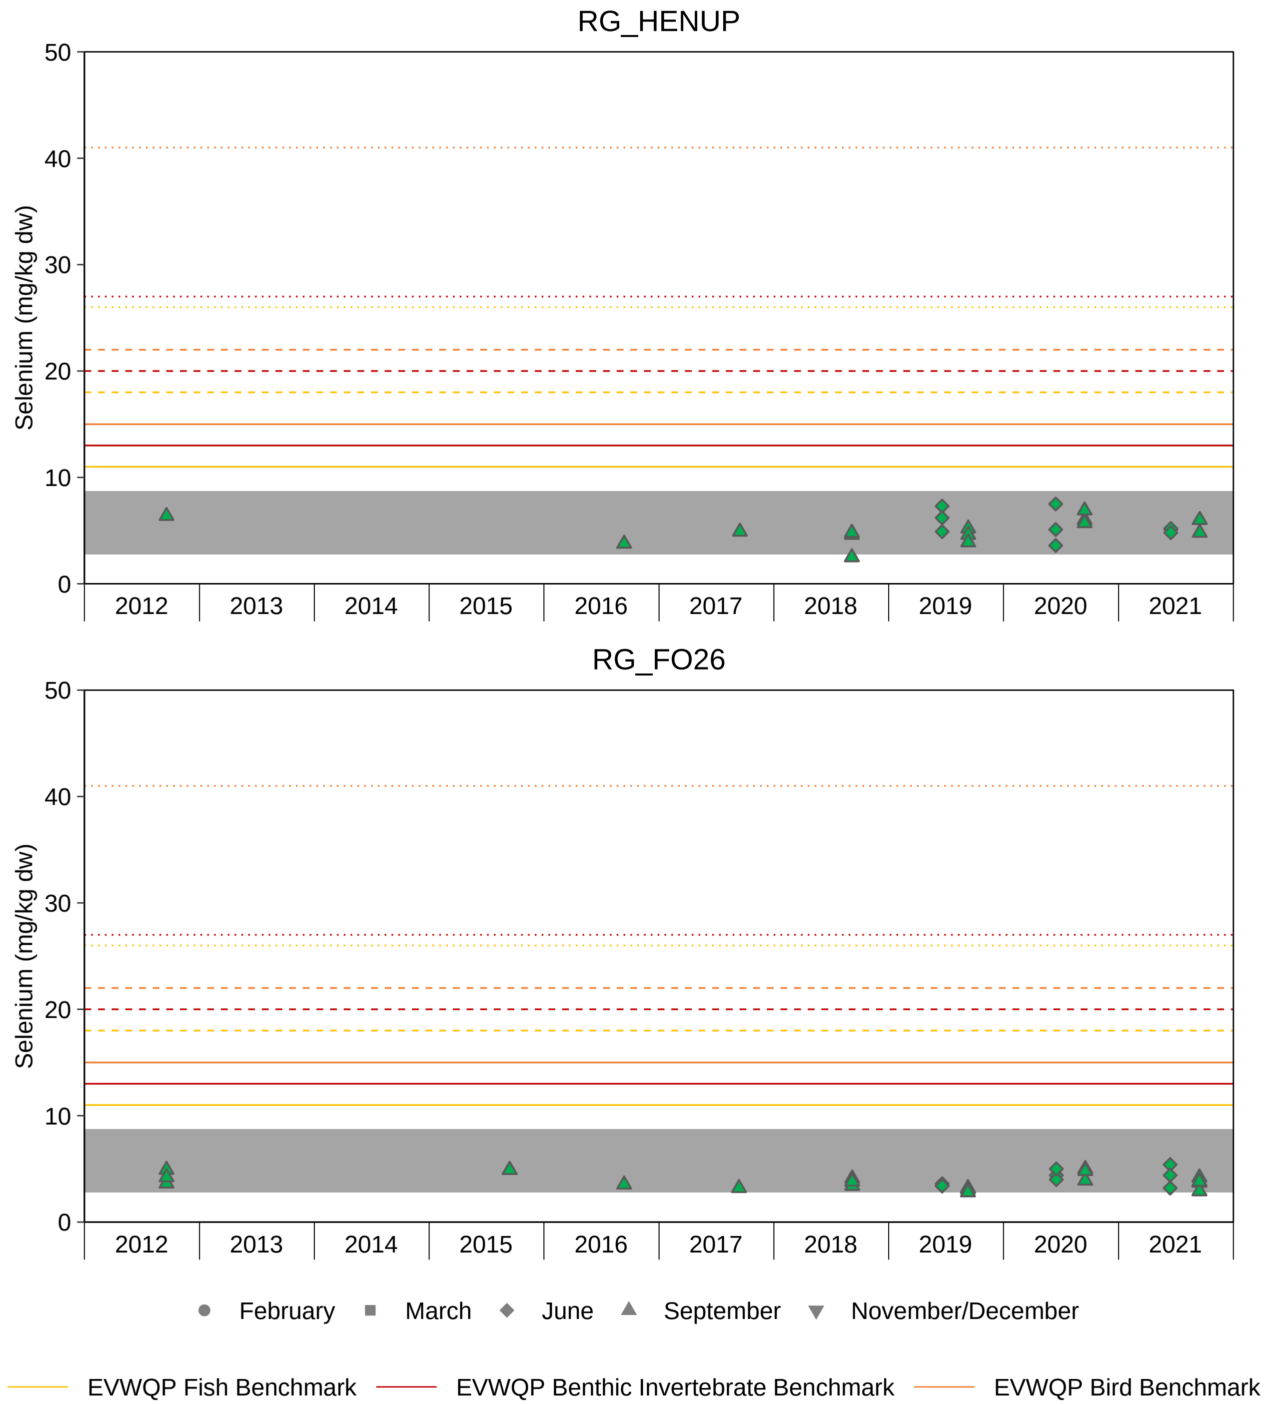

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

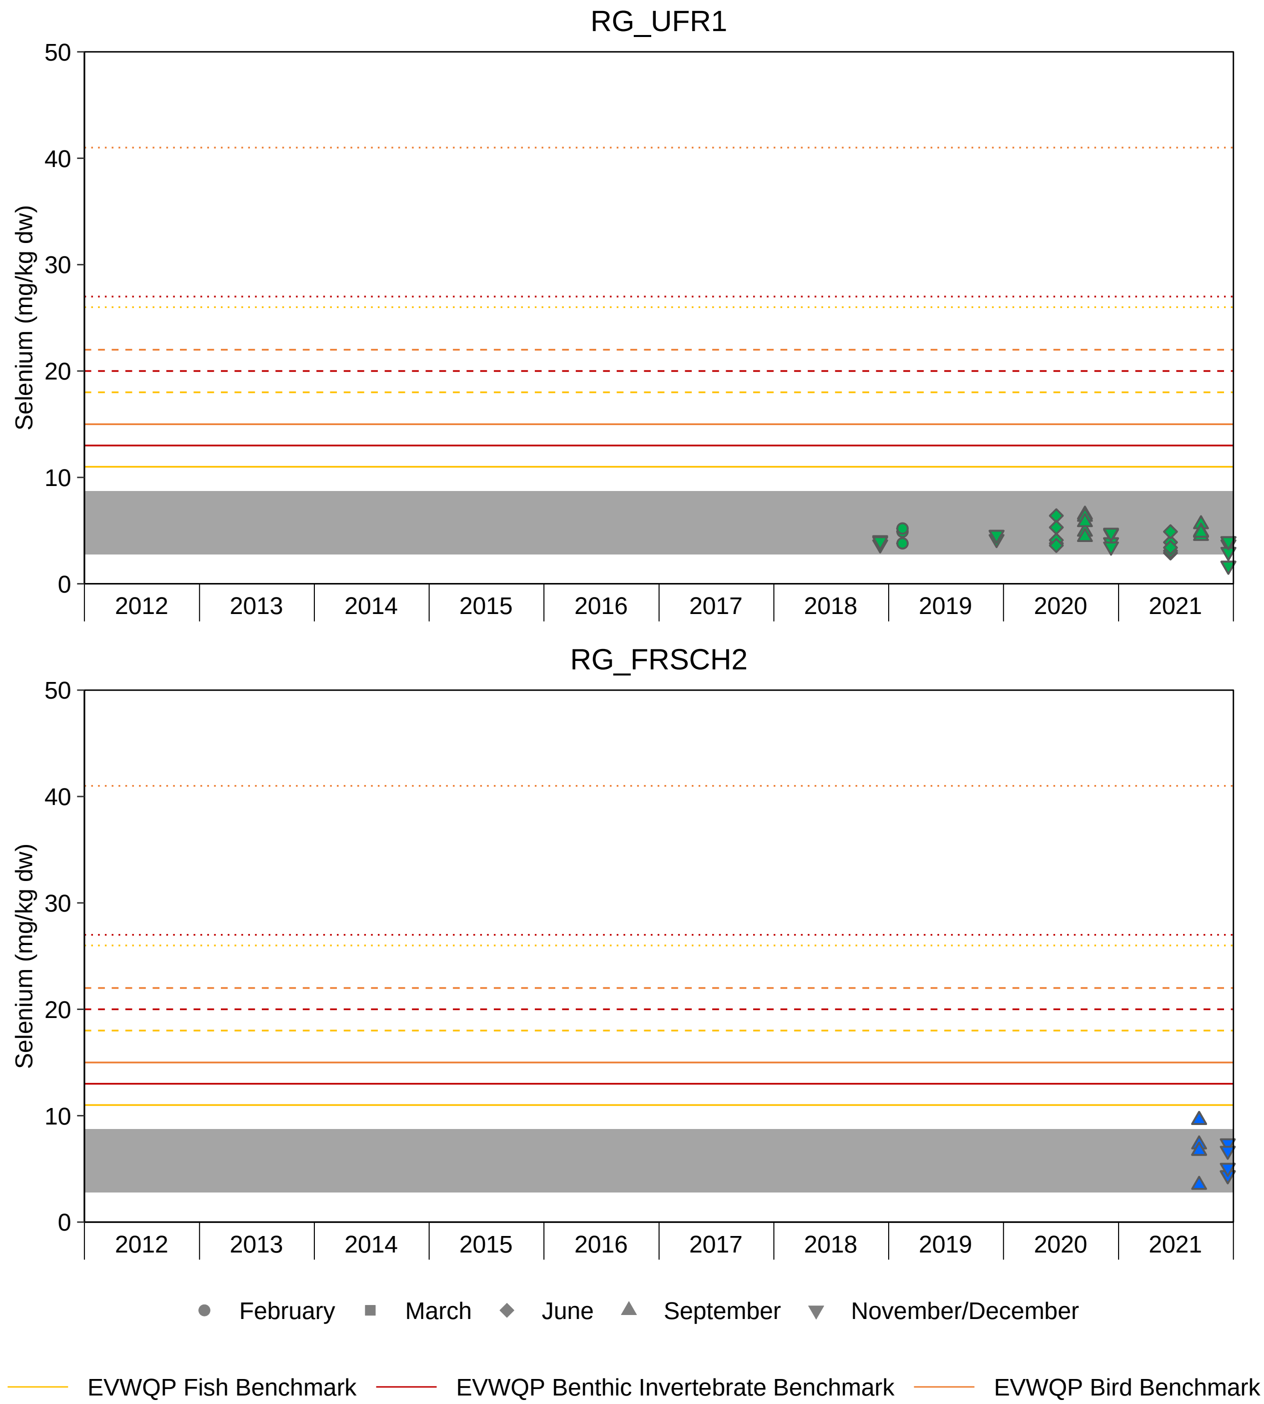

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

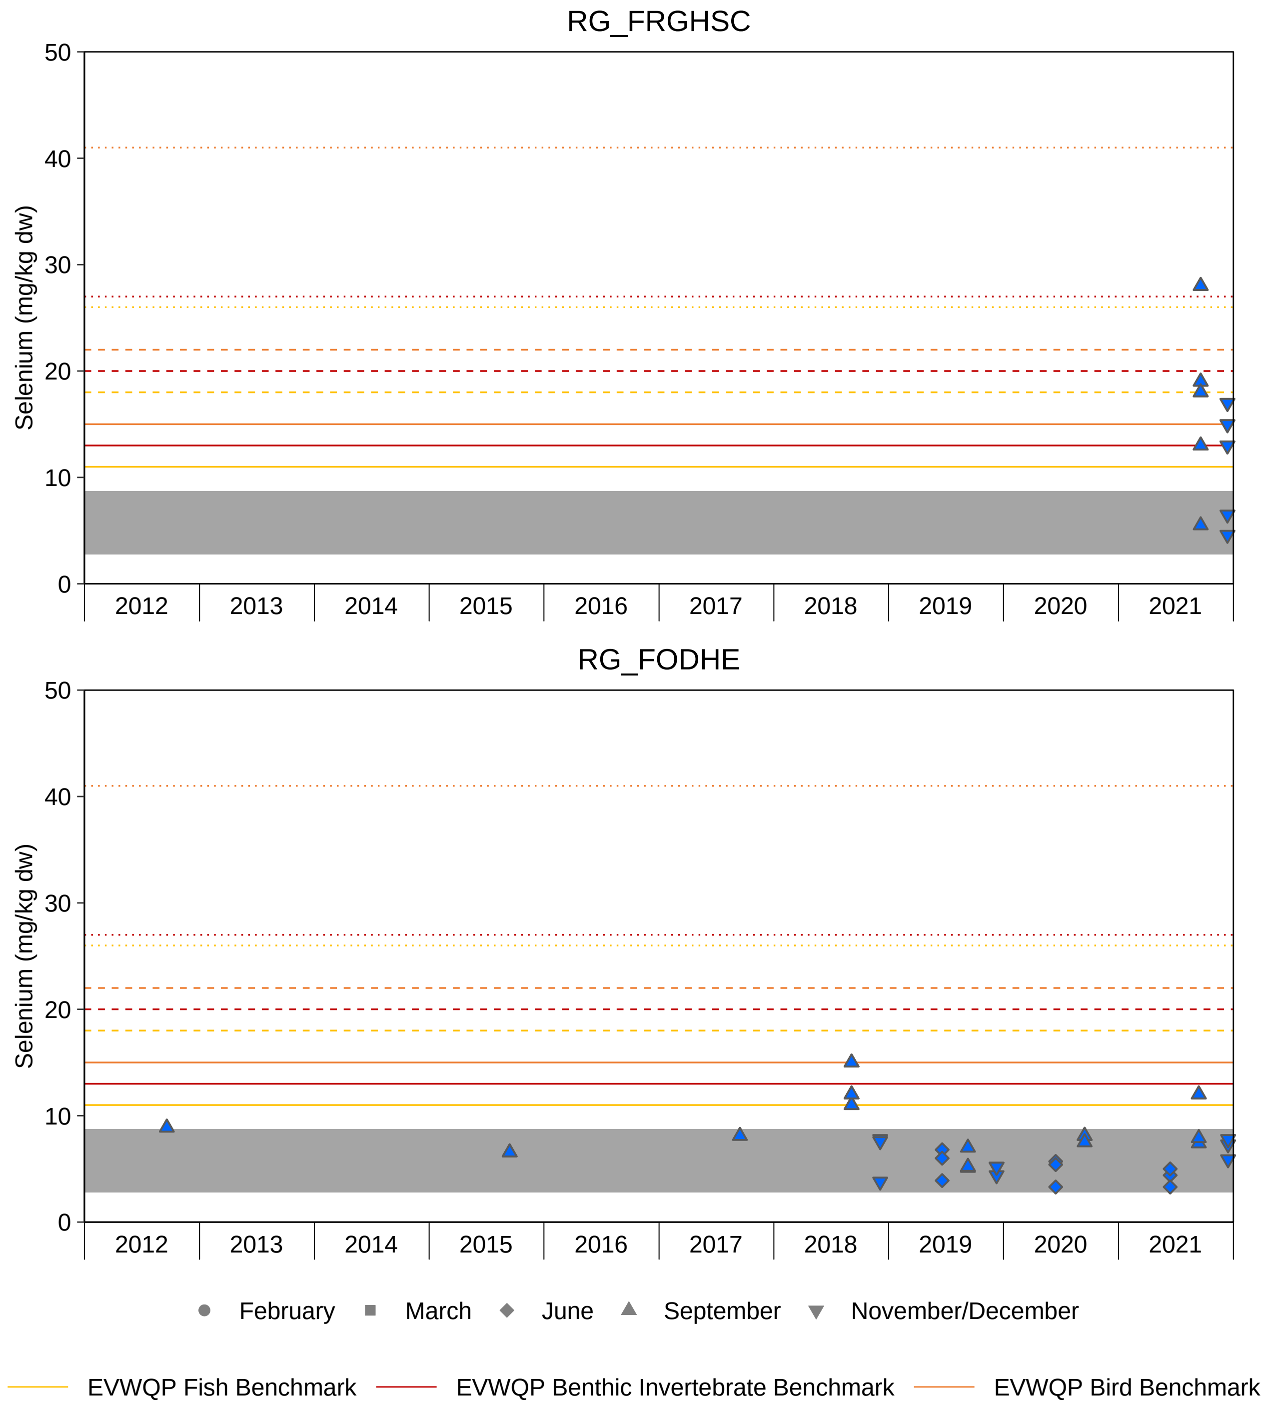

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

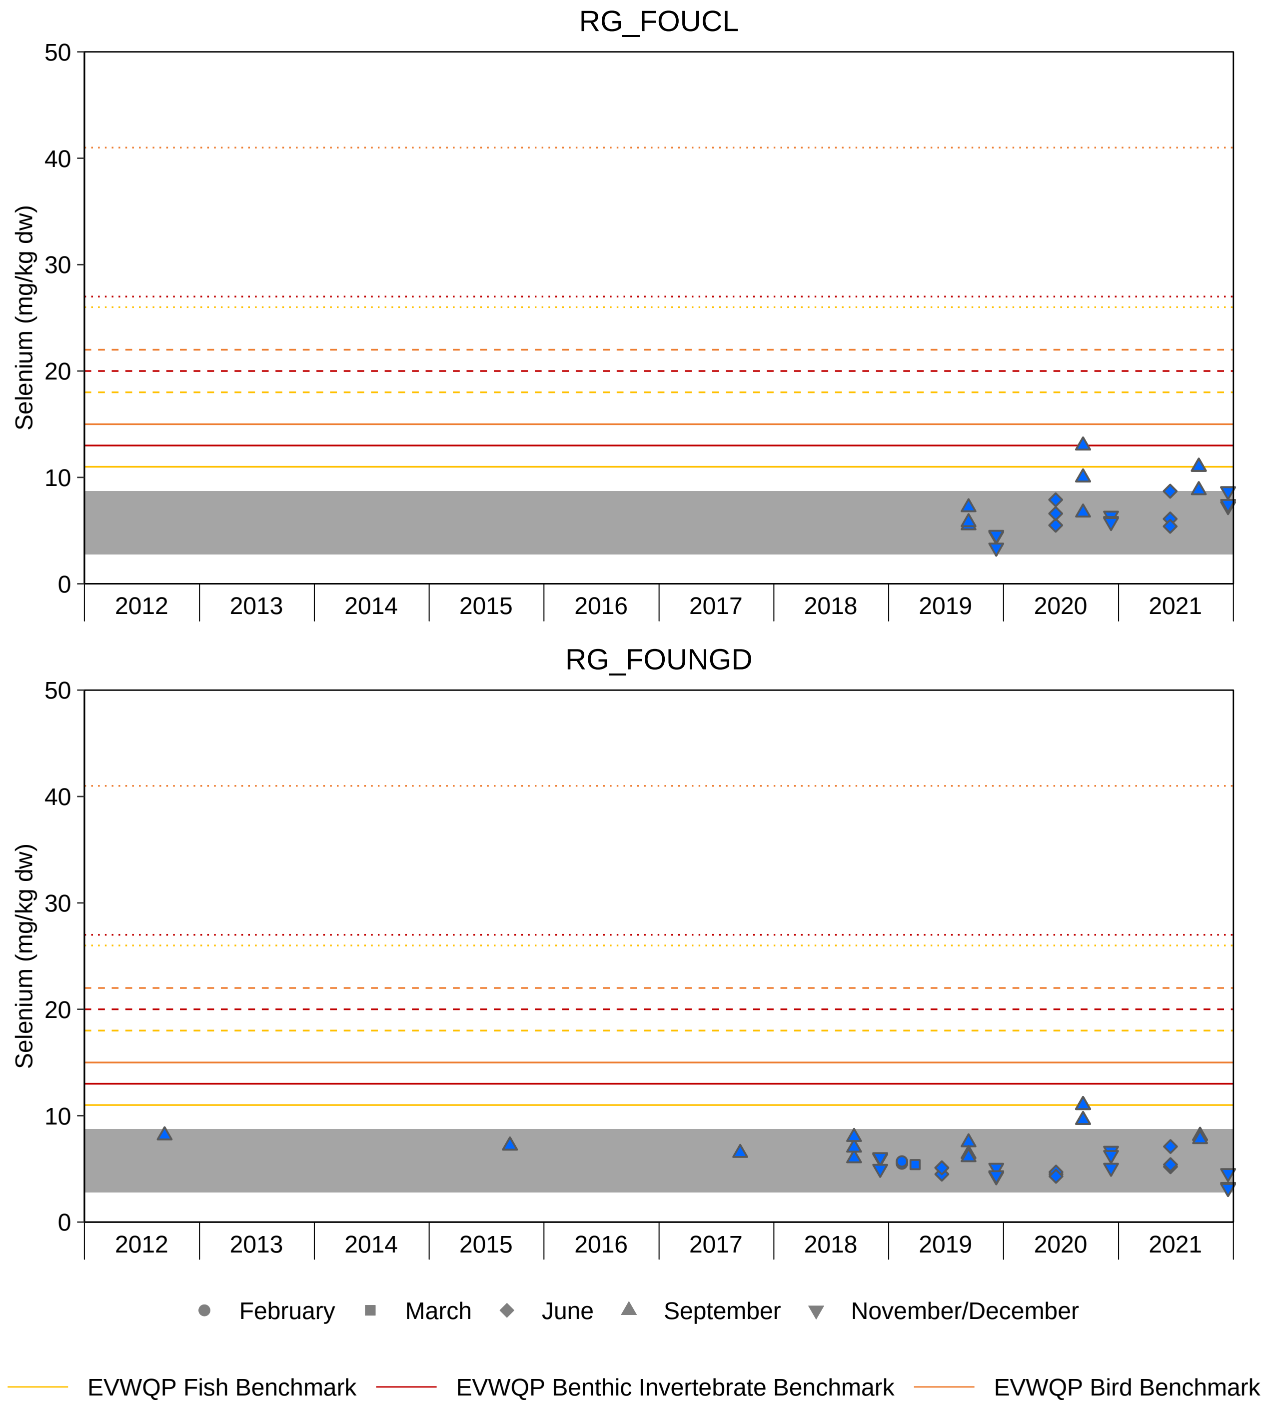

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

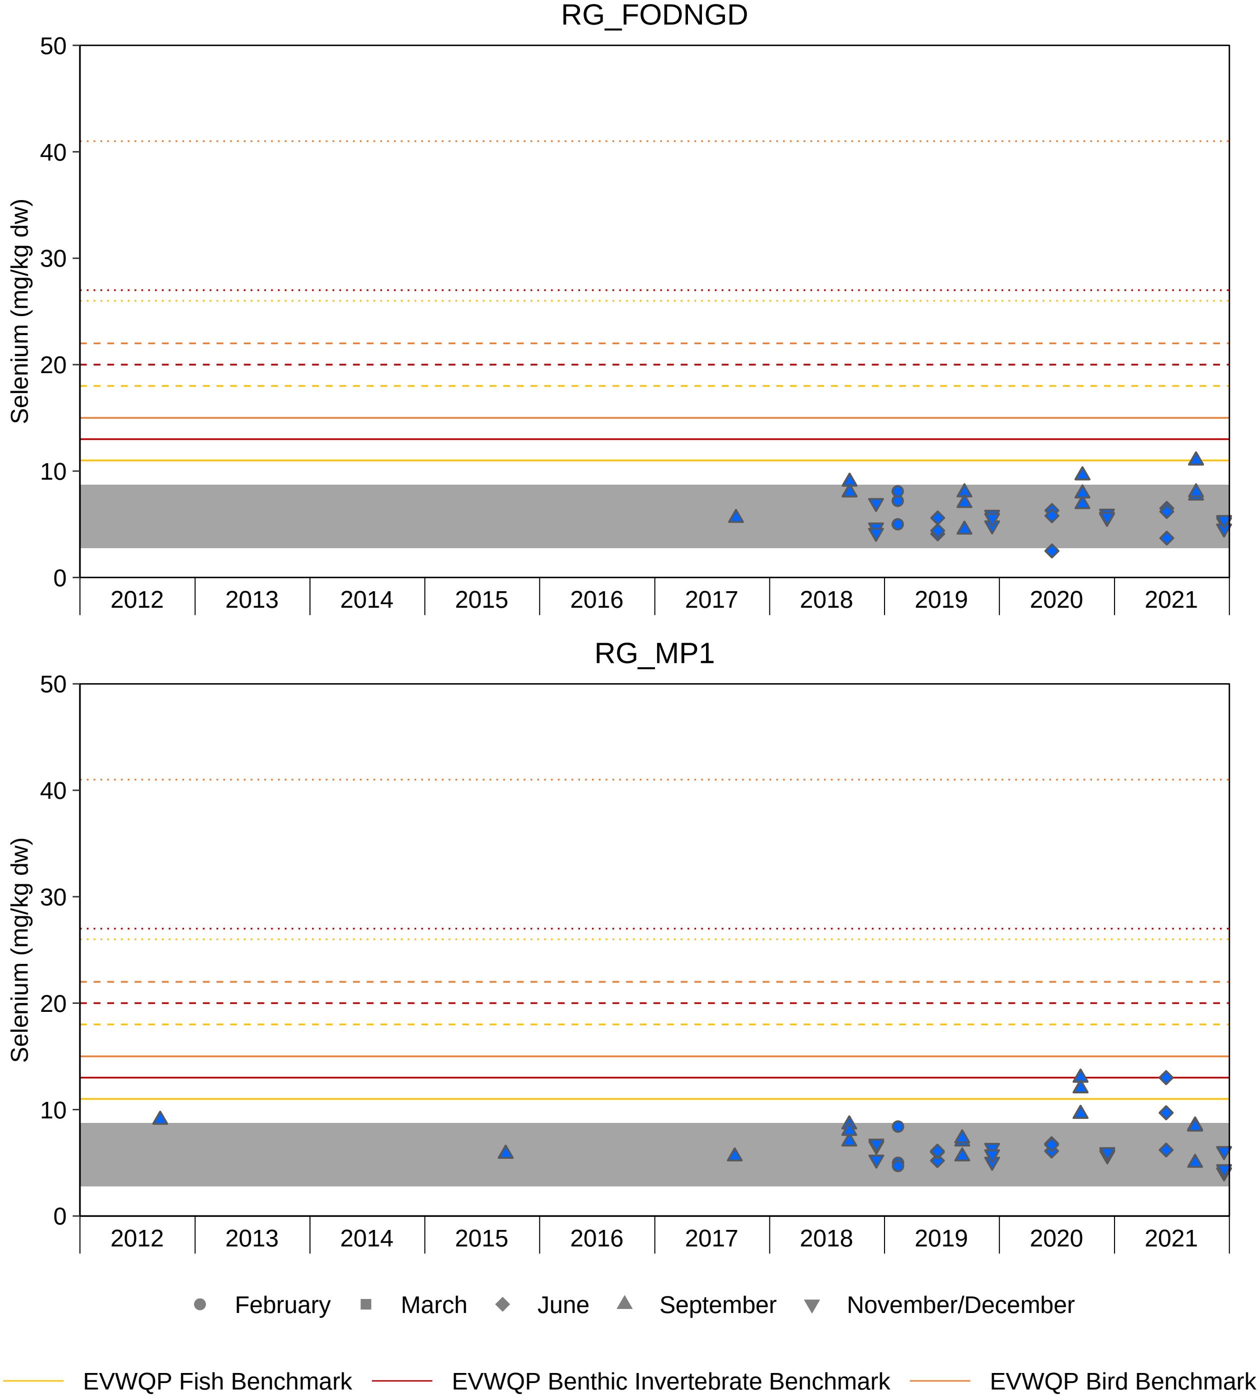

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

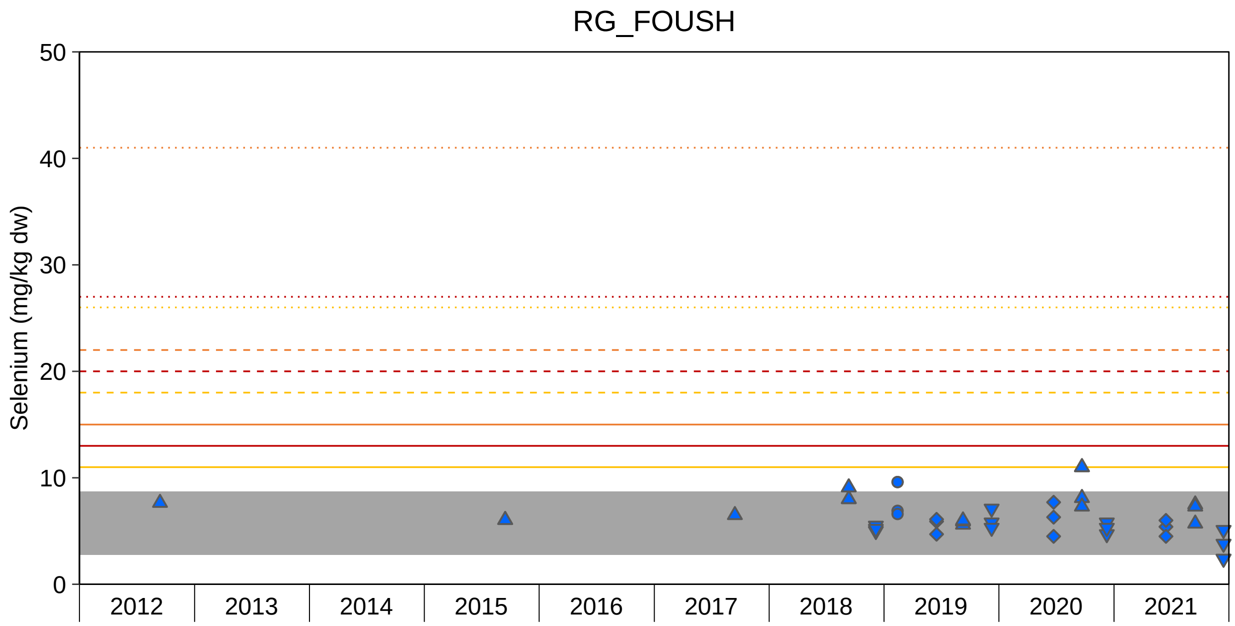
Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.



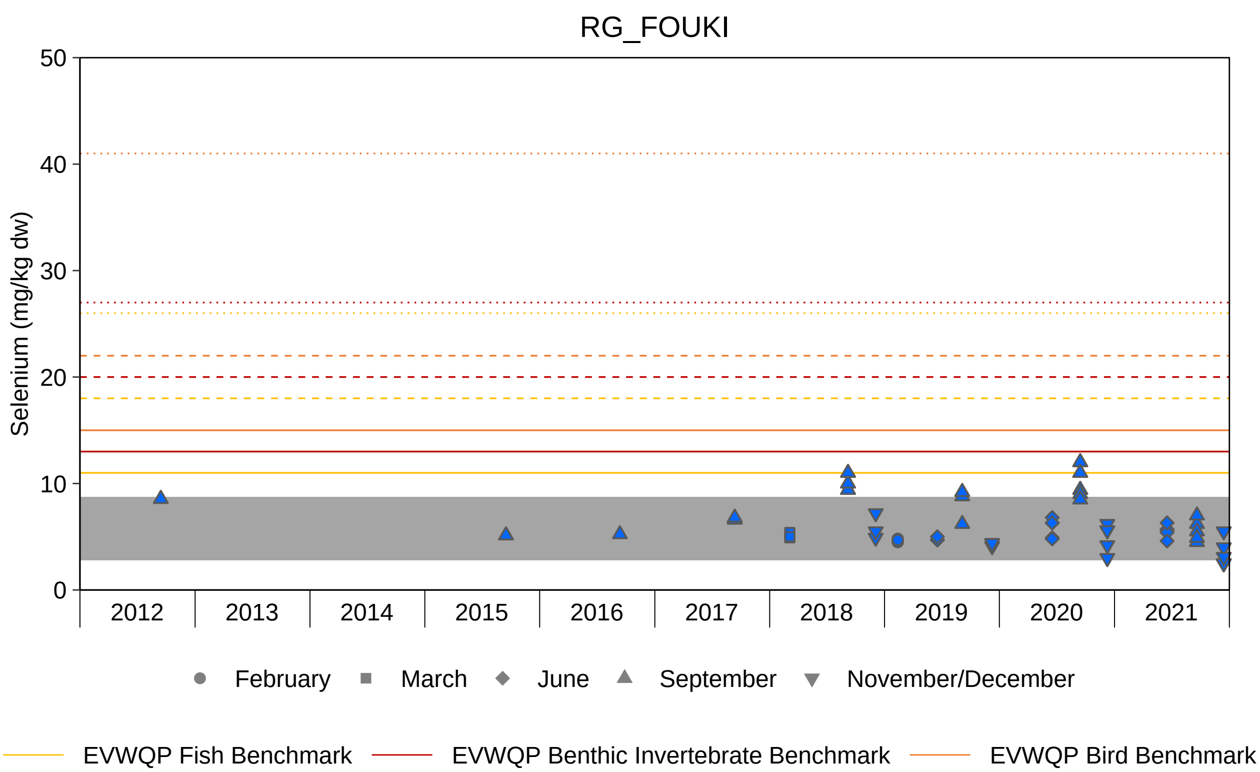


Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

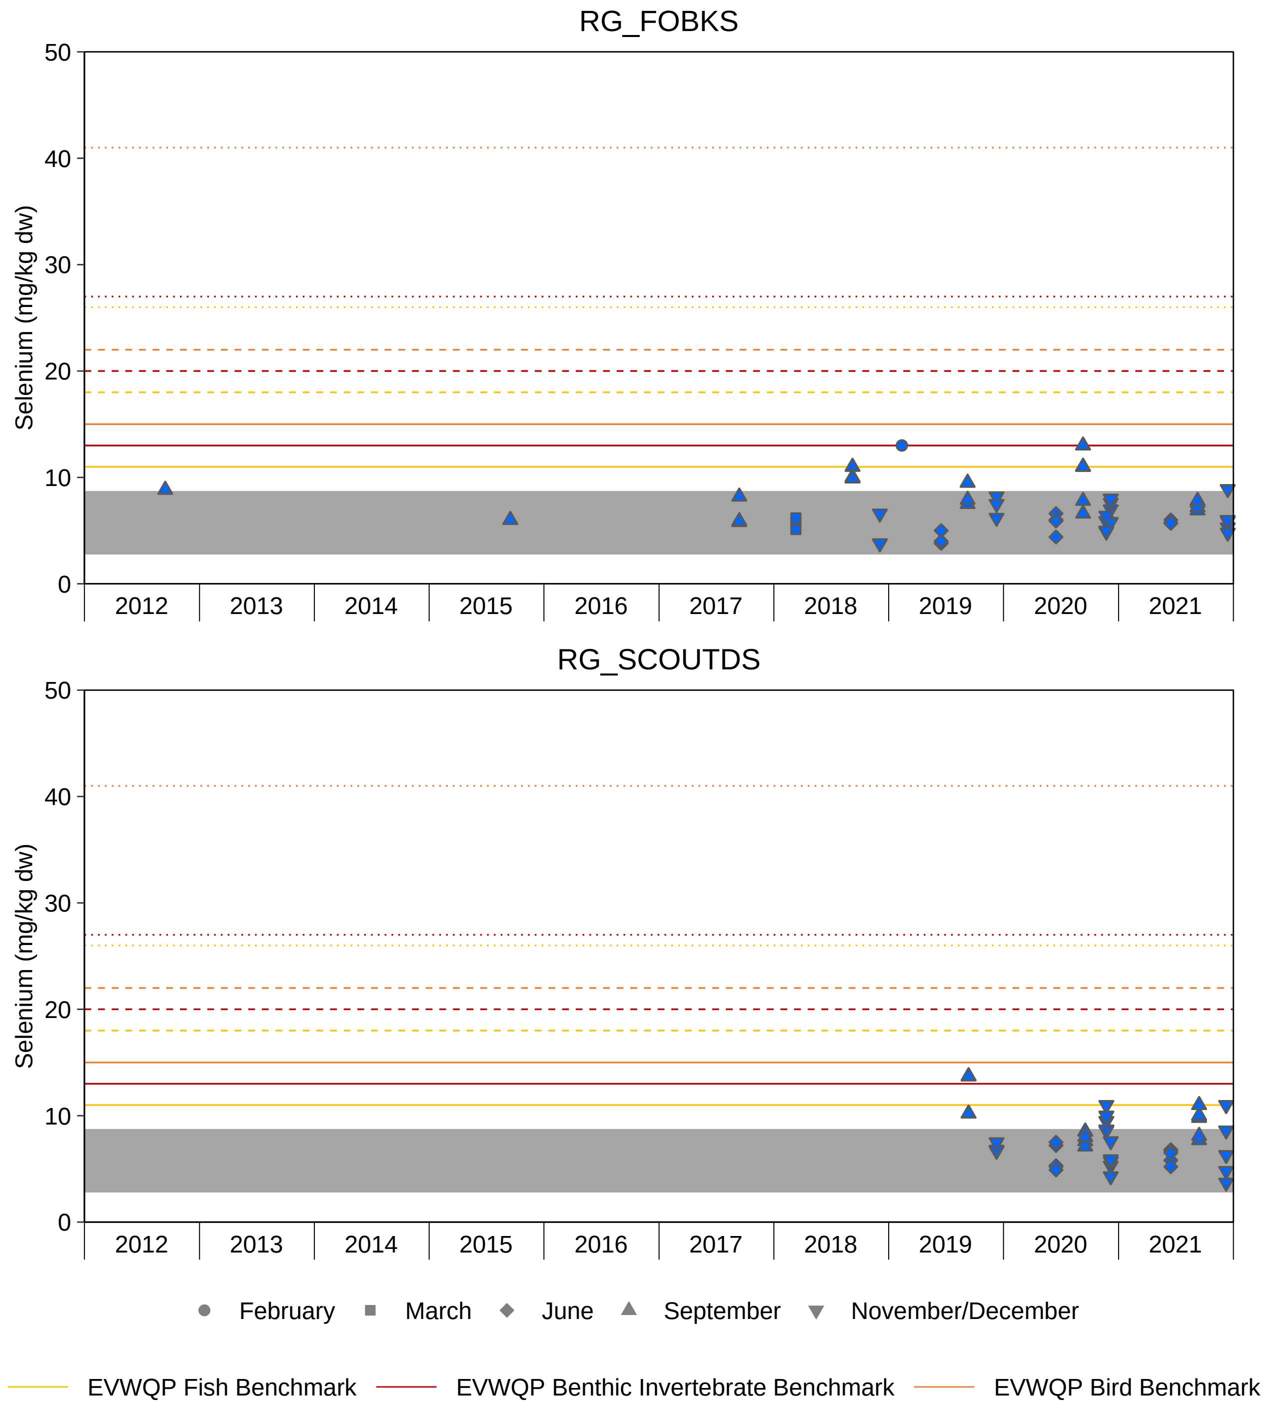

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

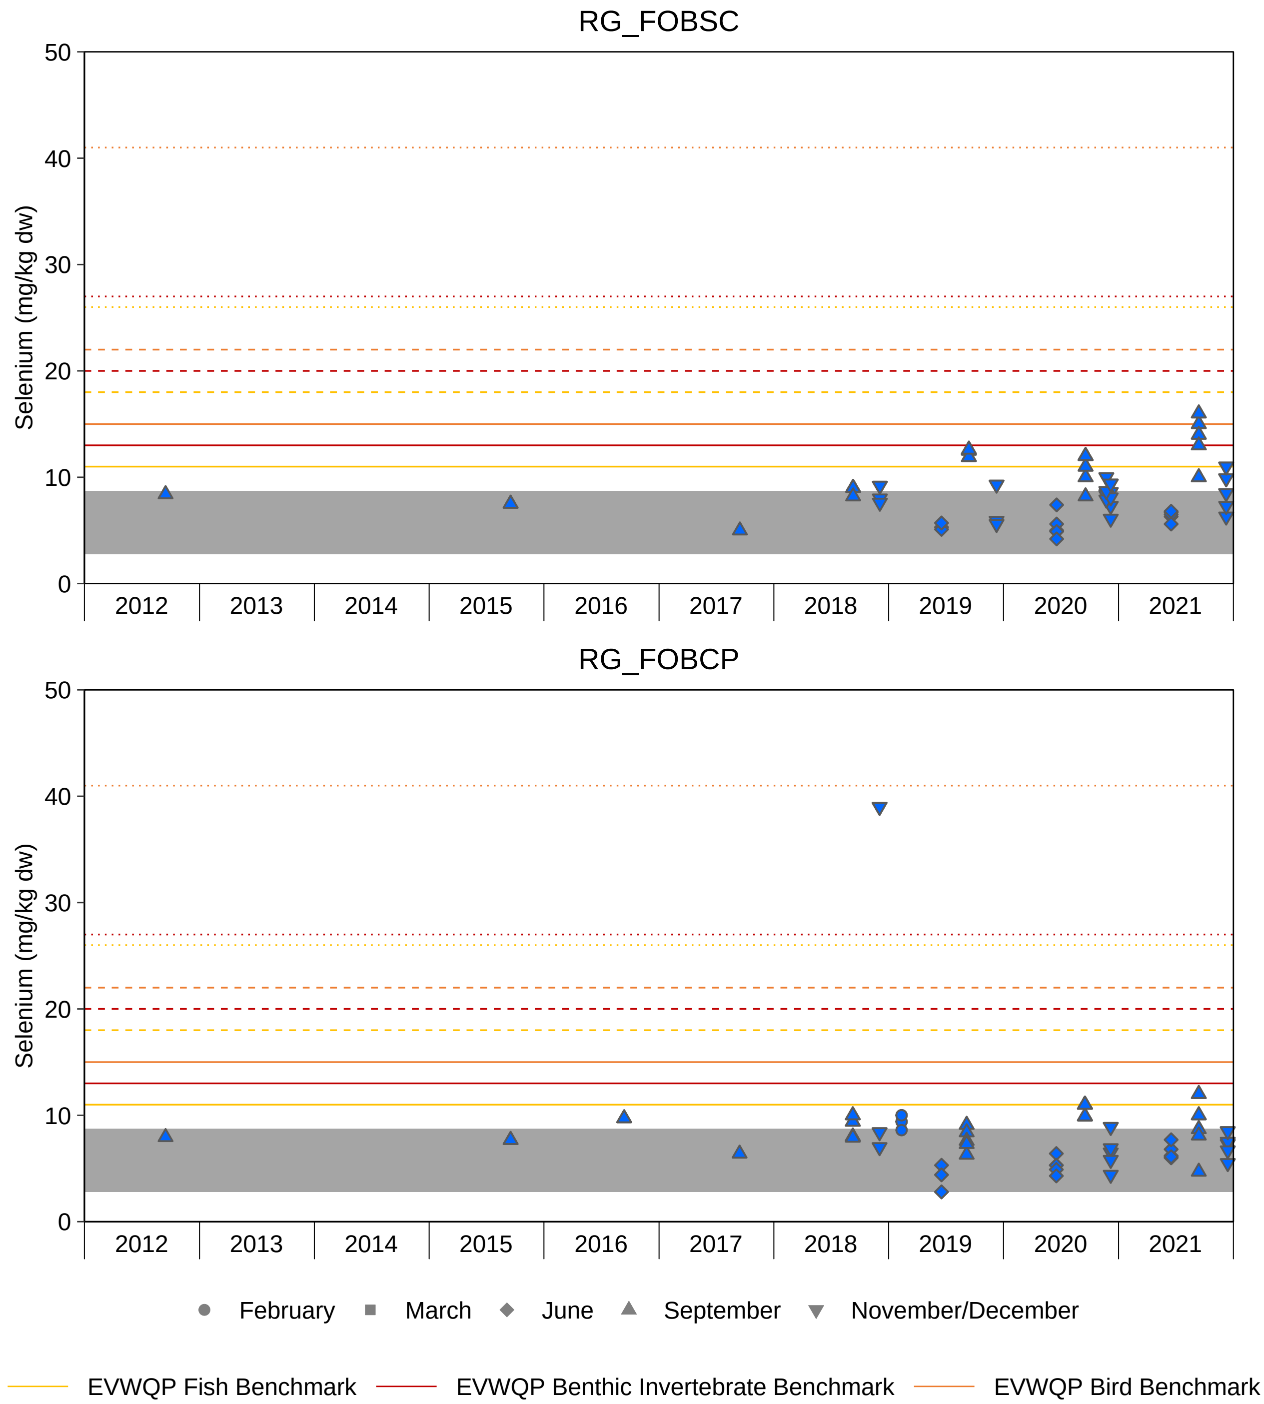

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

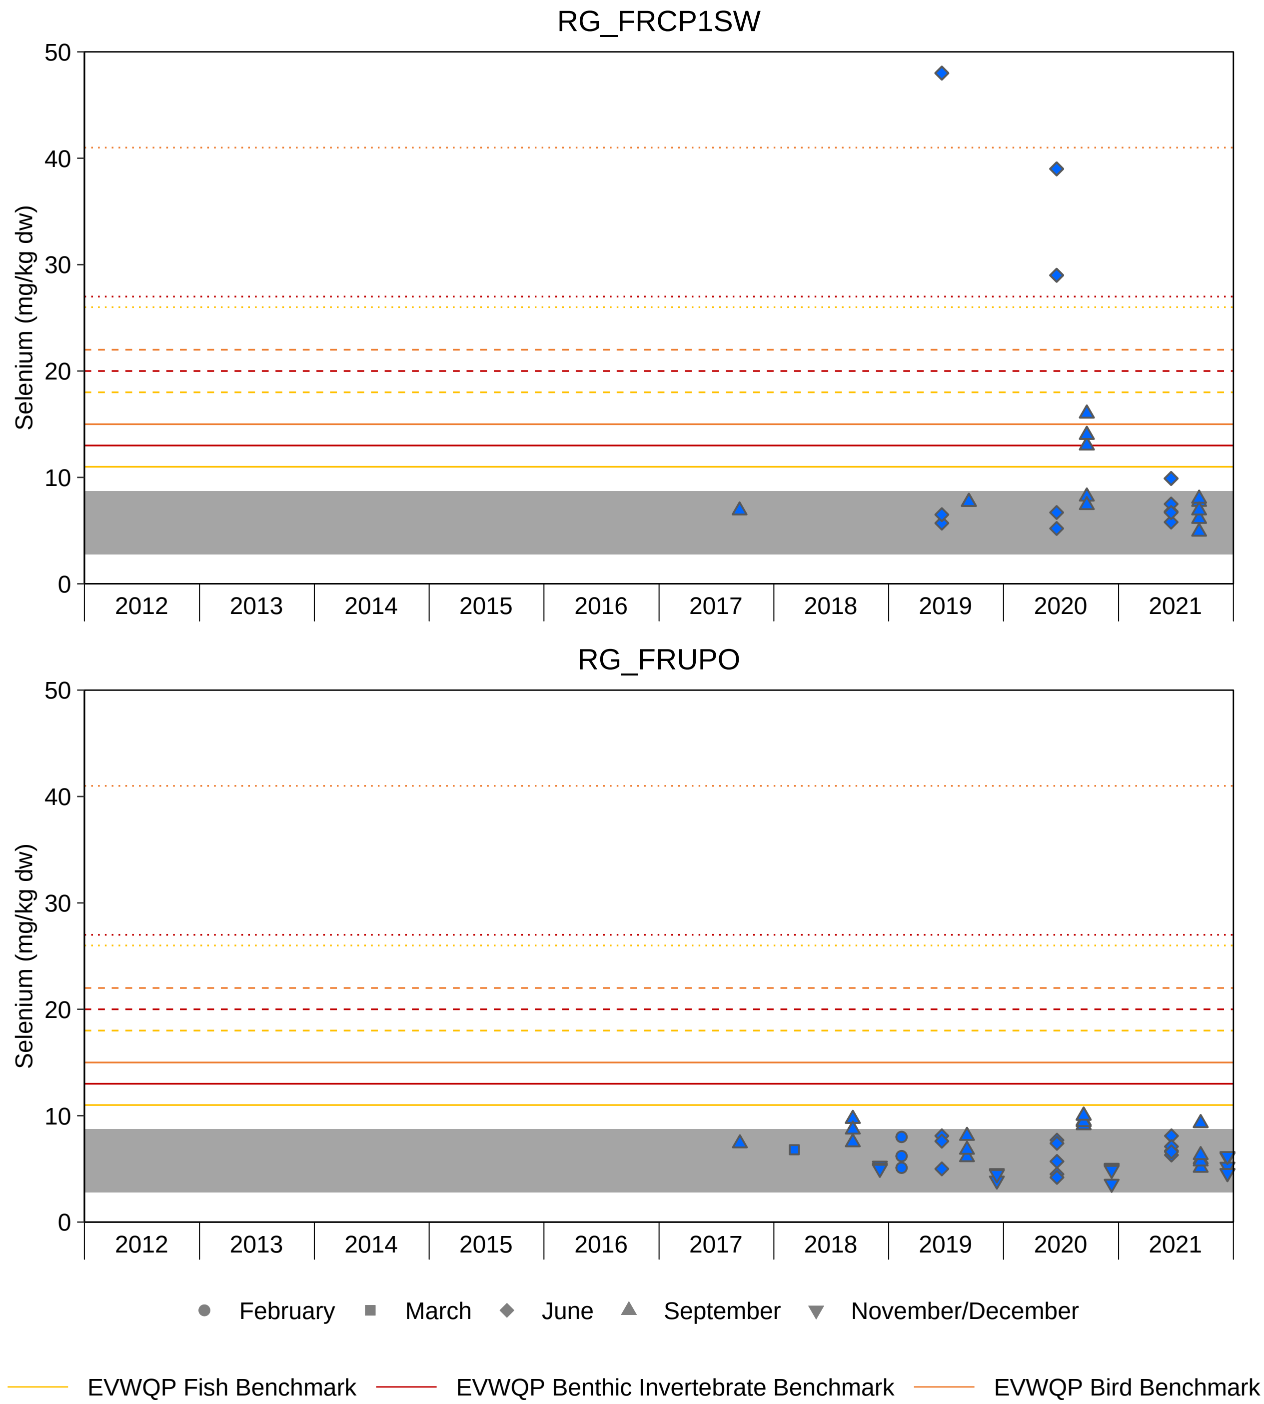

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

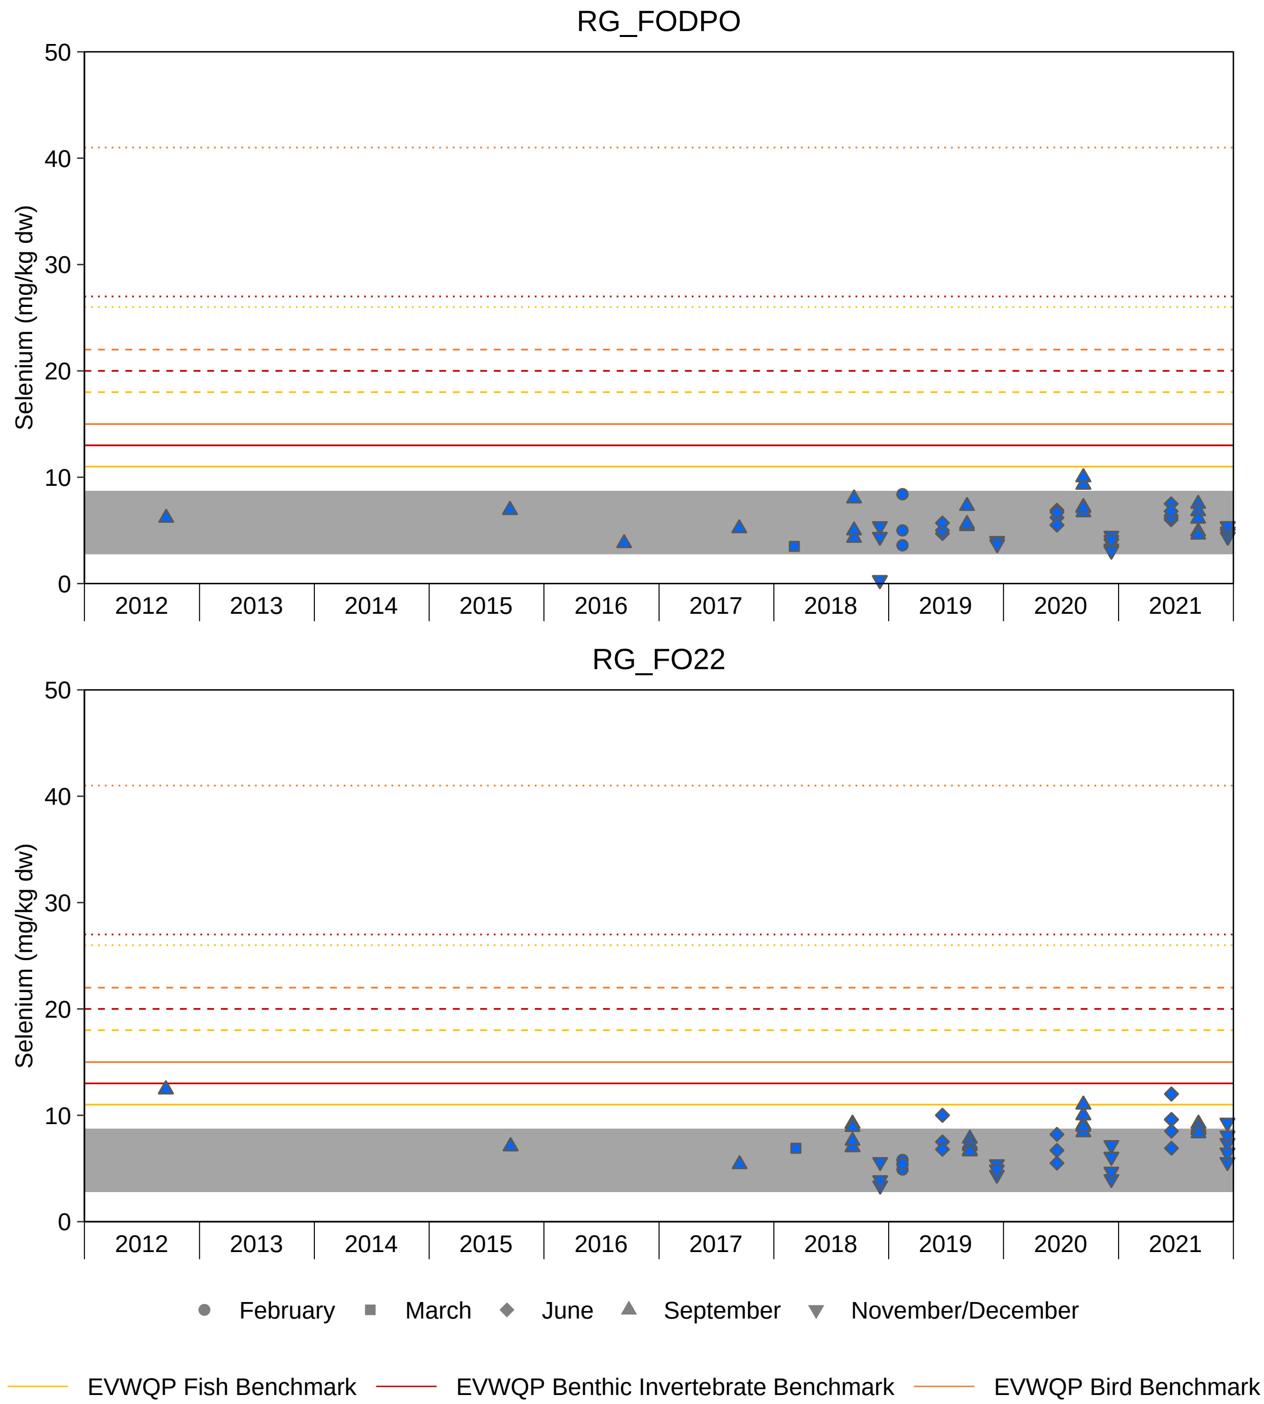

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

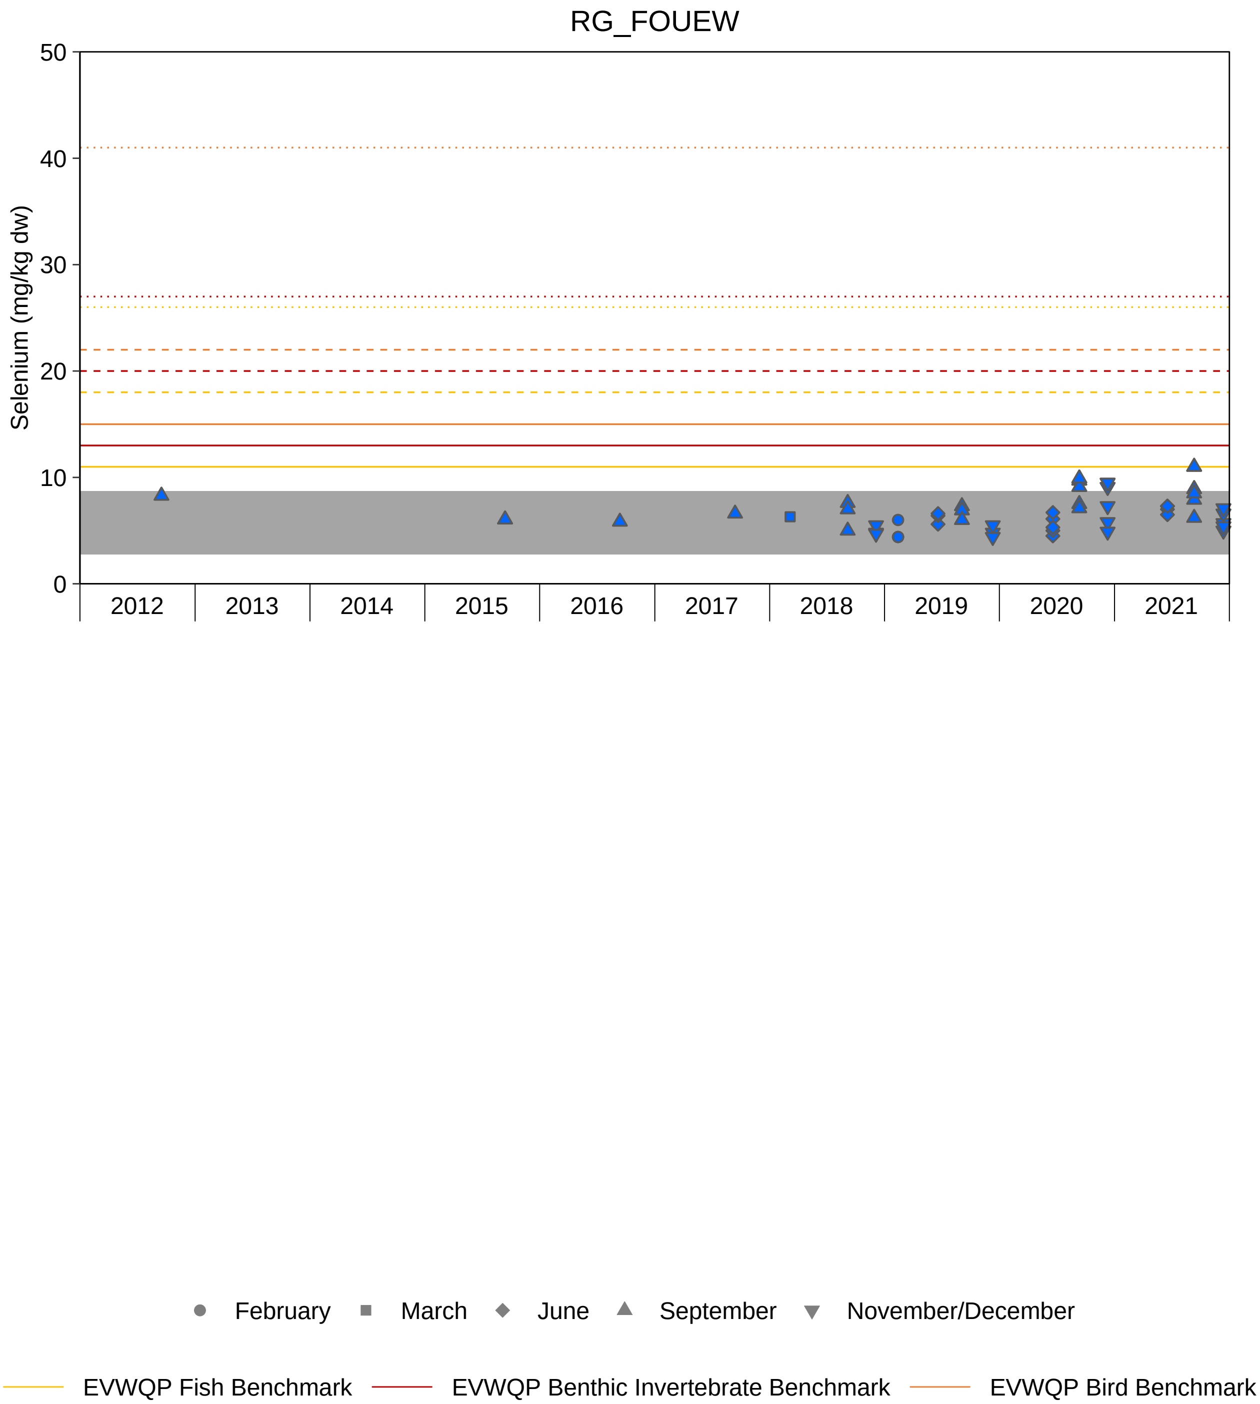

Figure E.3: Composite−taxa Benthic Invertebrate Tissue Concentrations, FRO LAEMP, 2012 to 2021

Notes: Green represents reference stations and blue represents mine−exposed stations. Gray shading represents the reference area normal range defined as the 2.5th and 97.5th percentiles of the distribution of reference area data (pooled 1996 to 2019 data) reported in the RAEMP. Level 1 benchmarks are shown with a solid line, Level 2 benchmarks are shown with a dashed line, and Level 3 benchmarks are shown with a dotted line.

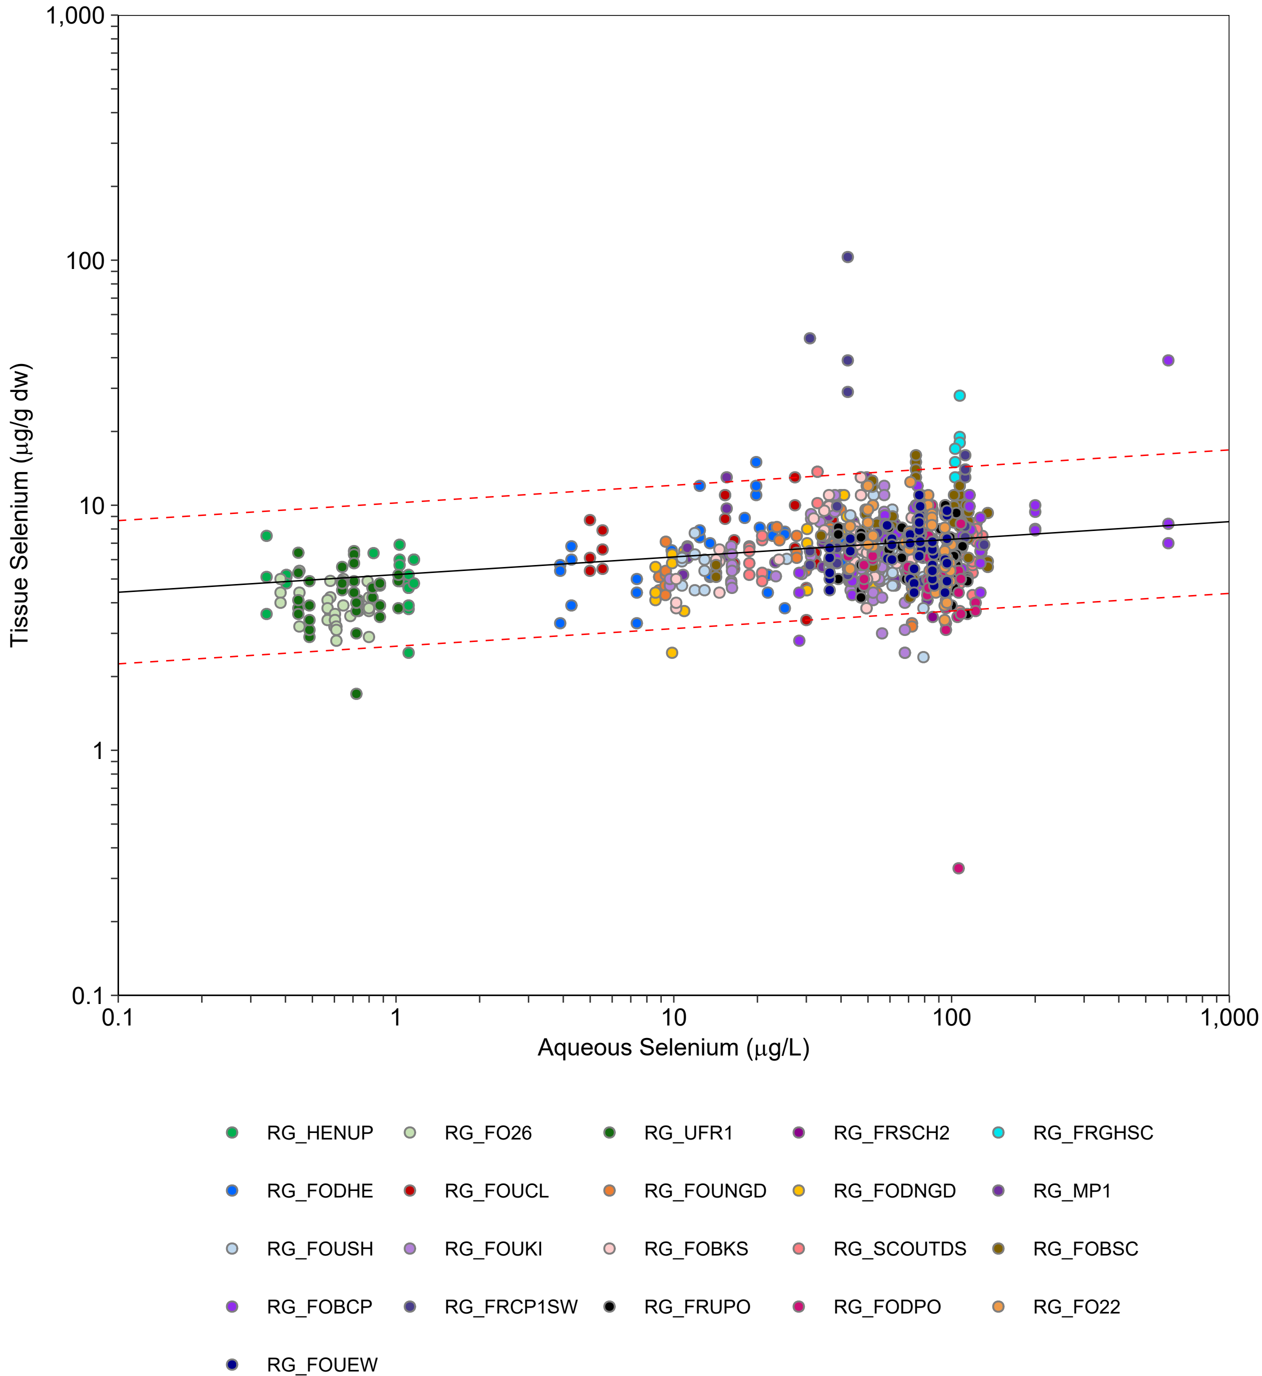

Figure E.4: Observed and Modelled Selenium Concentrations in Benthic Invertebrate Composite-taxa Samples Relative to Aqueous Selenium Concentrations at Biological Monitoring Areas Upstream and Downstream of Fording River Operations, FRO LAEMP, 2012 to 2021

Notes: Mean benthic invertebrate selenium concentrations (solid black line) were estimated using a one-step water to benthic invertebrate selenium accumulation model: log10[Se]benthic invertebrate=0.717+0.072 x log10[Se]aq (Golder 2020). The 95% prediction limits for a single value from the one-step water to benthic invertebrate selenium accumulation model are plotted as dashed red lines. Reference areas are shown in green.

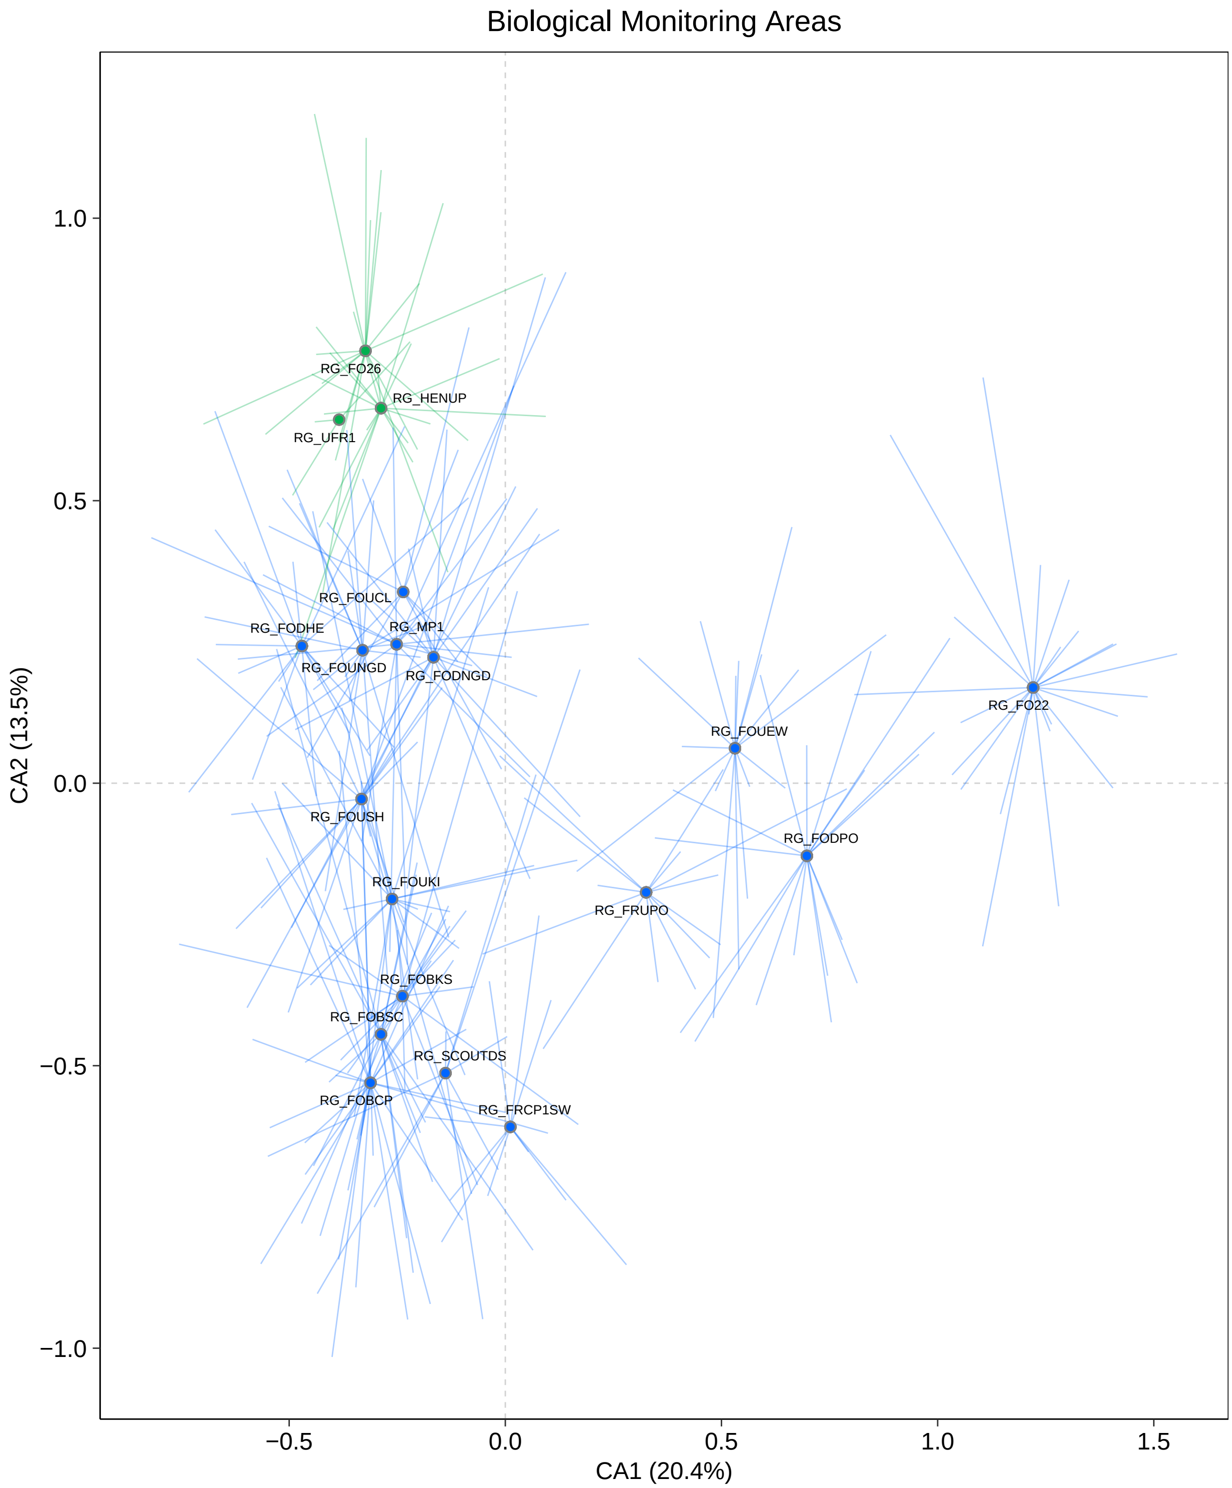

Figure E.5: Correspondence Analysis Bi−plot for Benthic Invertebrate Community Measured in FRO LAEMP, September 2012 to 2021

Notes: Reference areas are shown in green and mine−exposed areas are shown in blue. Analysis was completed on log10(x+1) transformed data. Areas with fewer than five taxa present were removed from analysis. Taxa that were present at less than five areas and contributed less 0.05% of the total abundance were removed from analysis.

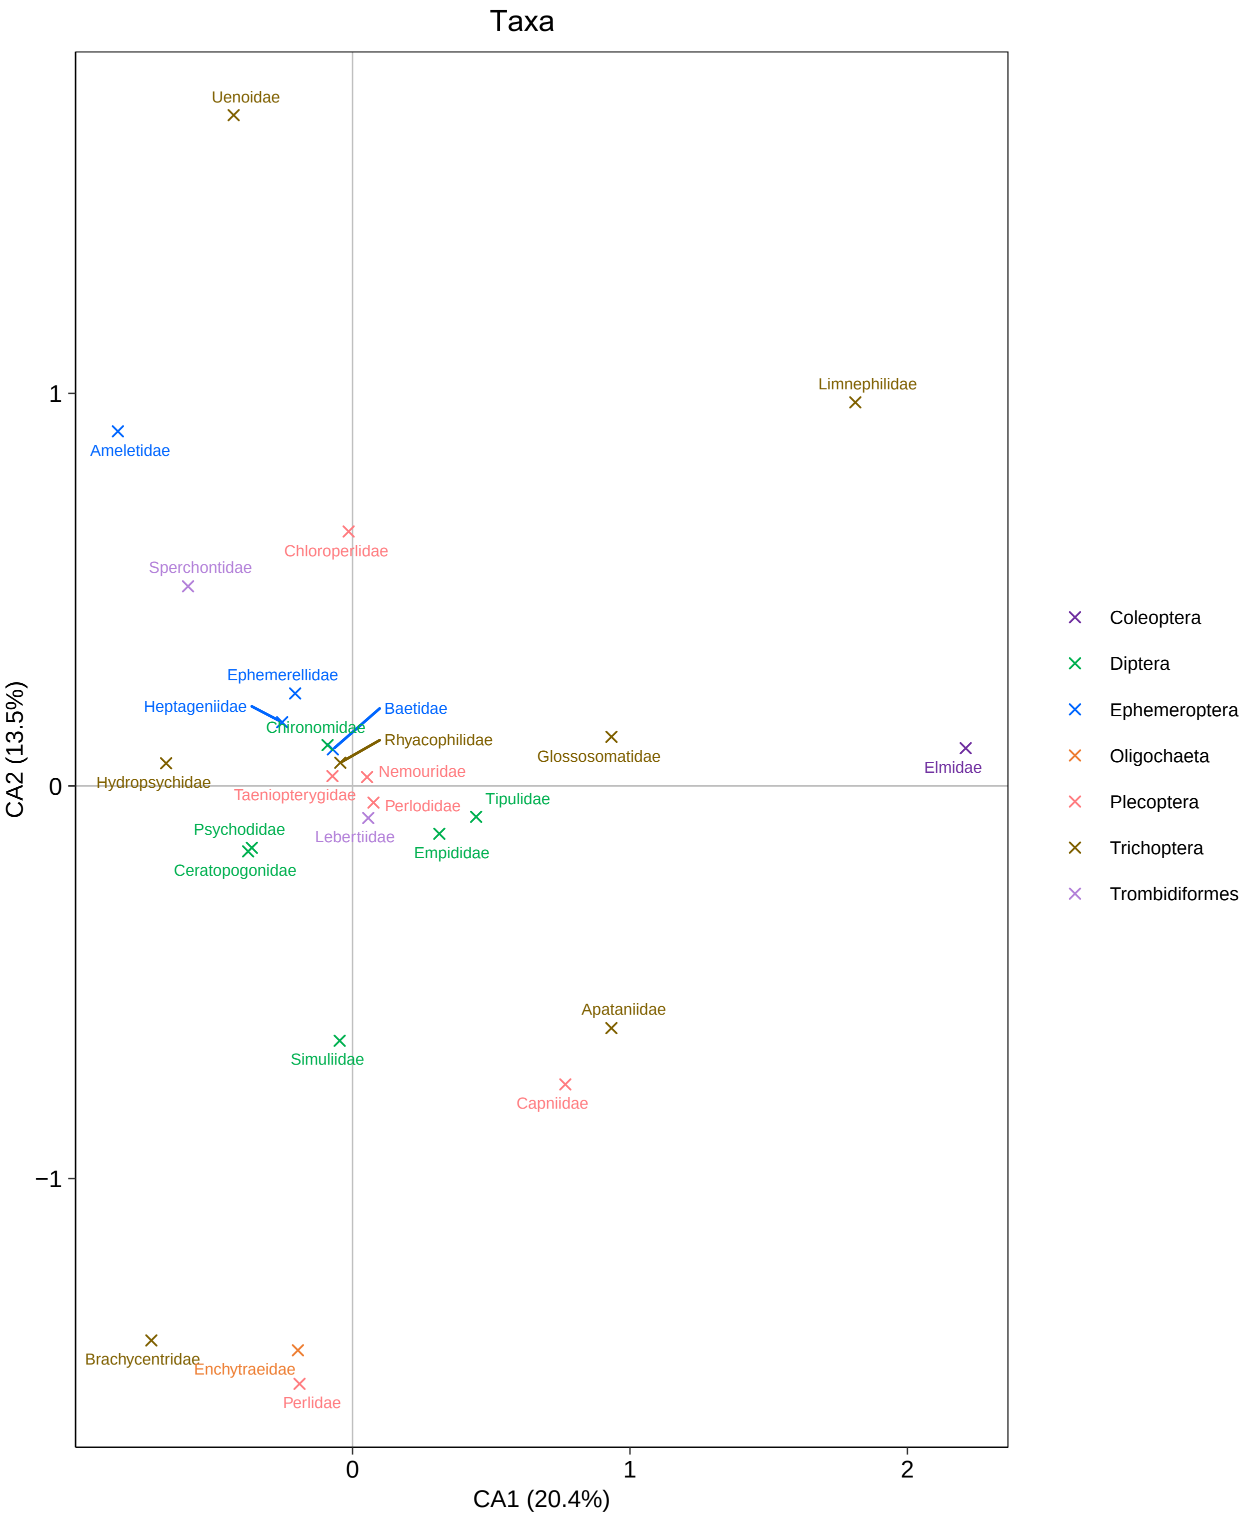

Figure E.6: Family Level Correspondence Analysis Bi−plot for Benthic Invertebrate Community Measured in FRO LAEMP, September 2012 to 2021

Notes: Reference areas are shown in green and mine−exposed areas are shown in blue. Analysis was completed on log10(x+1) transformed data. Areas with fewer than five taxa present were removed from analysis. Taxa that were present at less than five areas and contributed less 0.05% of the total abundance were removed from analysis. Different Colors represent different taxa orders outlined in the legend

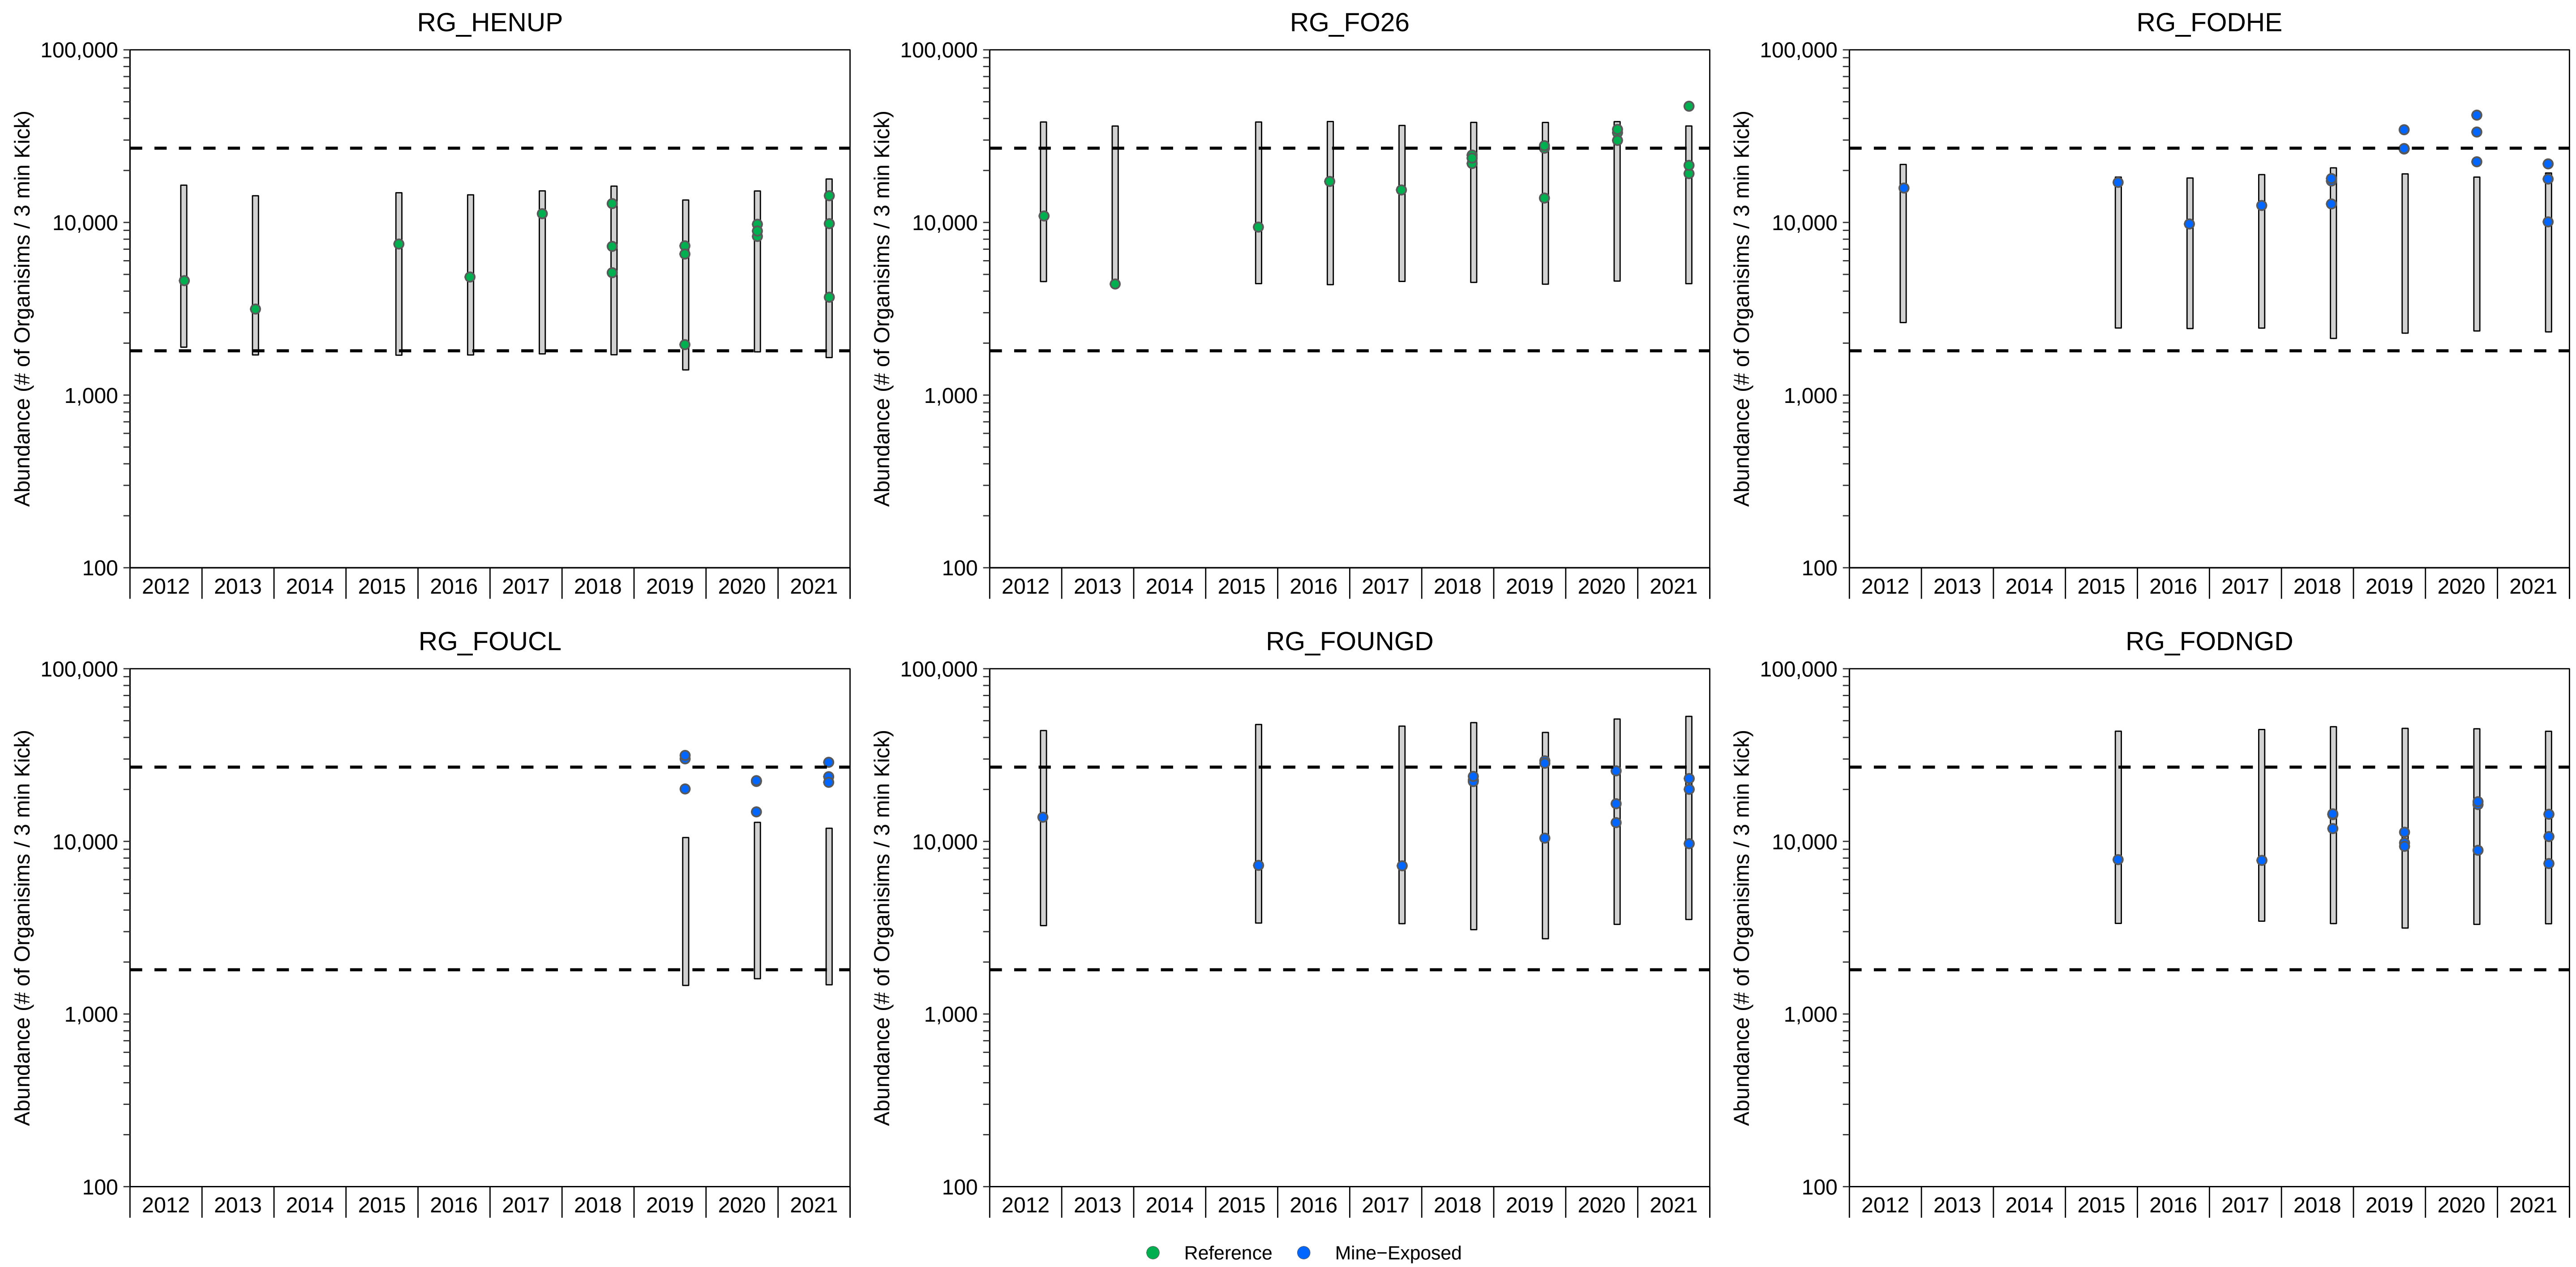

Figure E.7: Benthic Invertebrate Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

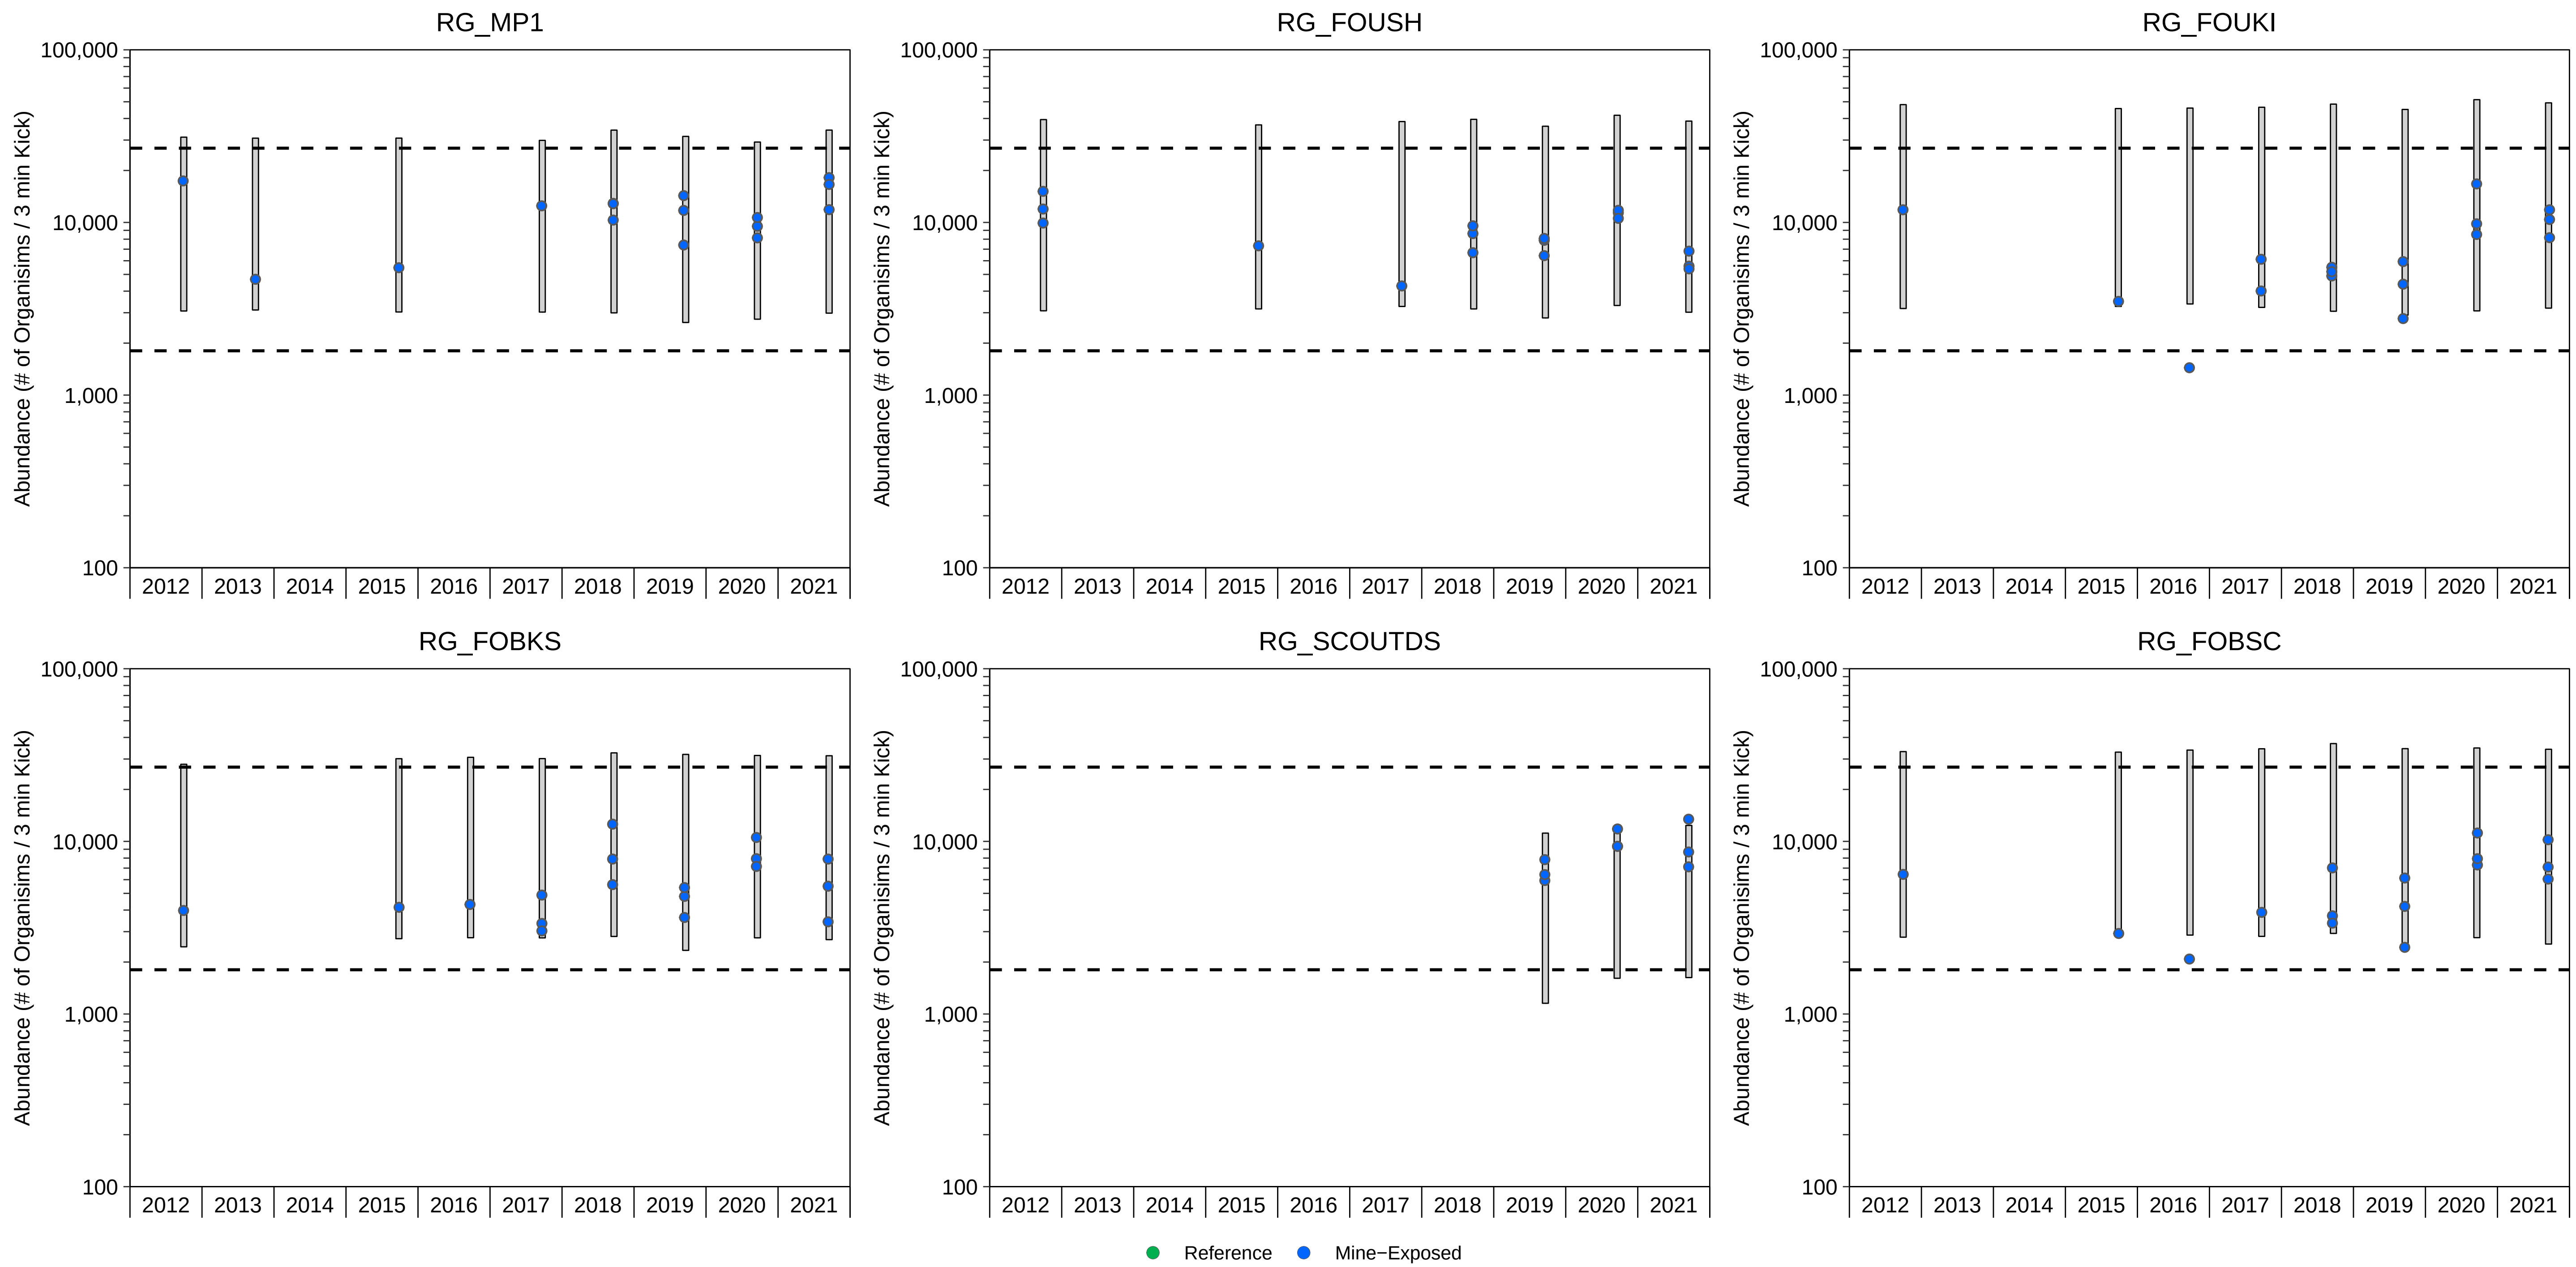

Figure E.7: Benthic Invertebrate Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

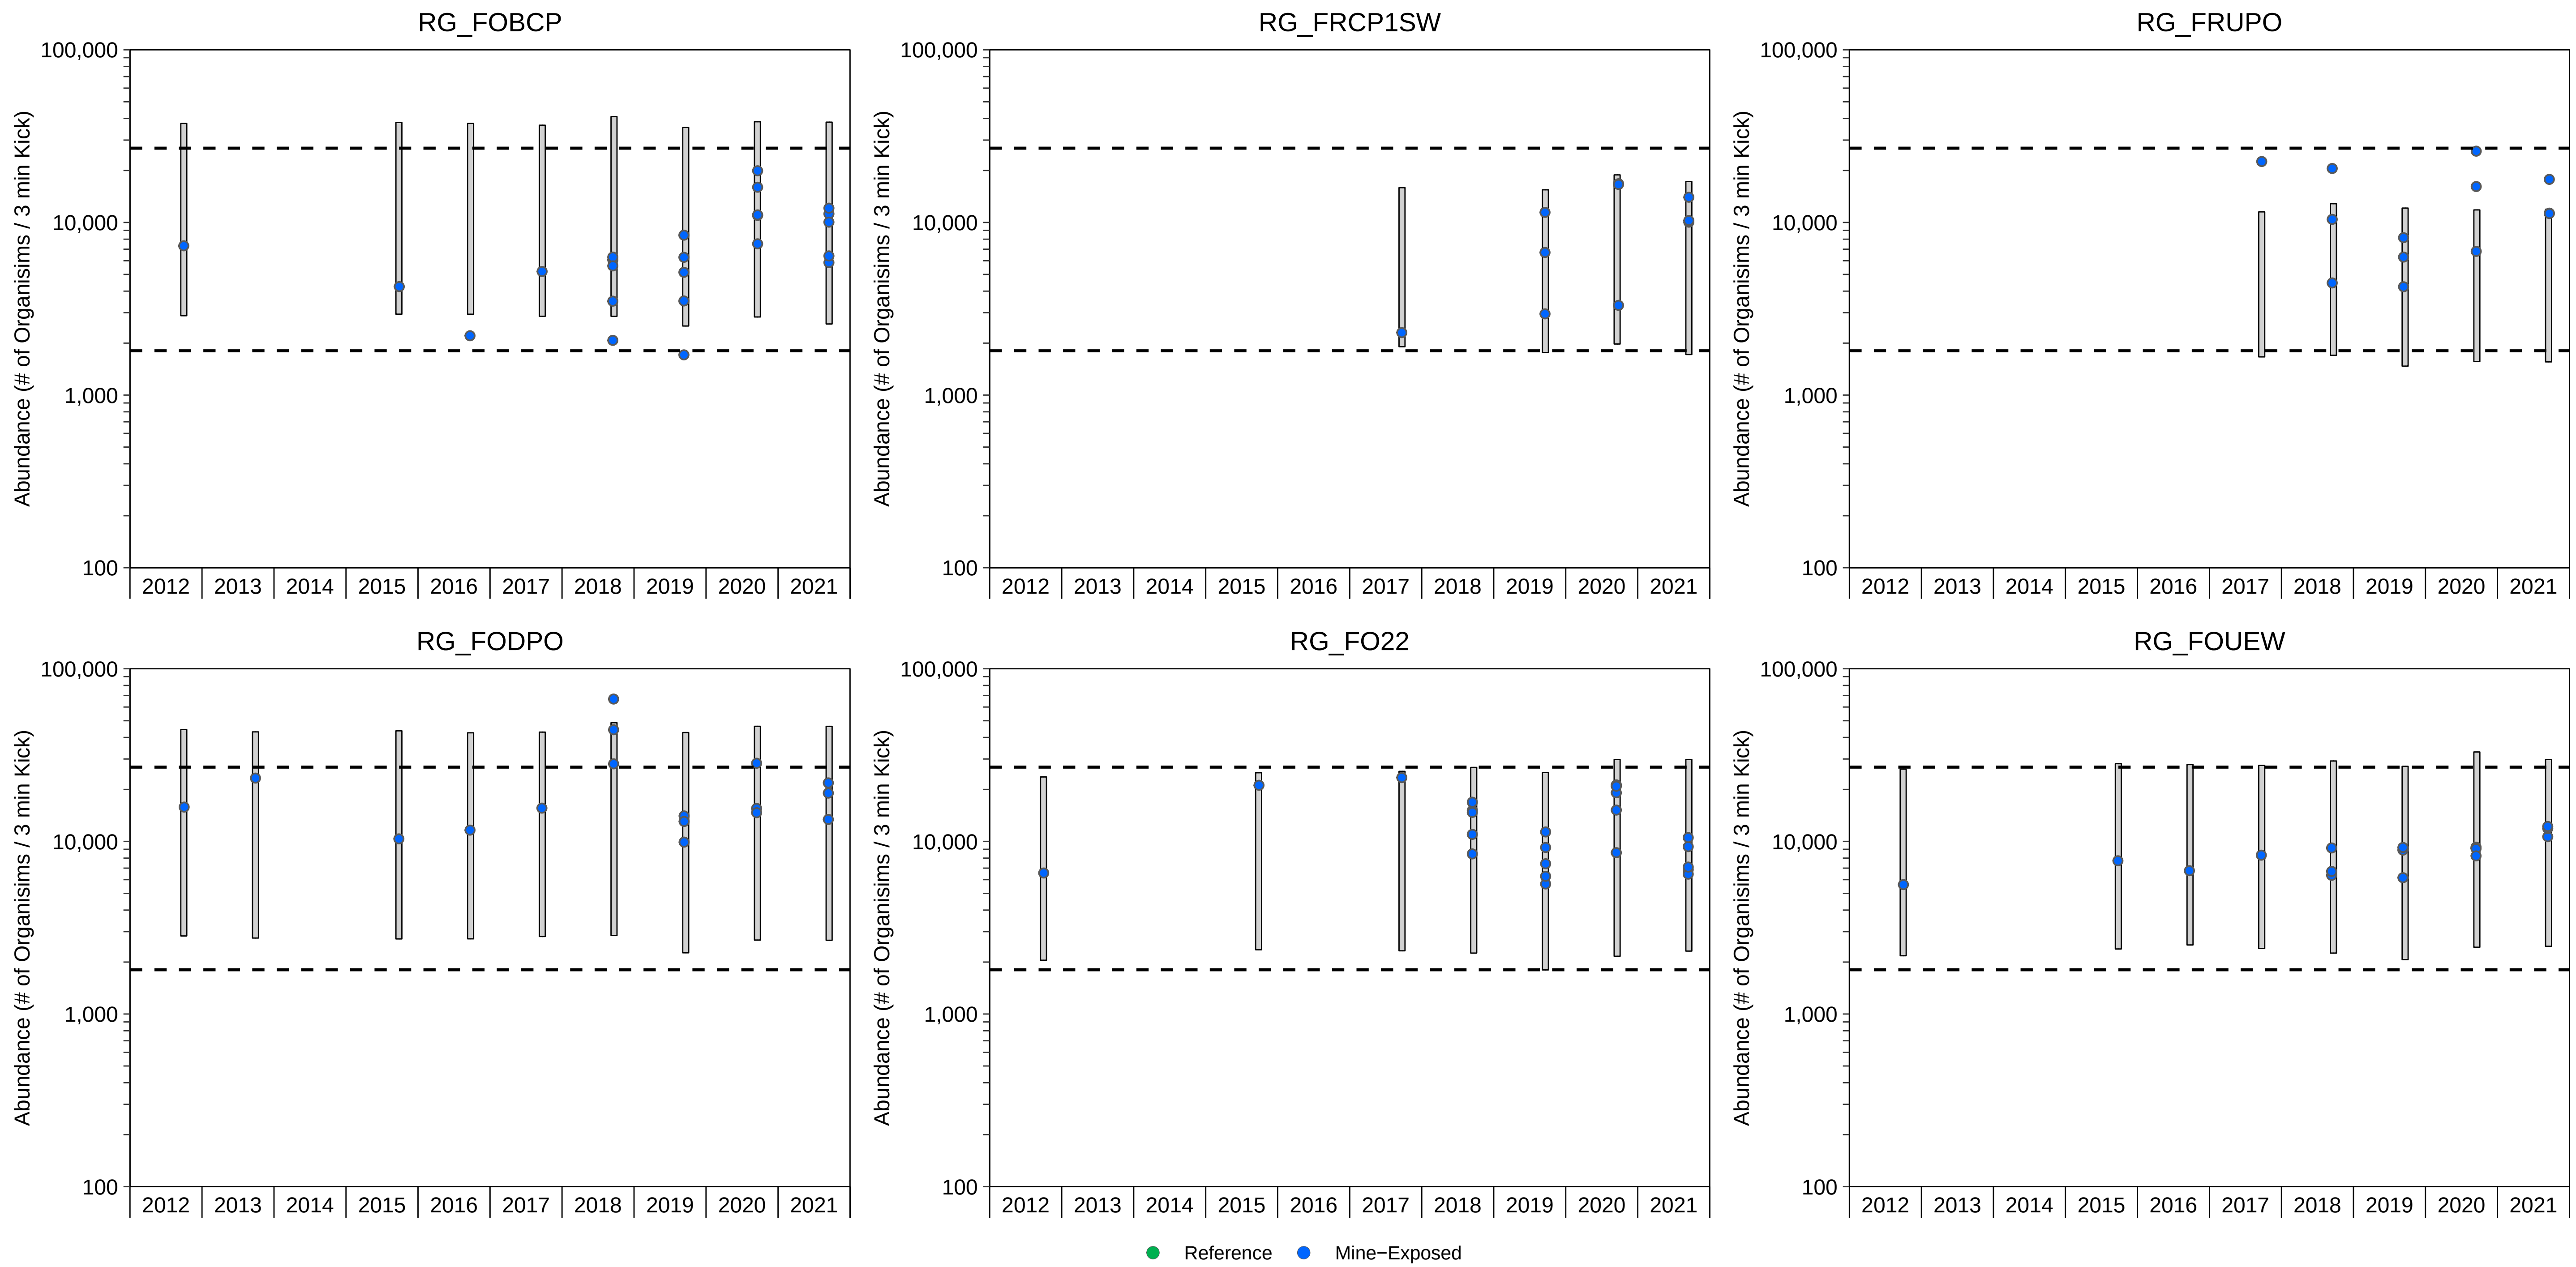

Figure E.7: Benthic Invertebrate Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

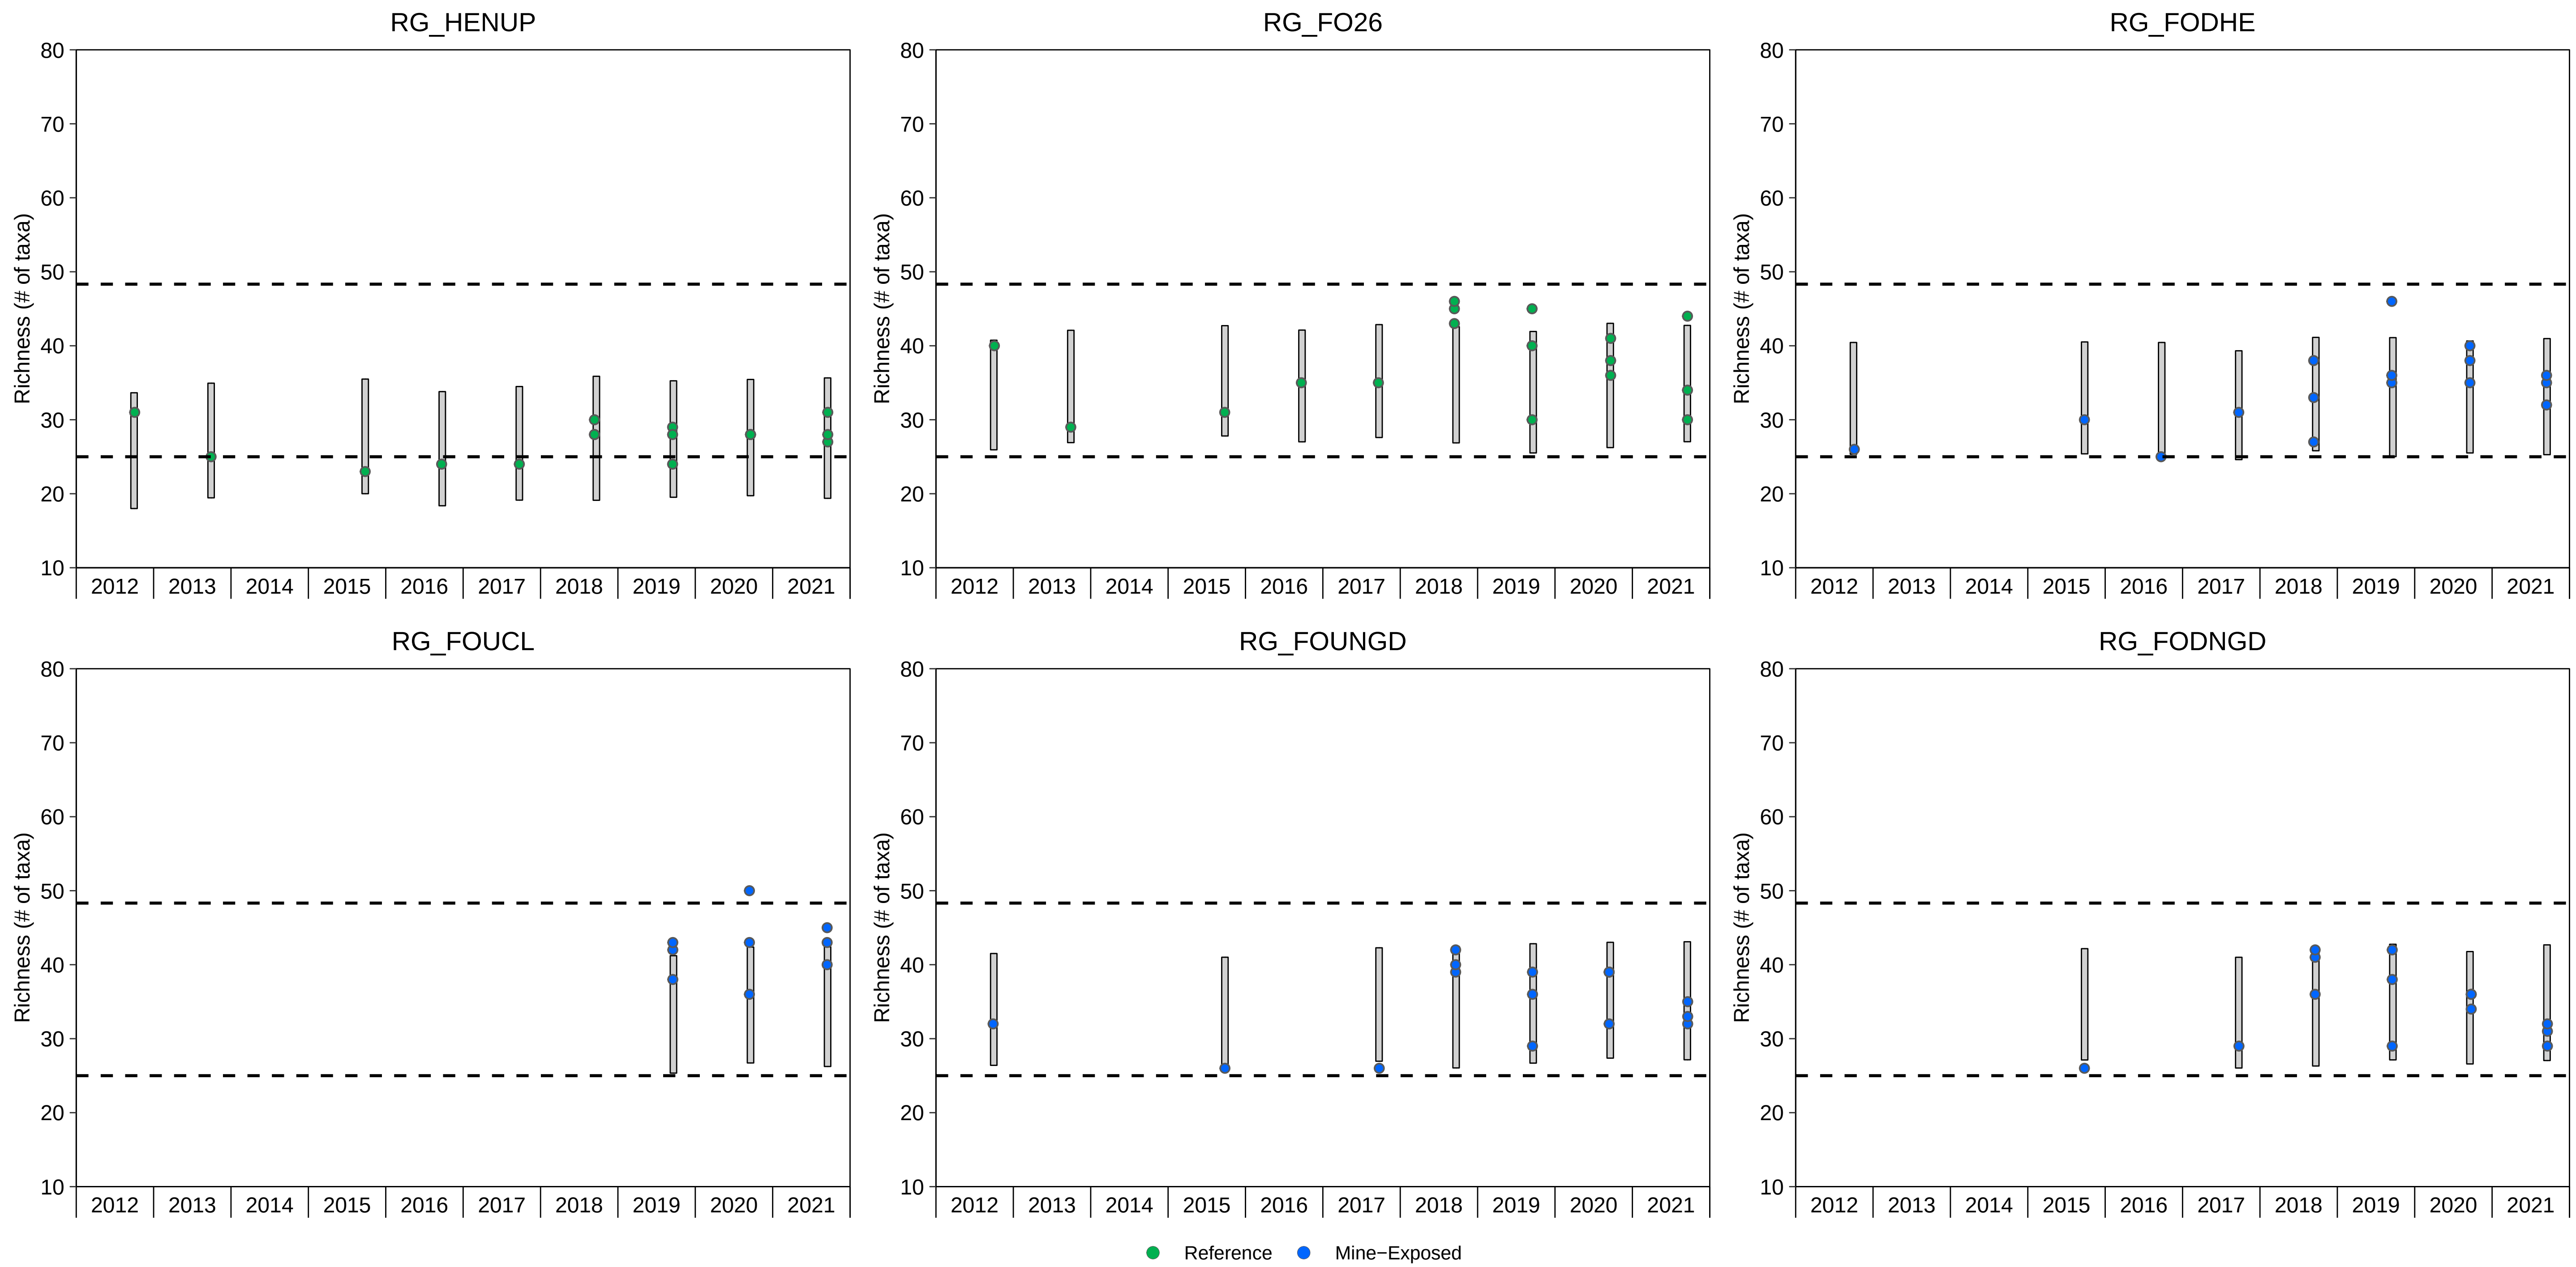

Figure E.8: Benthic Invertebrate Richness in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

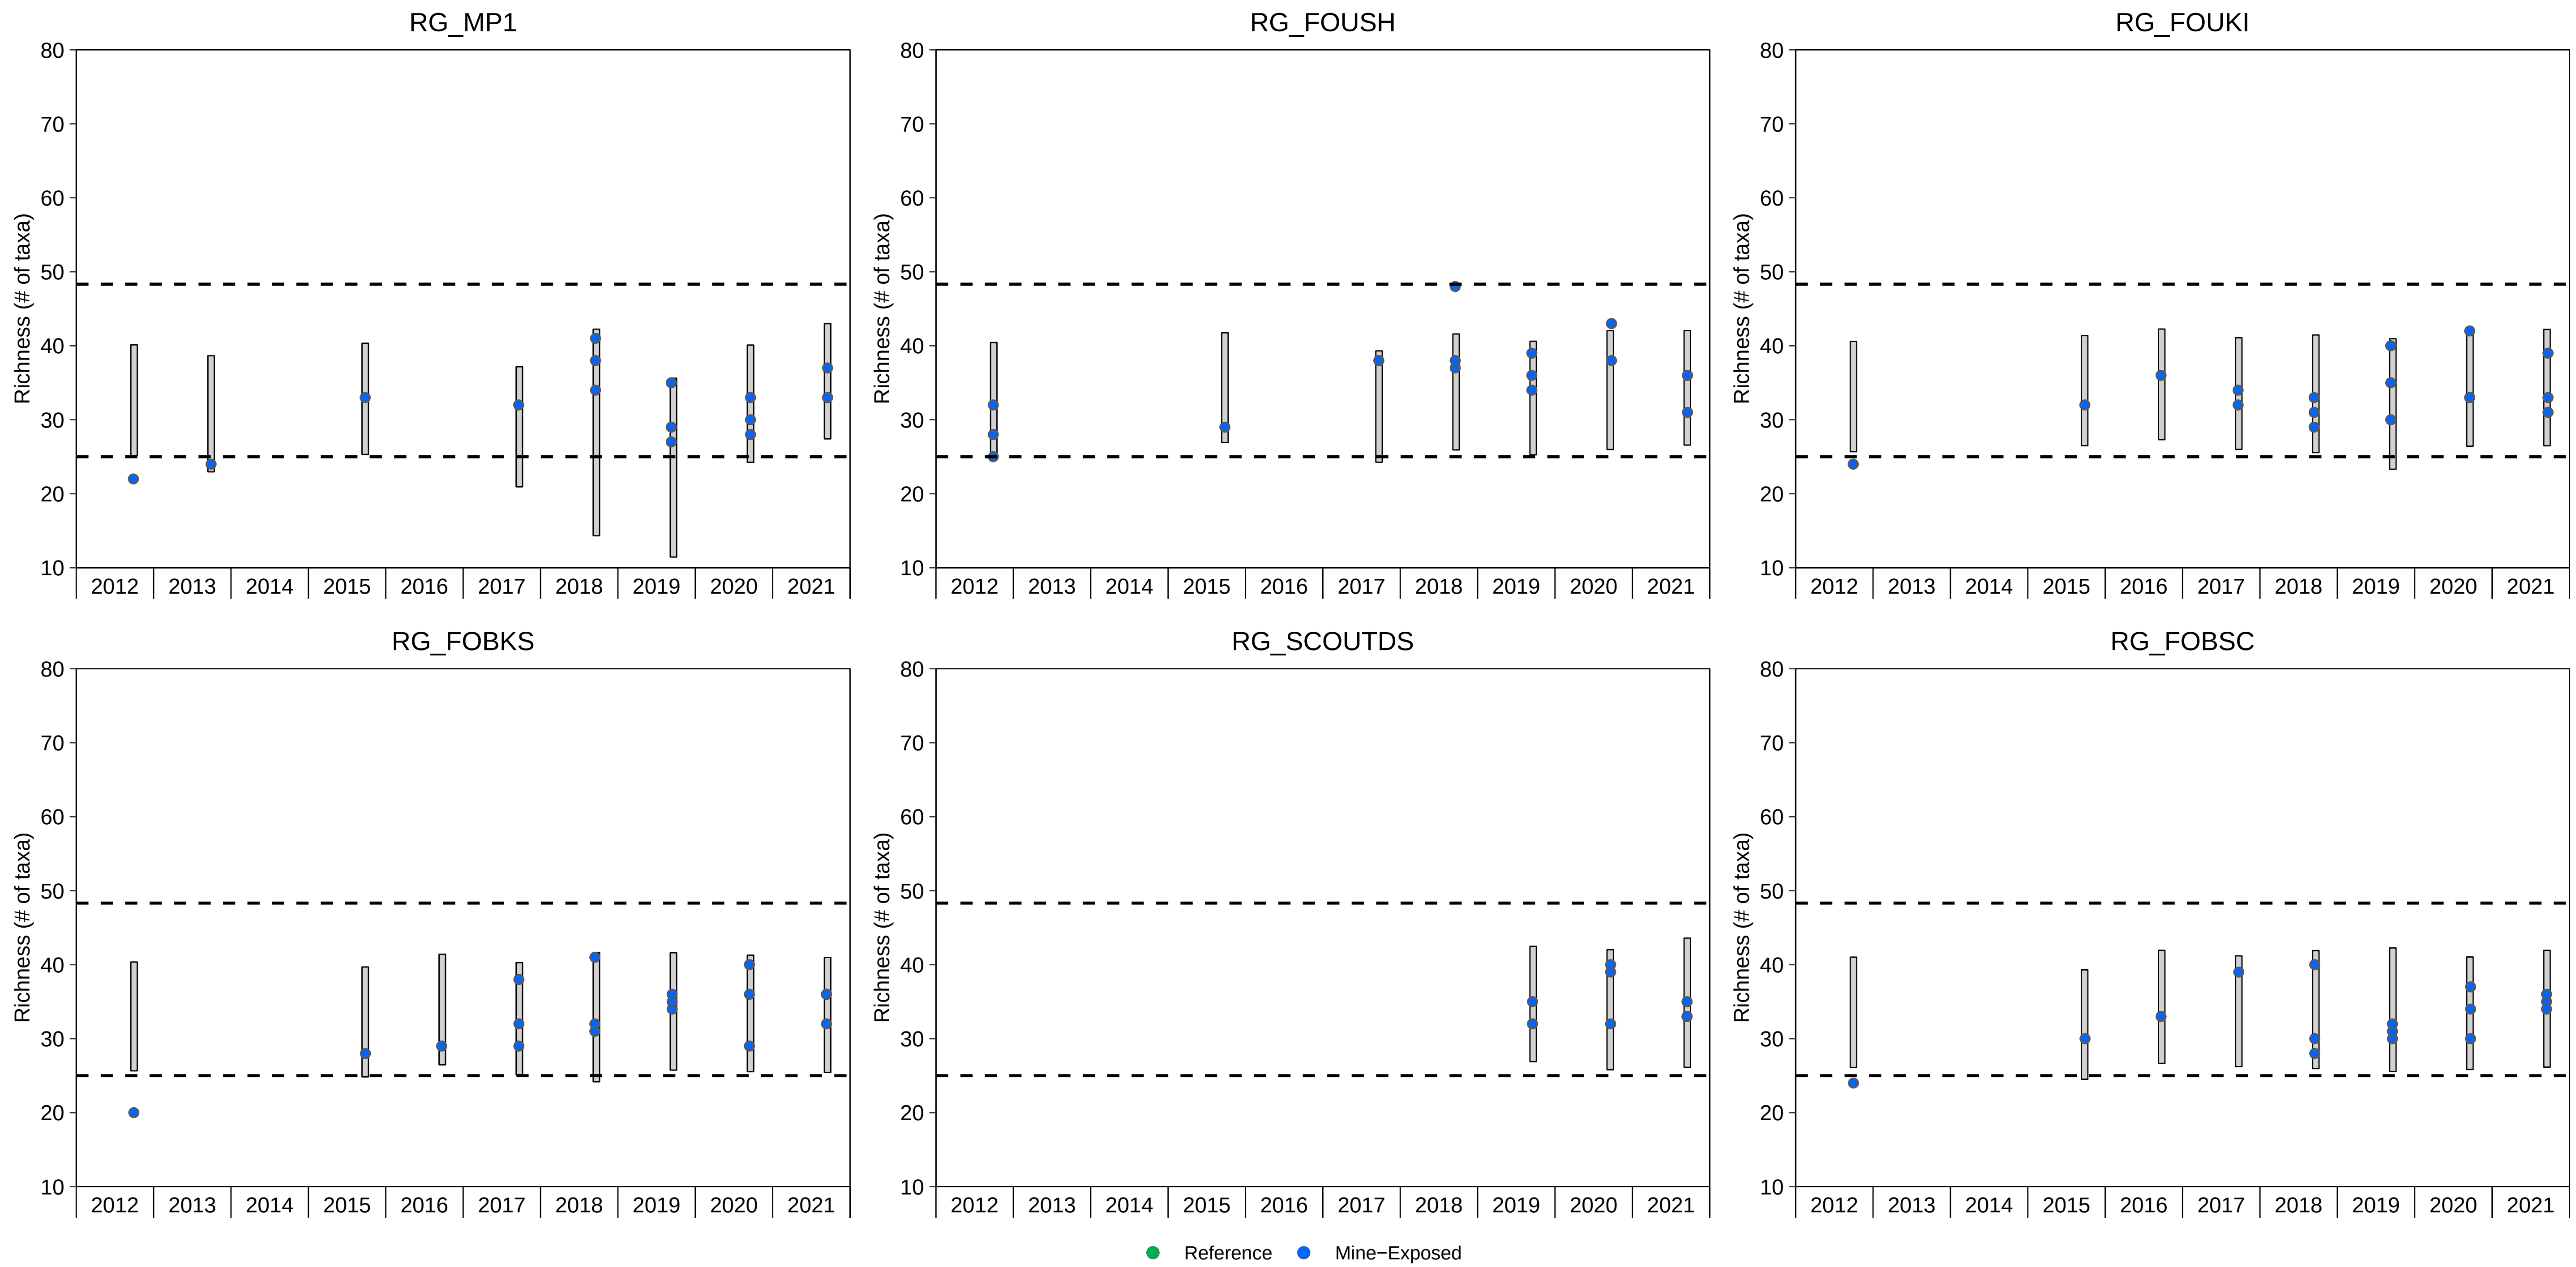

Figure E.8: Benthic Invertebrate Richness in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

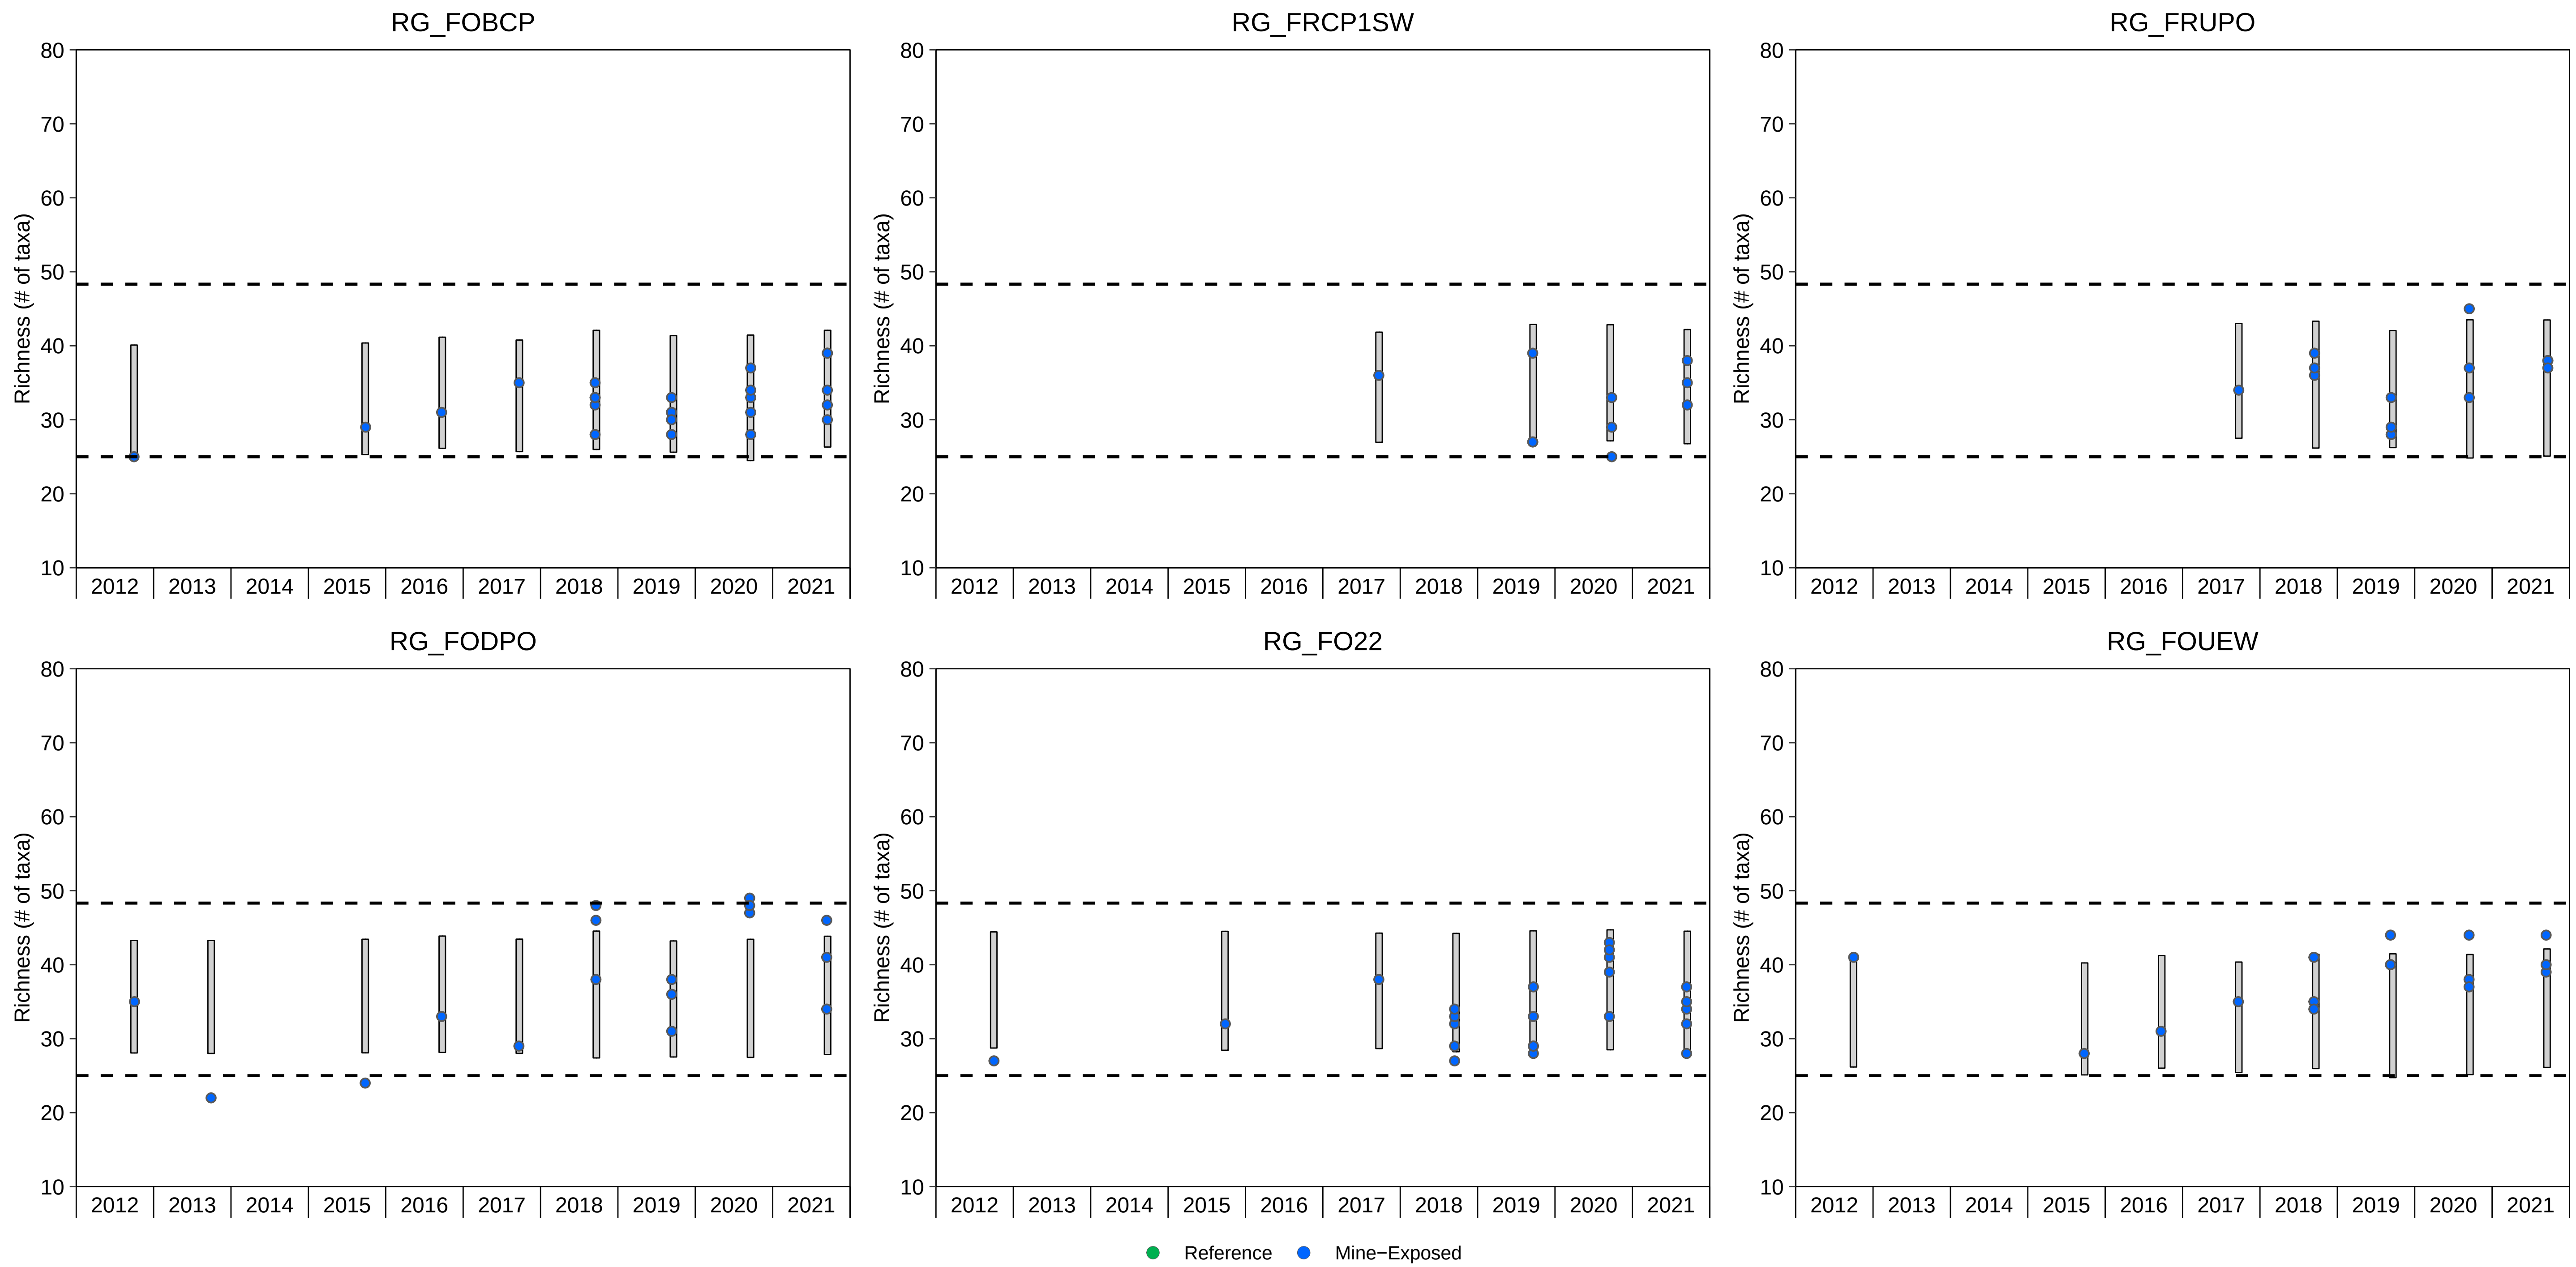

Figure E.8: Benthic Invertebrate Richness in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

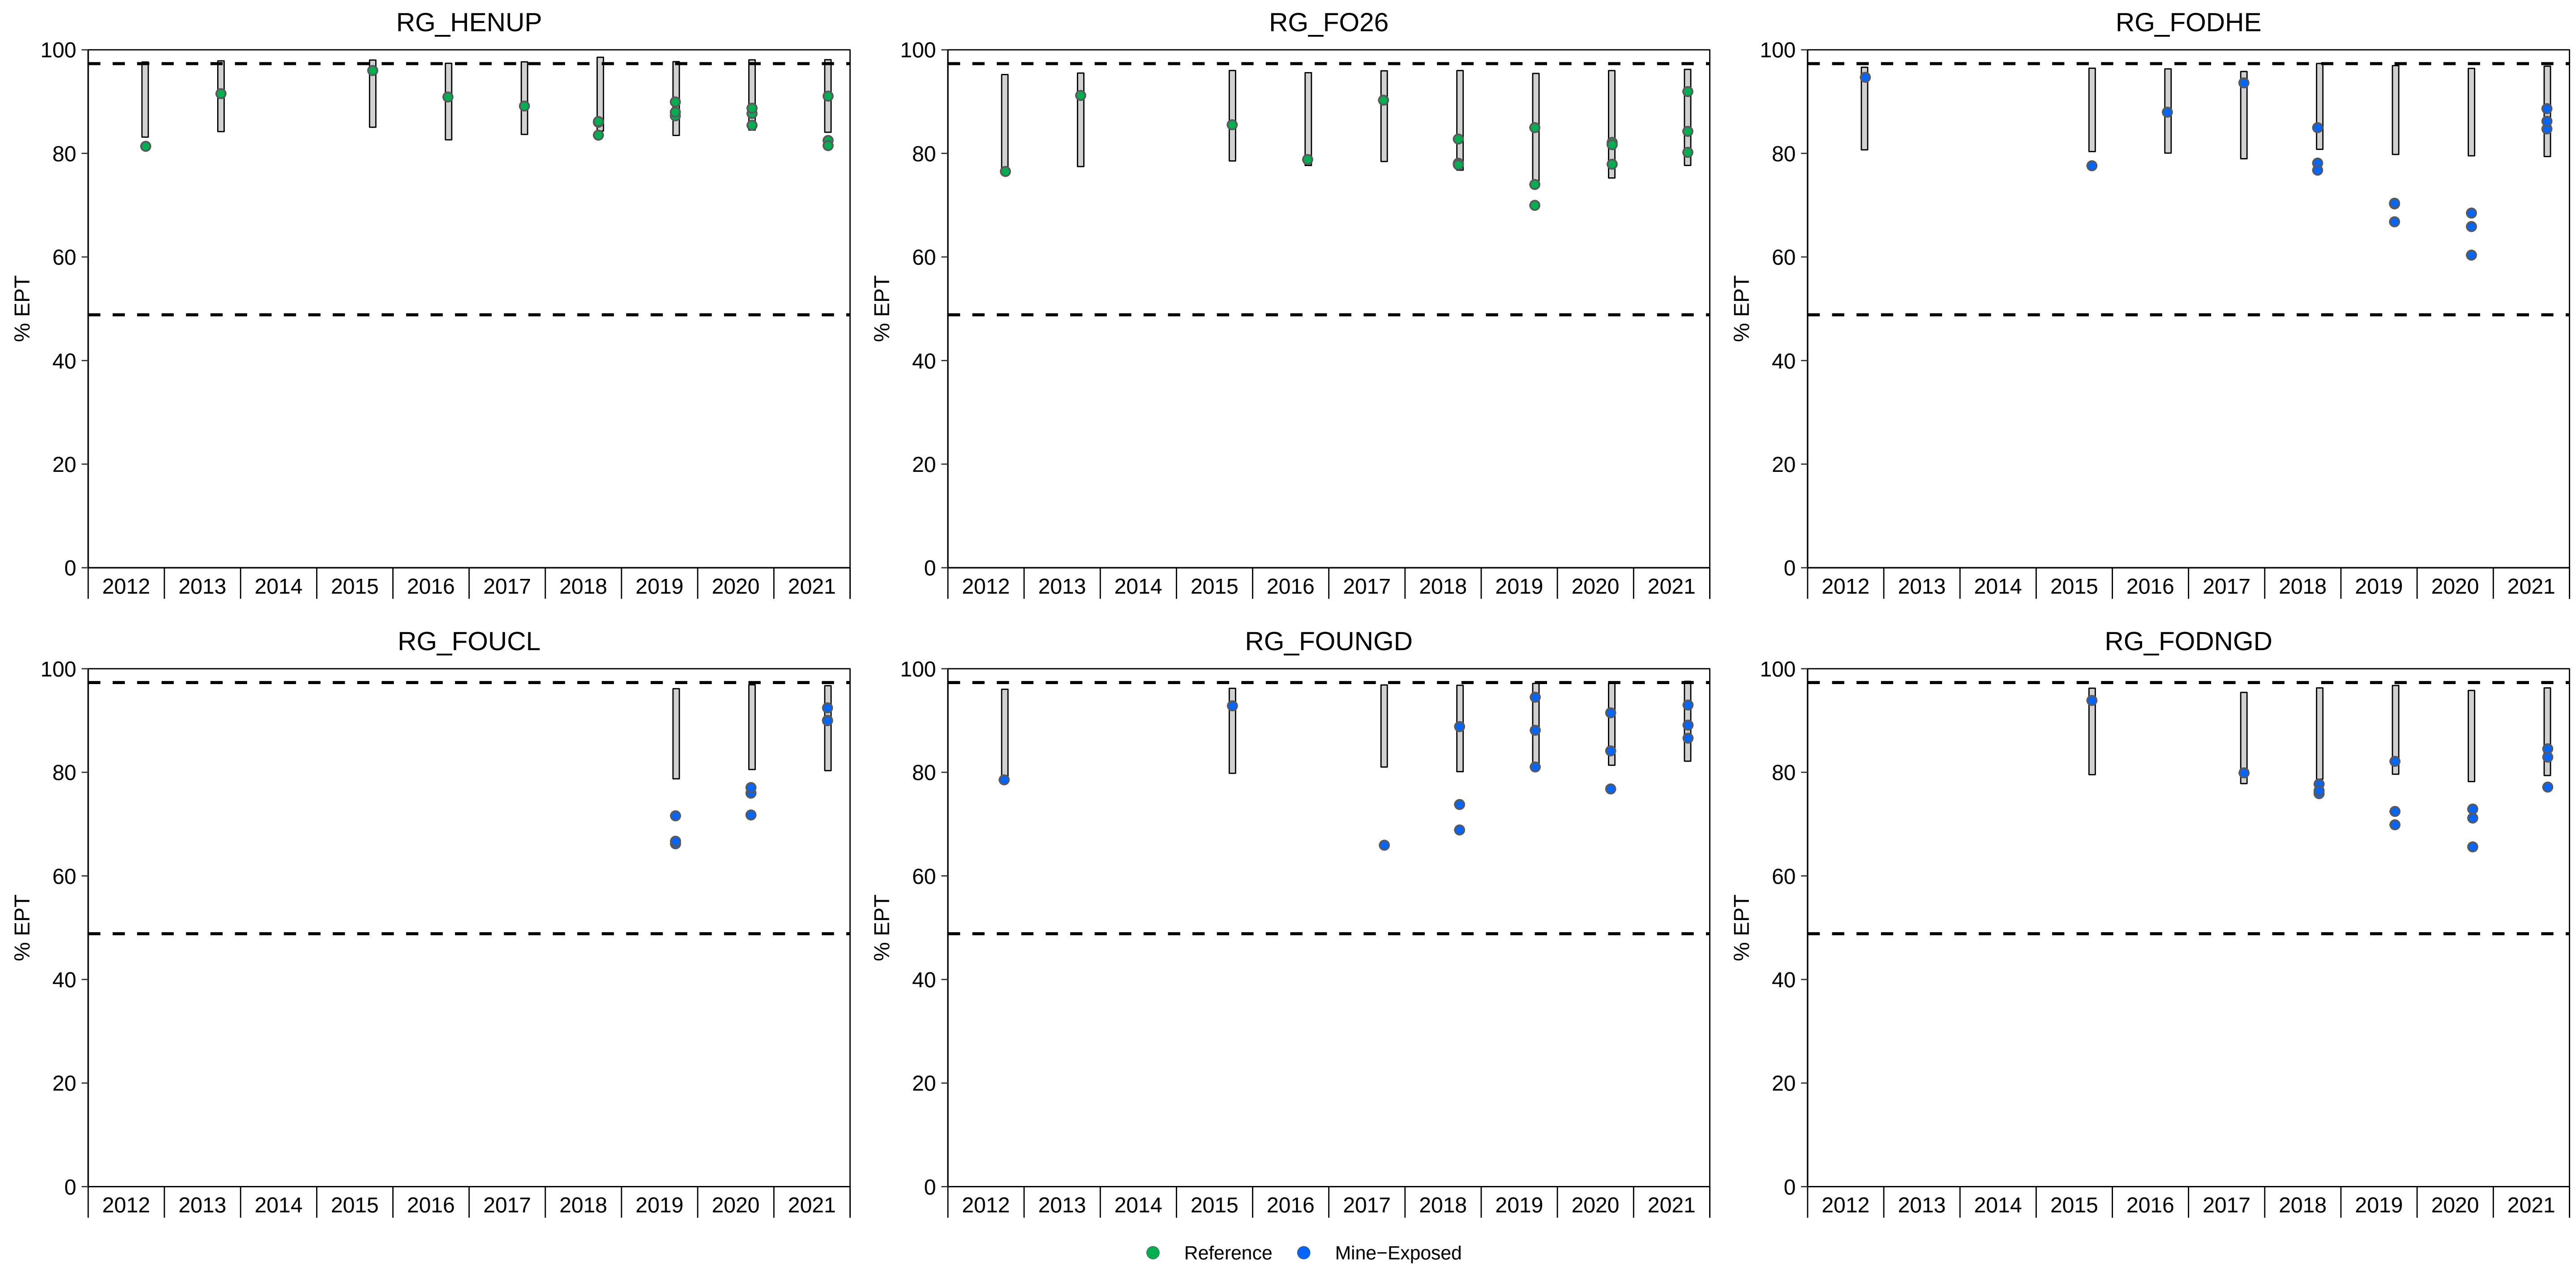

Figure E.9: Benthic Invertebrate % EPT in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

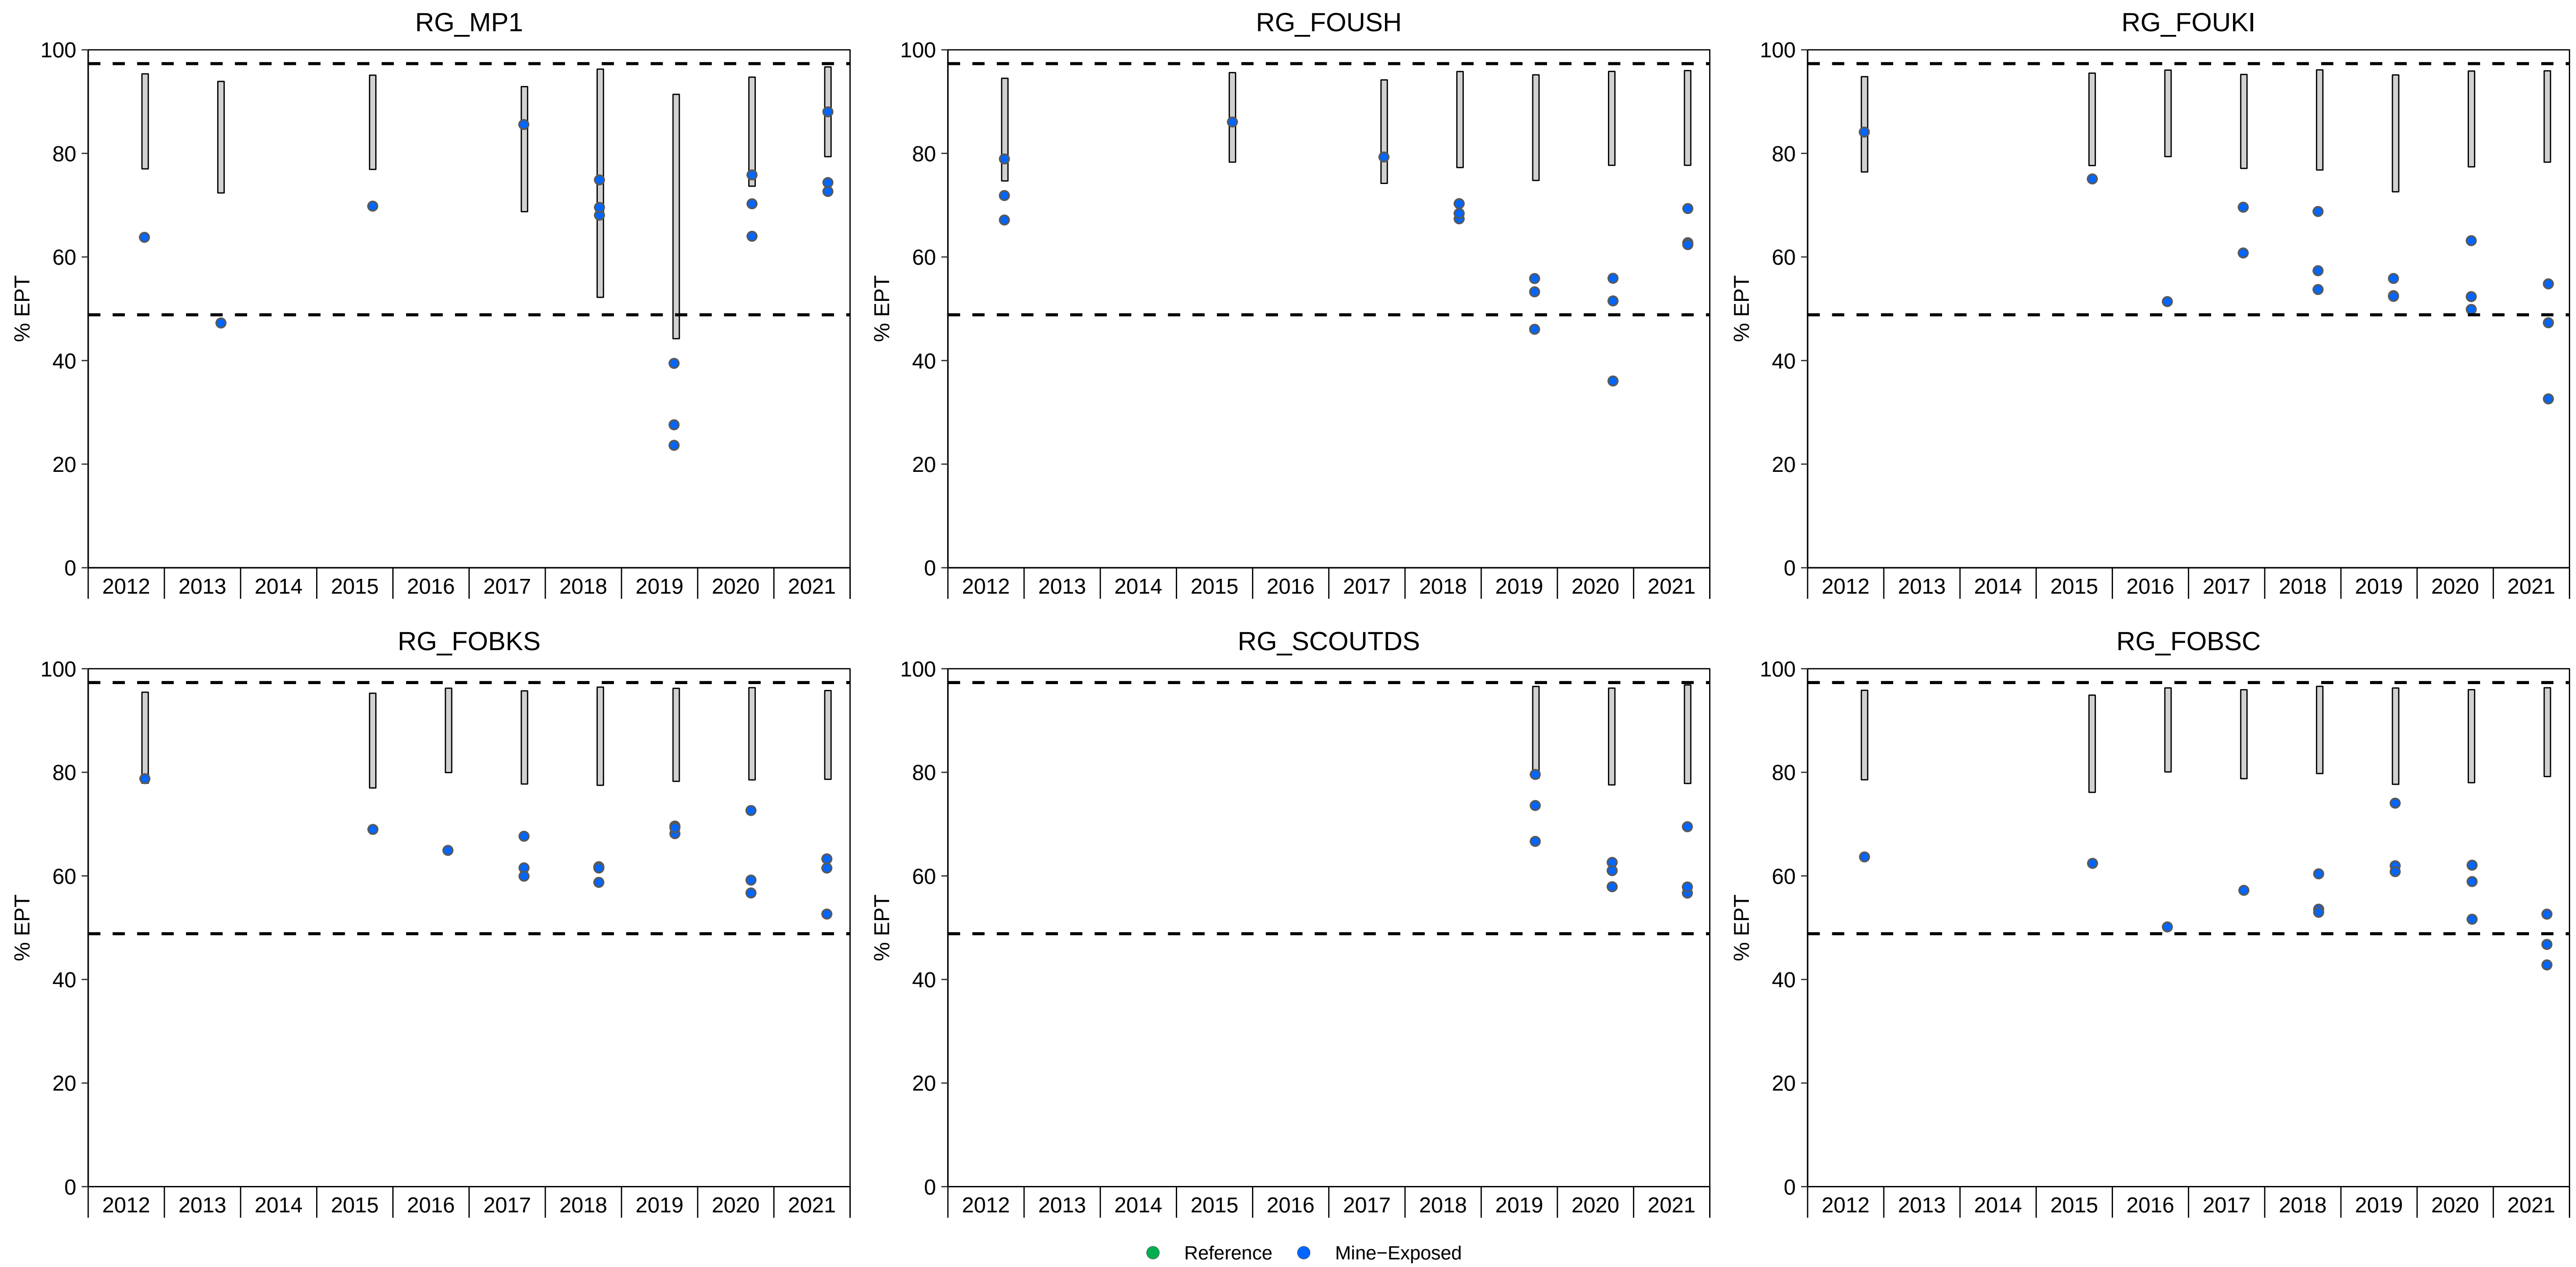

Figure E.9: Benthic Invertebrate % EPT in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

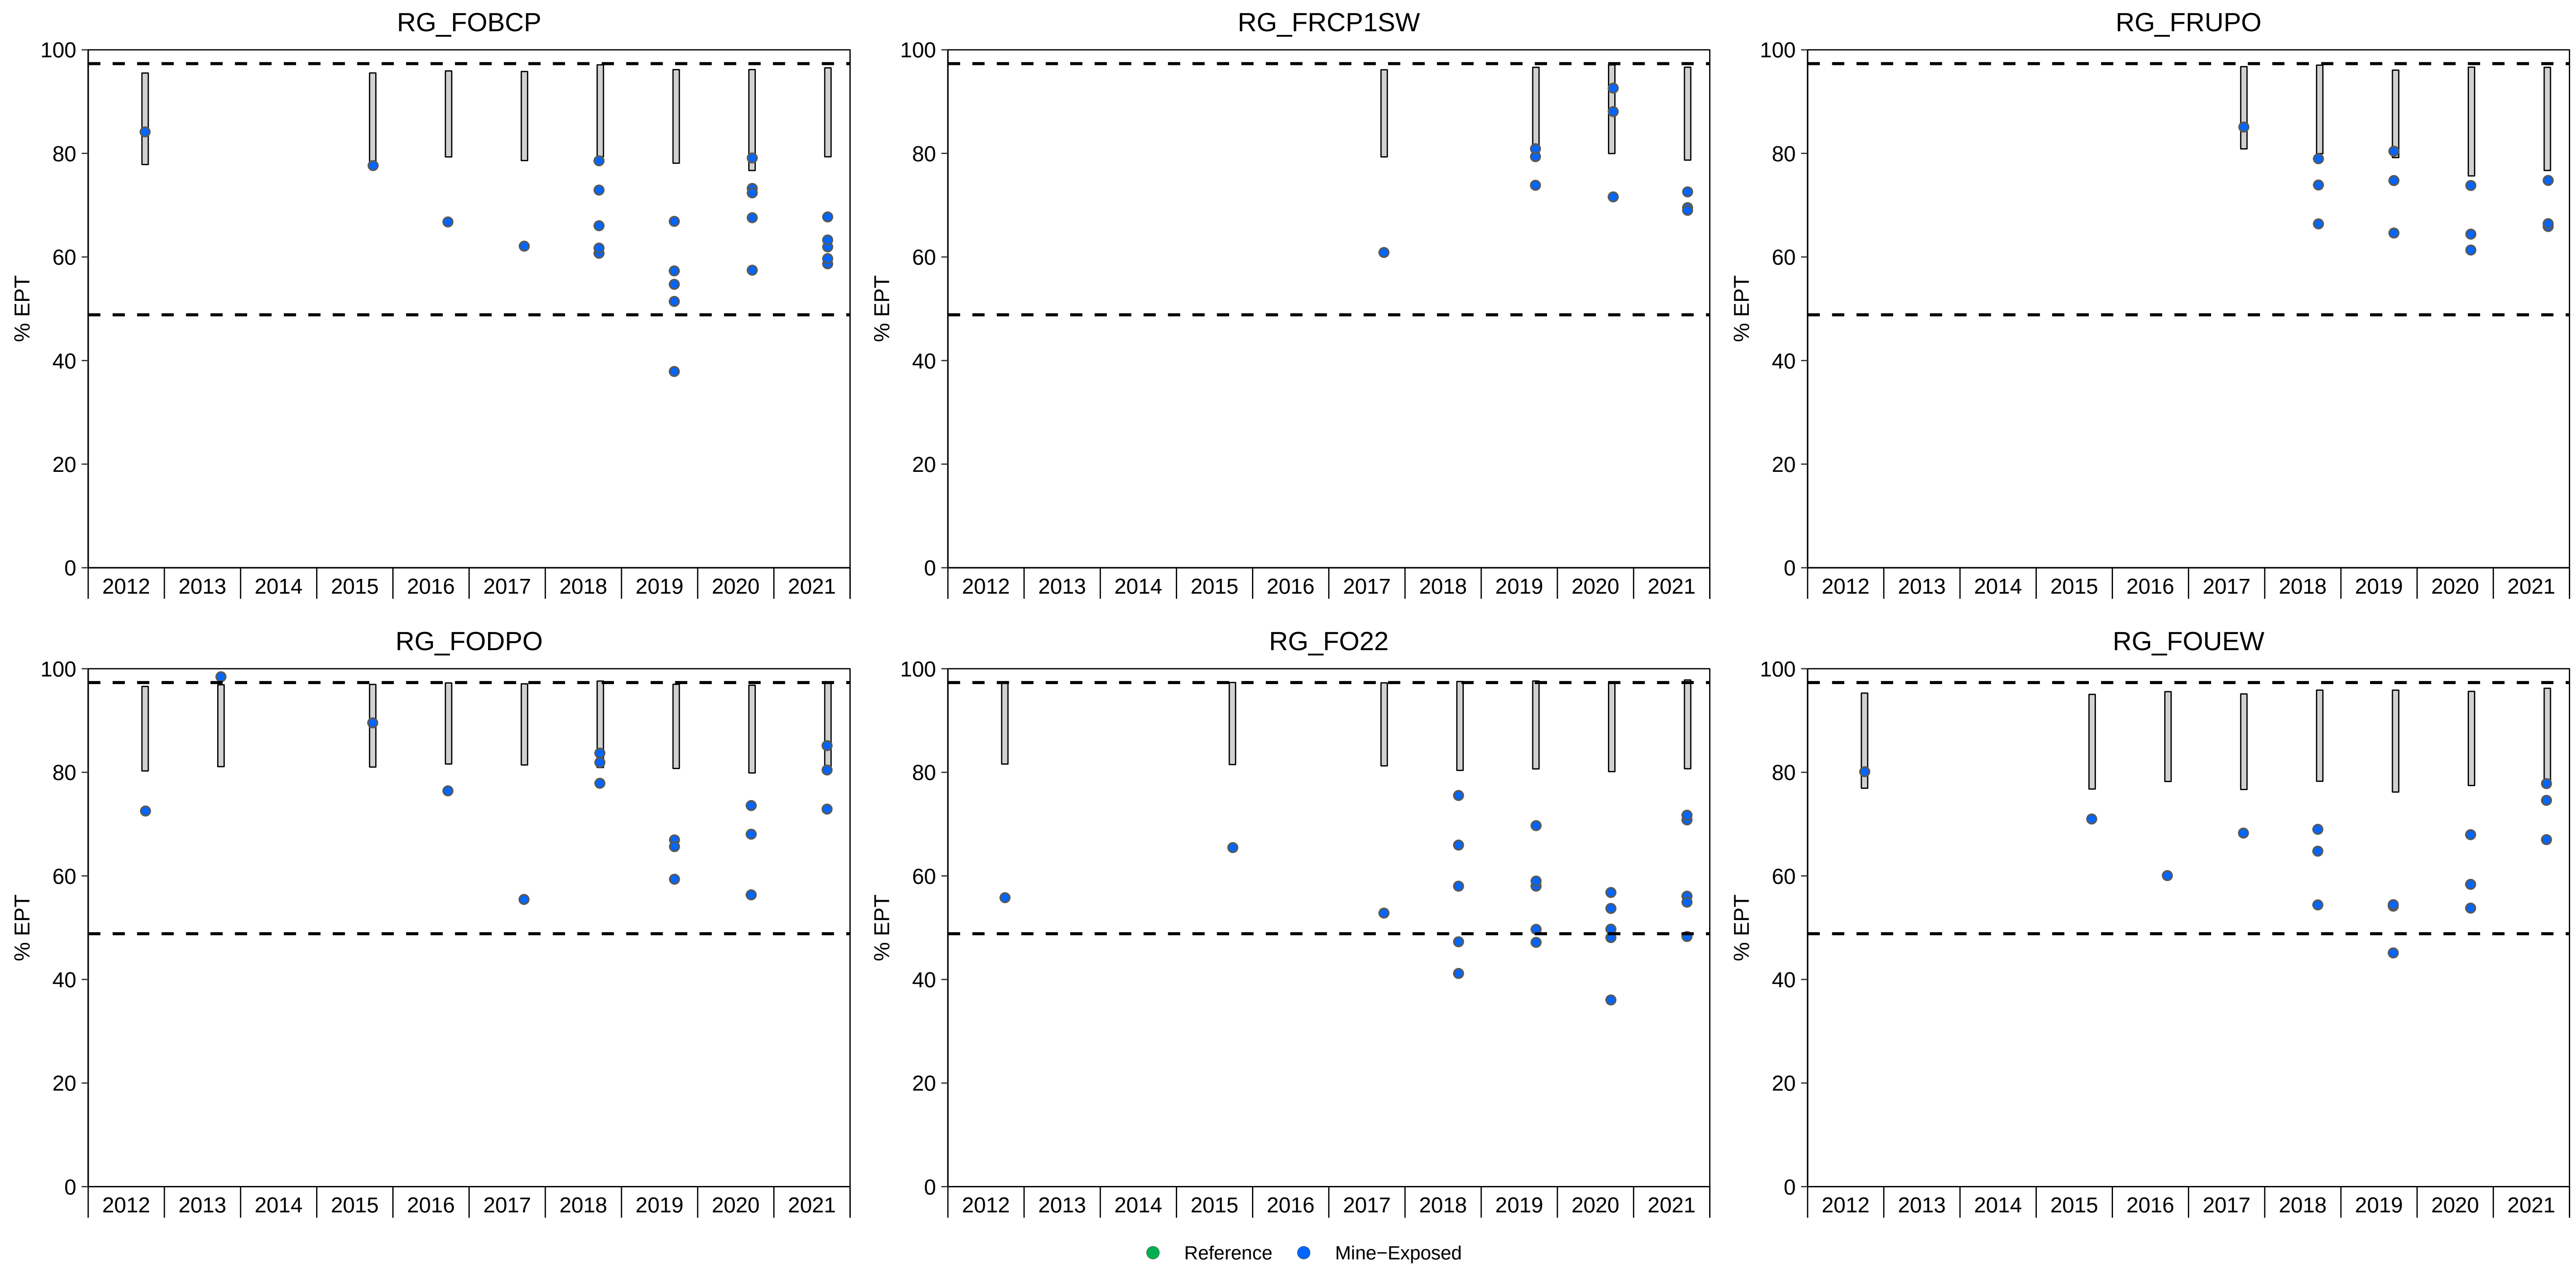

Figure E.9: Benthic Invertebrate % EPT in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

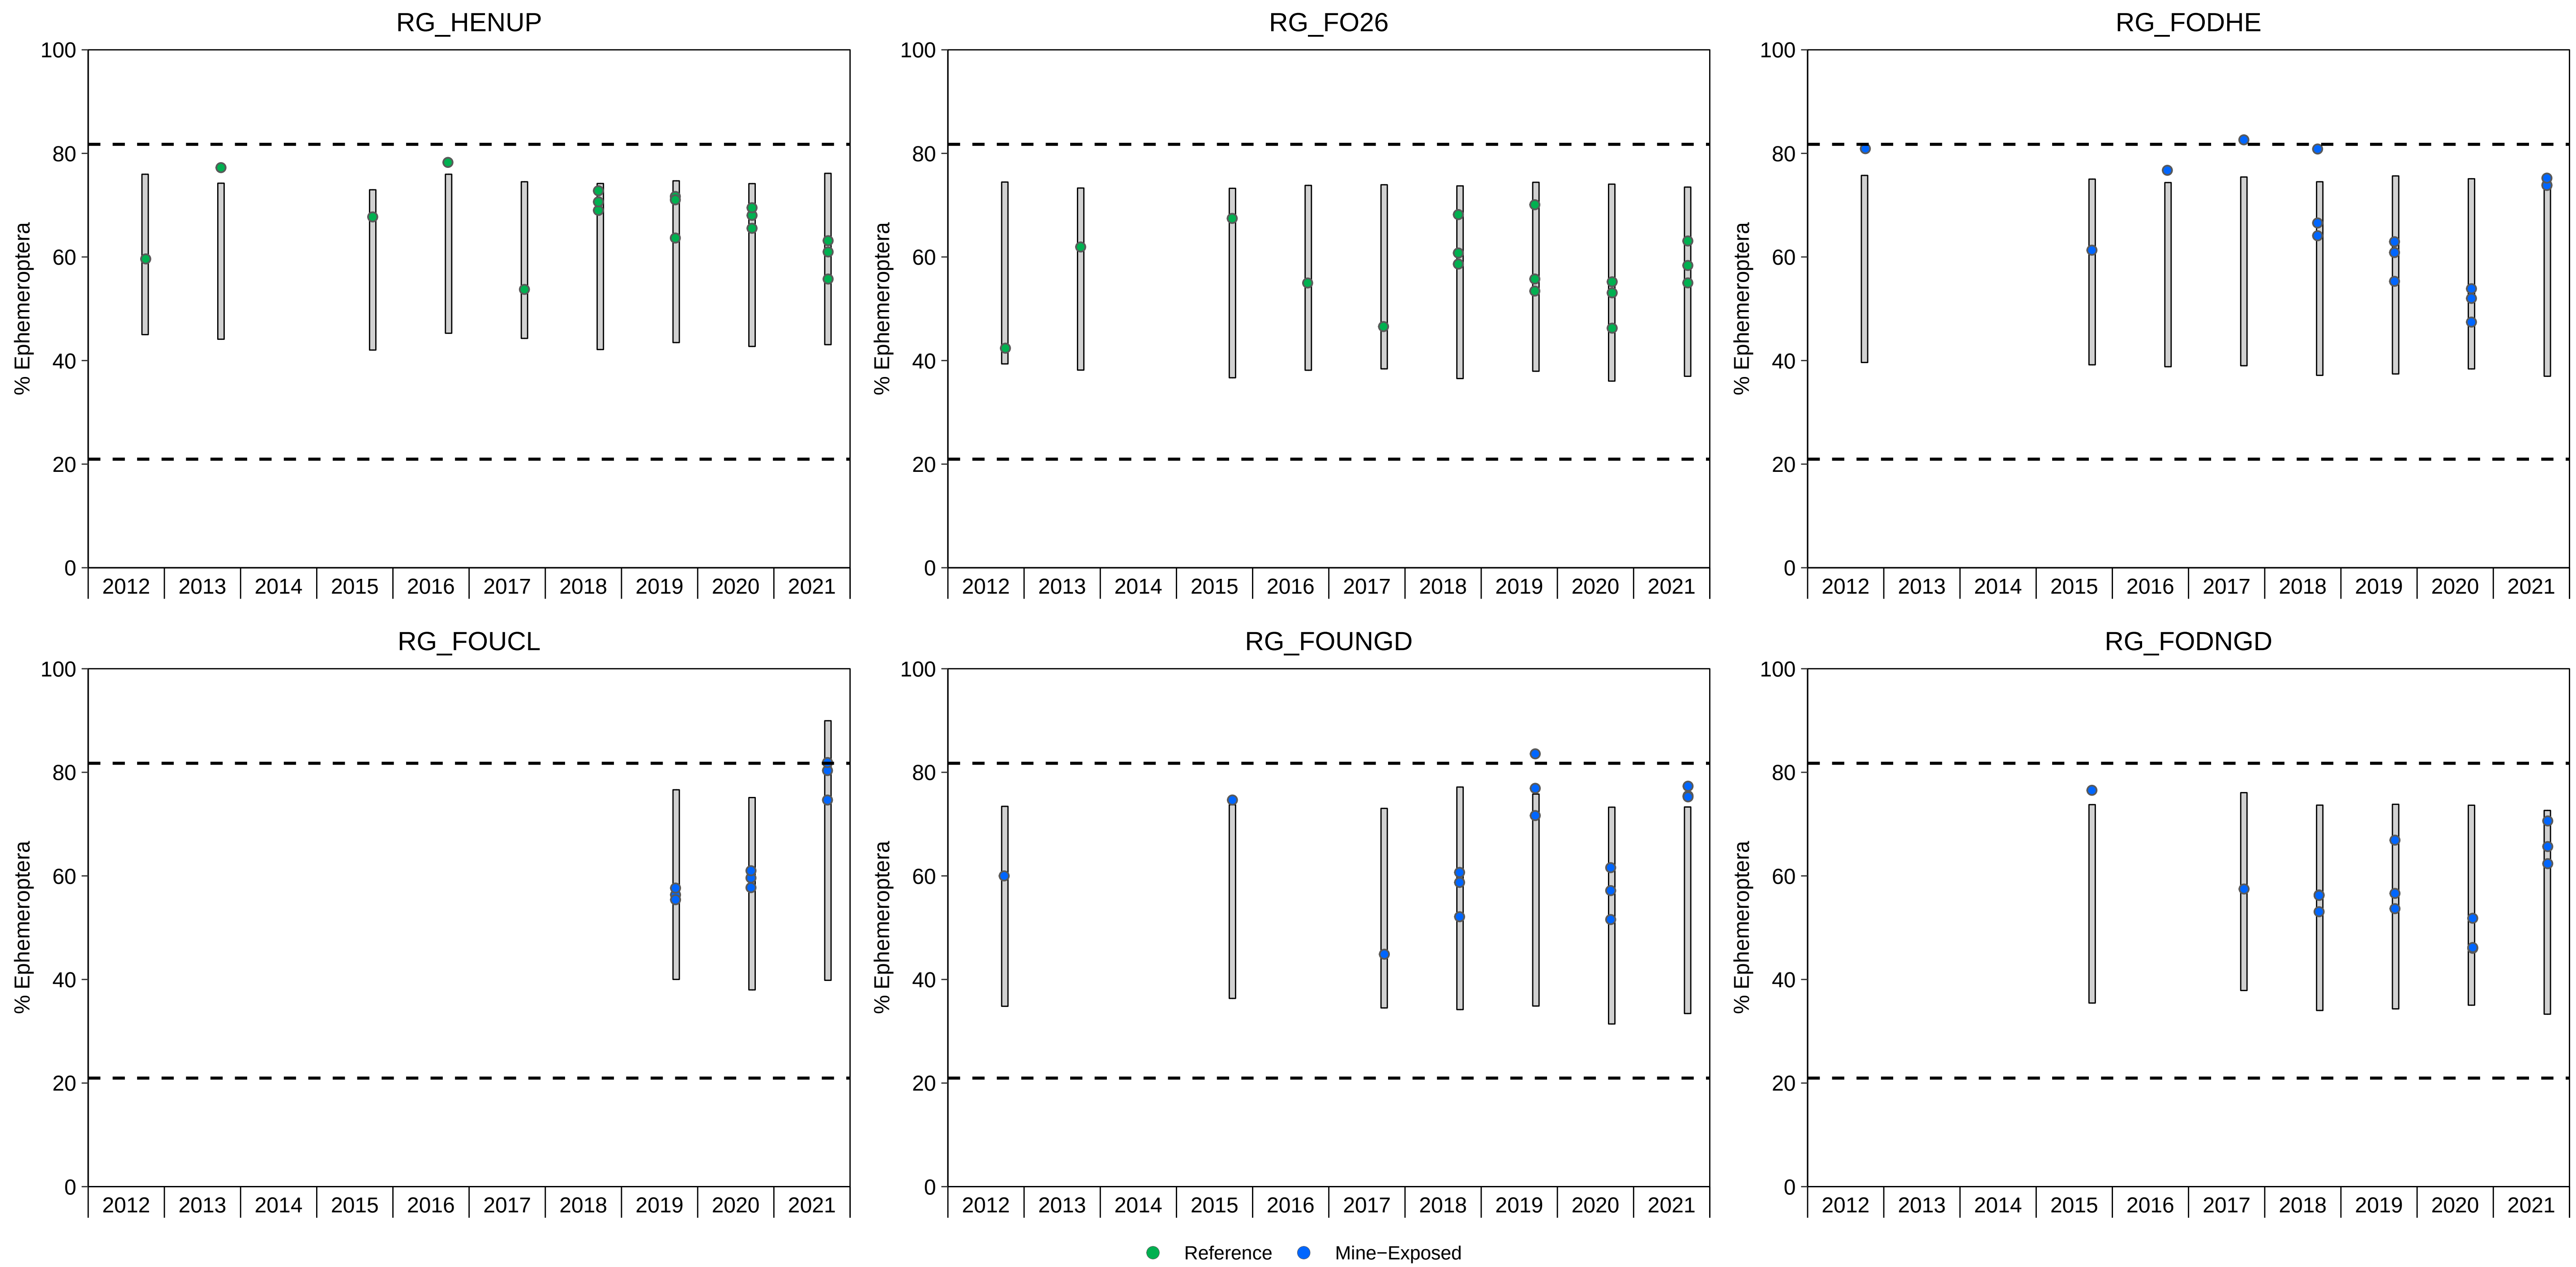

Figure E.10: Benthic Invertebrate % Ephemeroptera in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

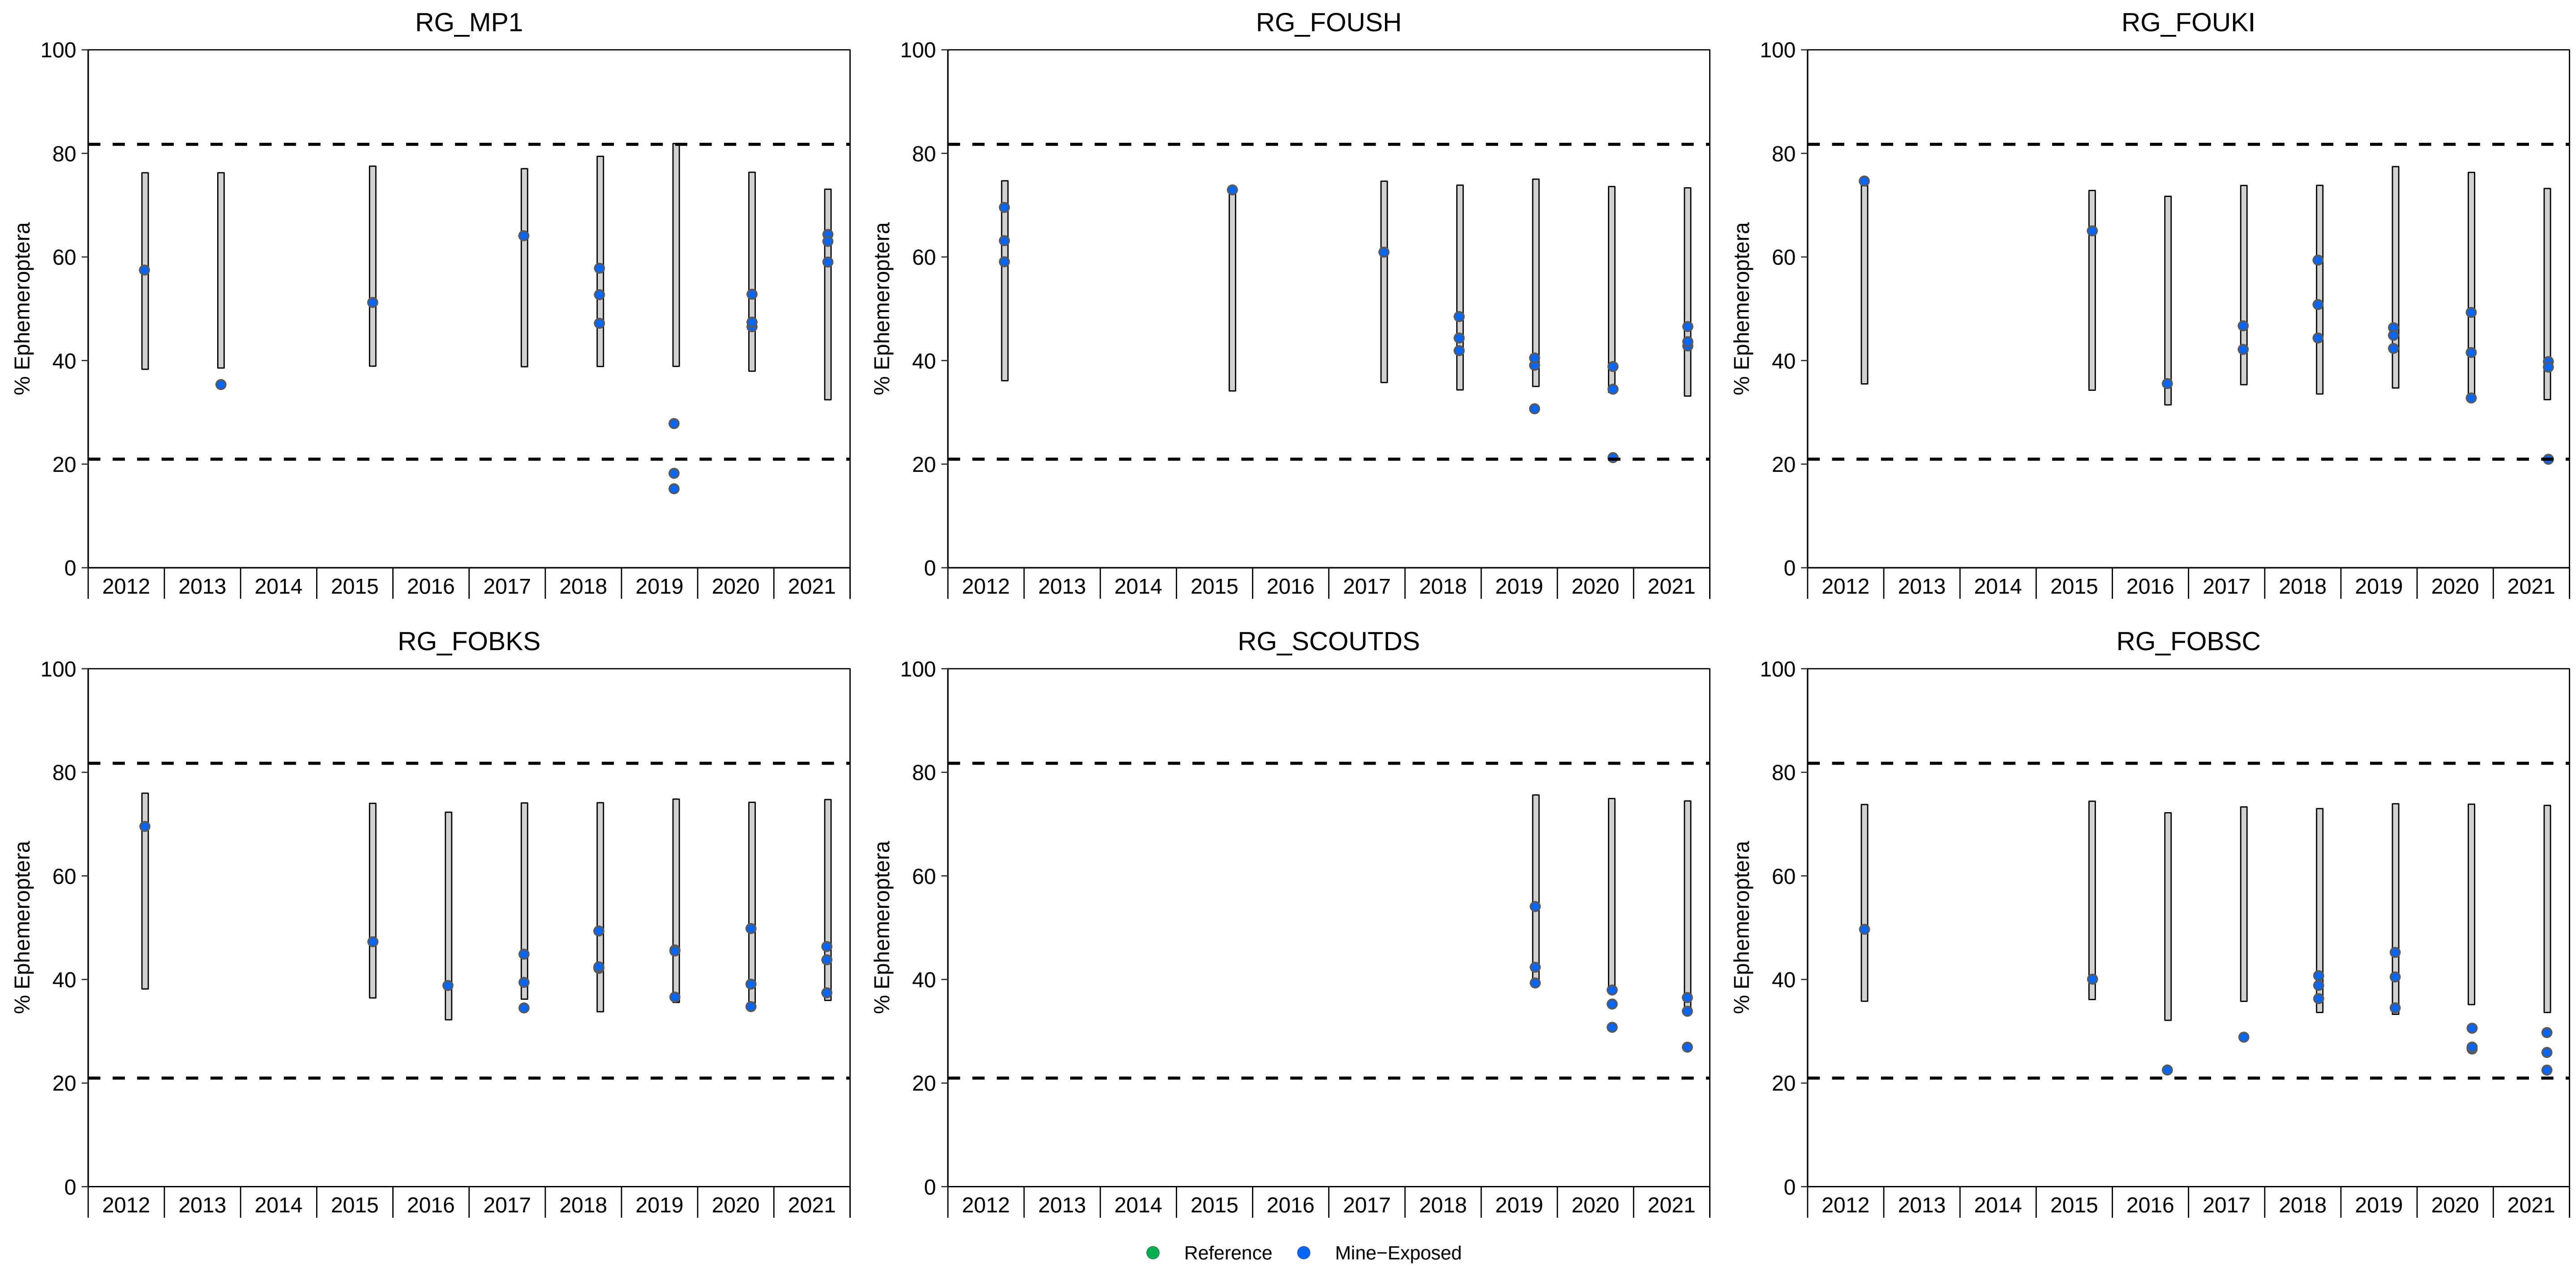

Figure E.10: Benthic Invertebrate % Ephemeroptera in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

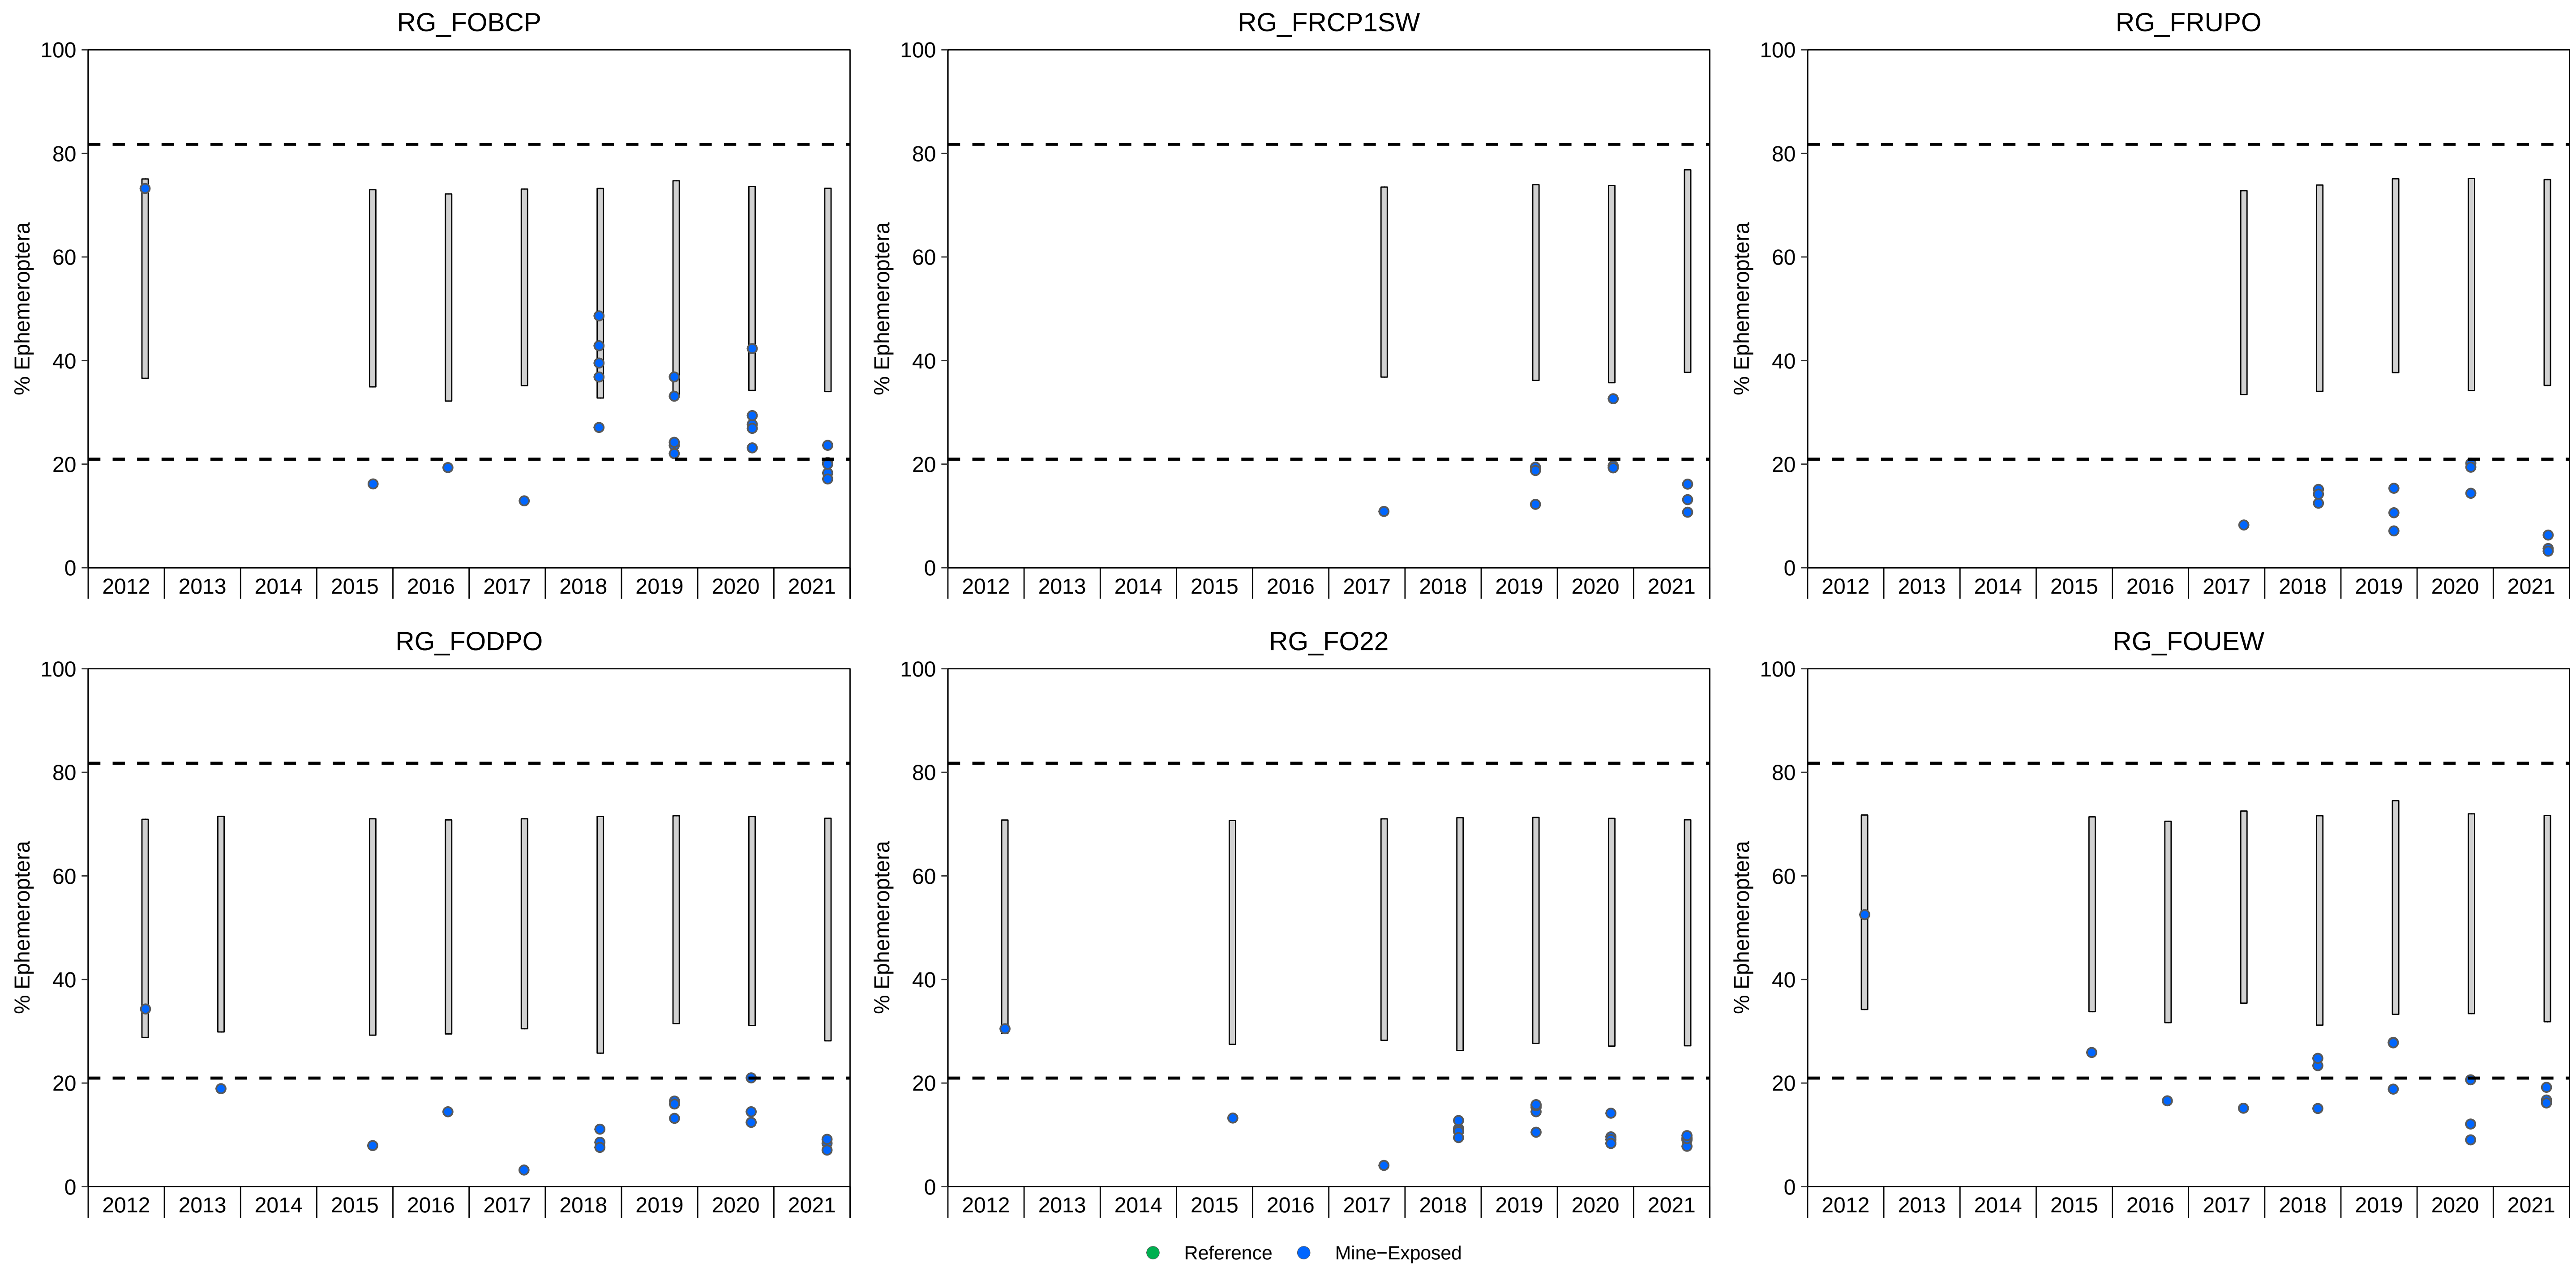

Figure E.10: Benthic Invertebrate % Ephemeroptera in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

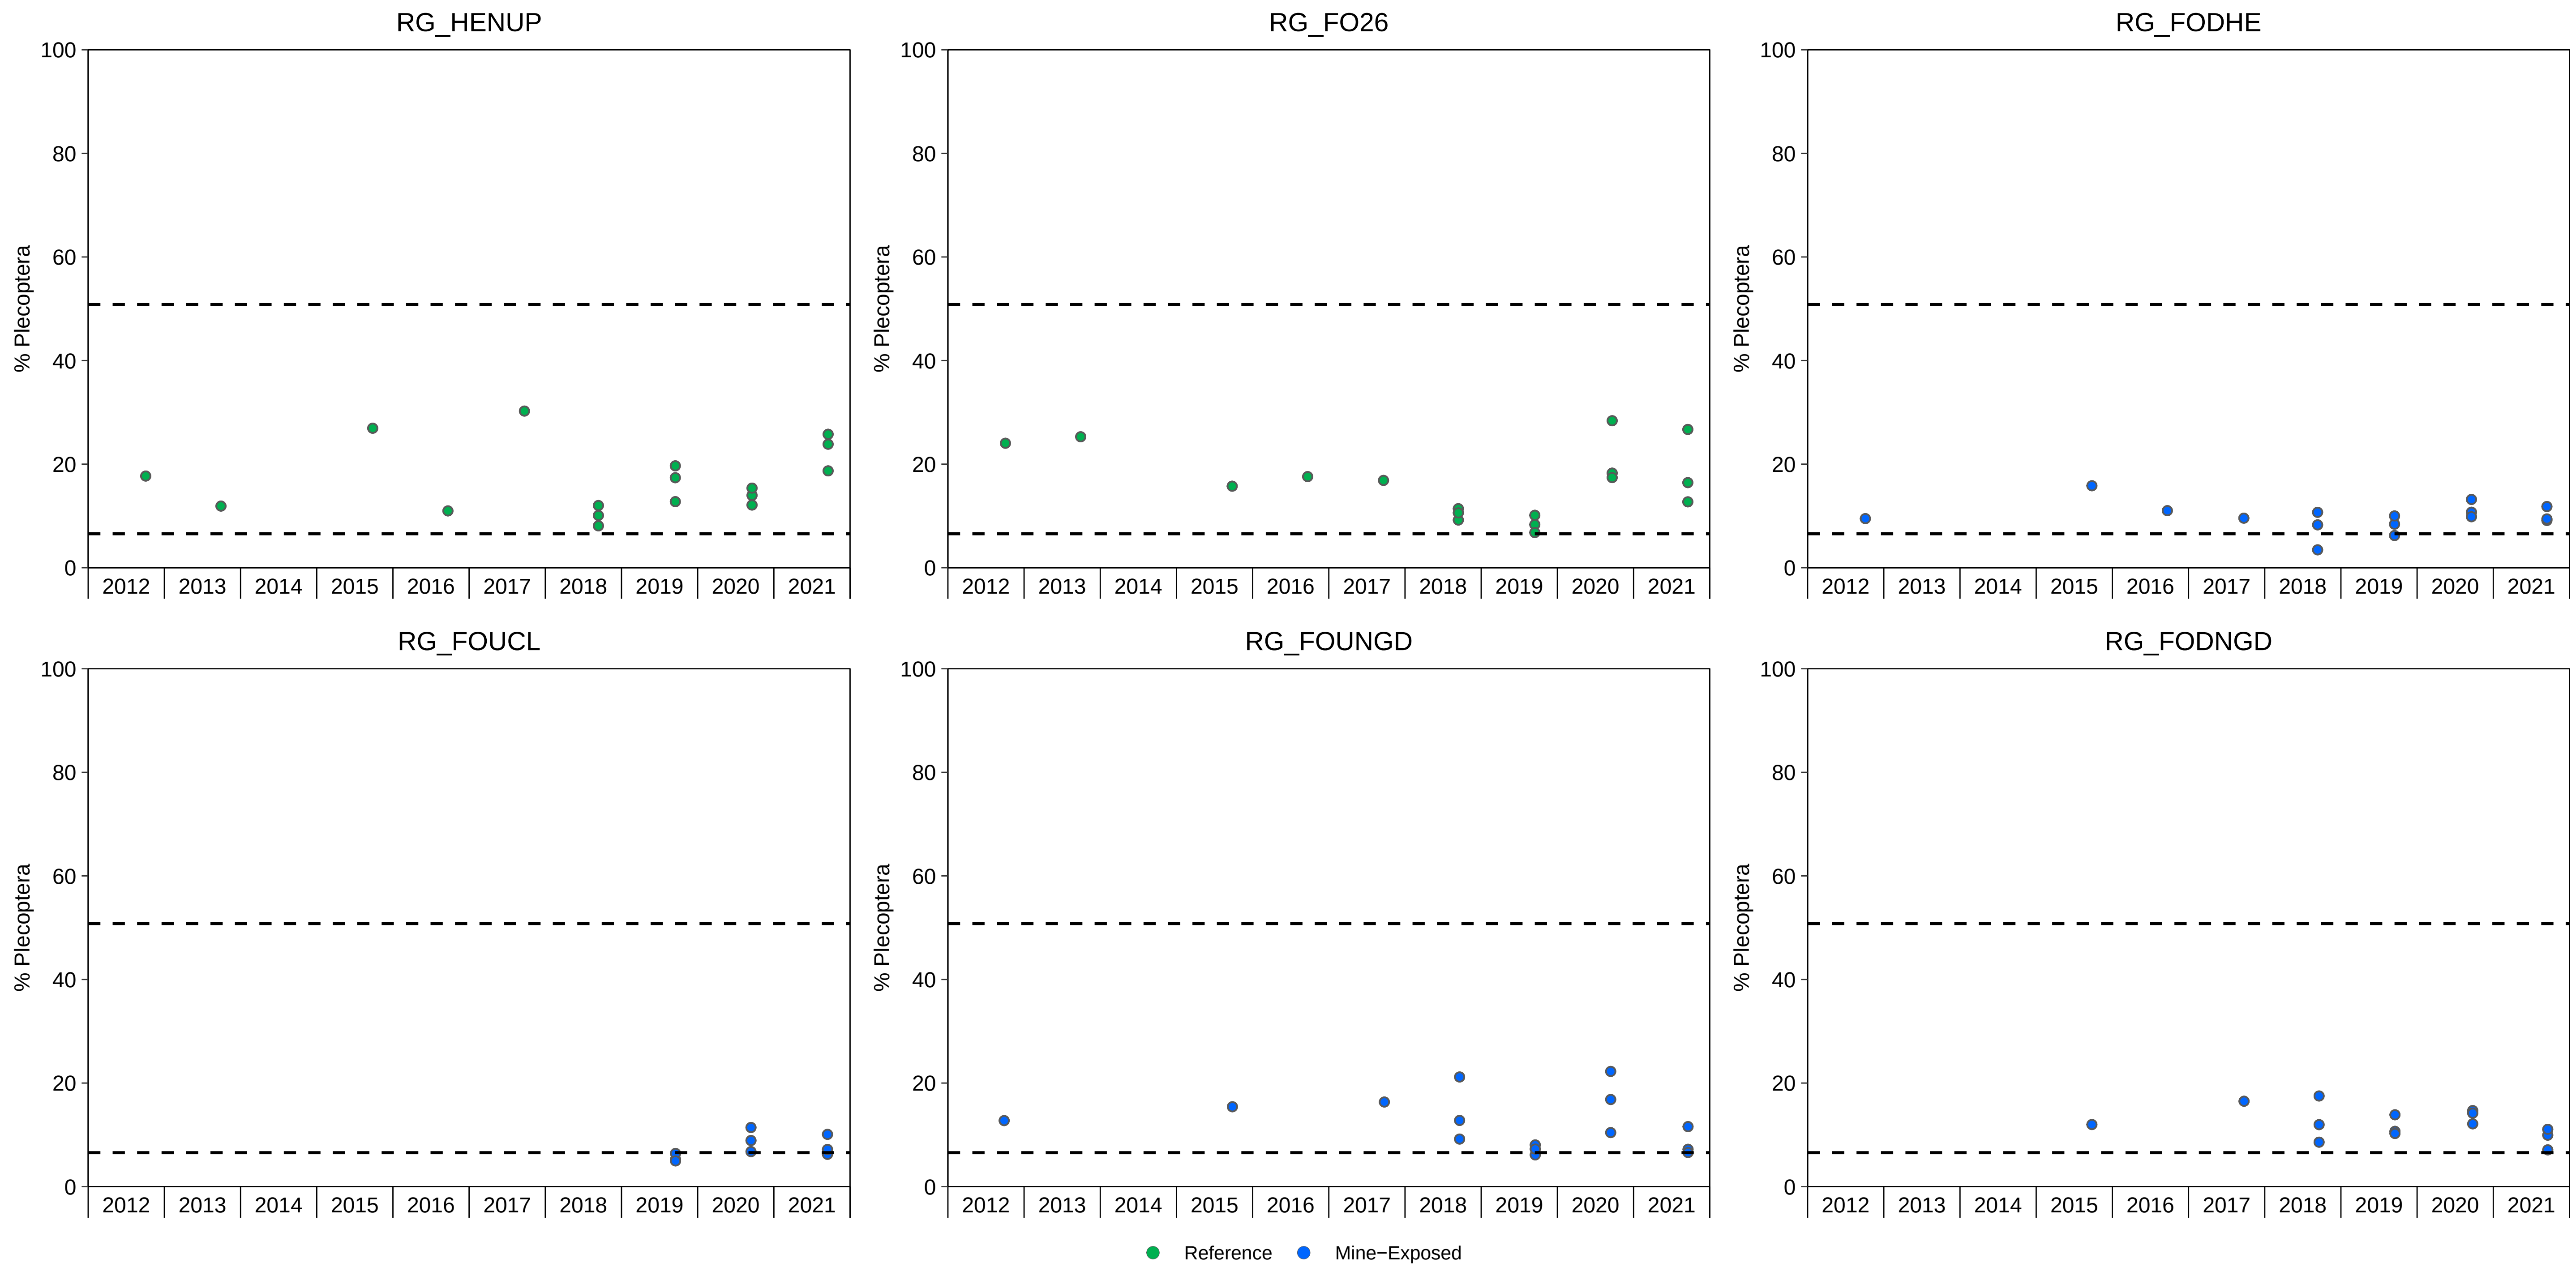

Figure E.11: Benthic Invertebrate % Plecoptera in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

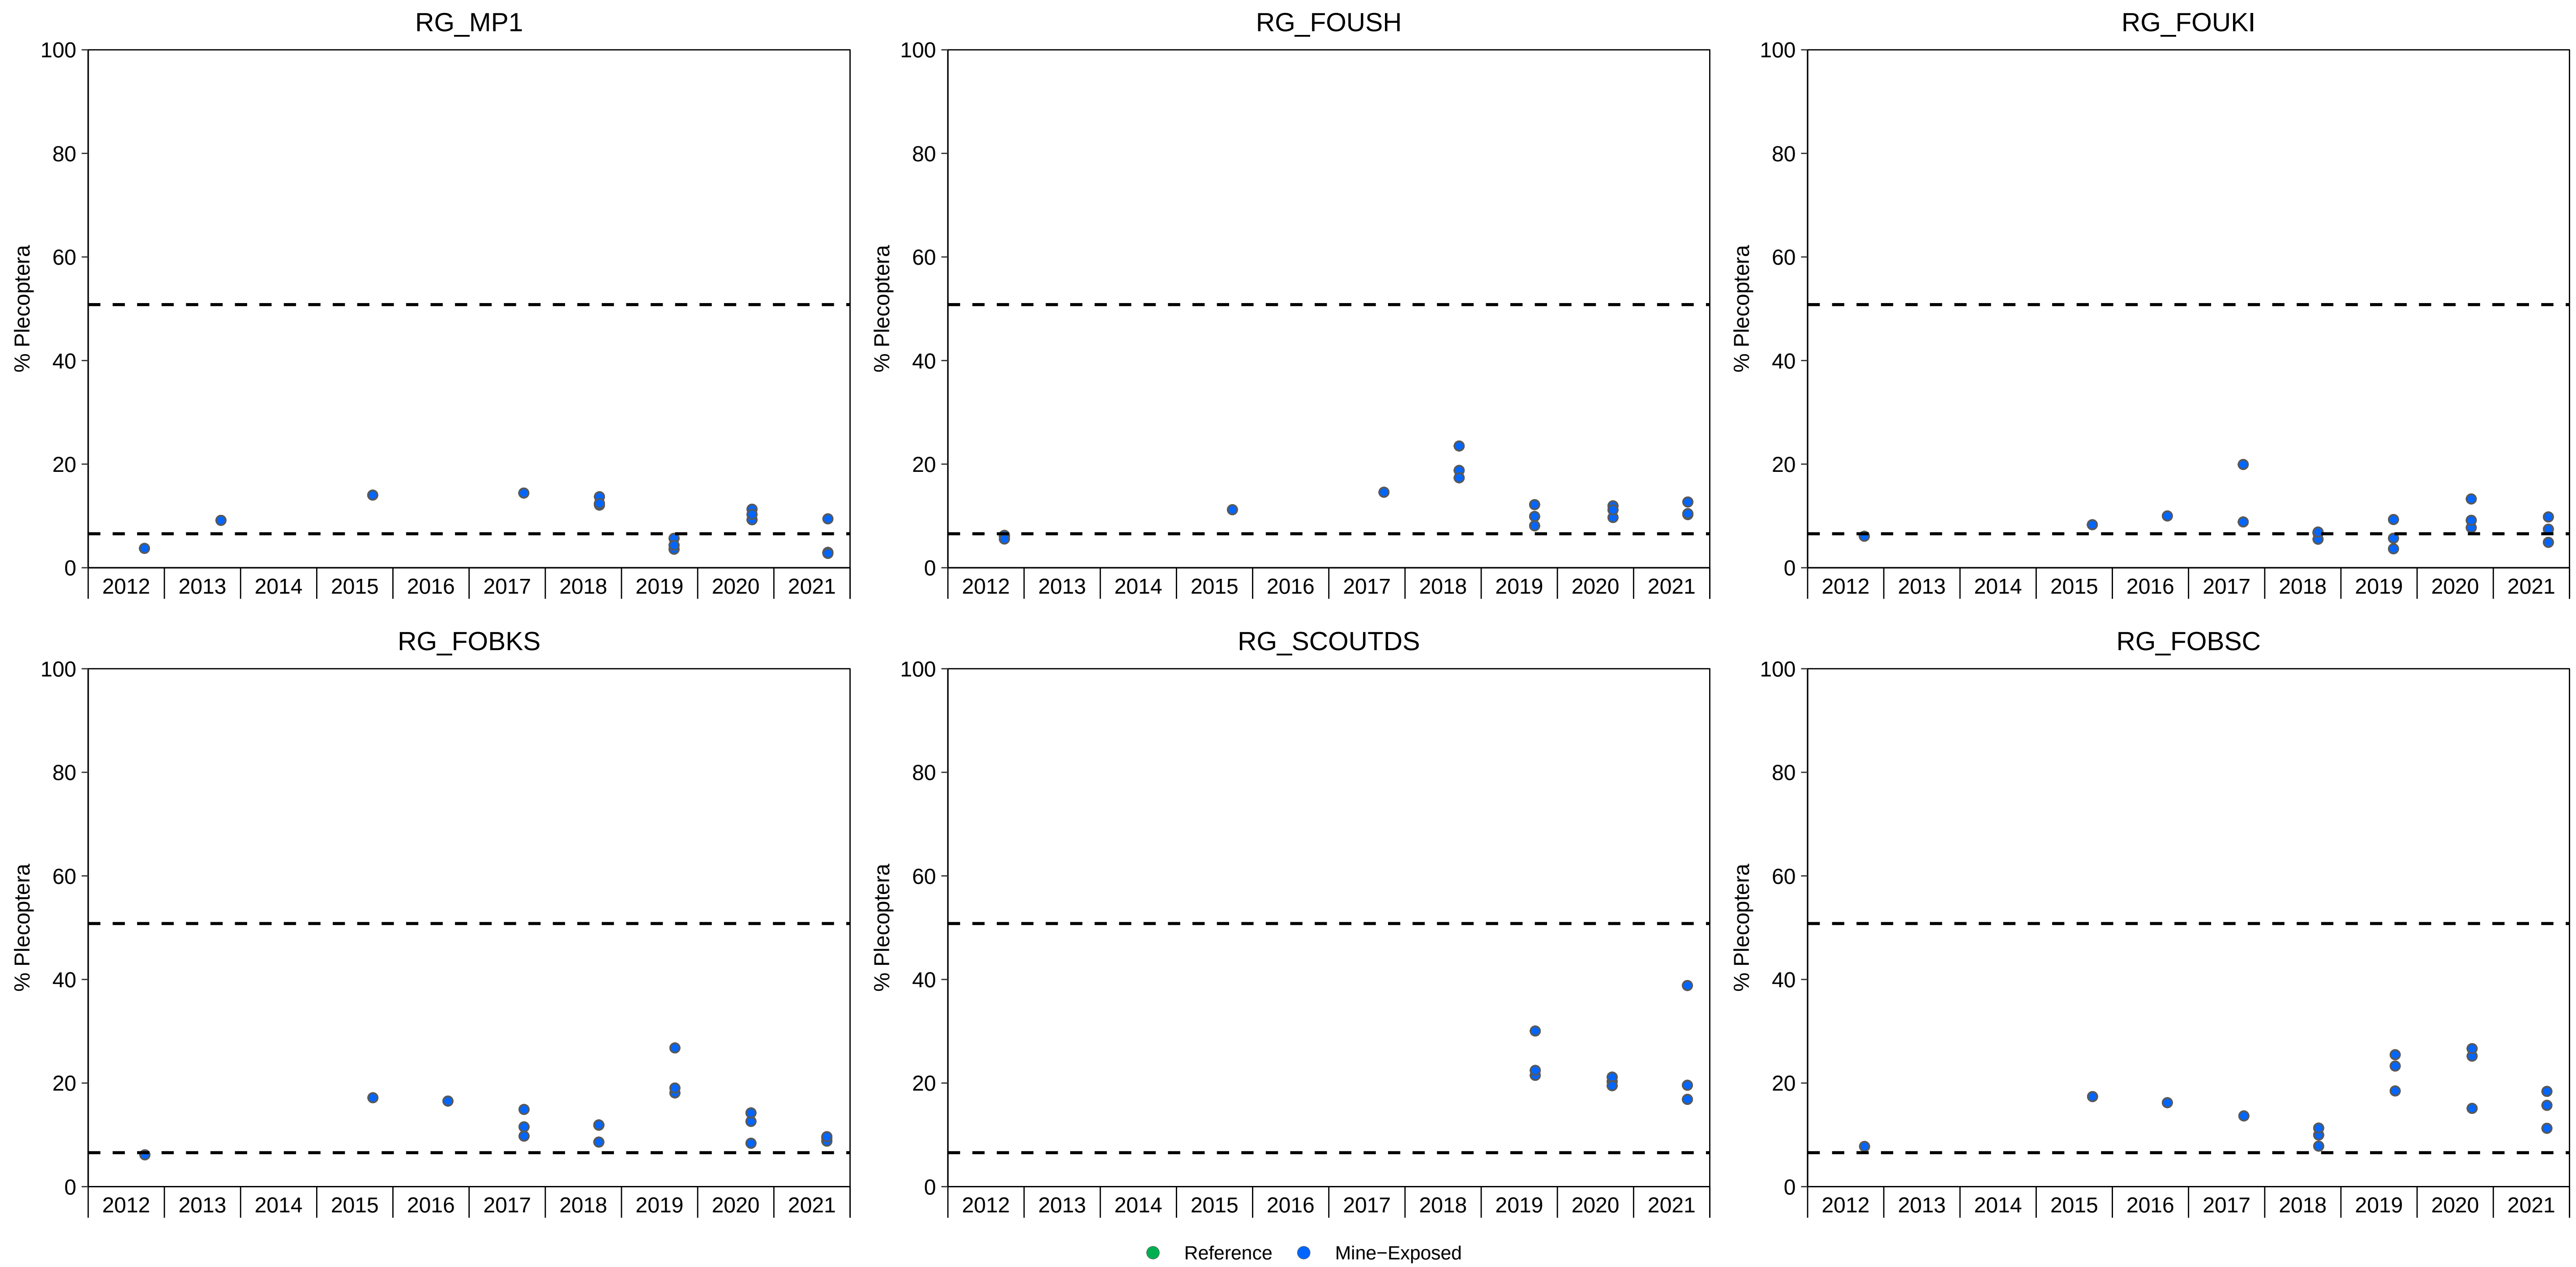

Figure E.11: Benthic Invertebrate % Plecoptera in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

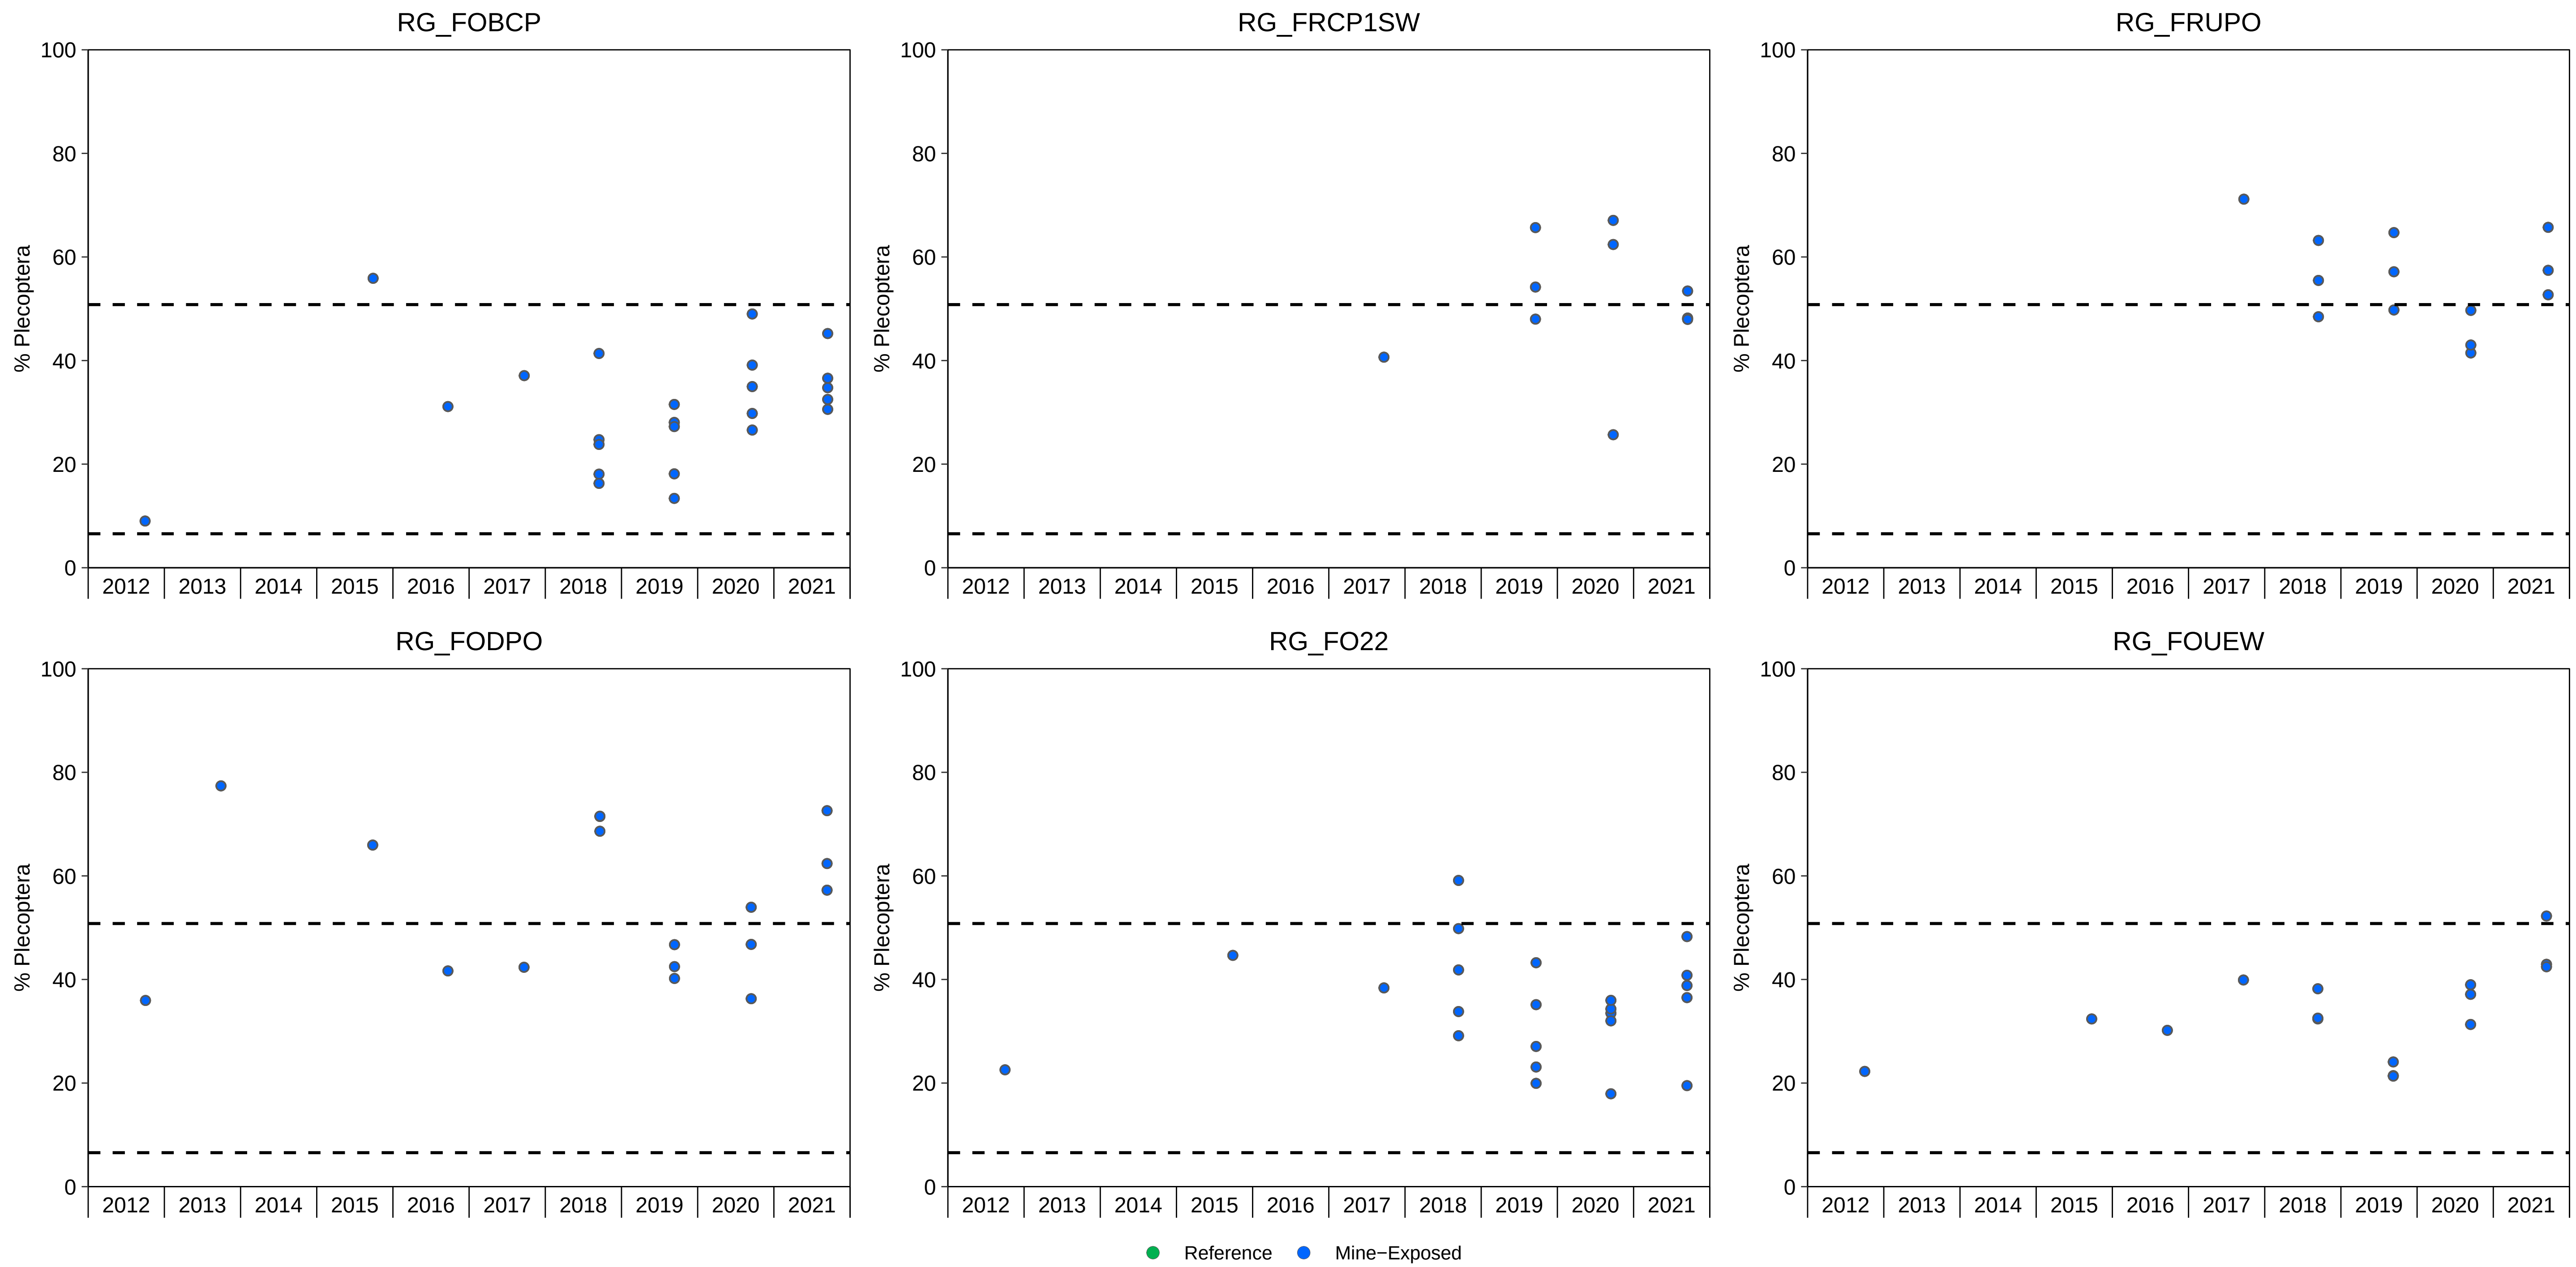

Figure E.11: Benthic Invertebrate % Plecoptera in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

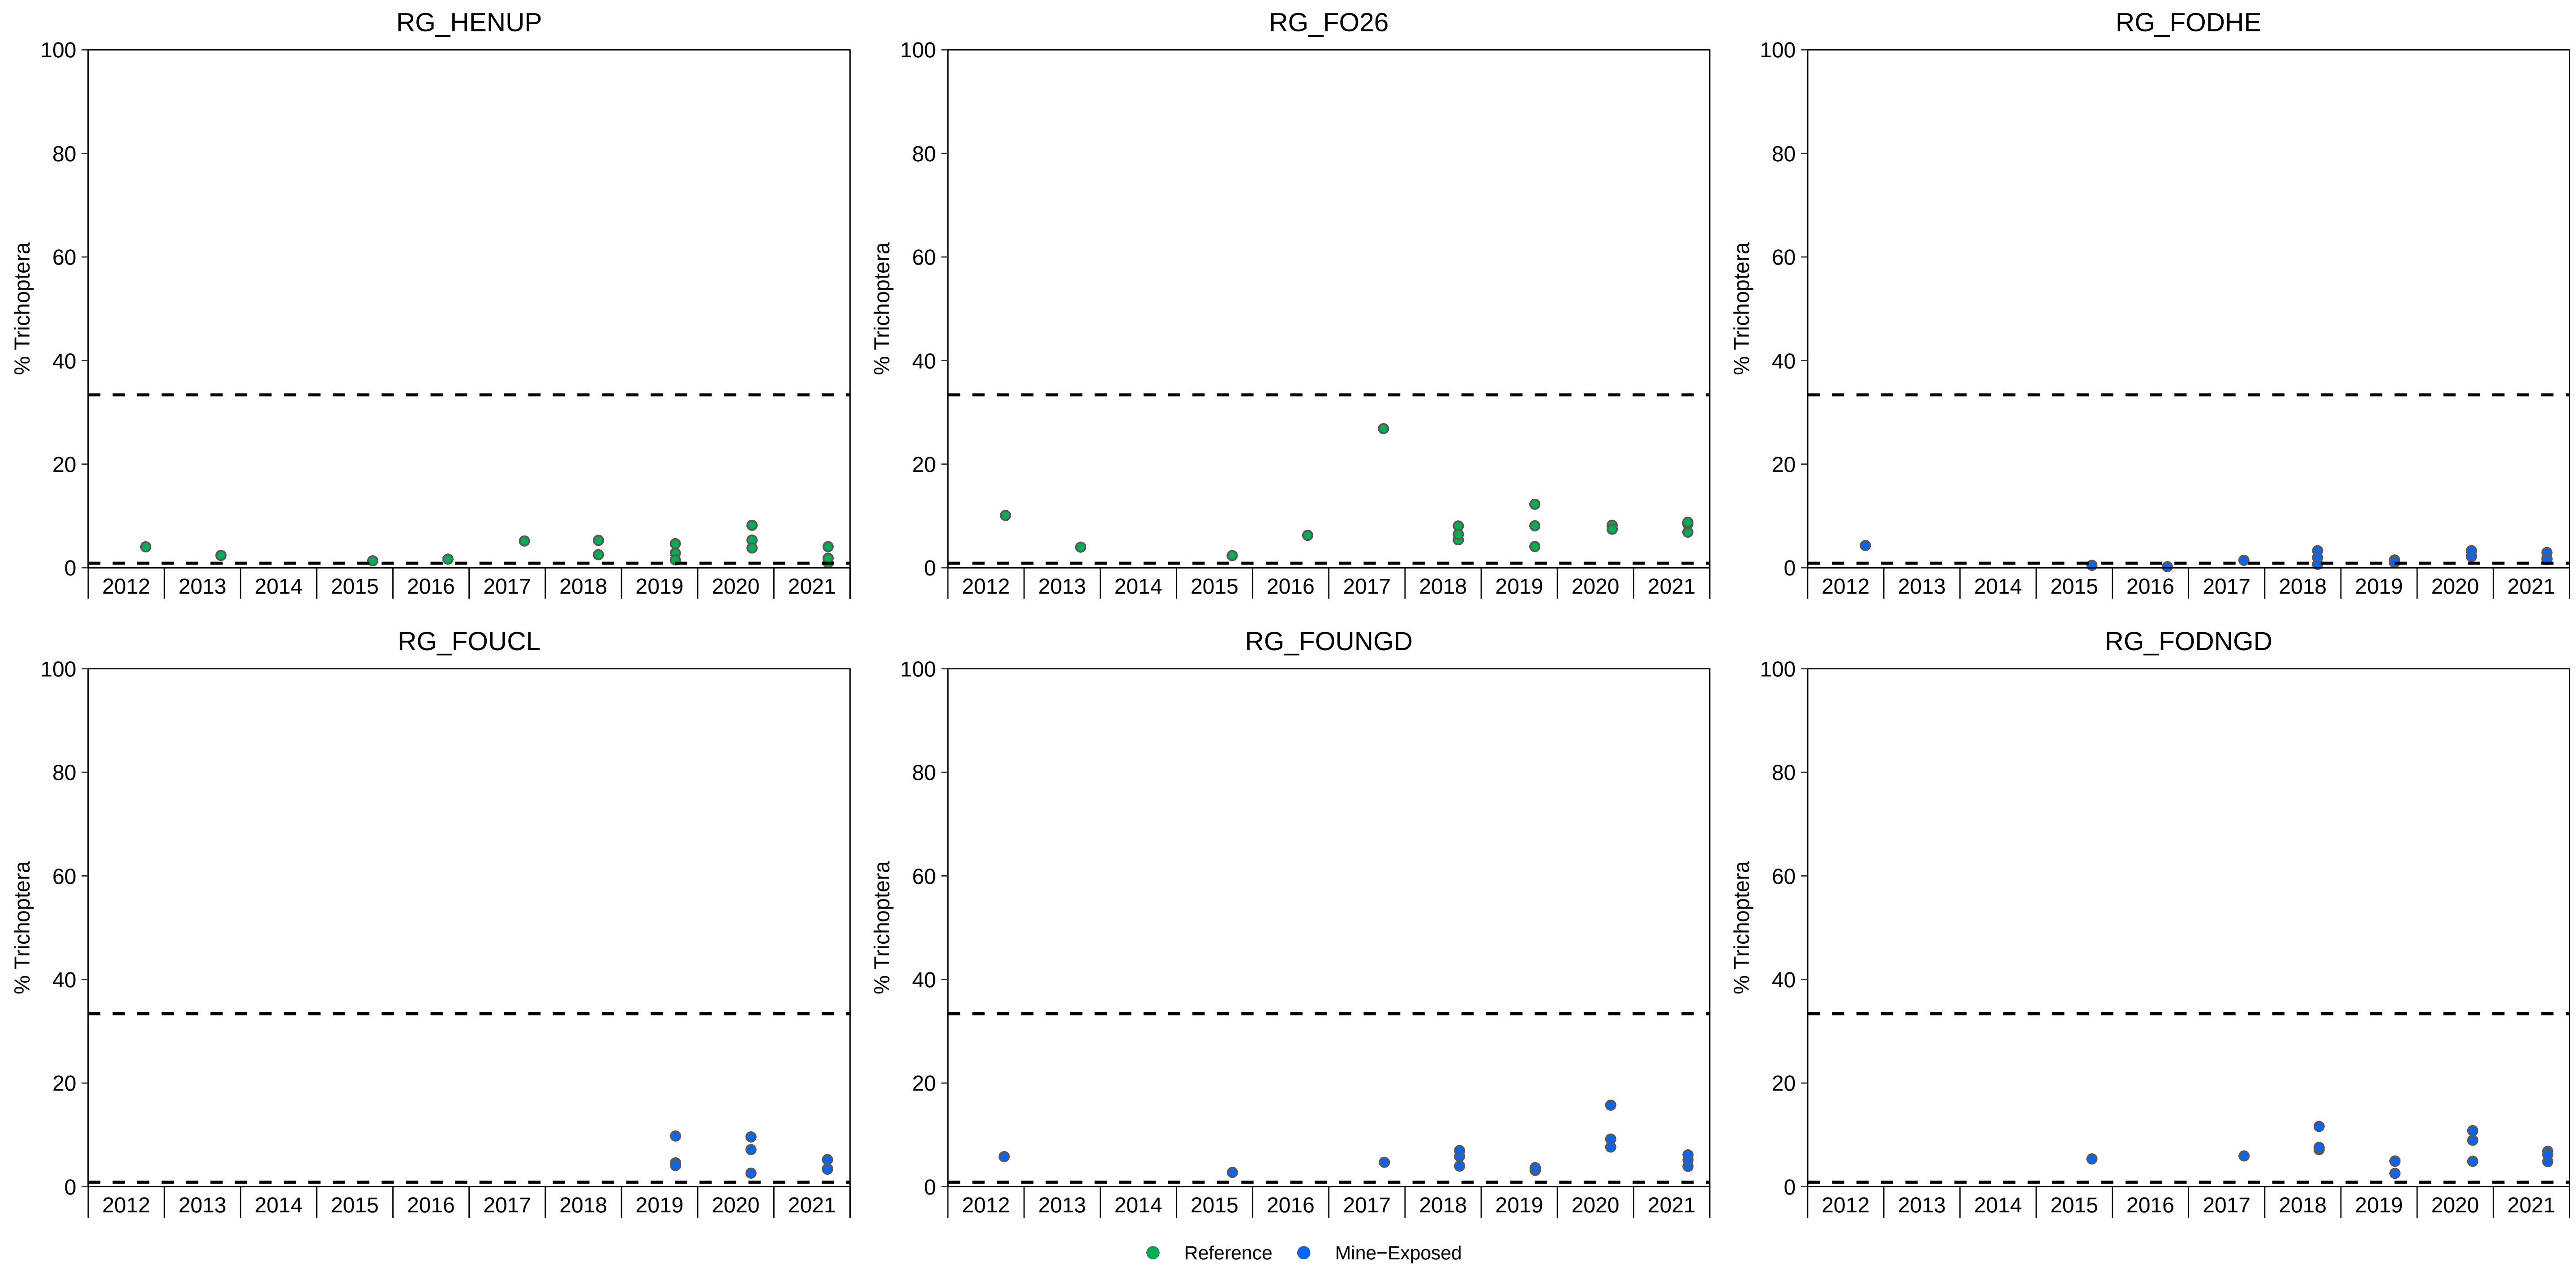

Figure E.12: Benthic Invertebrate % Trichoptera in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

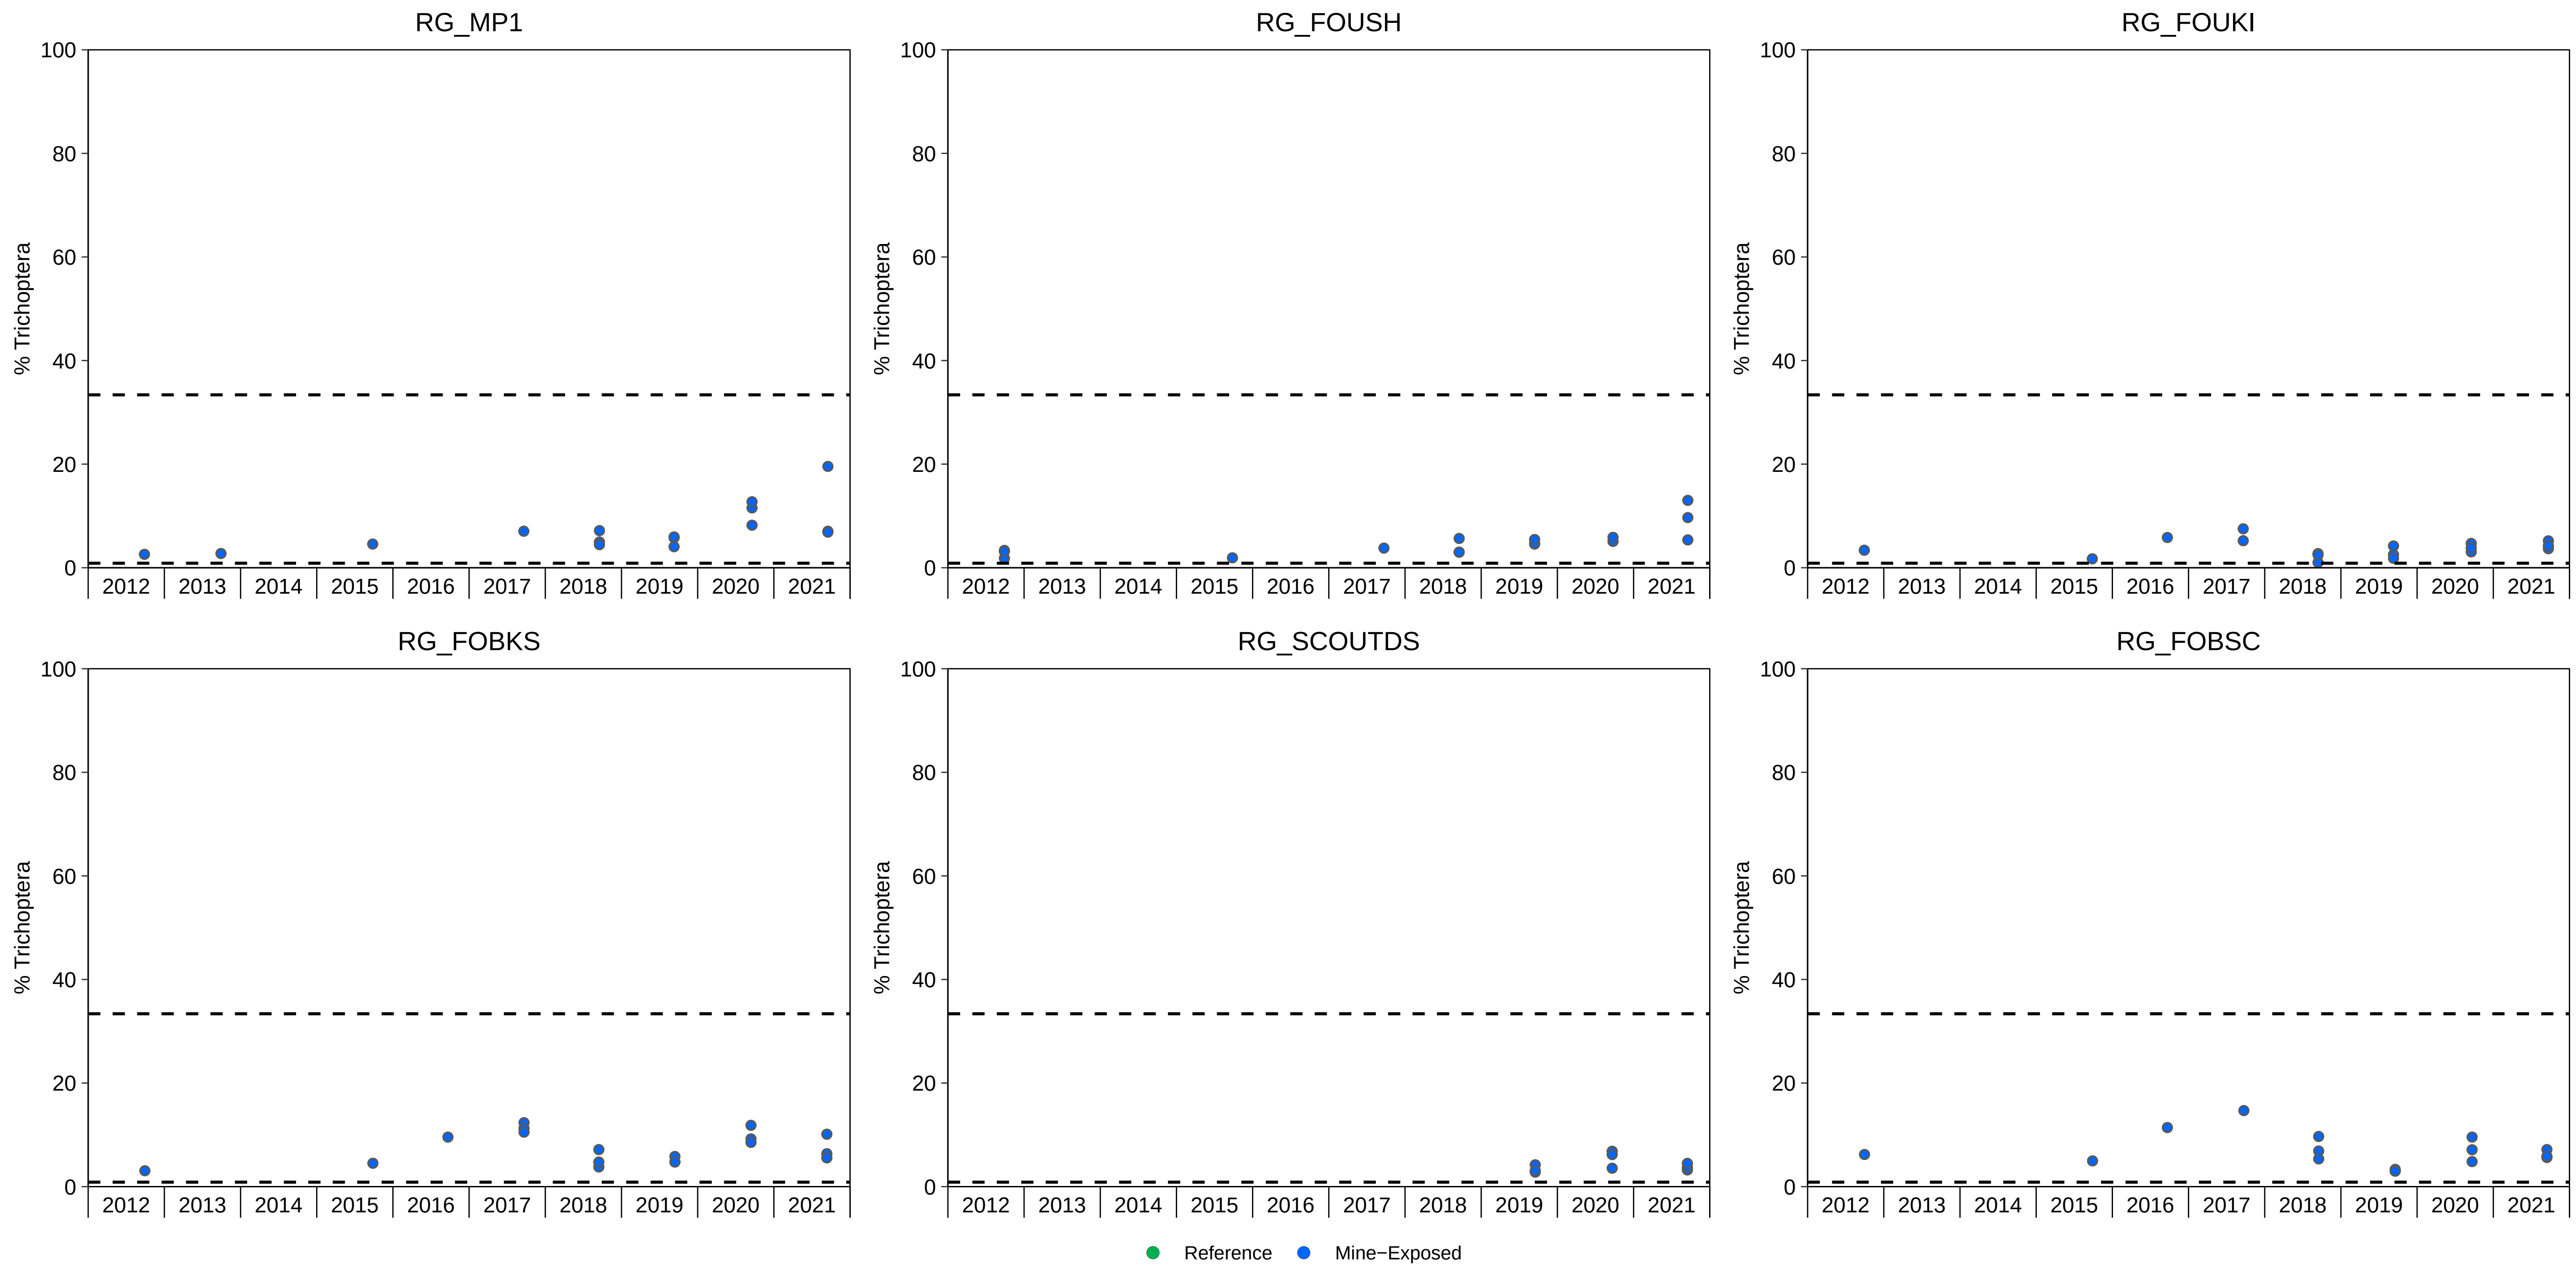

Figure E.12: Benthic Invertebrate % Trichoptera in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

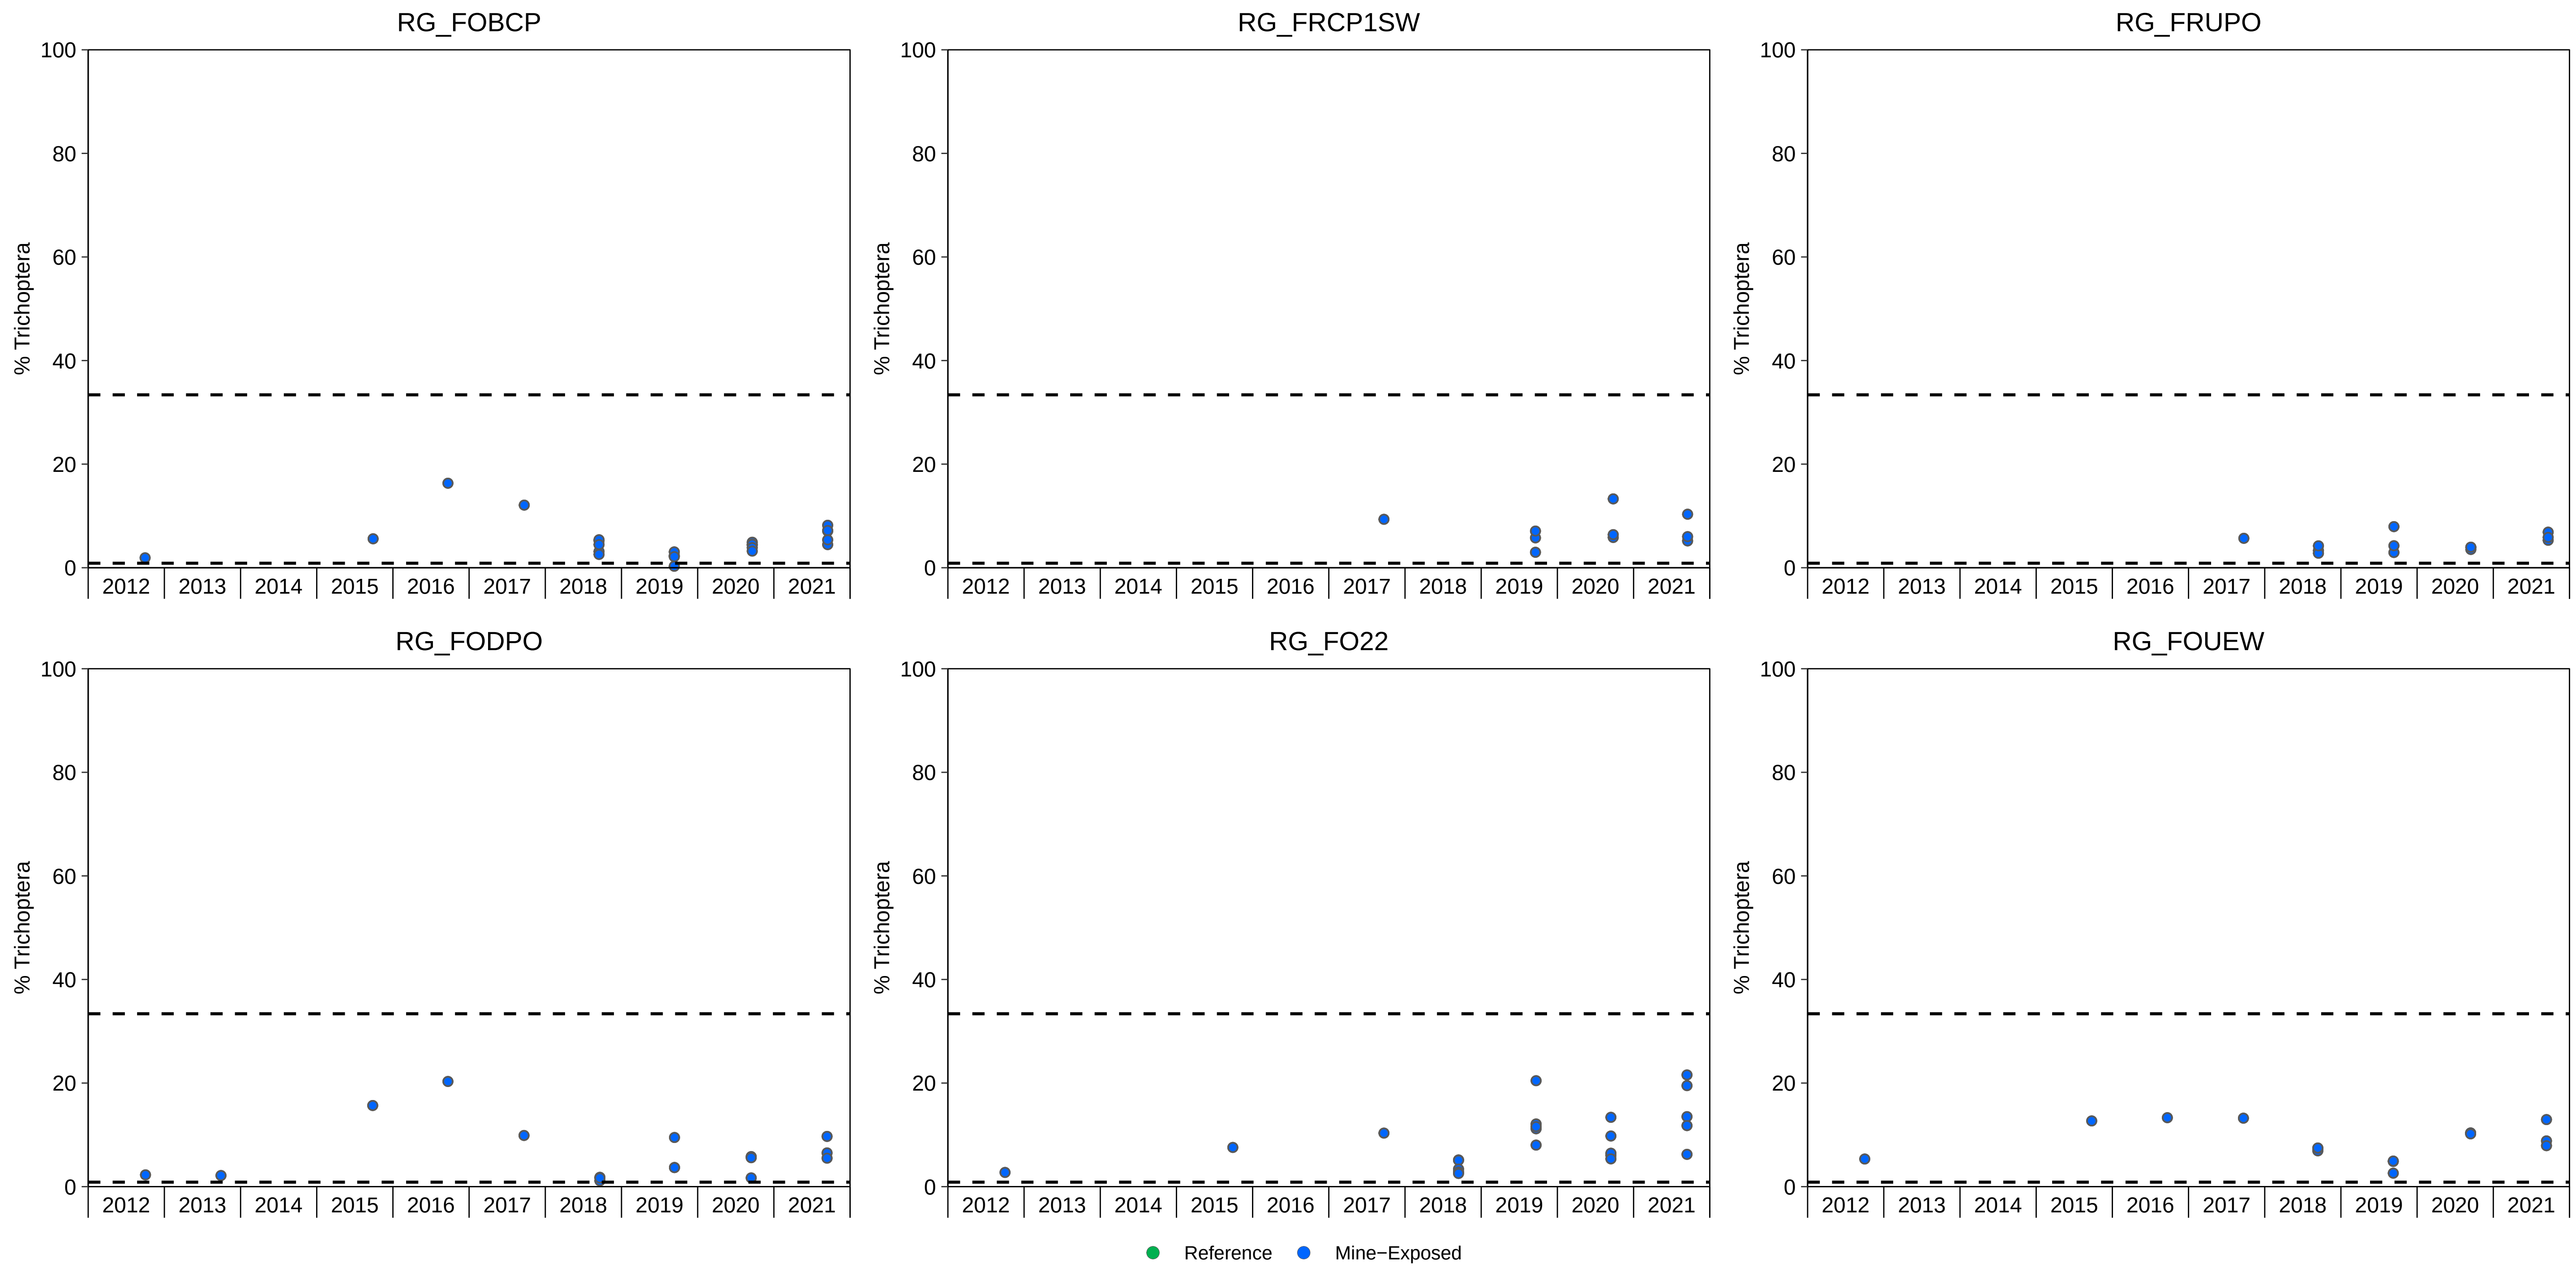

Figure E.12: Benthic Invertebrate % Trichoptera in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

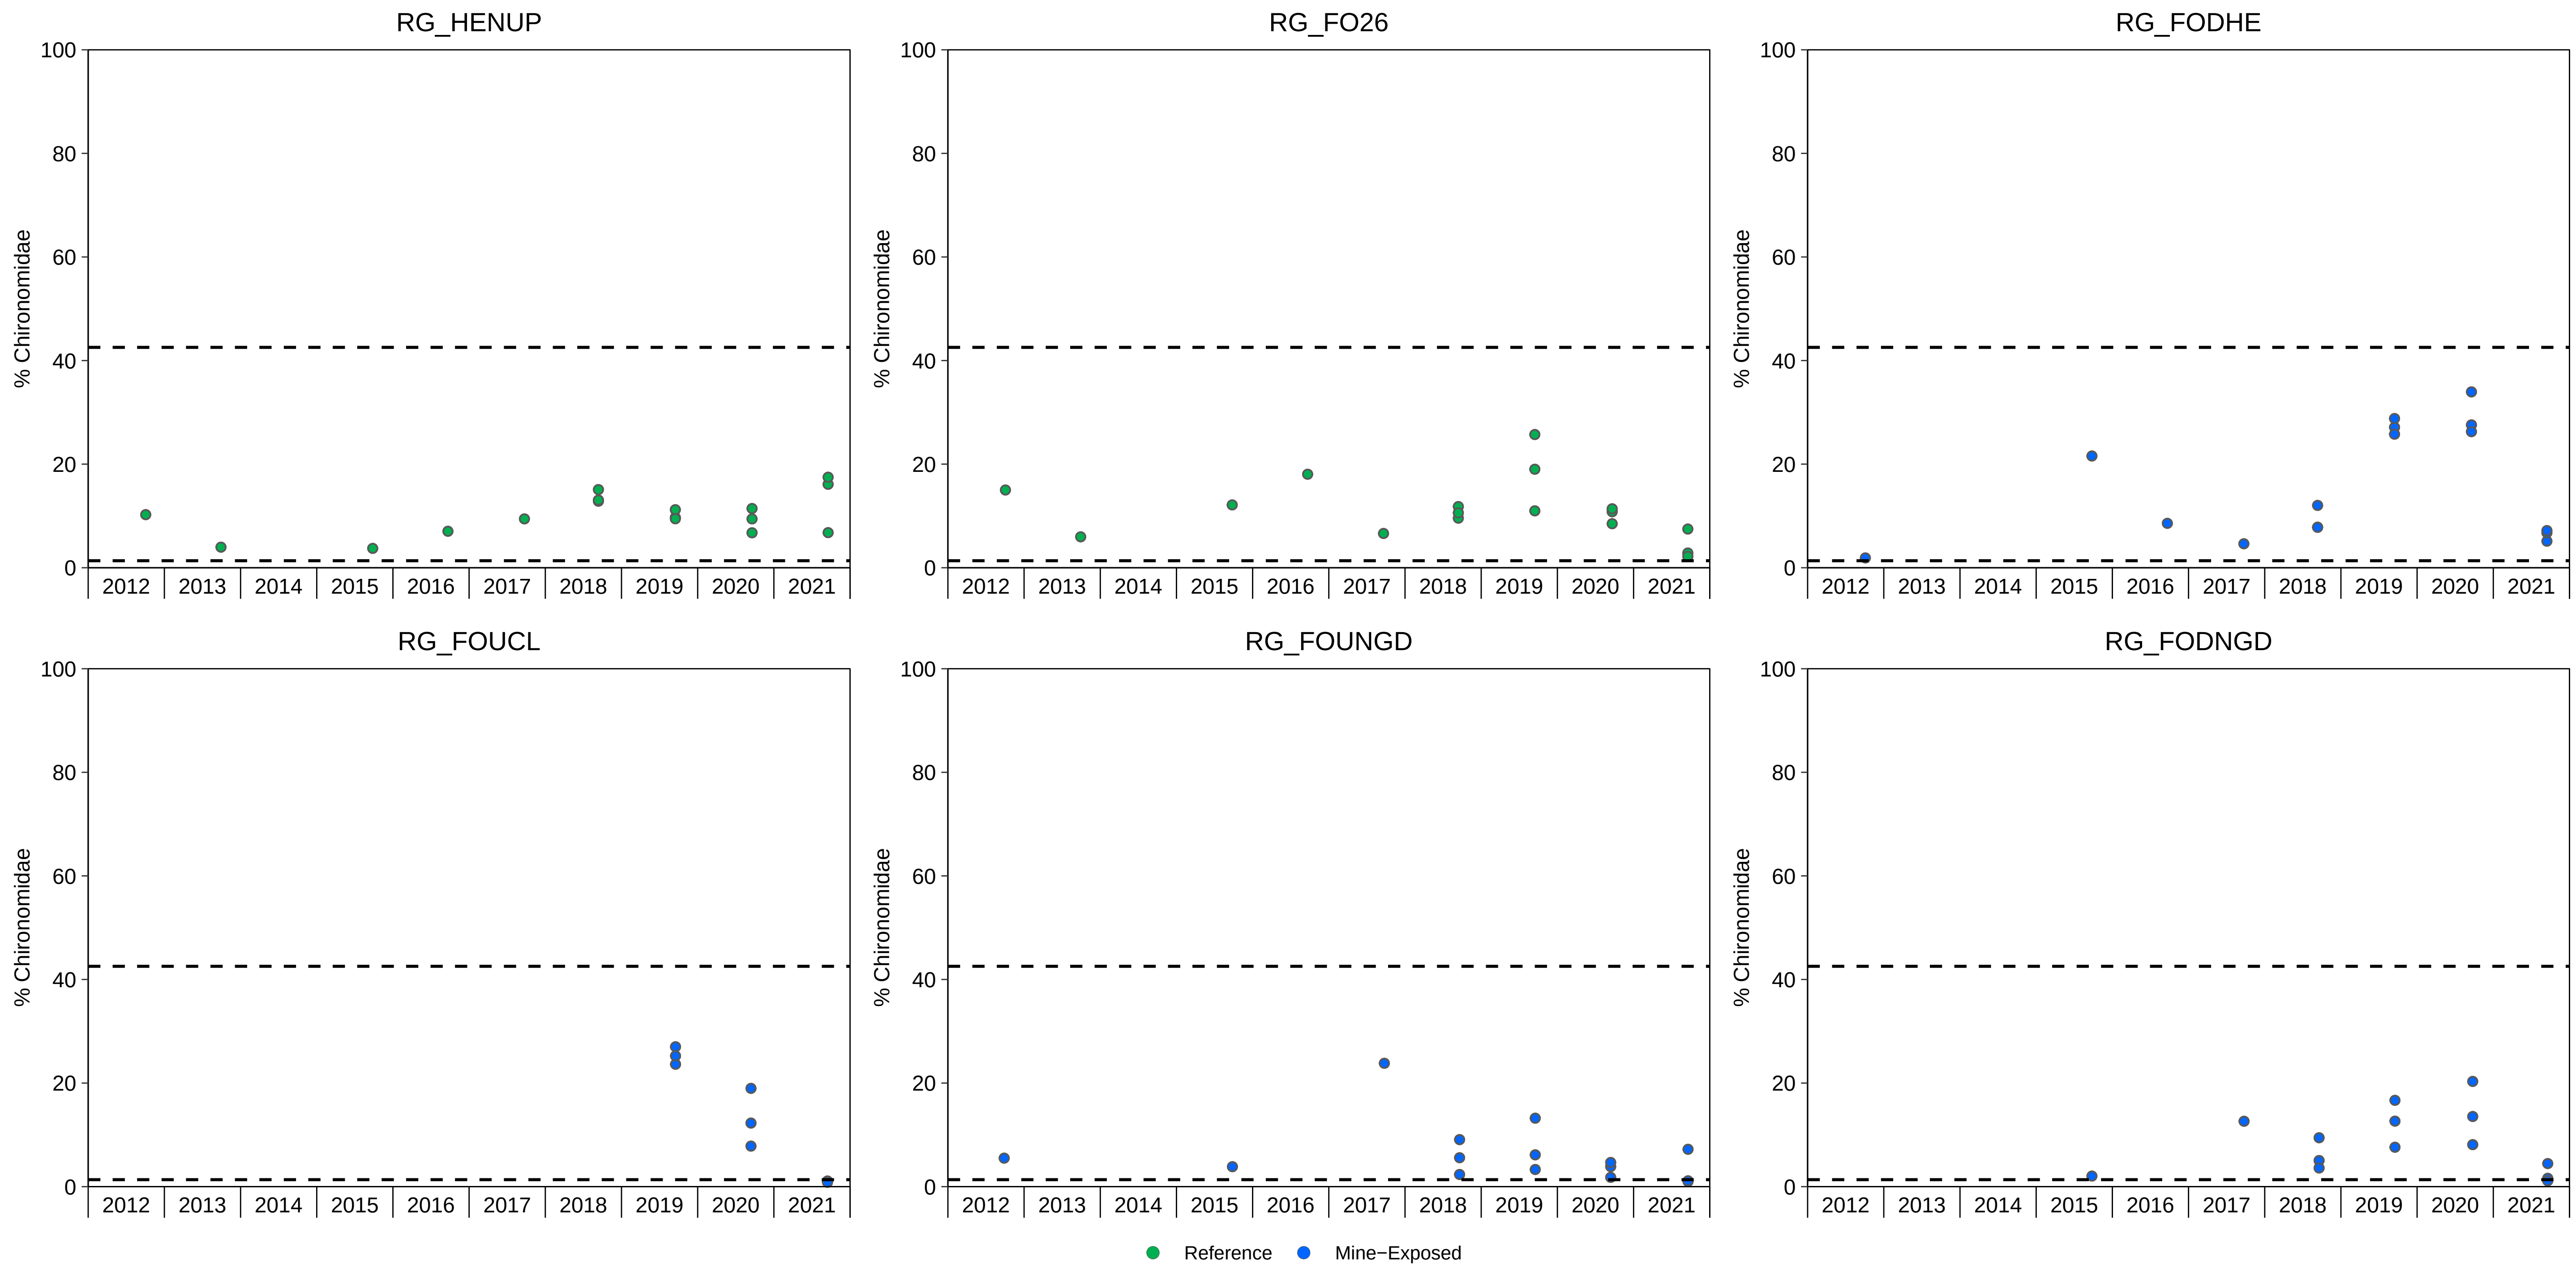

Figure E.13: Benthic Invertebrate % Chironomidae in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

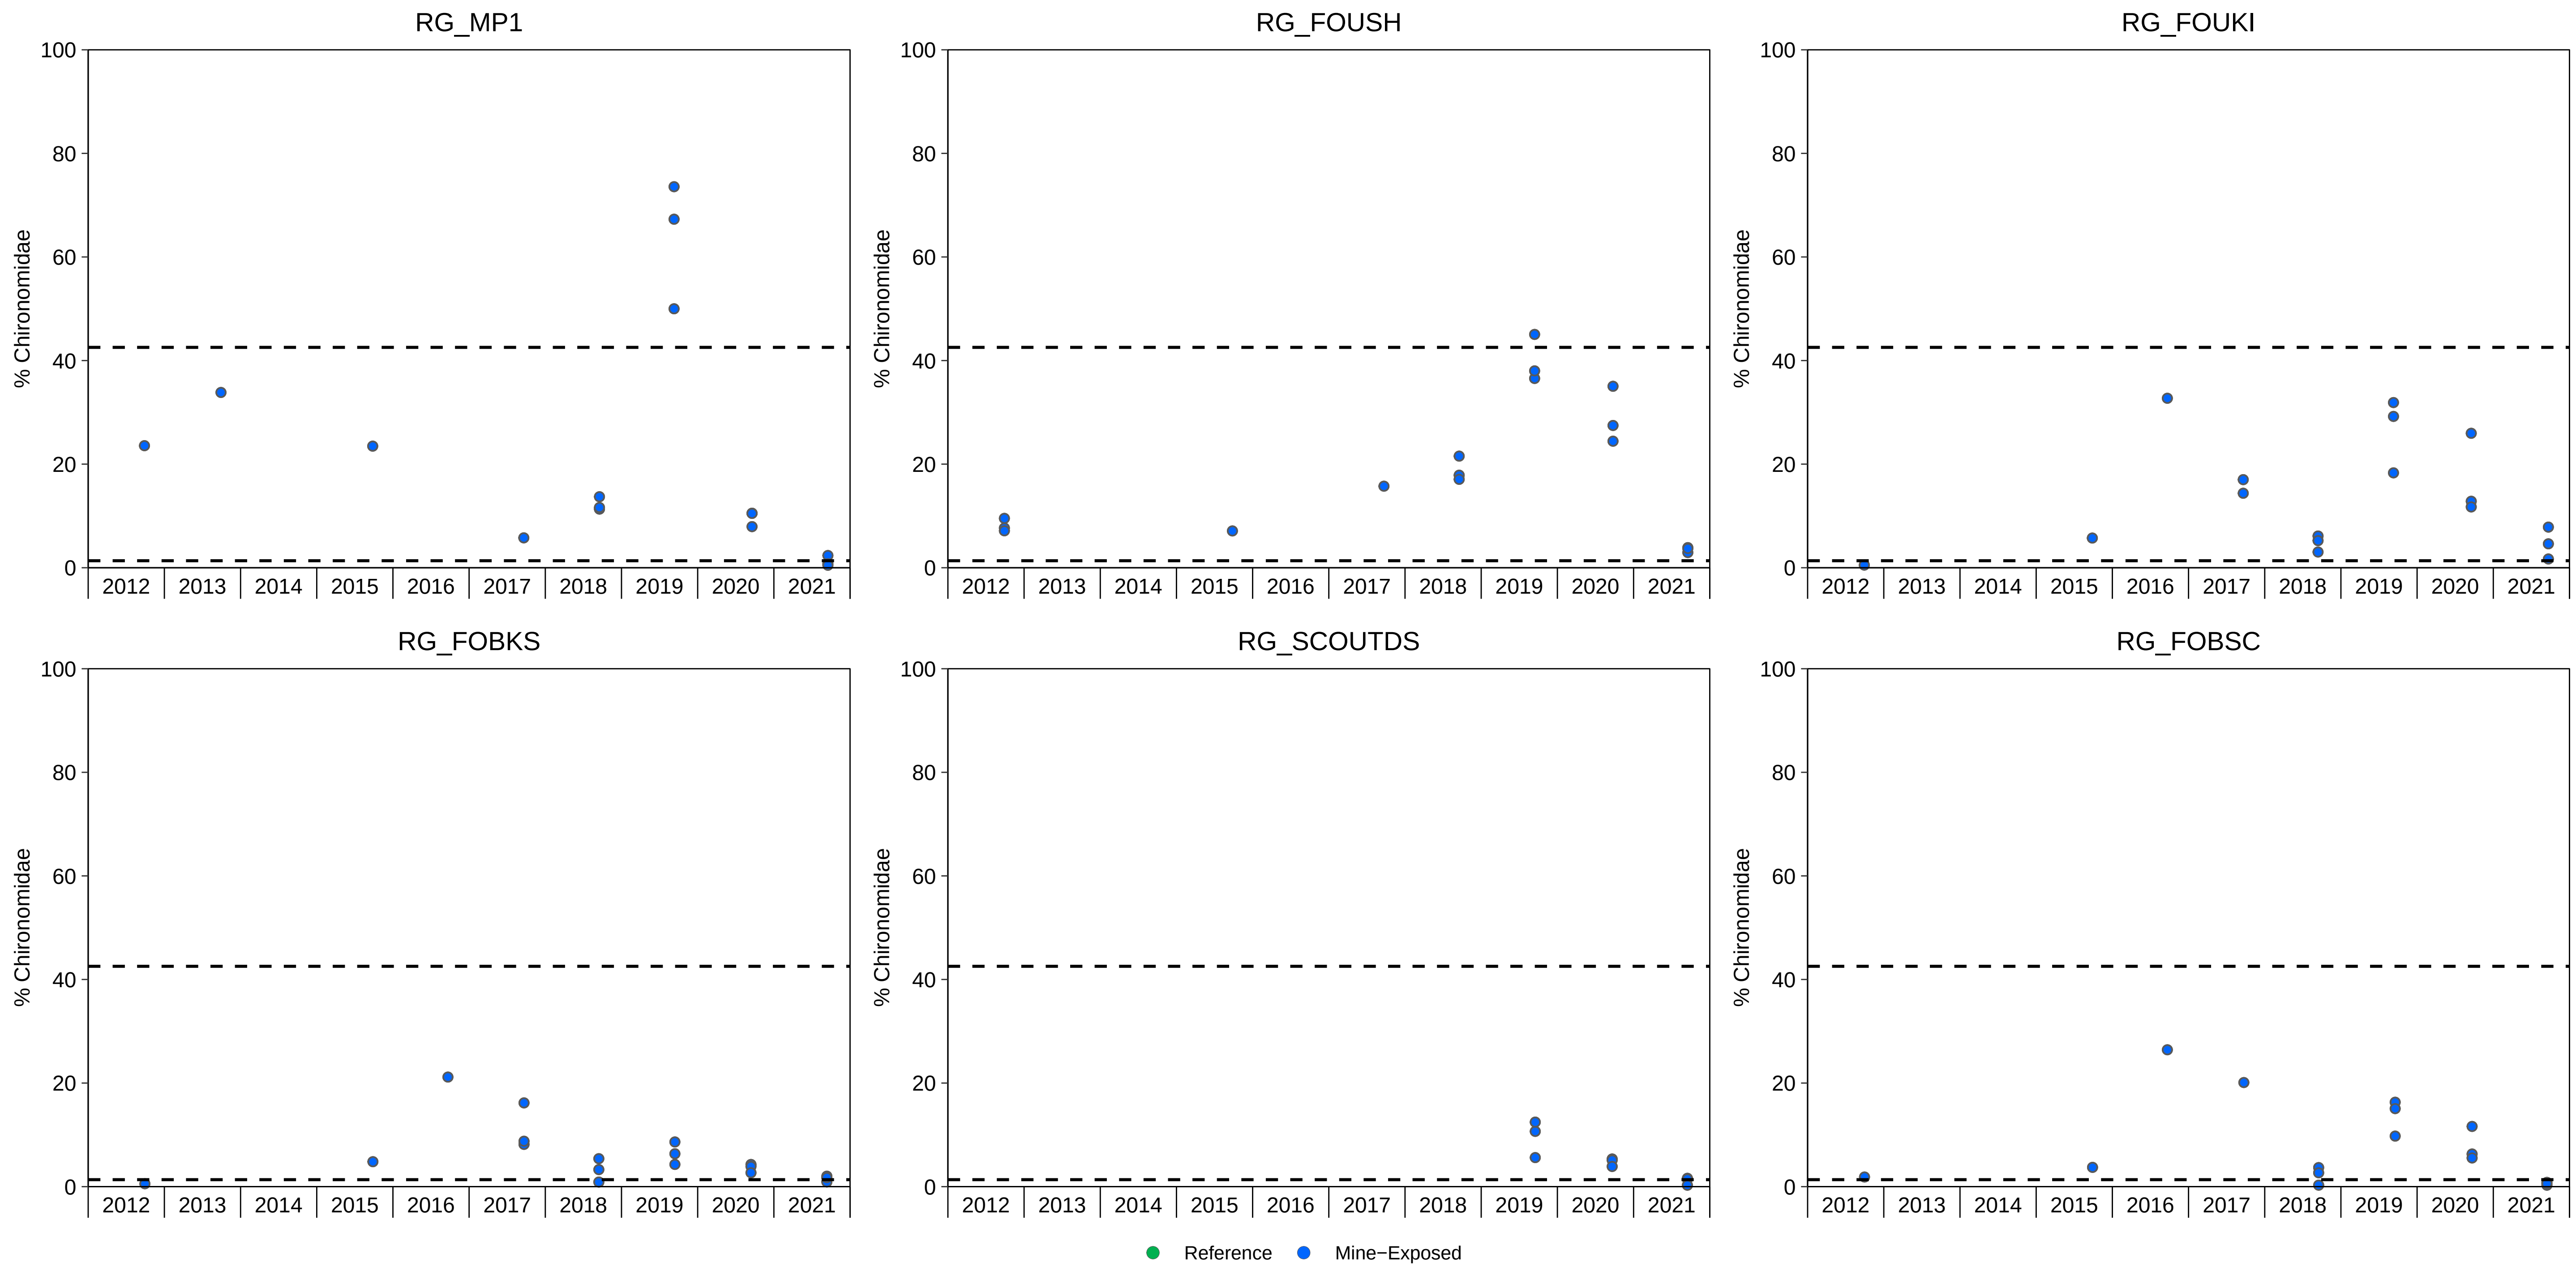

Figure E.13: Benthic Invertebrate % Chironomidae in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

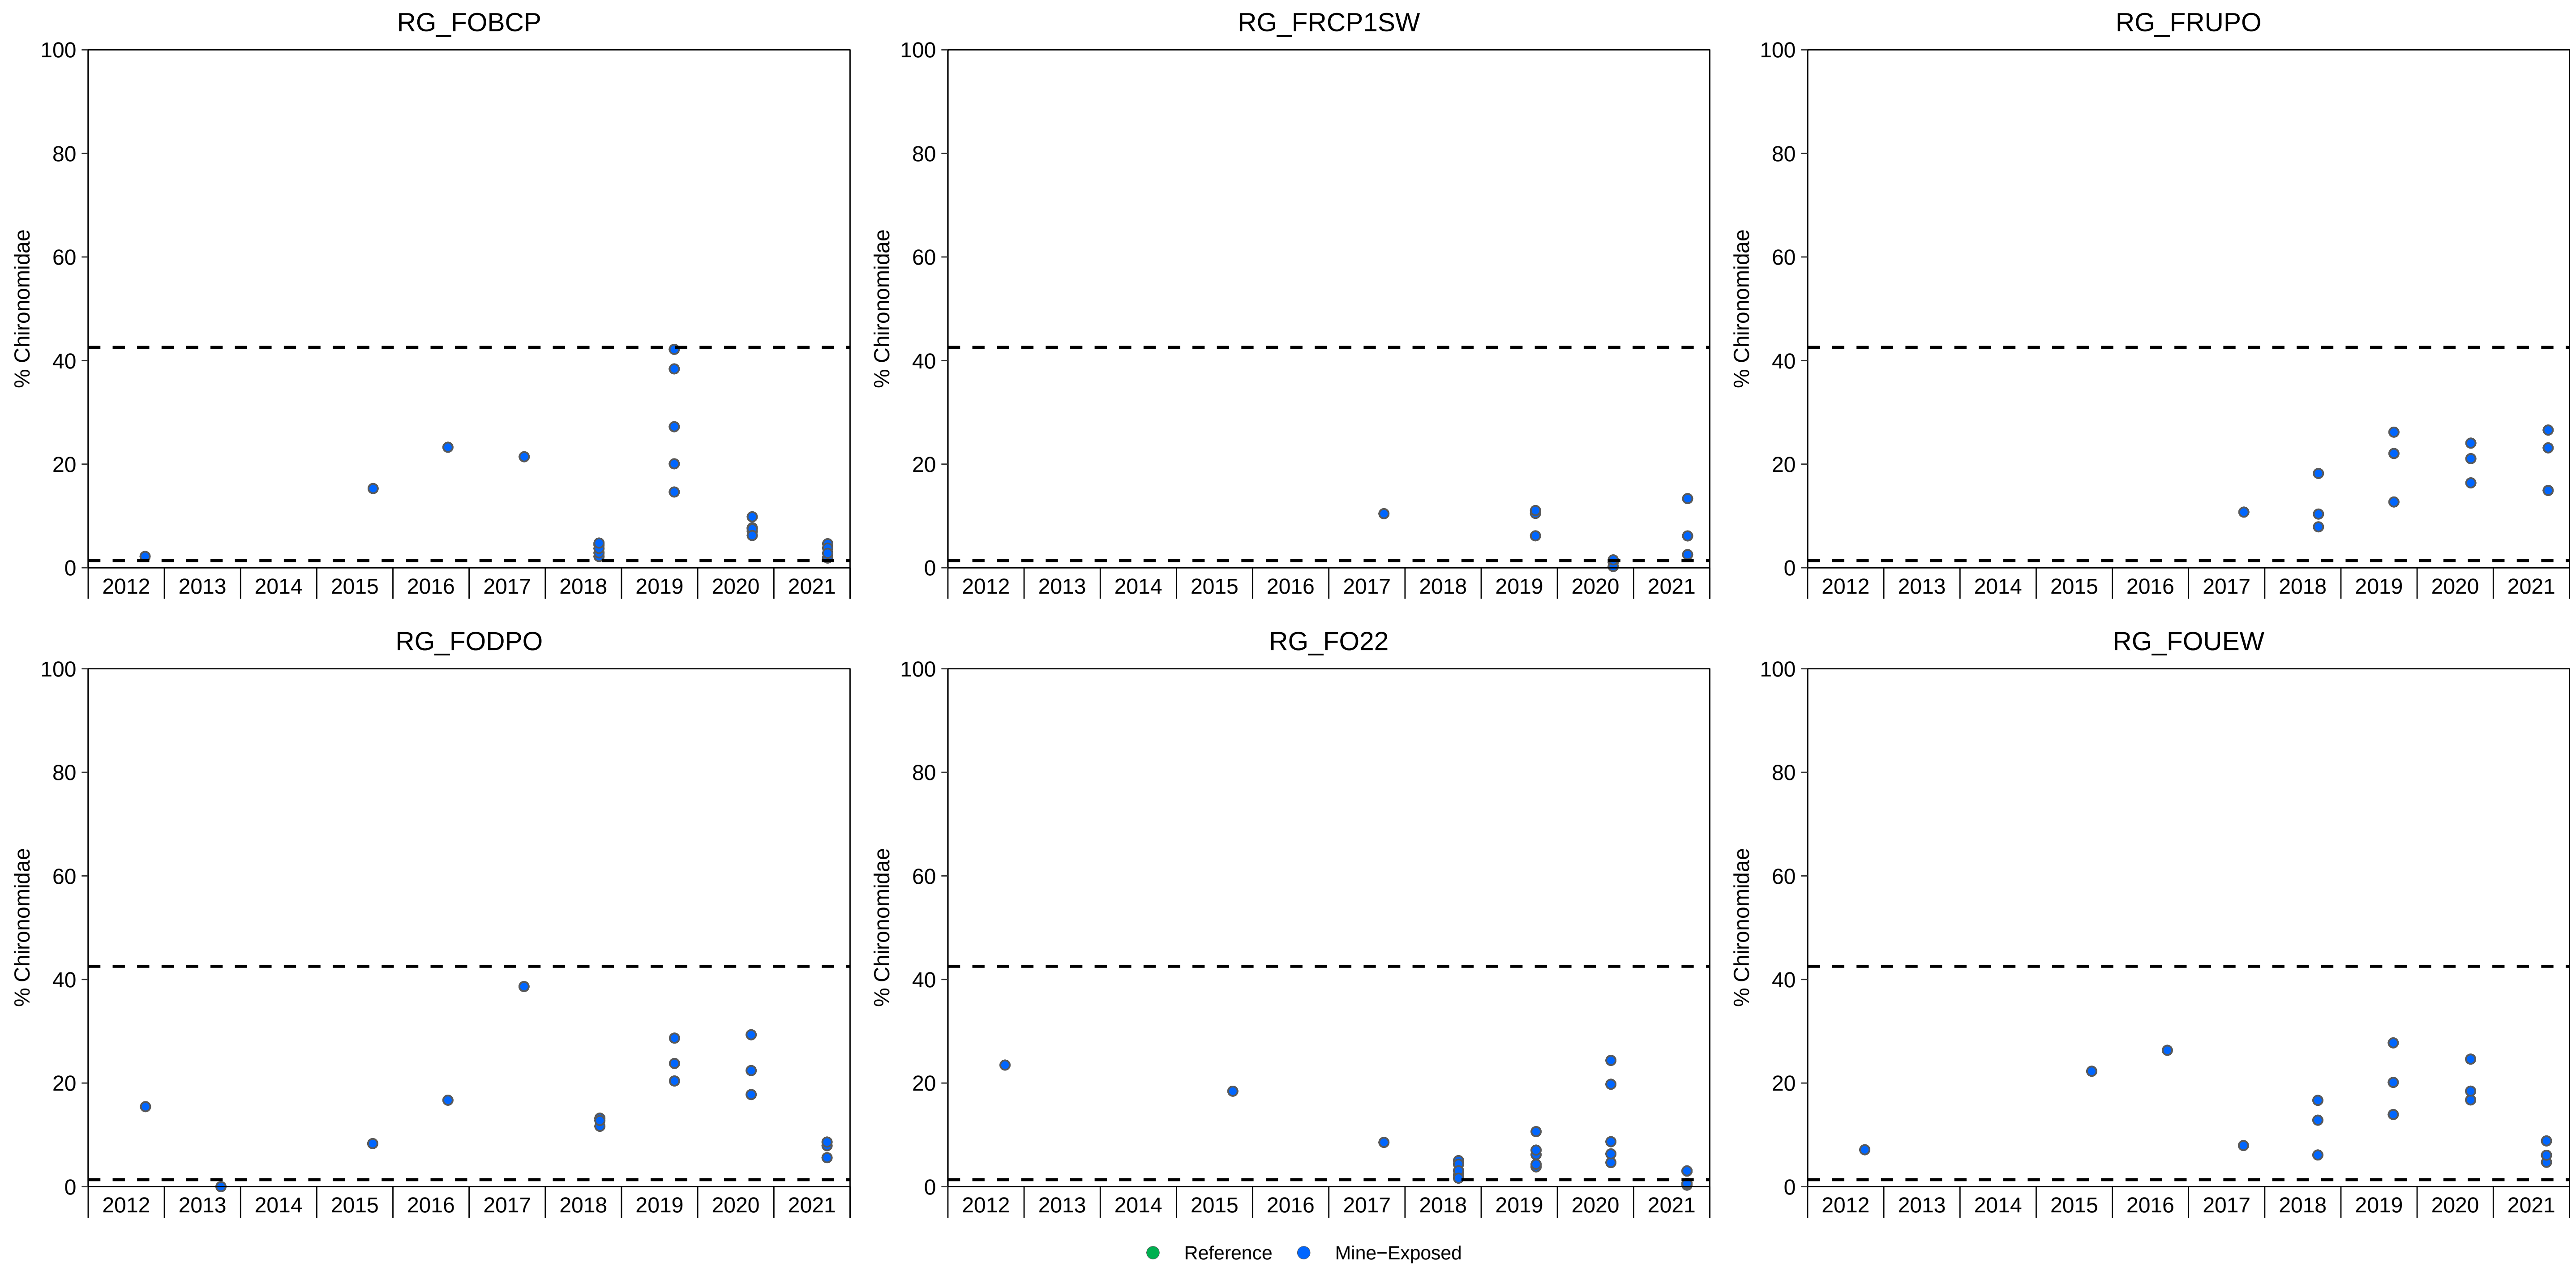

Figure E.13: Benthic Invertebrate % Chironomidae in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

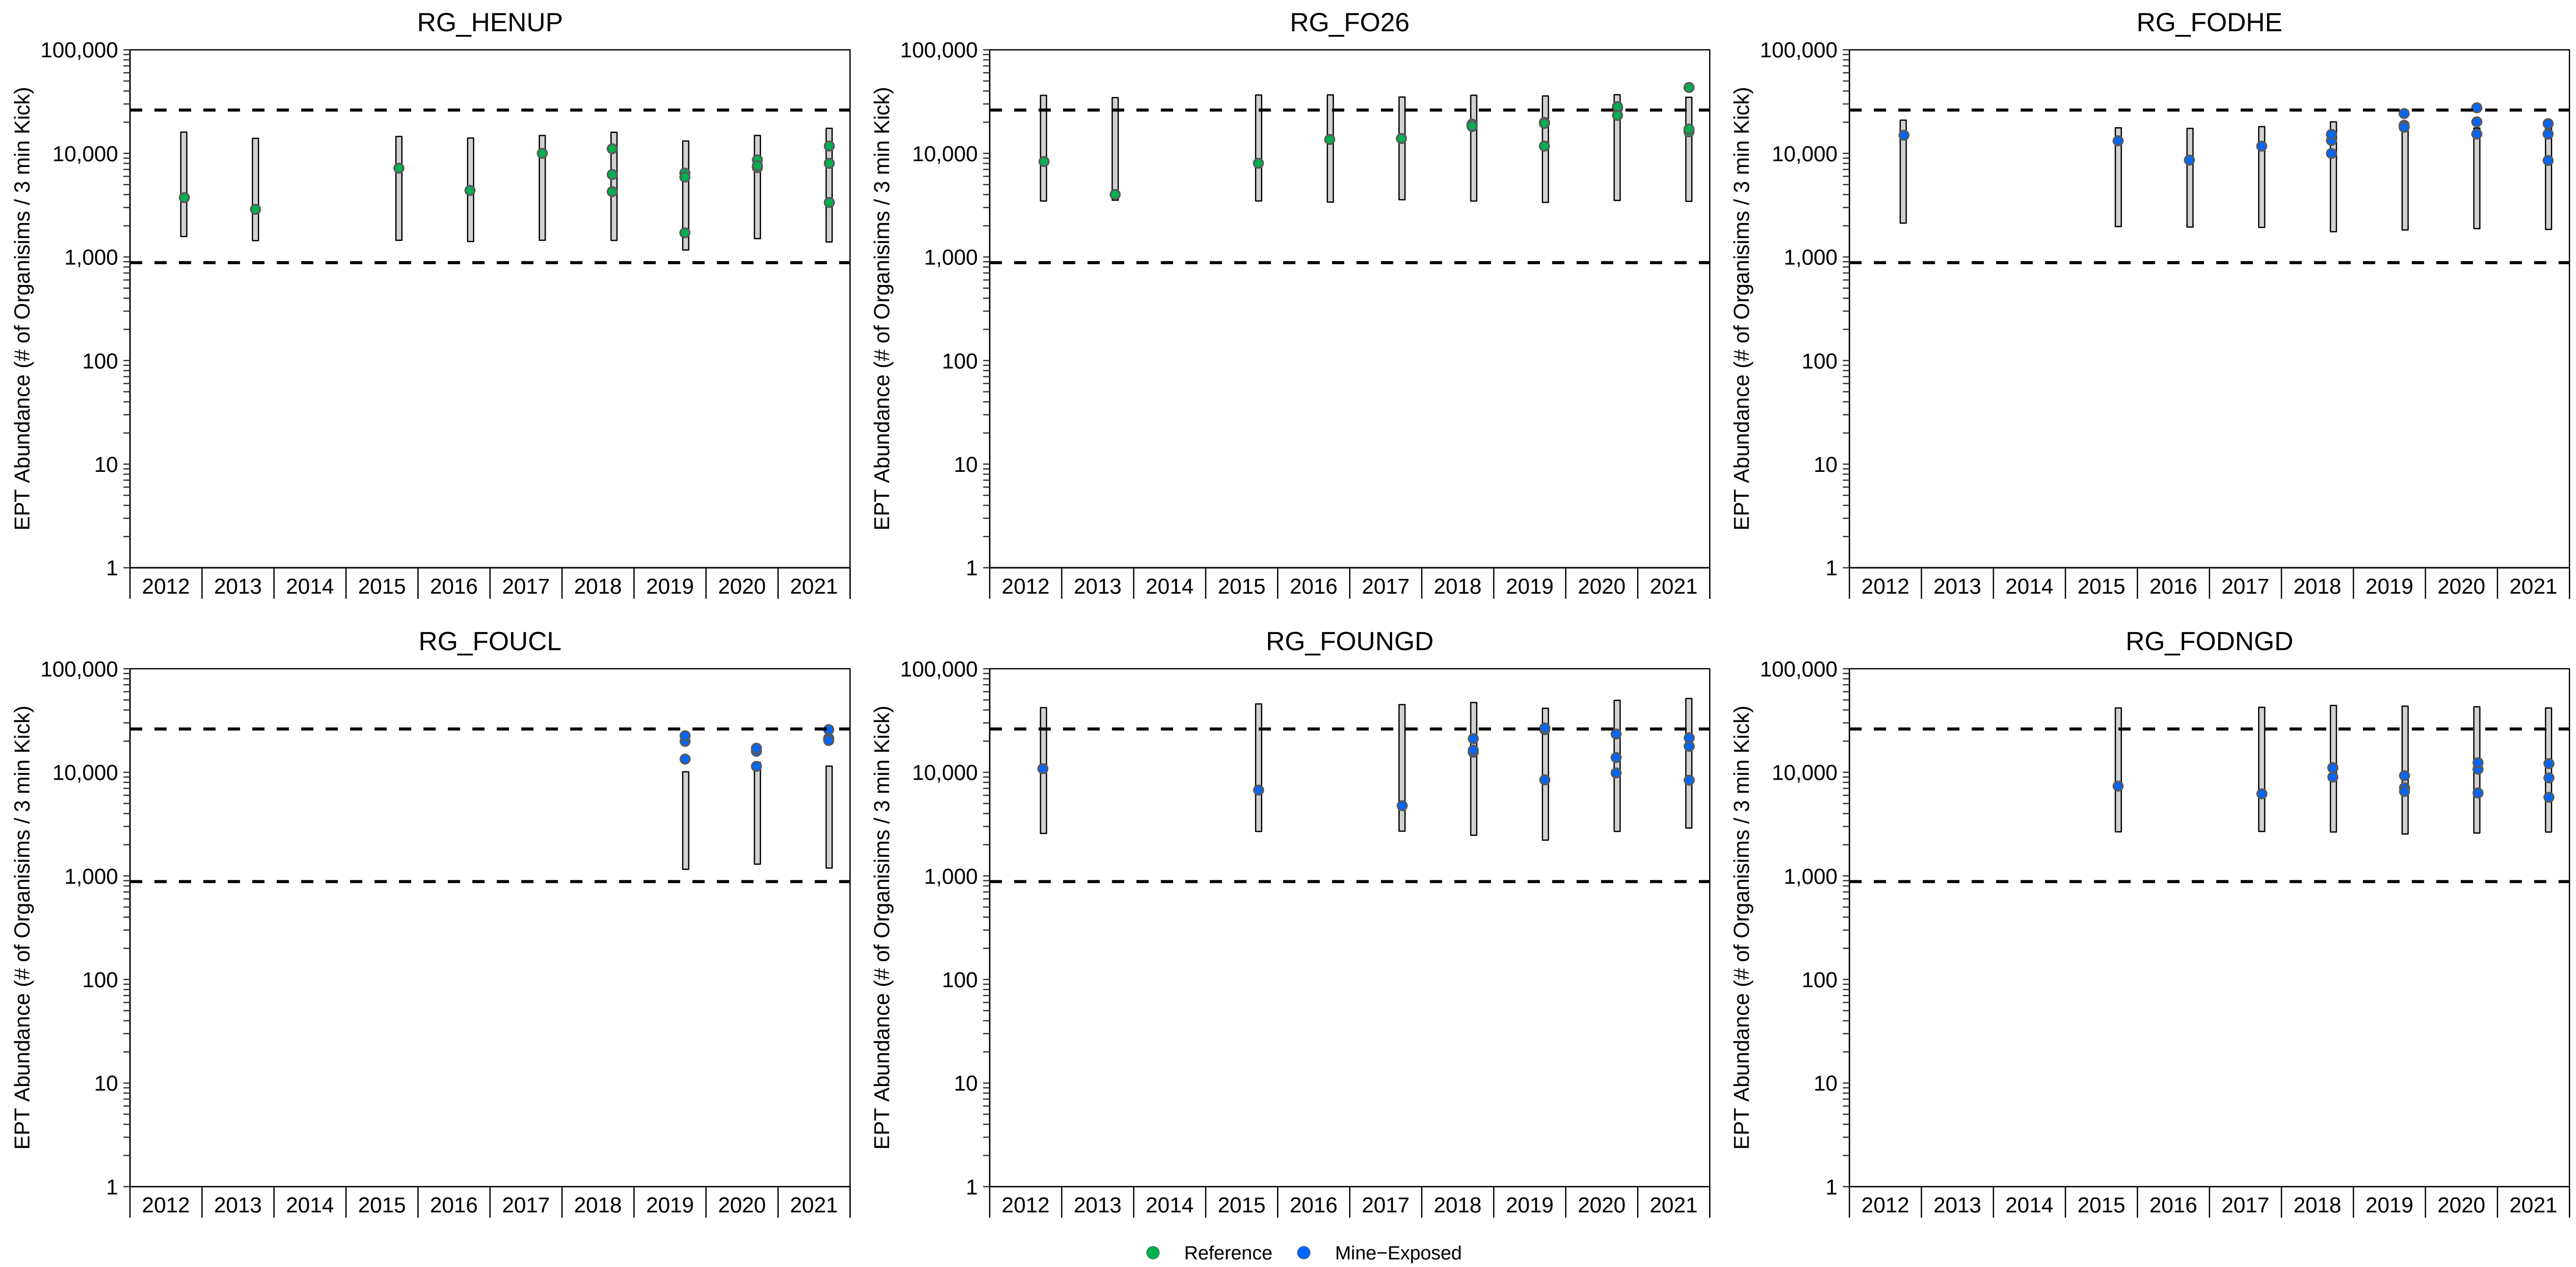

Figure E.14: Benthic Invertebrate EPT Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

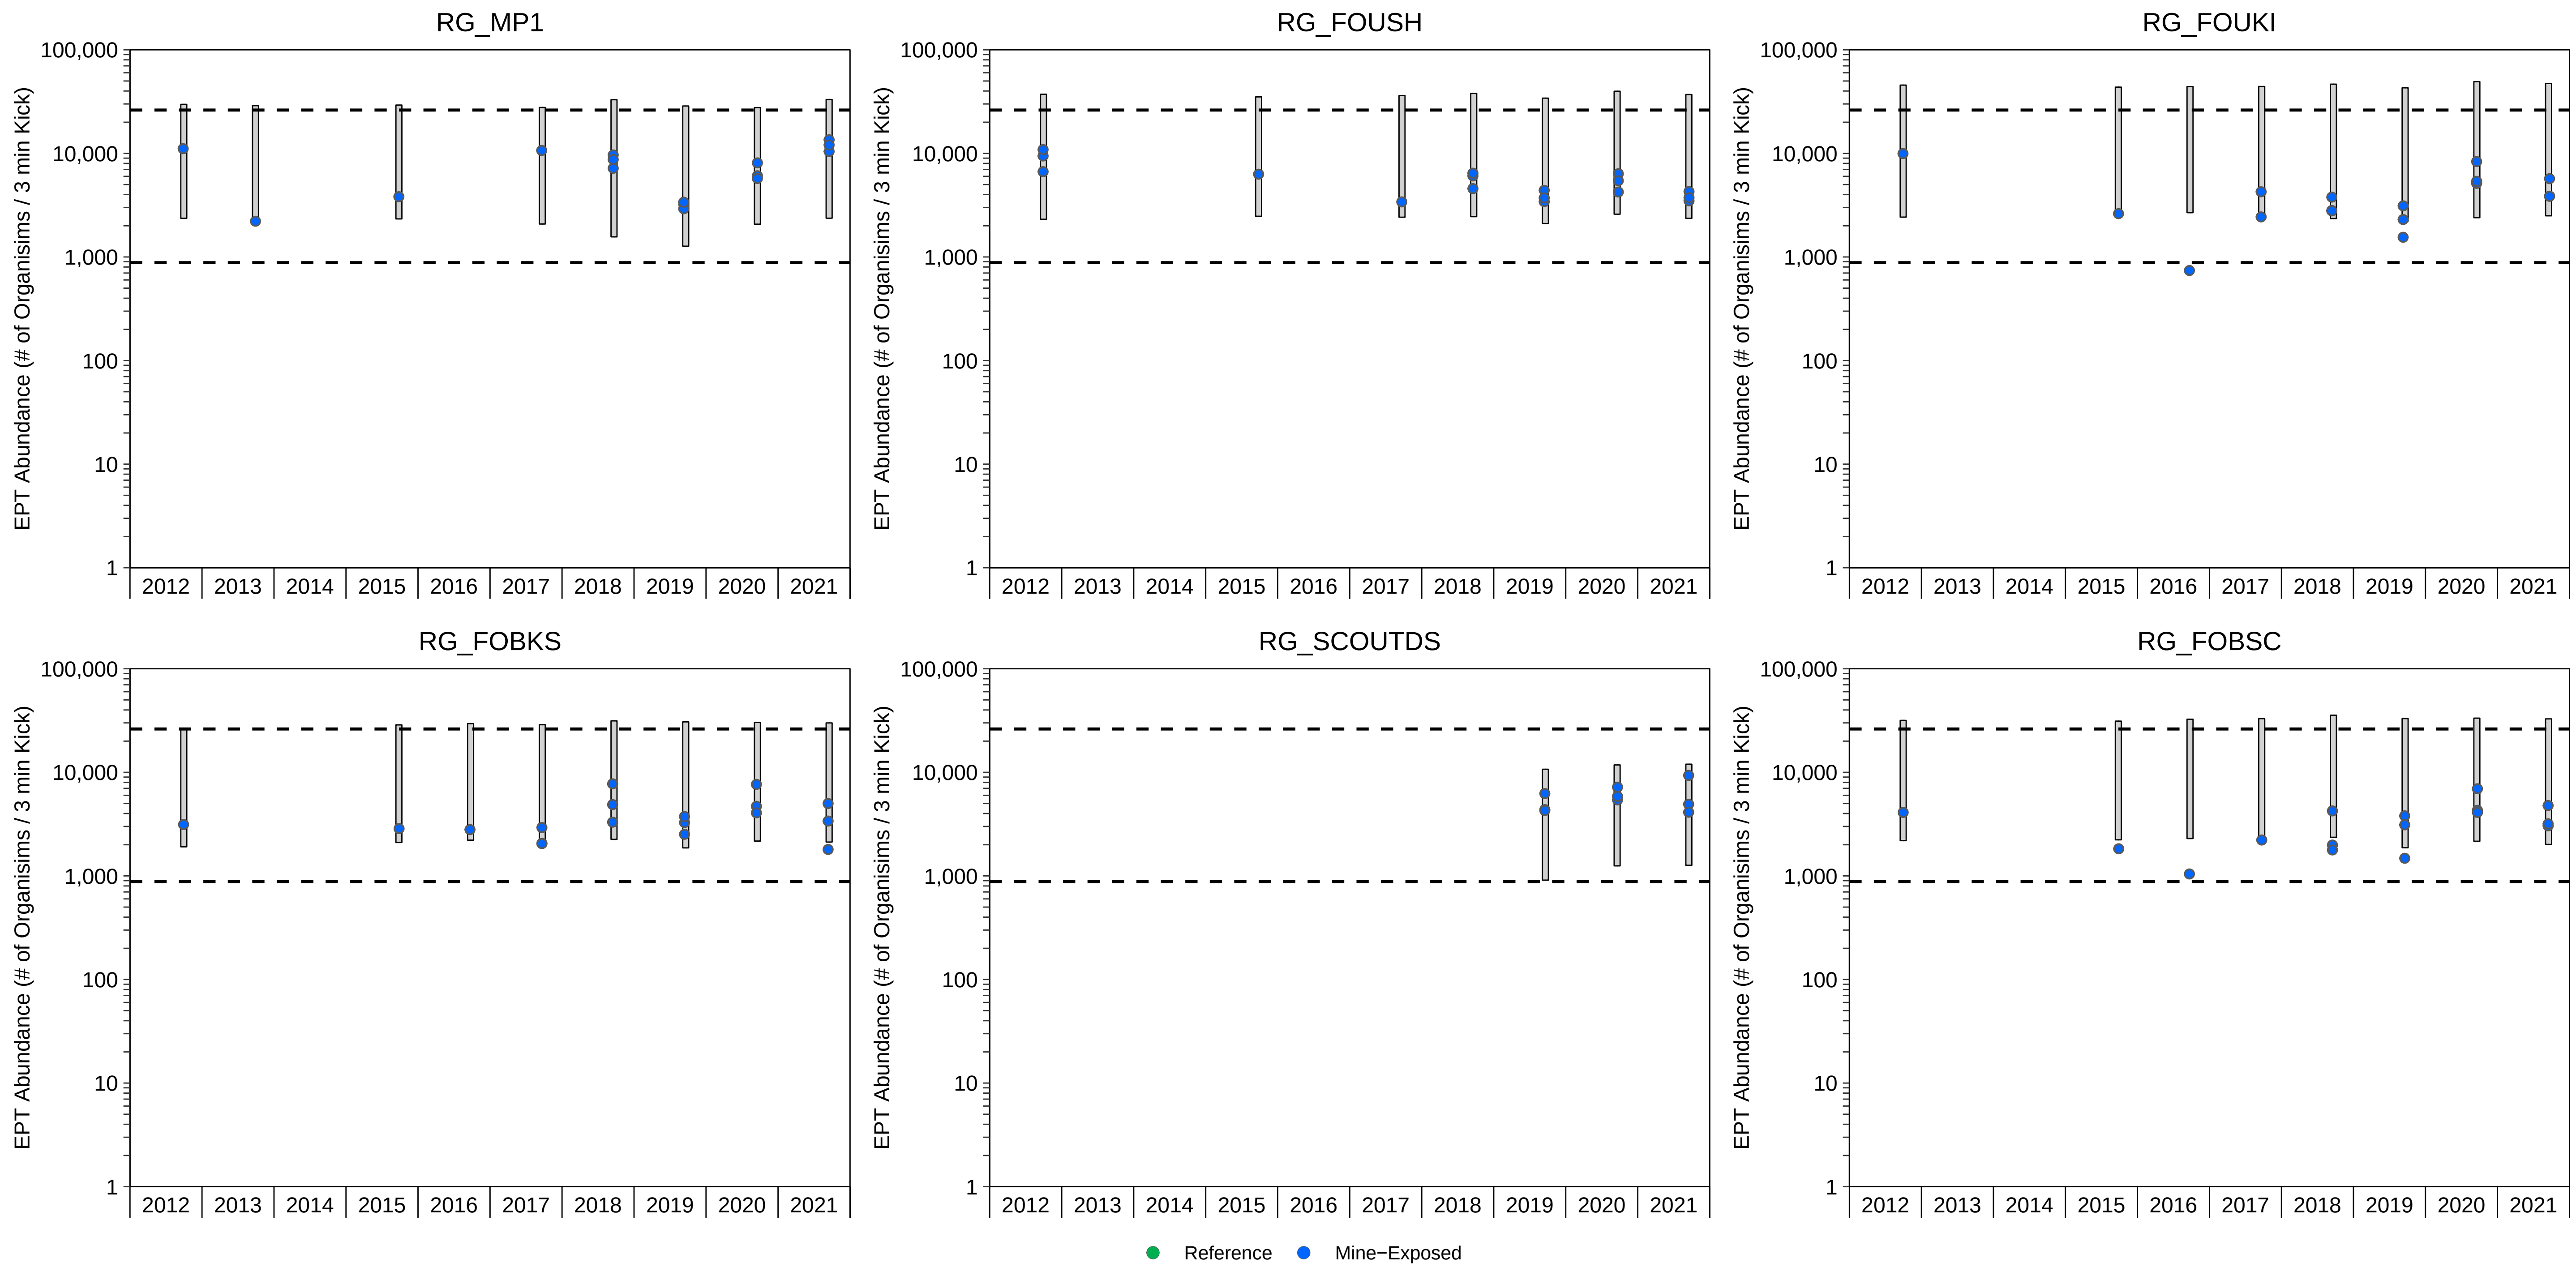

Figure E.14: Benthic Invertebrate EPT Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

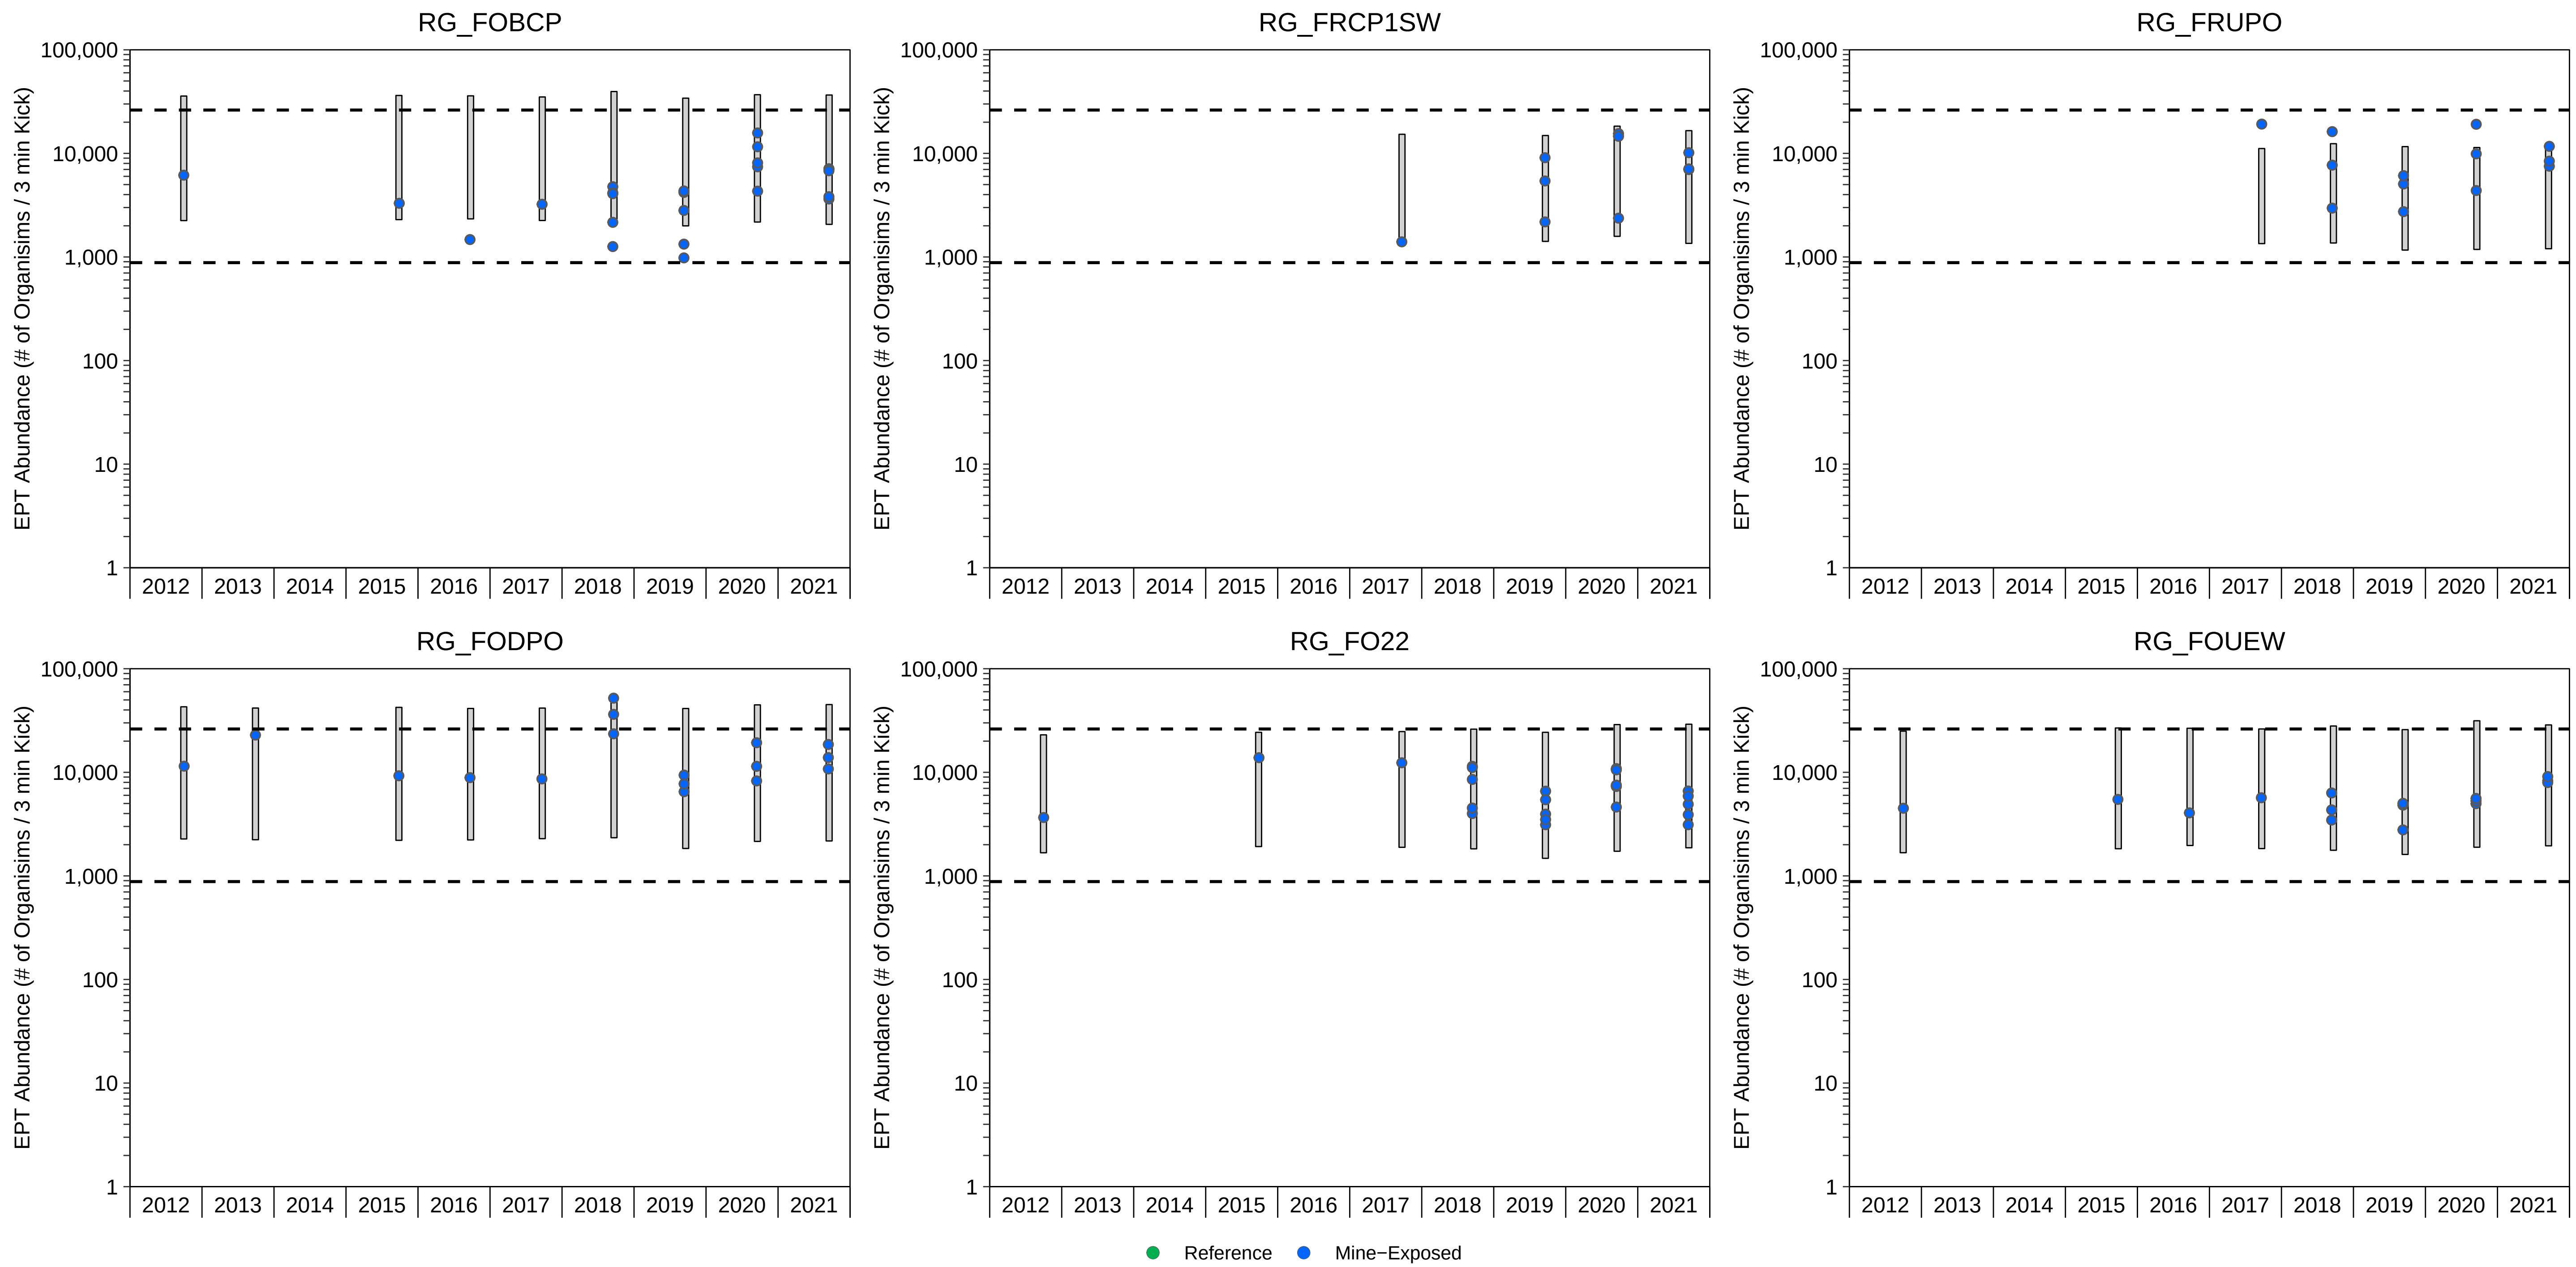

Figure E.14: Benthic Invertebrate EPT Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

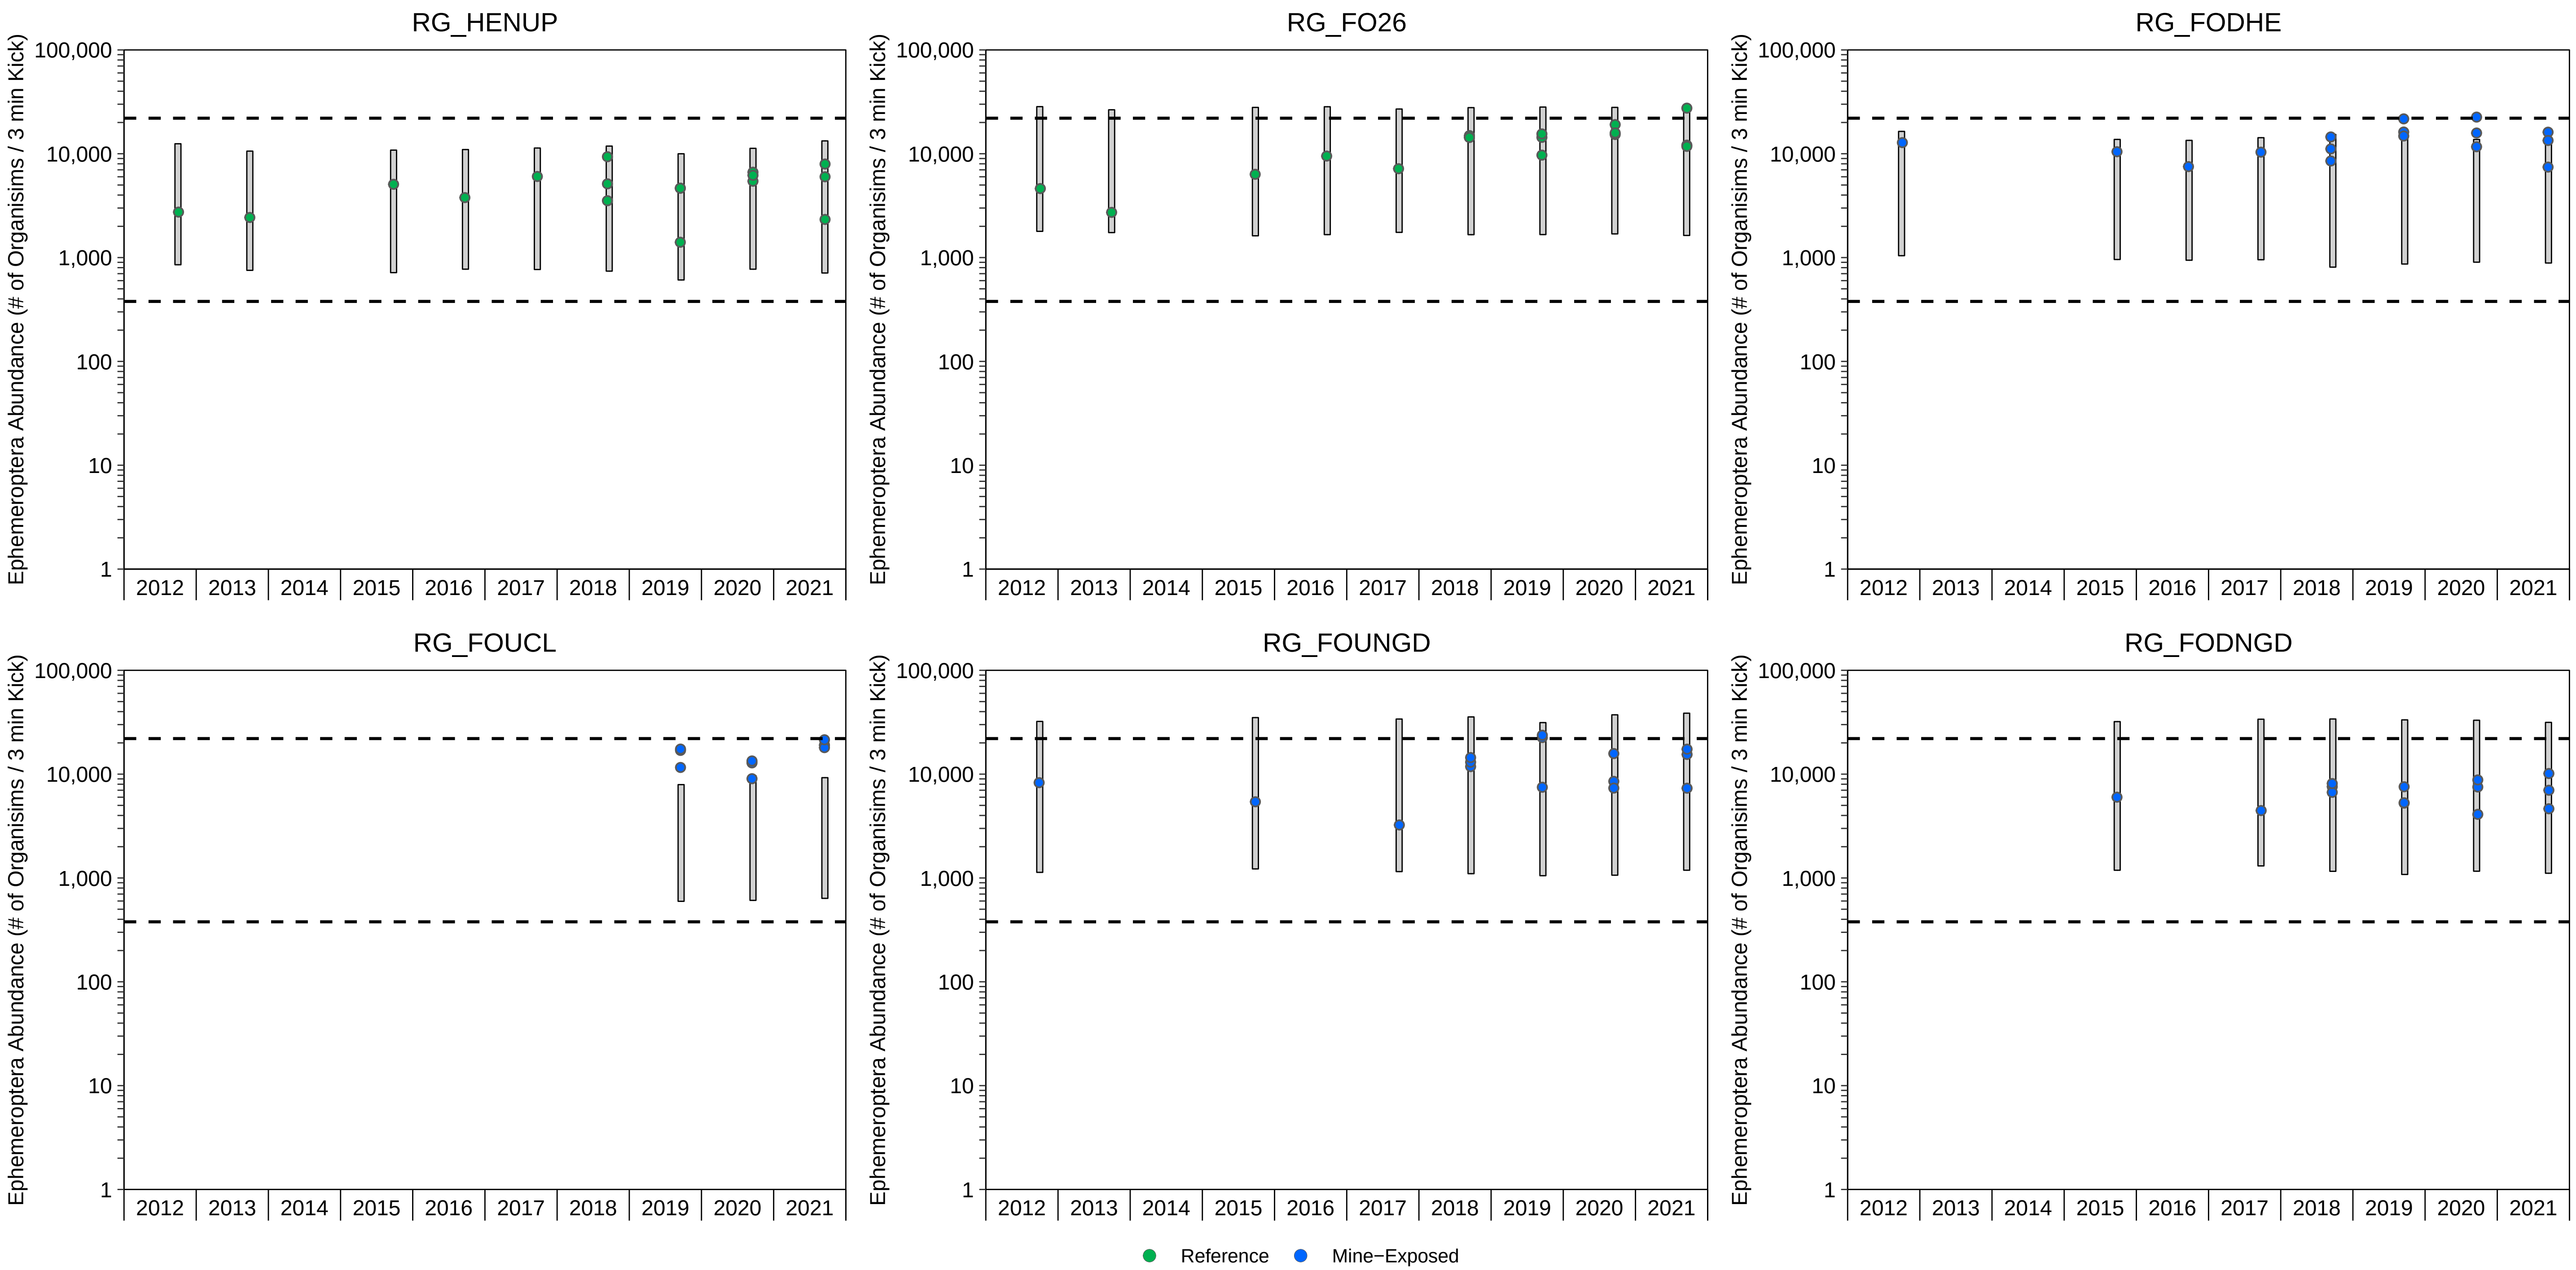

Figure E.15: Benthic Invertebrate Ephemeroptera Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

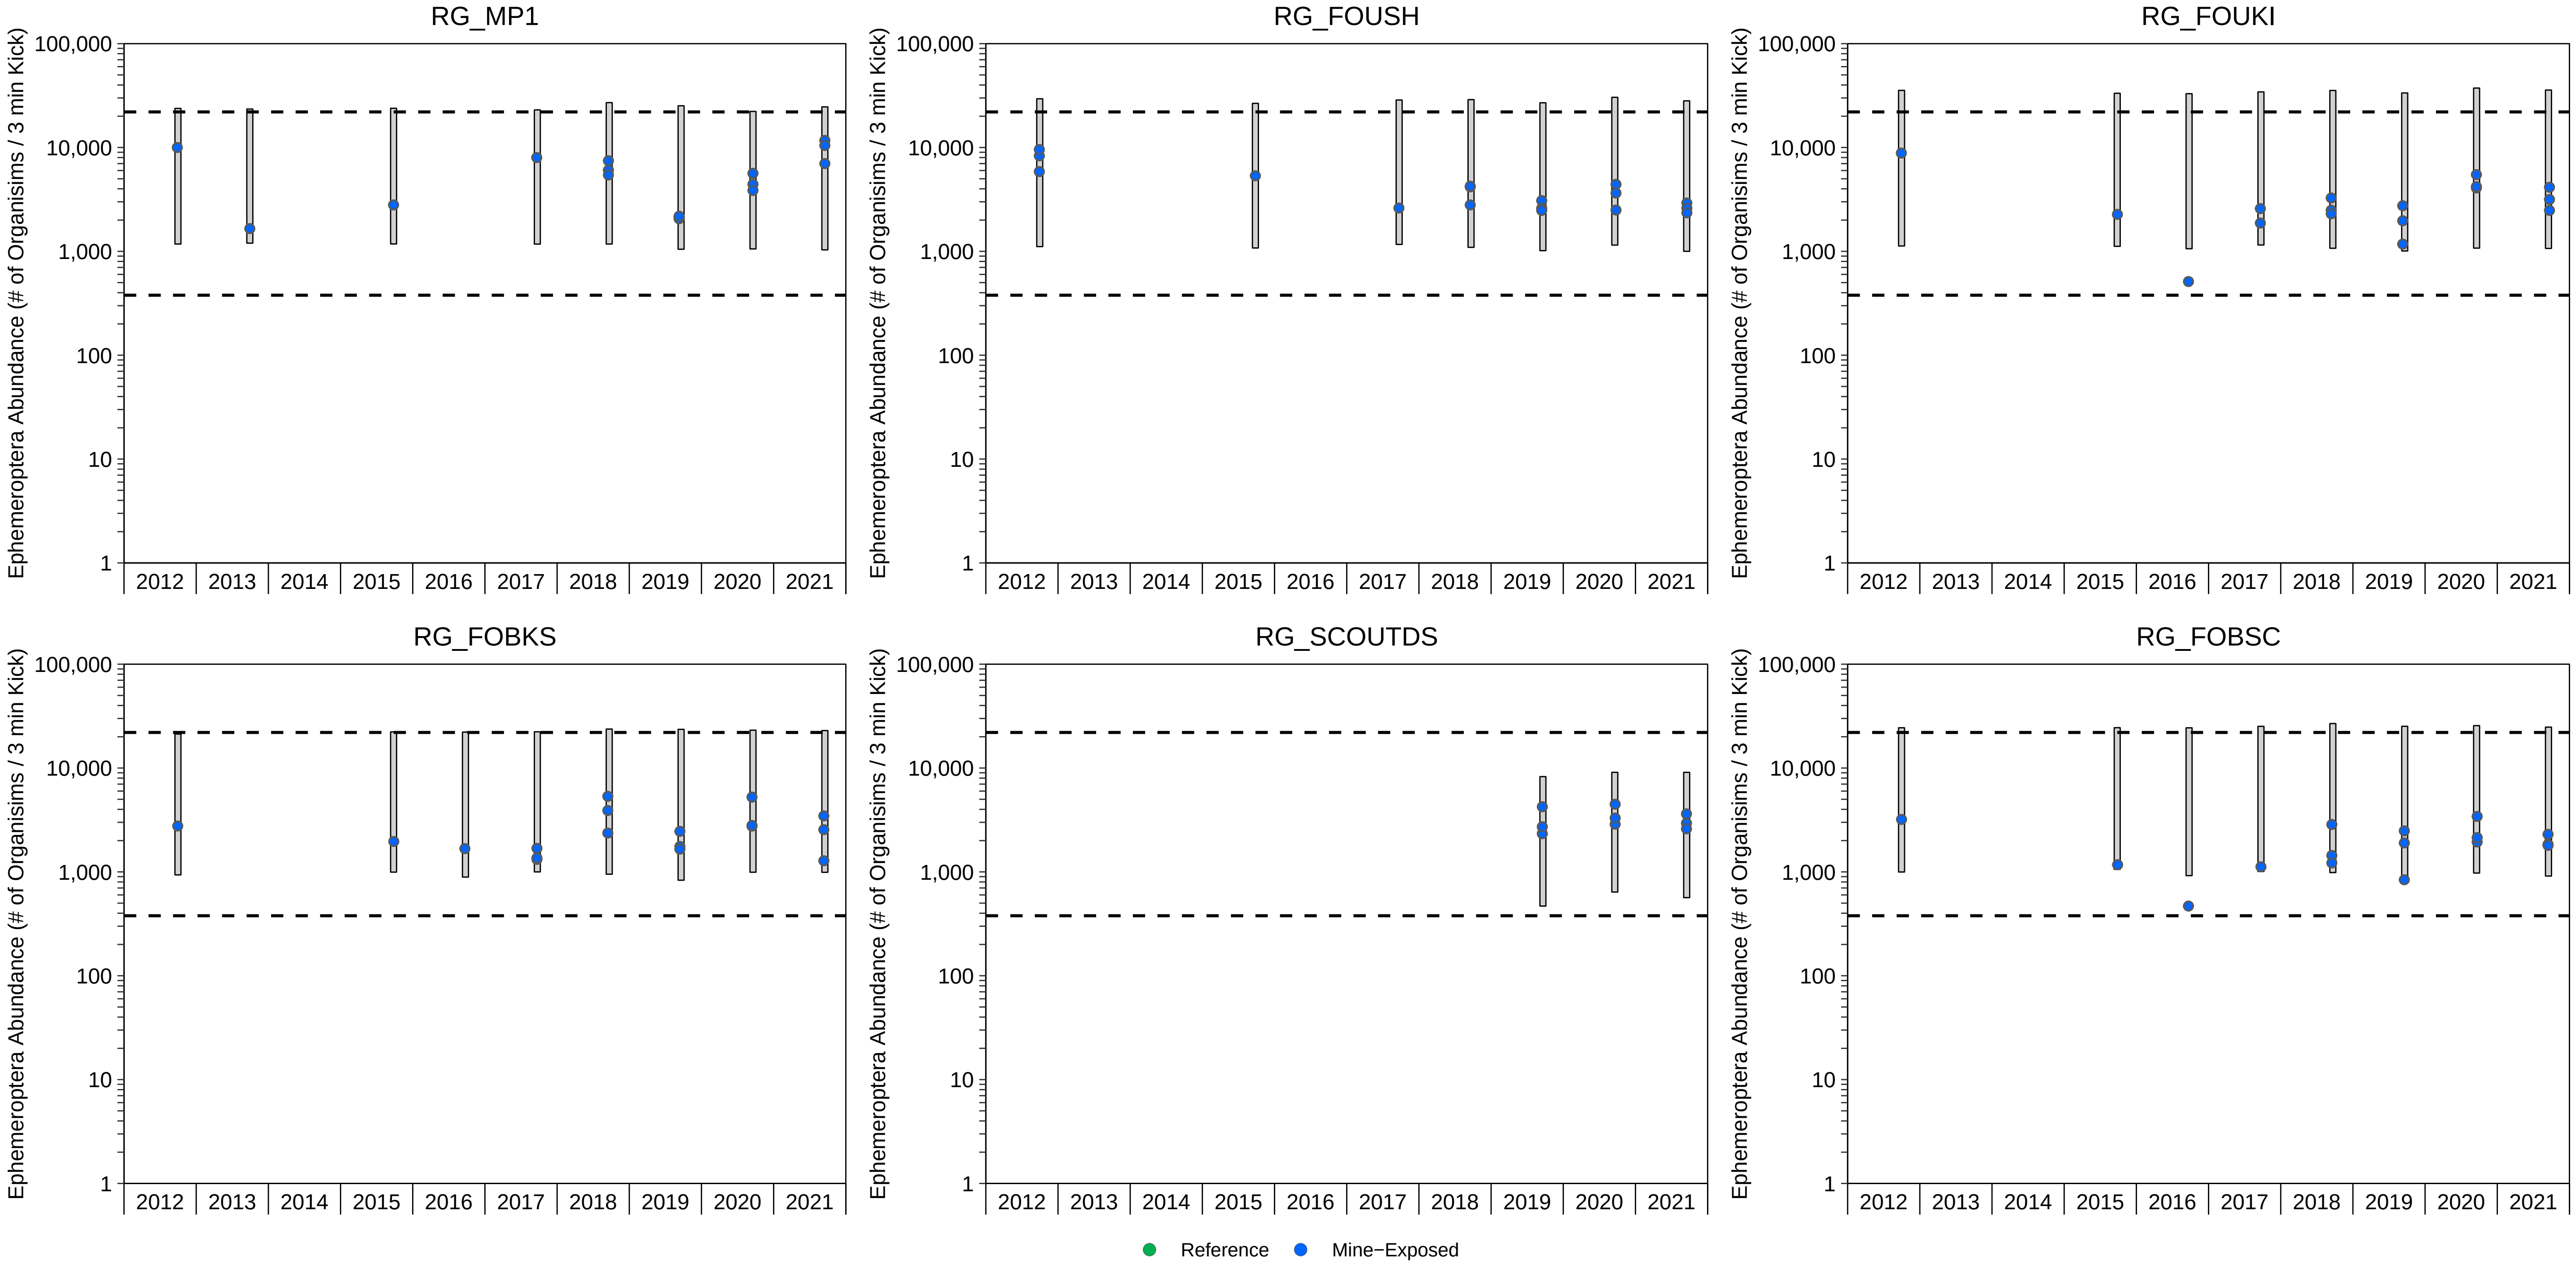

Figure E.15: Benthic Invertebrate Ephemeroptera Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

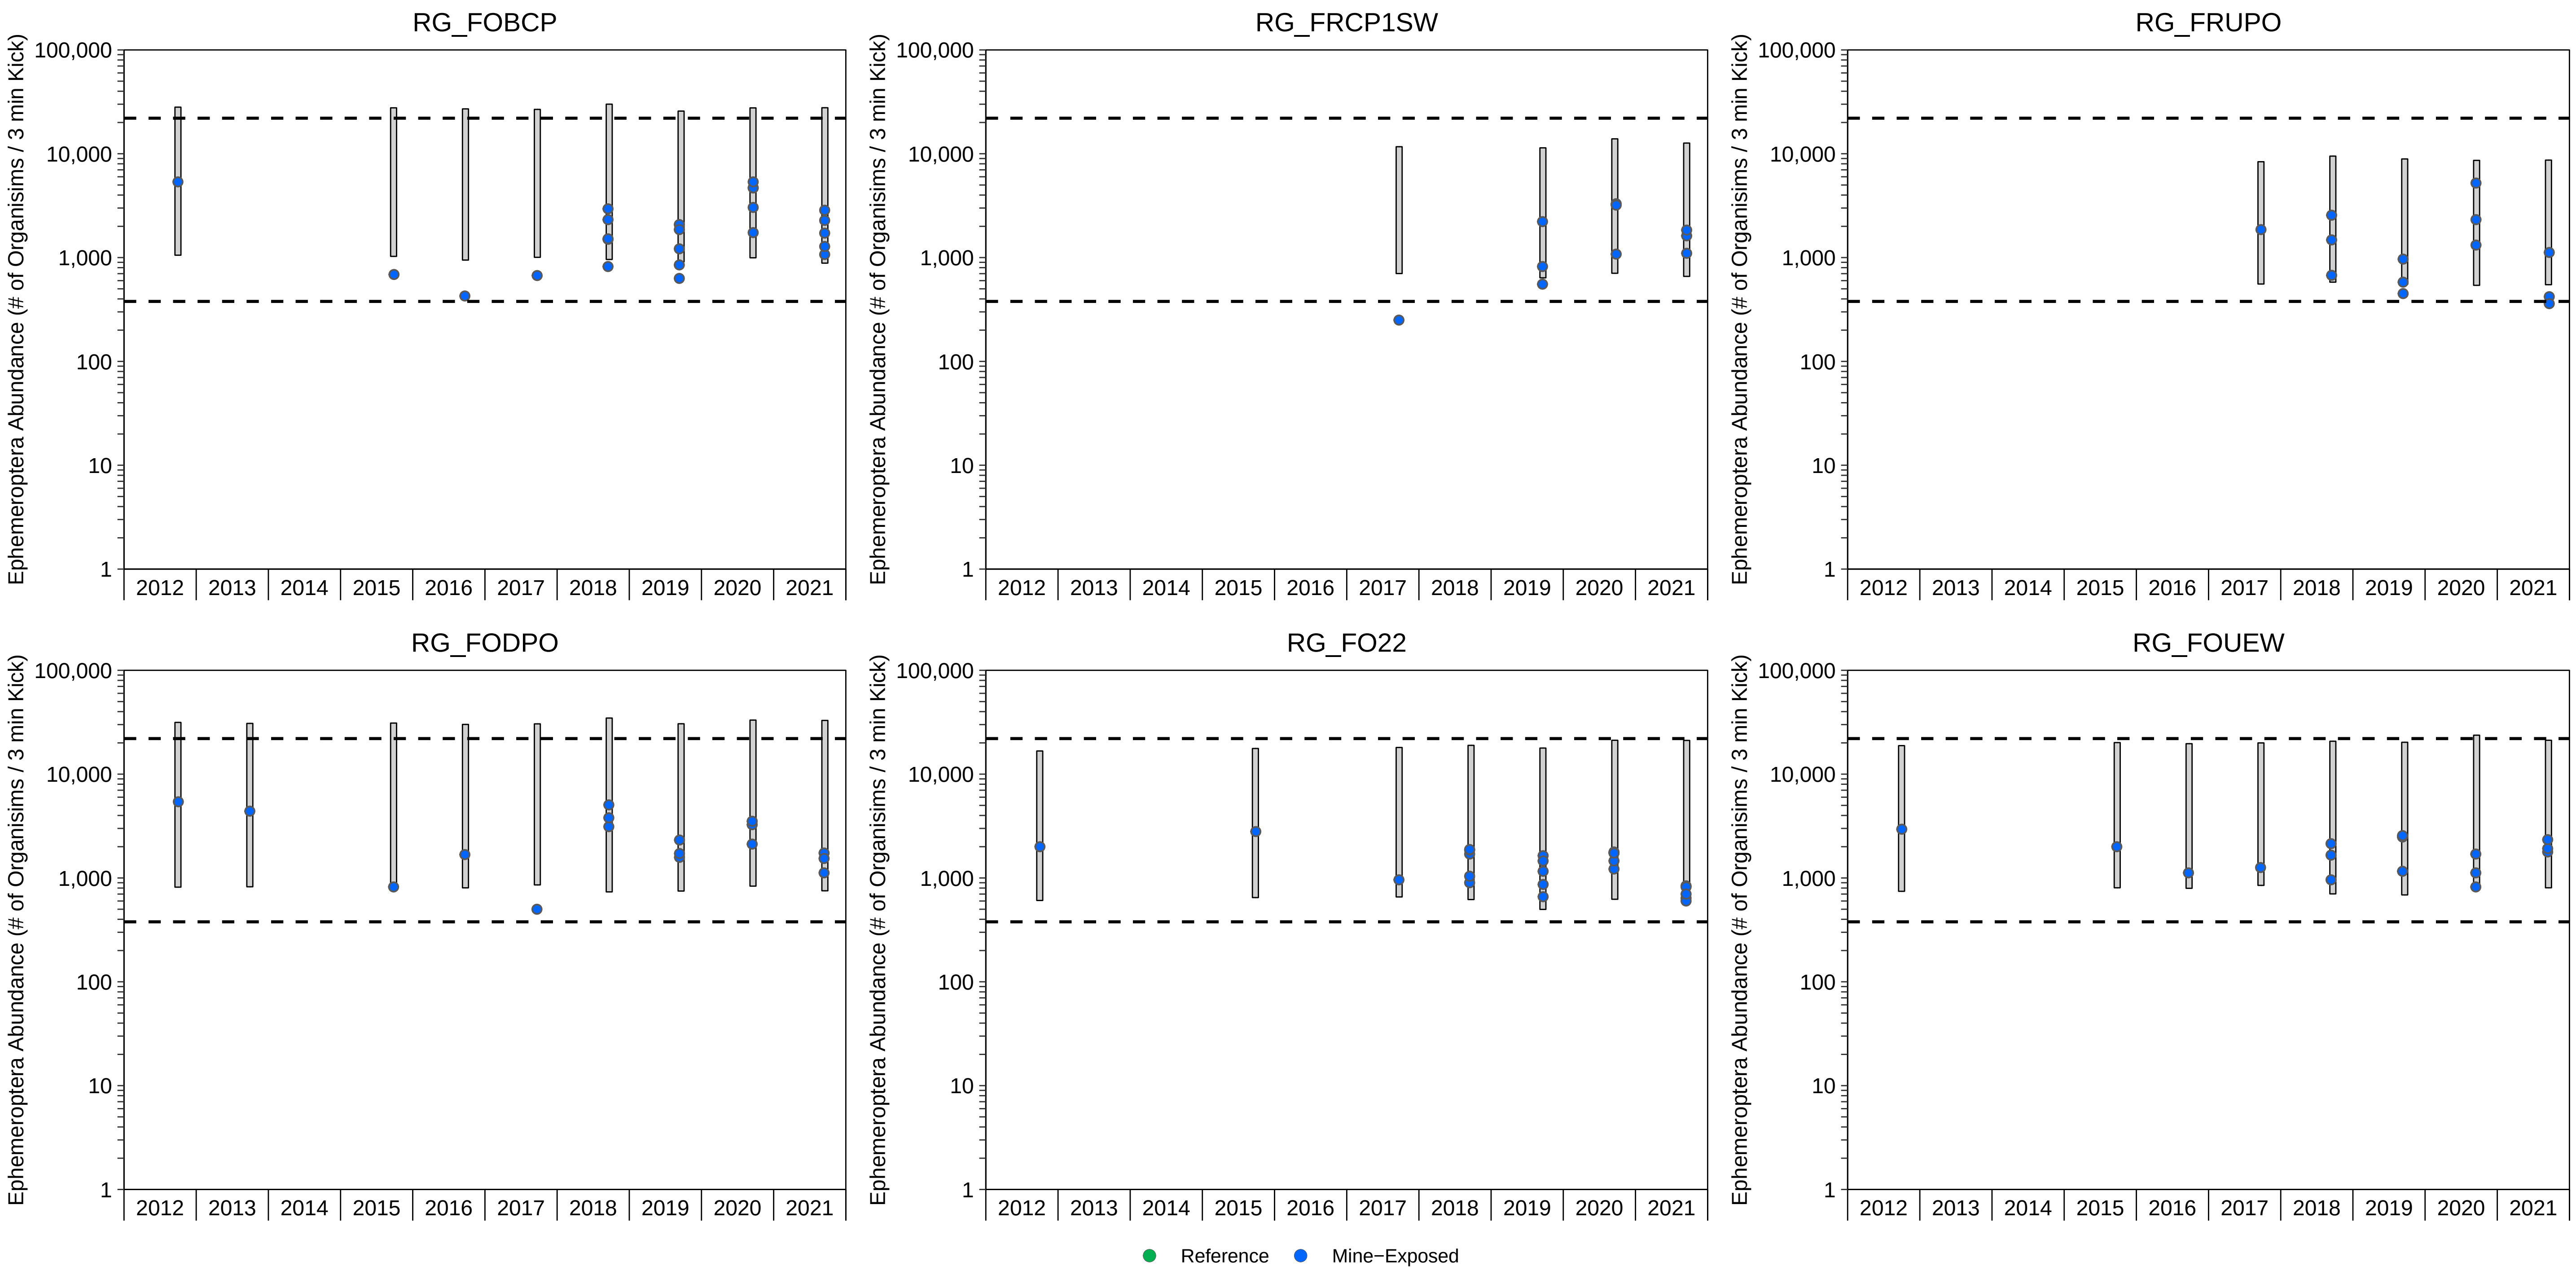

Figure E.15: Benthic Invertebrate Ephemeroptera Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Site specific normal ranges developed using regression models for the RAEMP (Minnow 2020a) are shown, when applicable, with grey shading (Minnow 2020a). Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

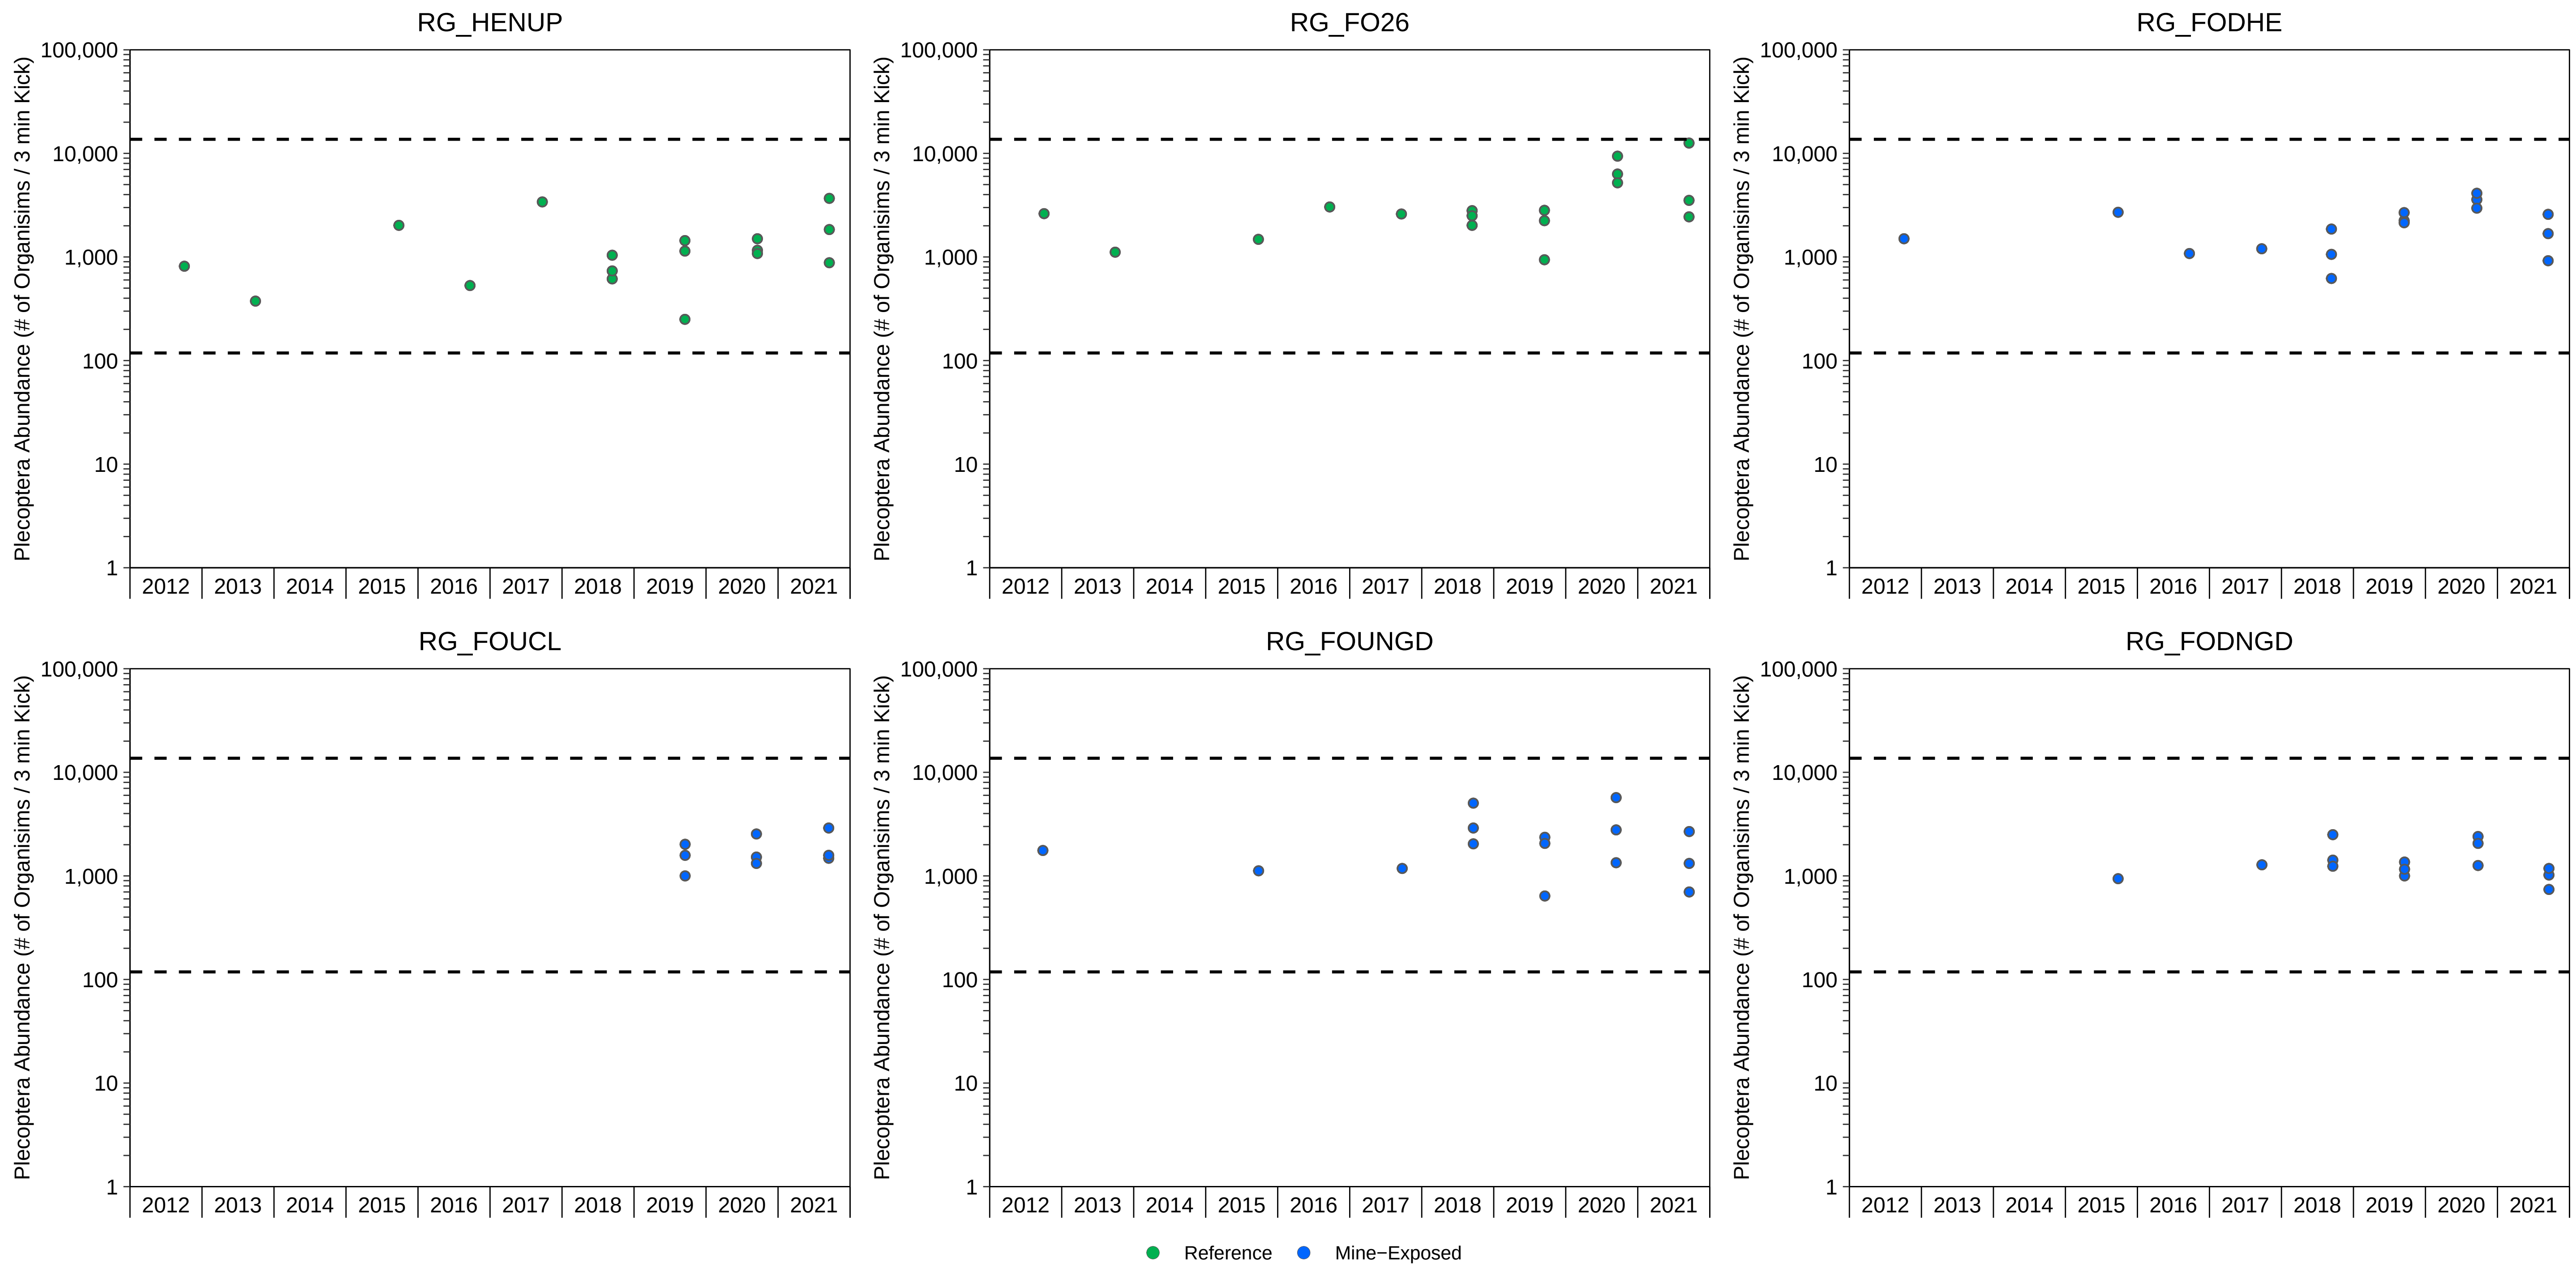

Figure E.16: **Benthic Invertebrate Plecoptera Abundance in September, FRO LAEMP, 2012 to 2021**

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

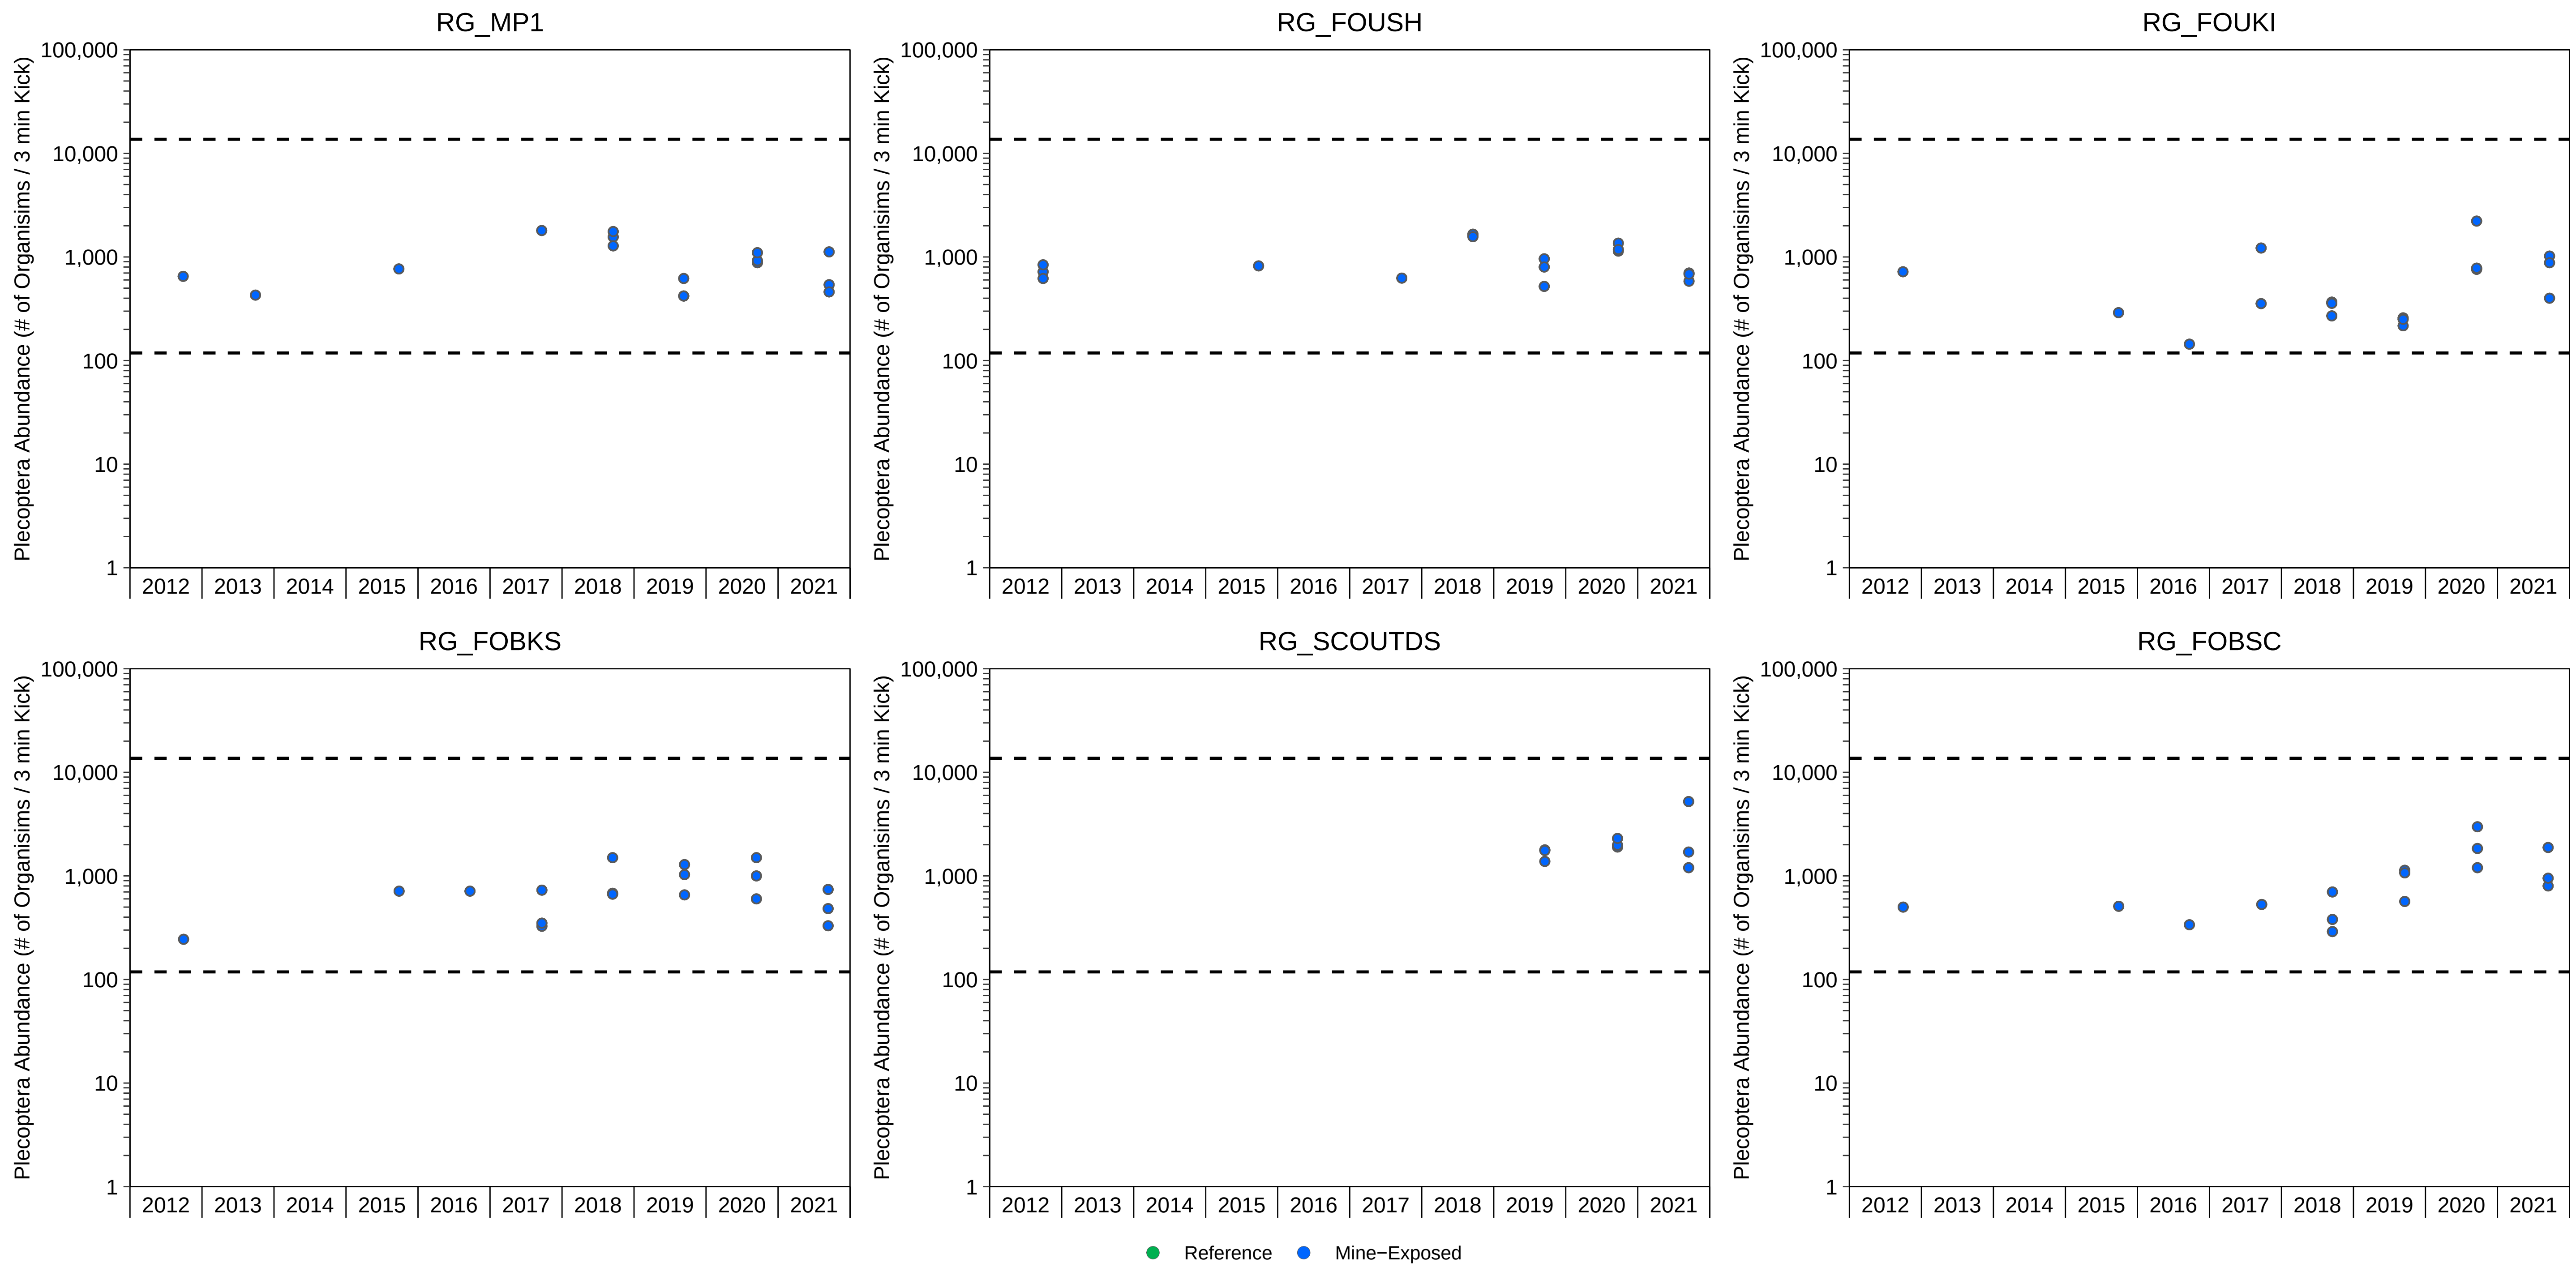

Figure E.16: Benthic Invertebrate Plecoptera Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

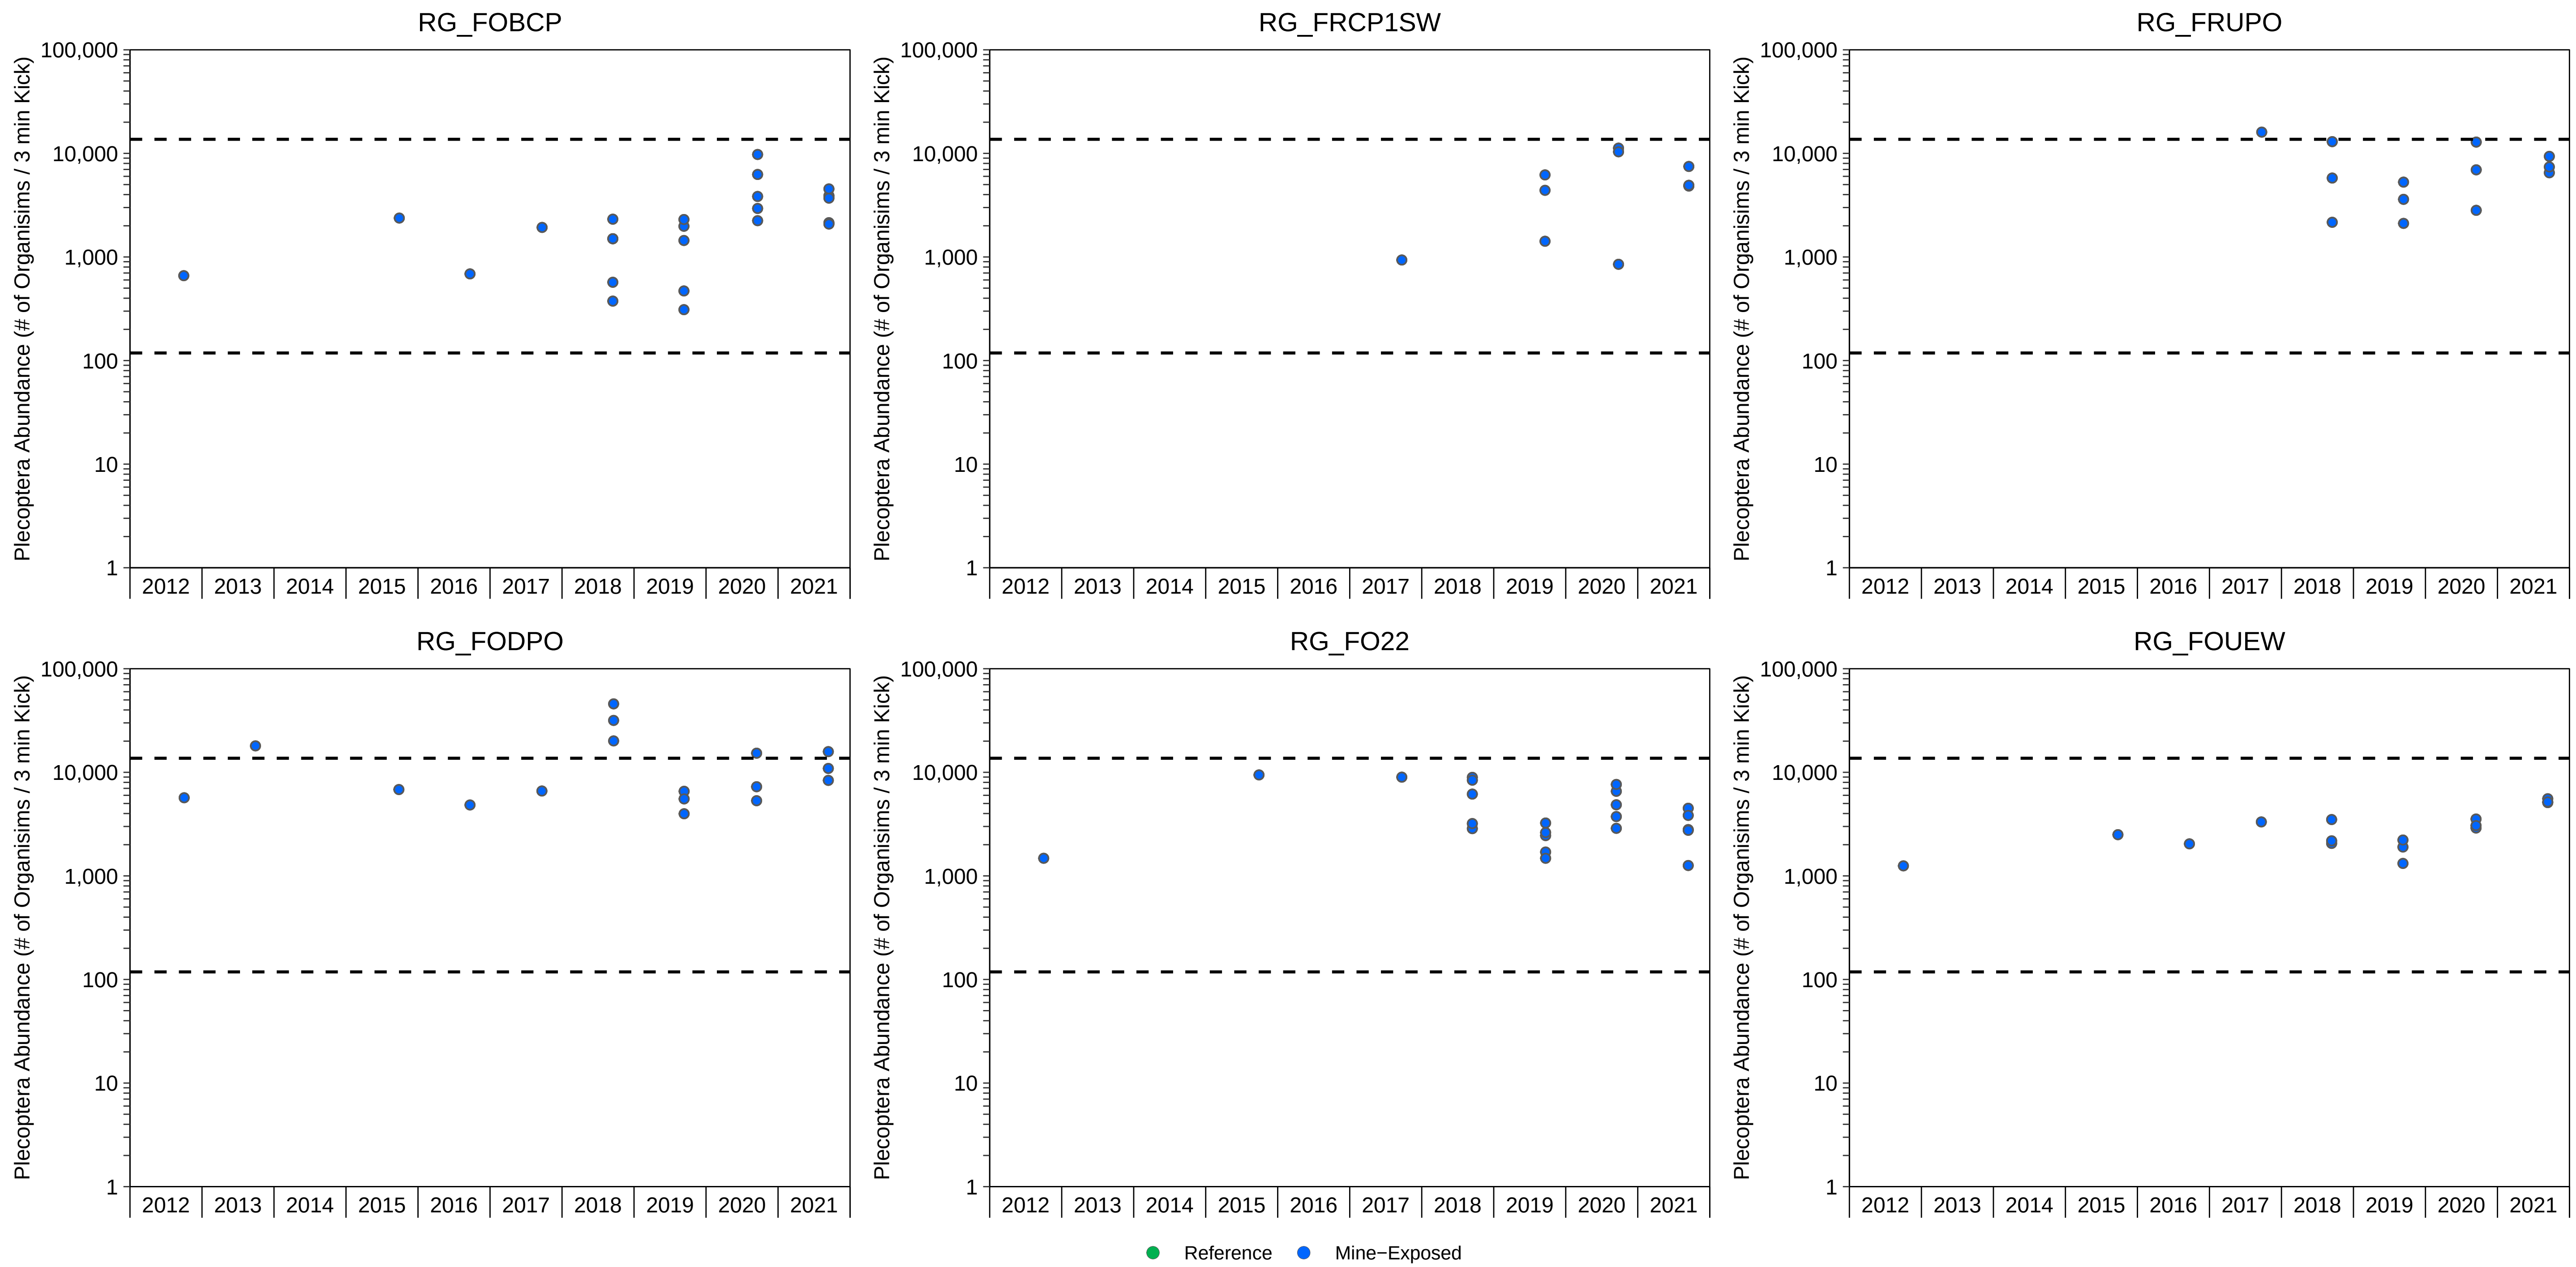

Figure E.16: Benthic Invertebrate Plecoptera Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

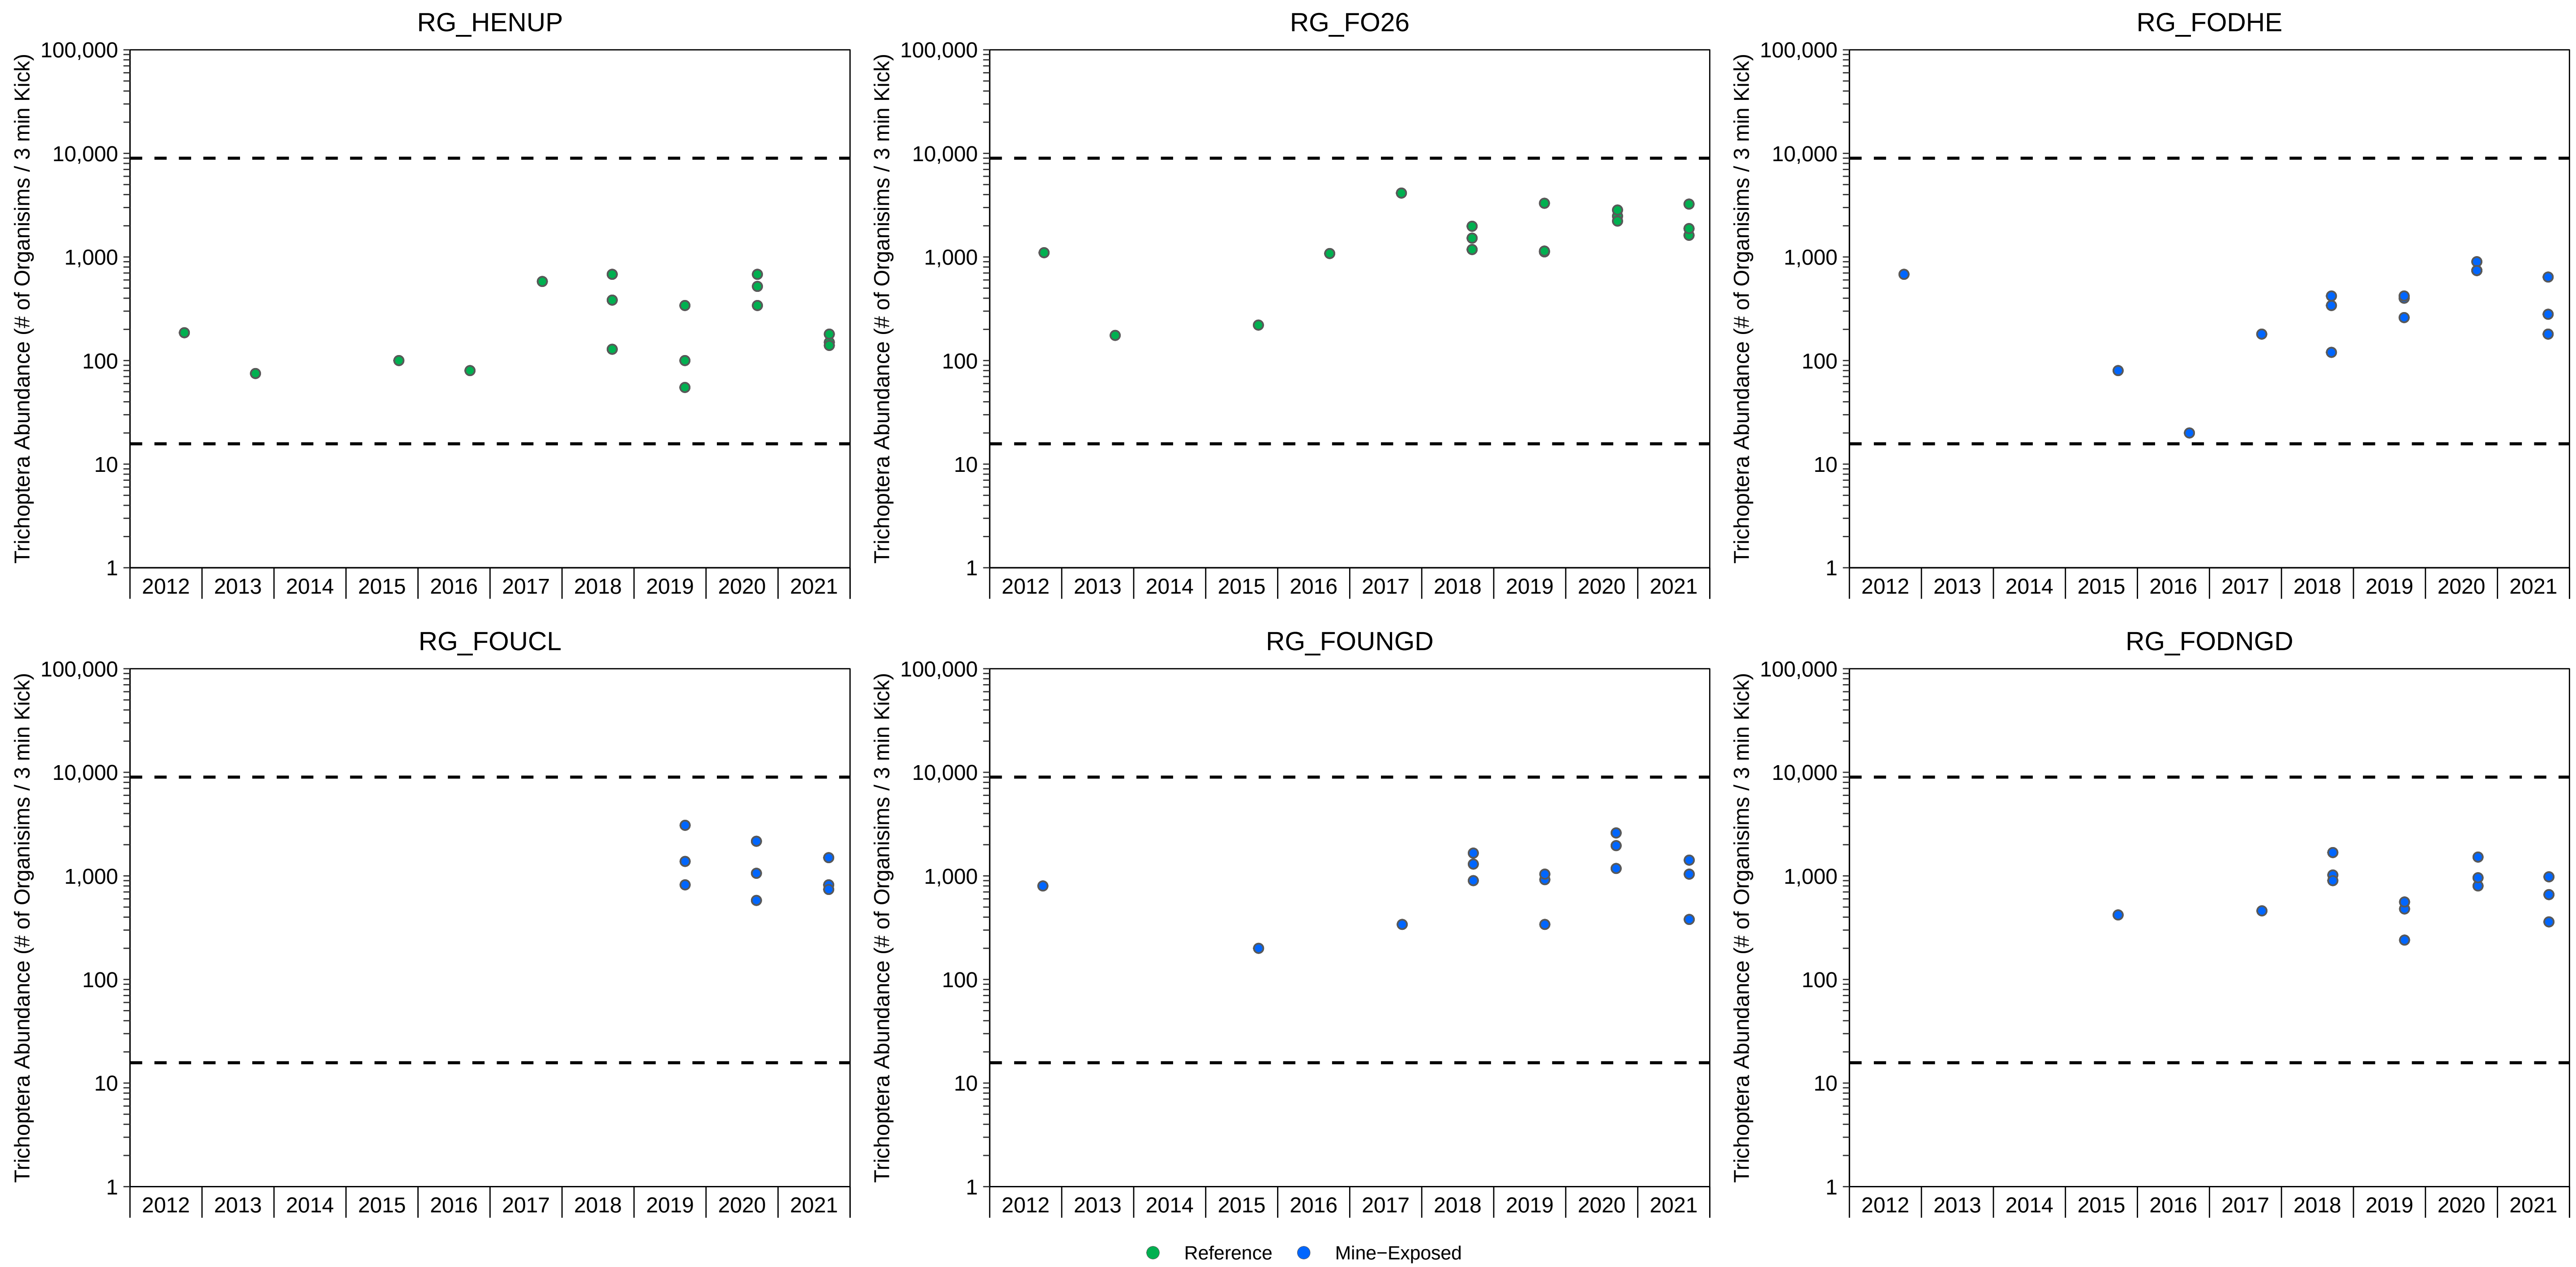

Figure E.17: Benthic Invertebrate Trichoptera Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

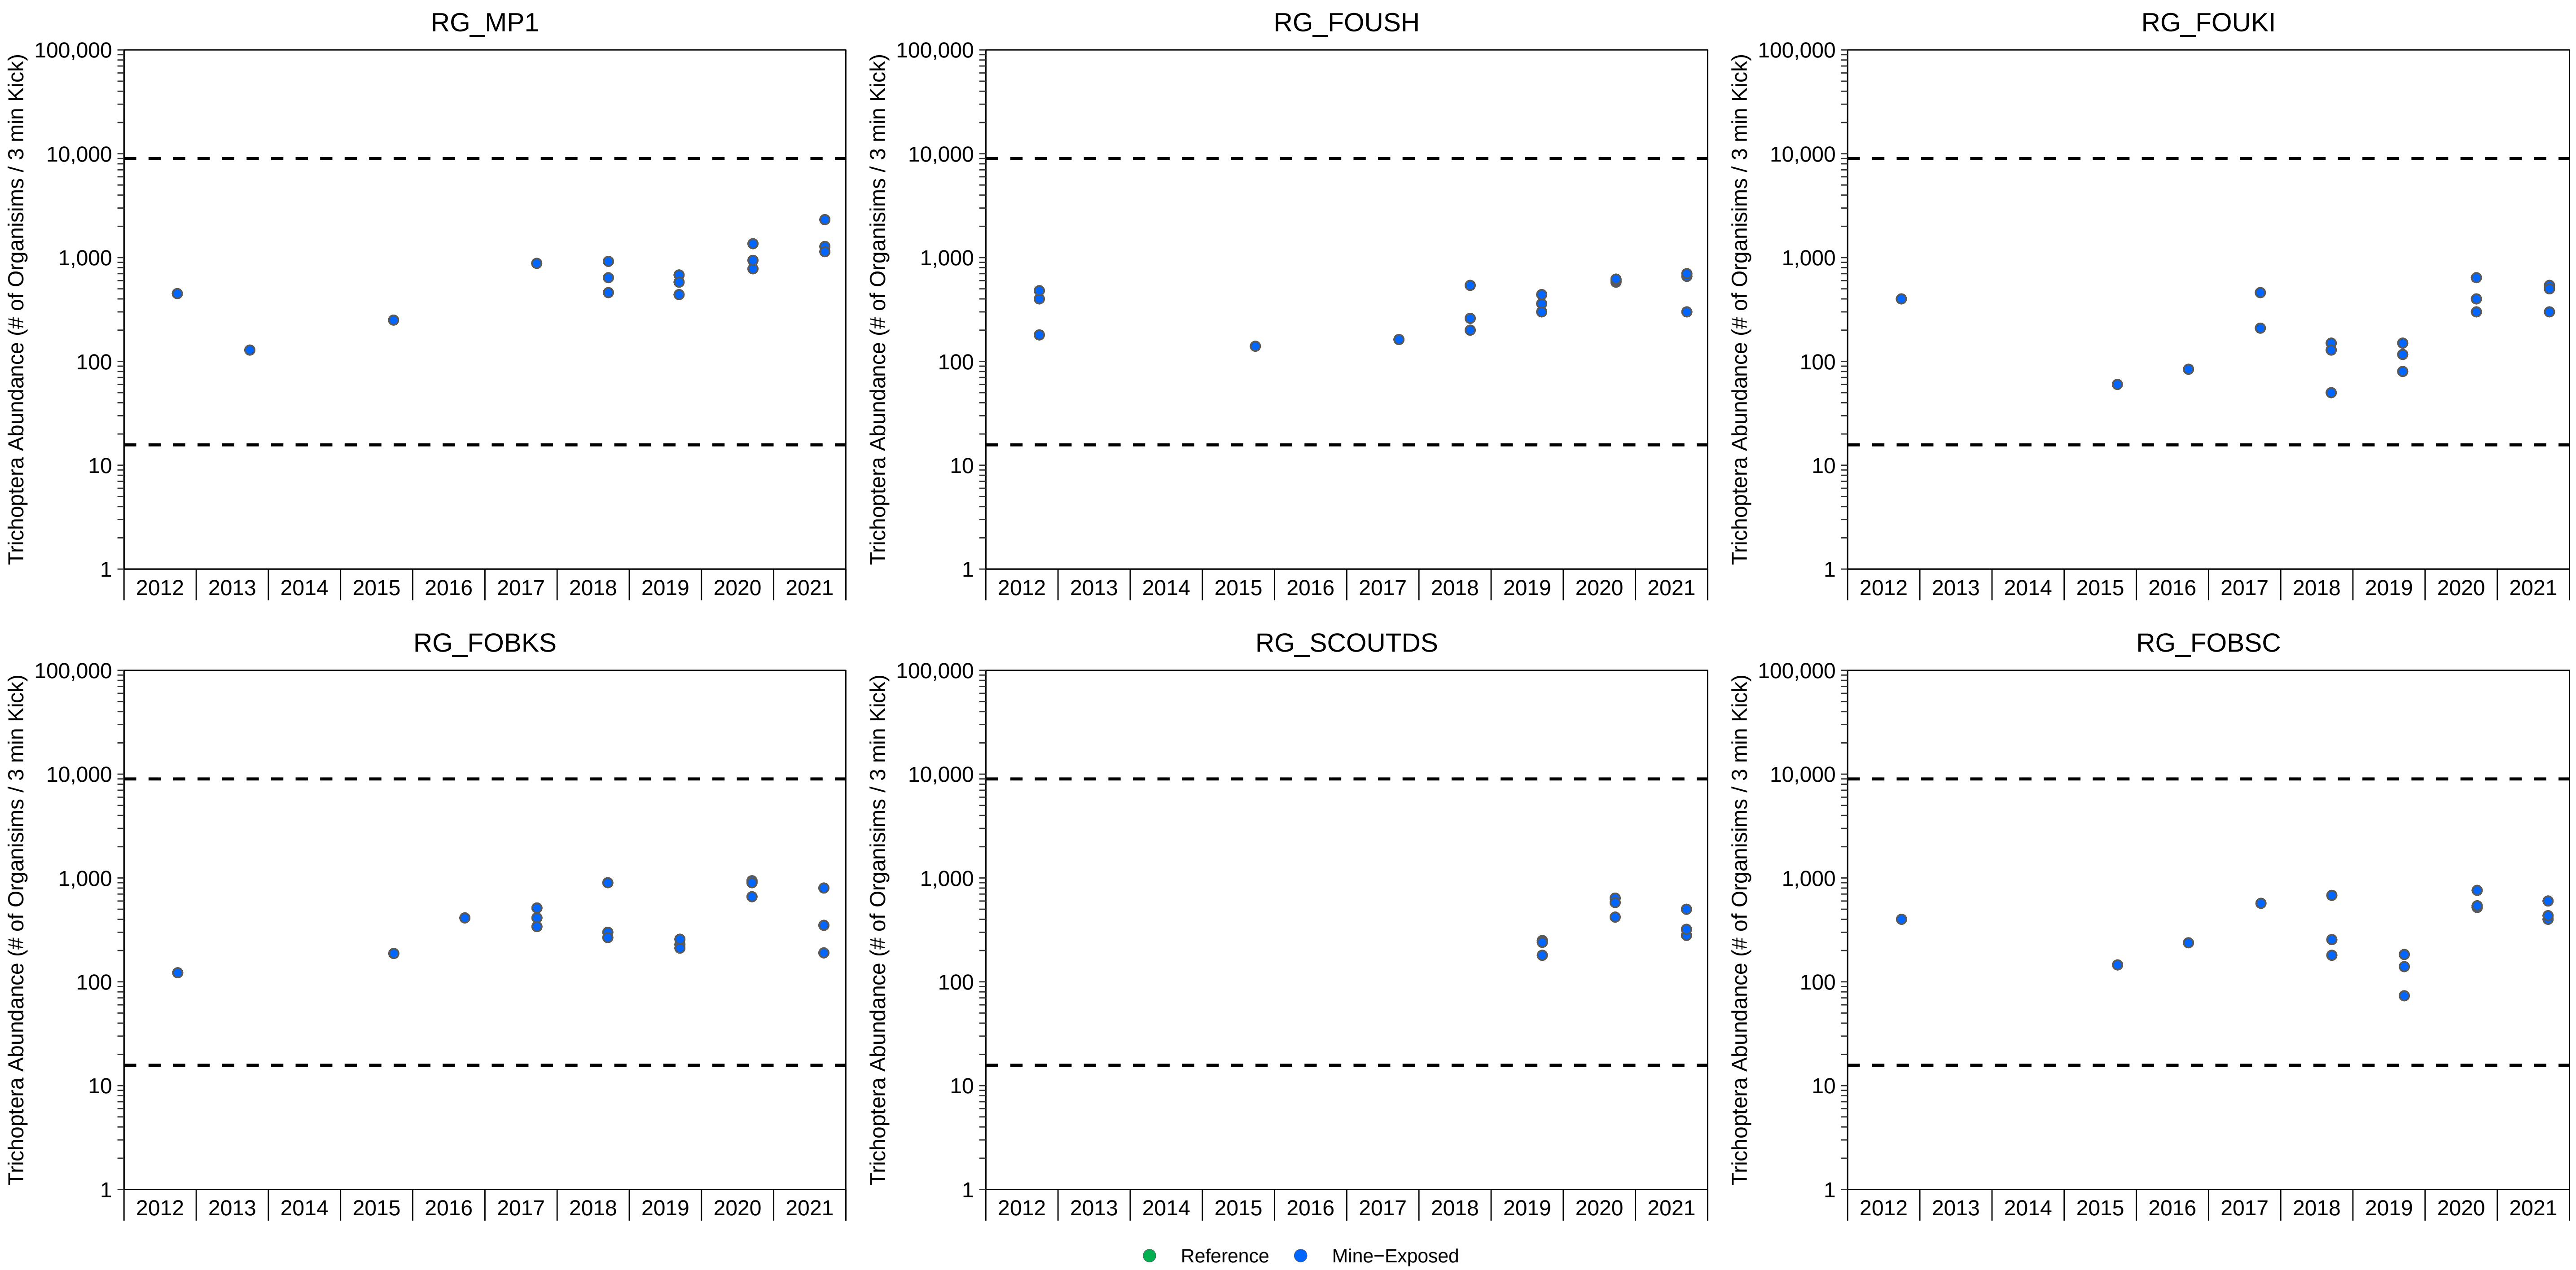

Figure E.17: Benthic Invertebrate Trichoptera Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

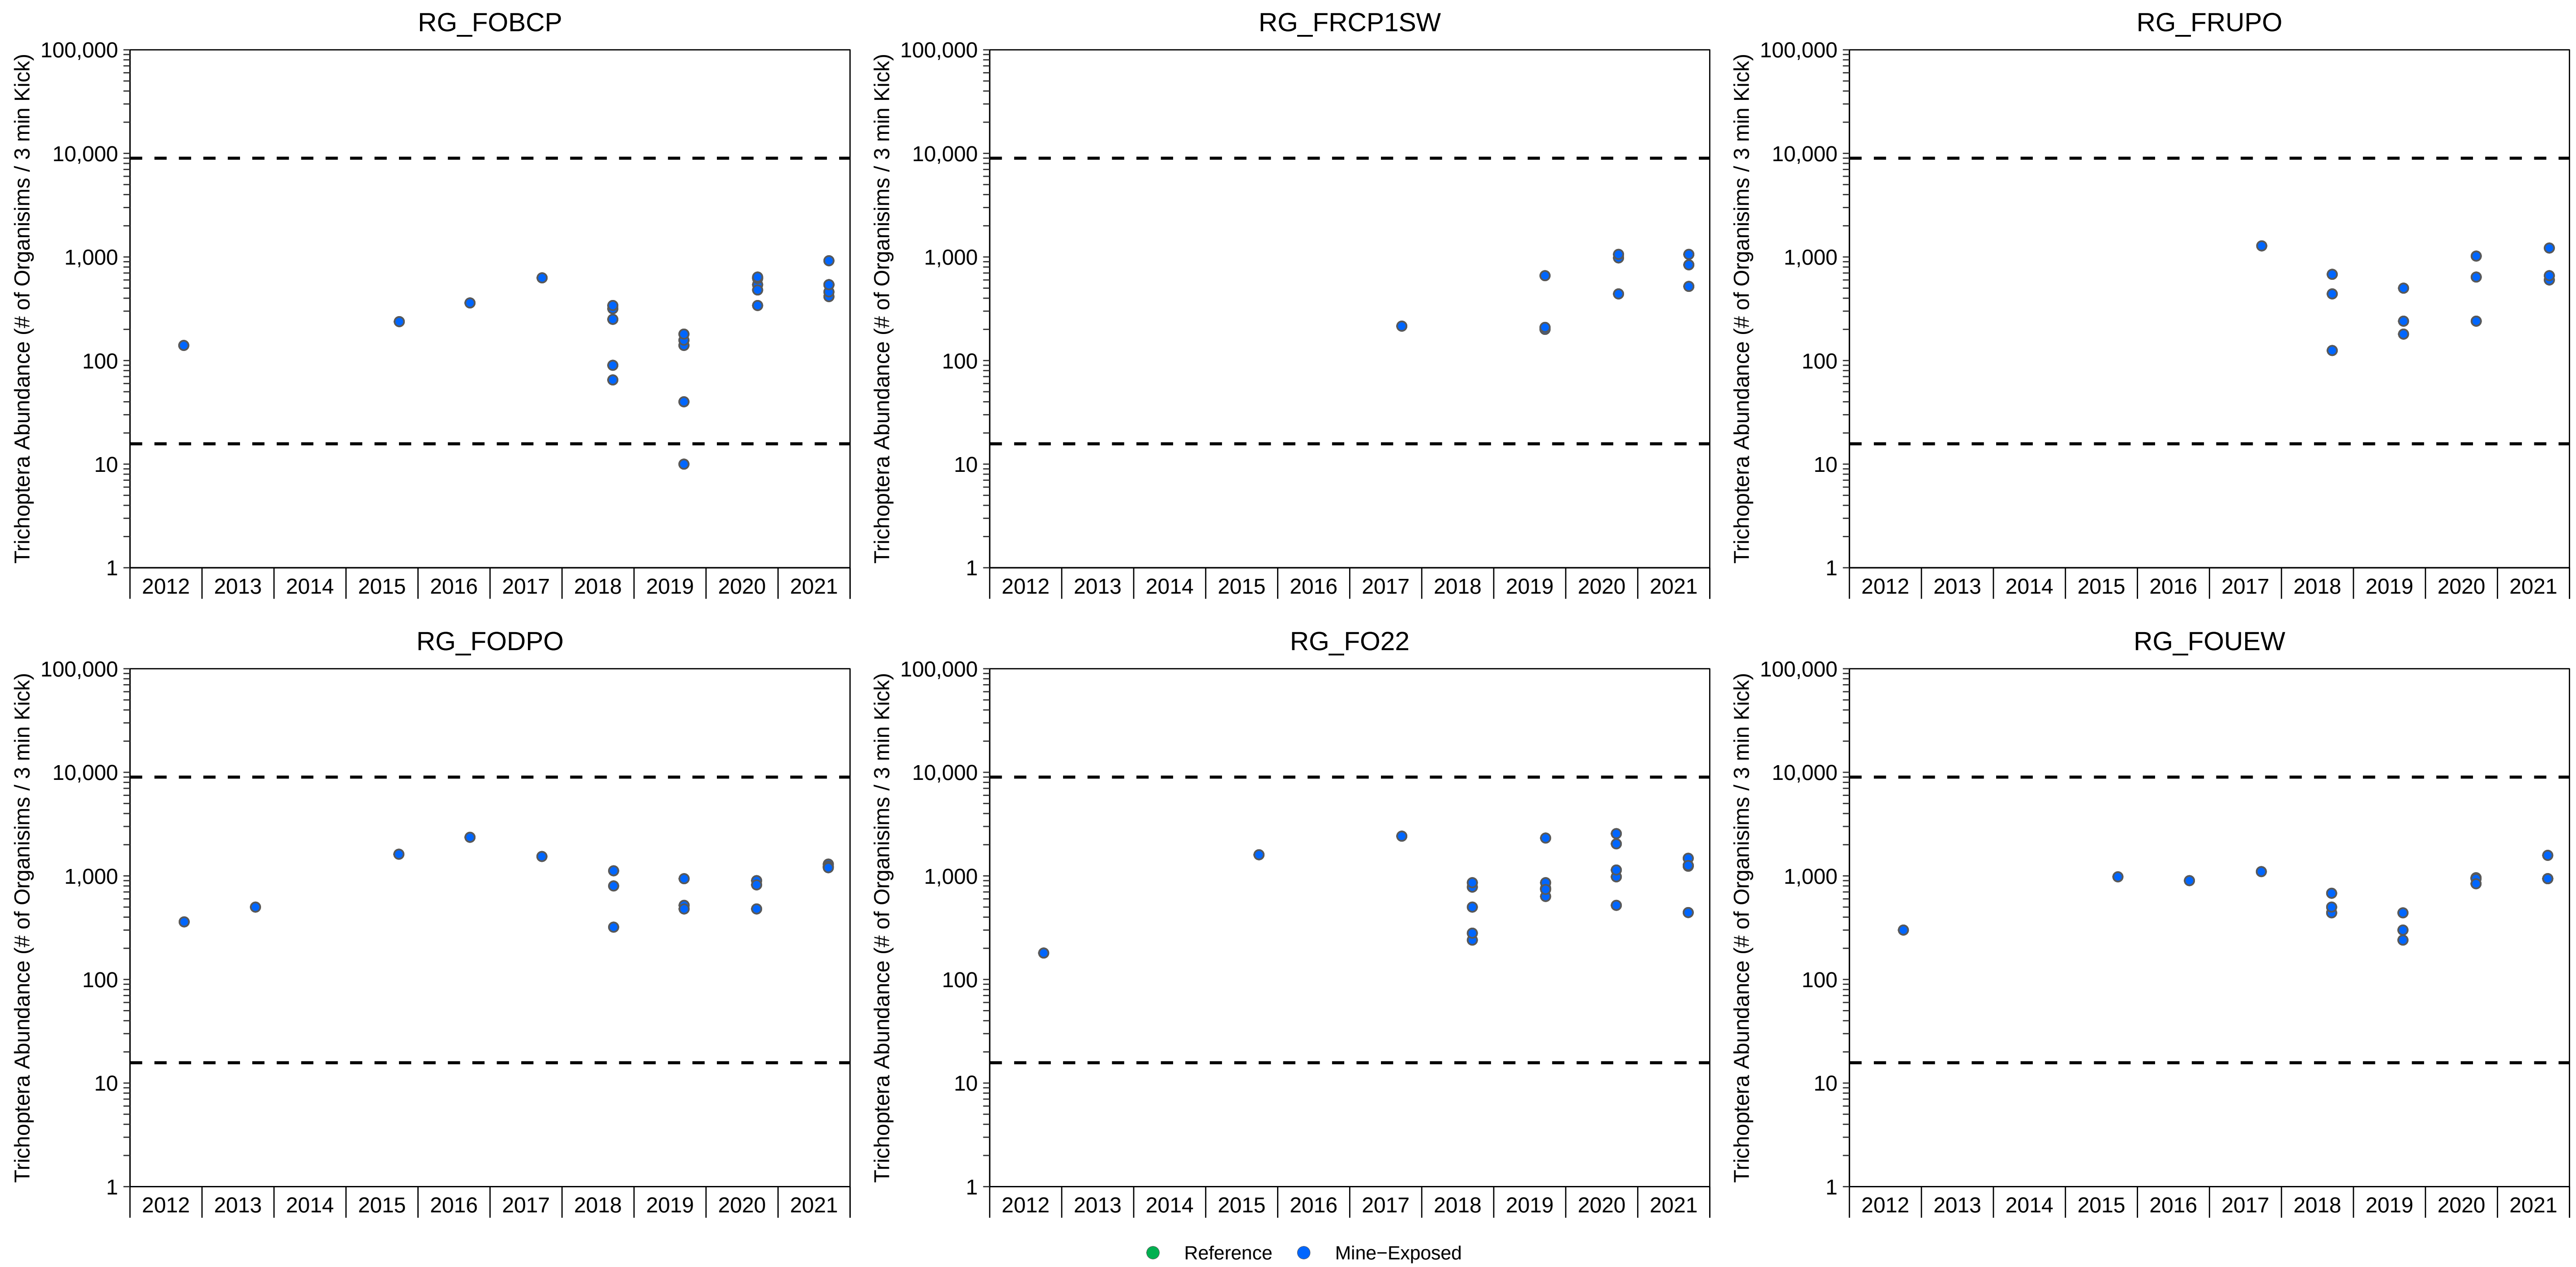

Figure E.17: Benthic Invertebrate Trichoptera Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

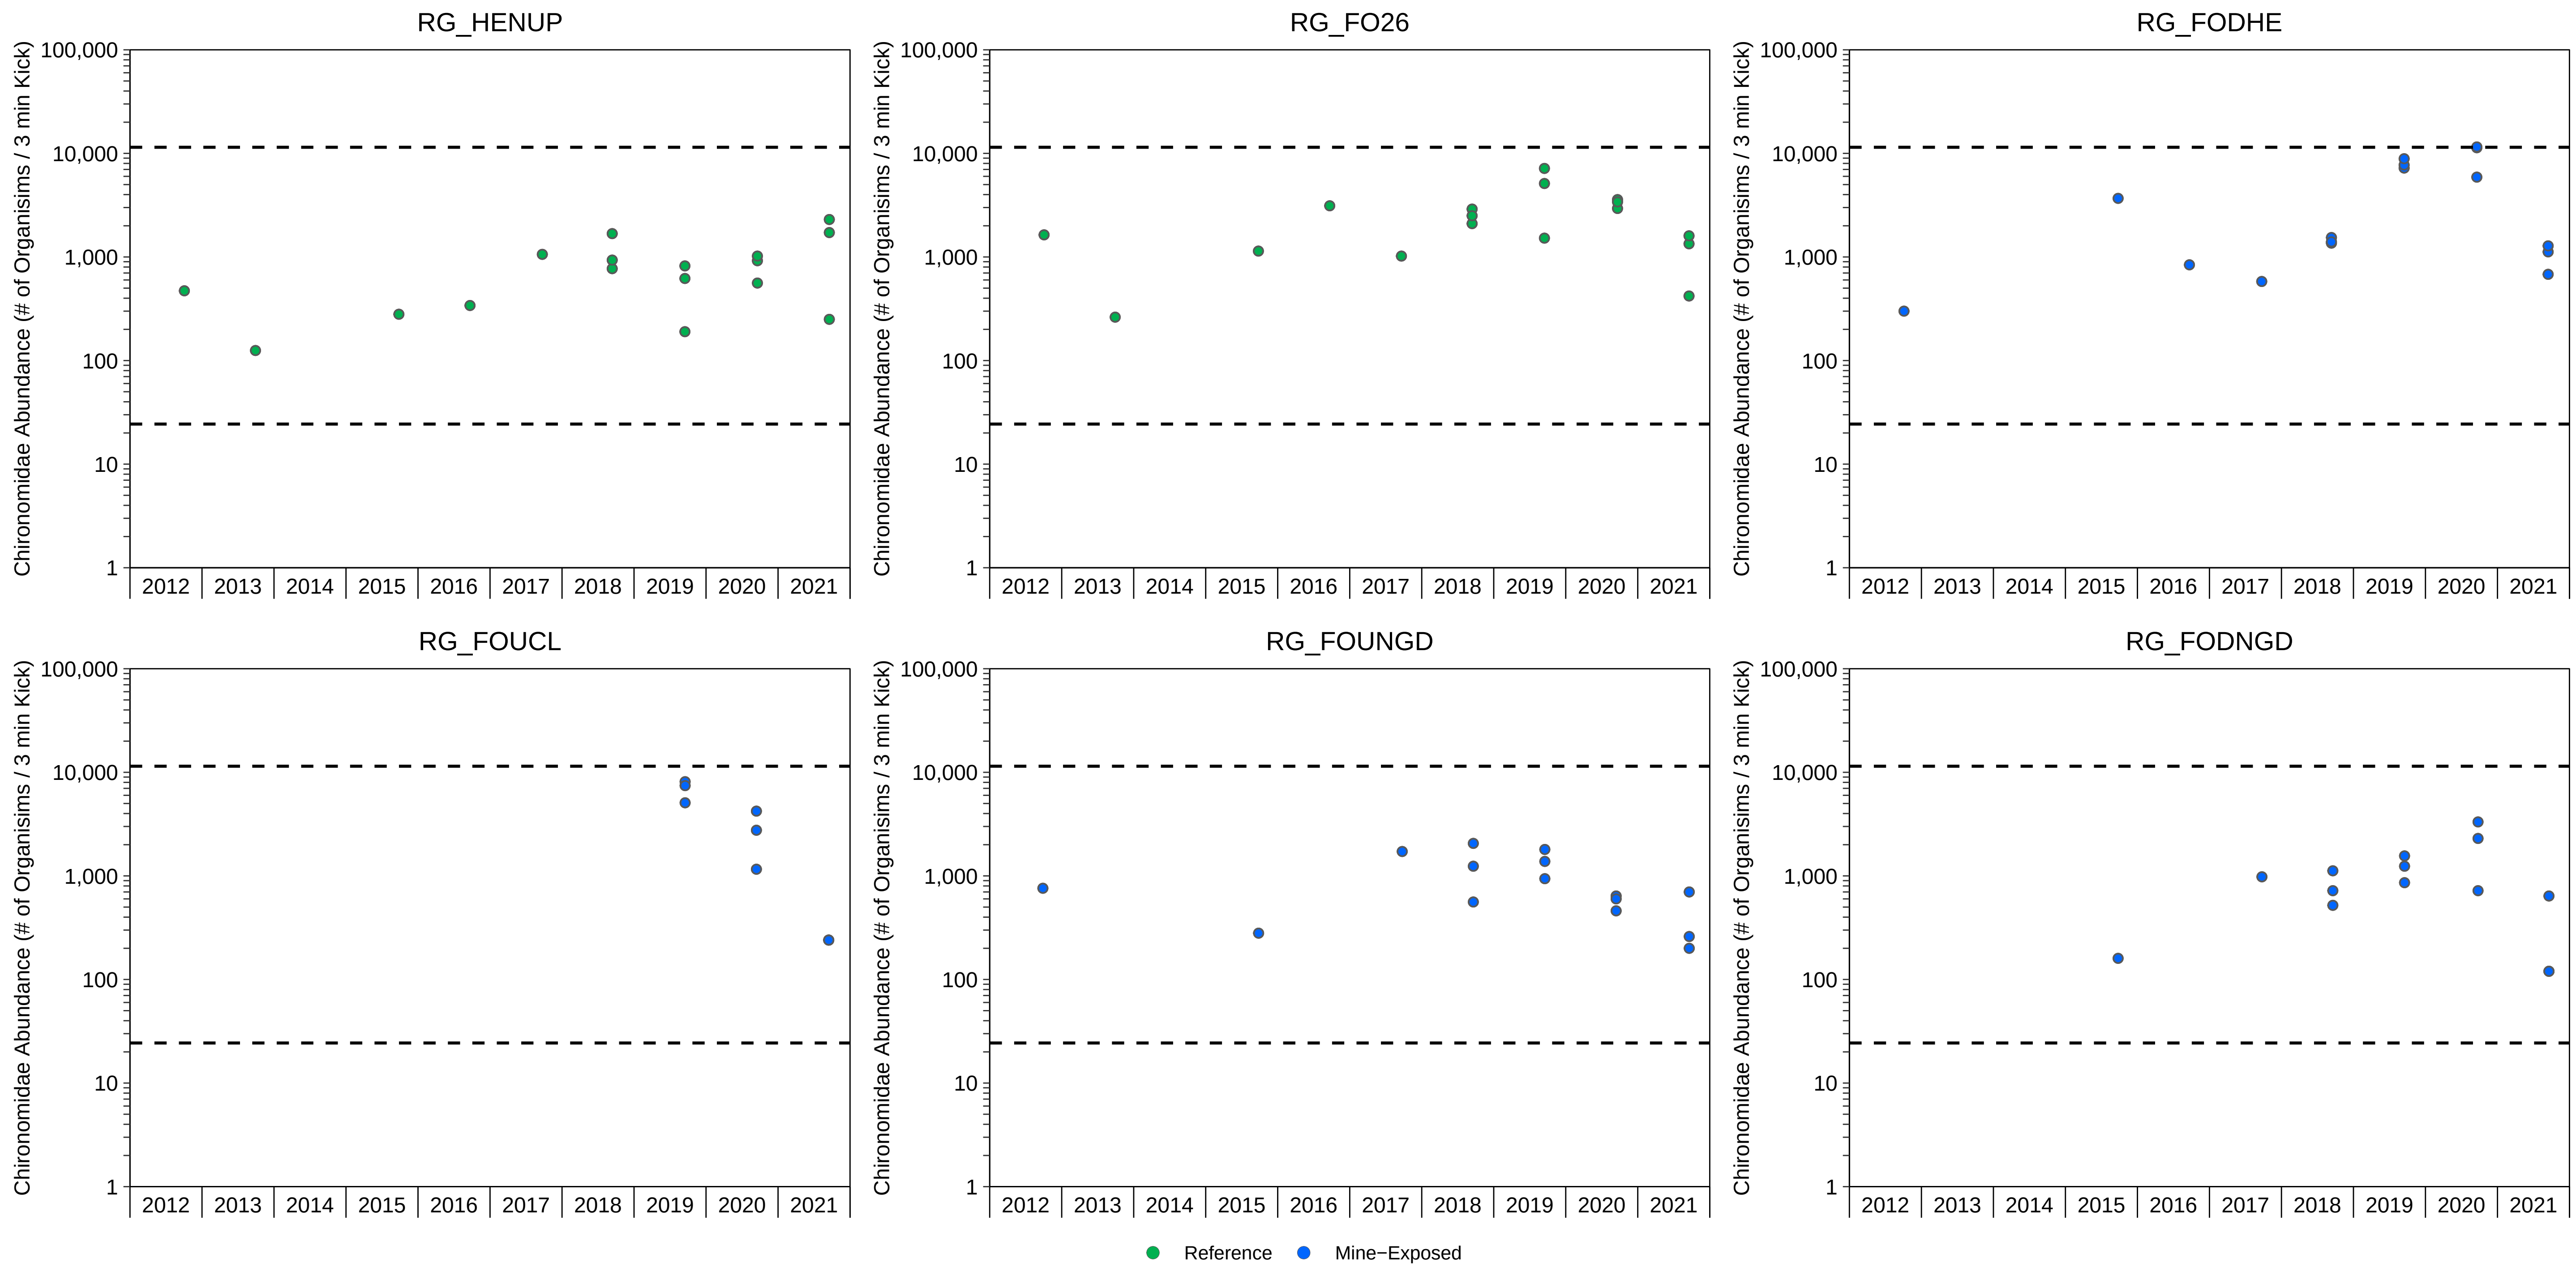

Figure E.18: Benthic Invertebrate Chironomidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

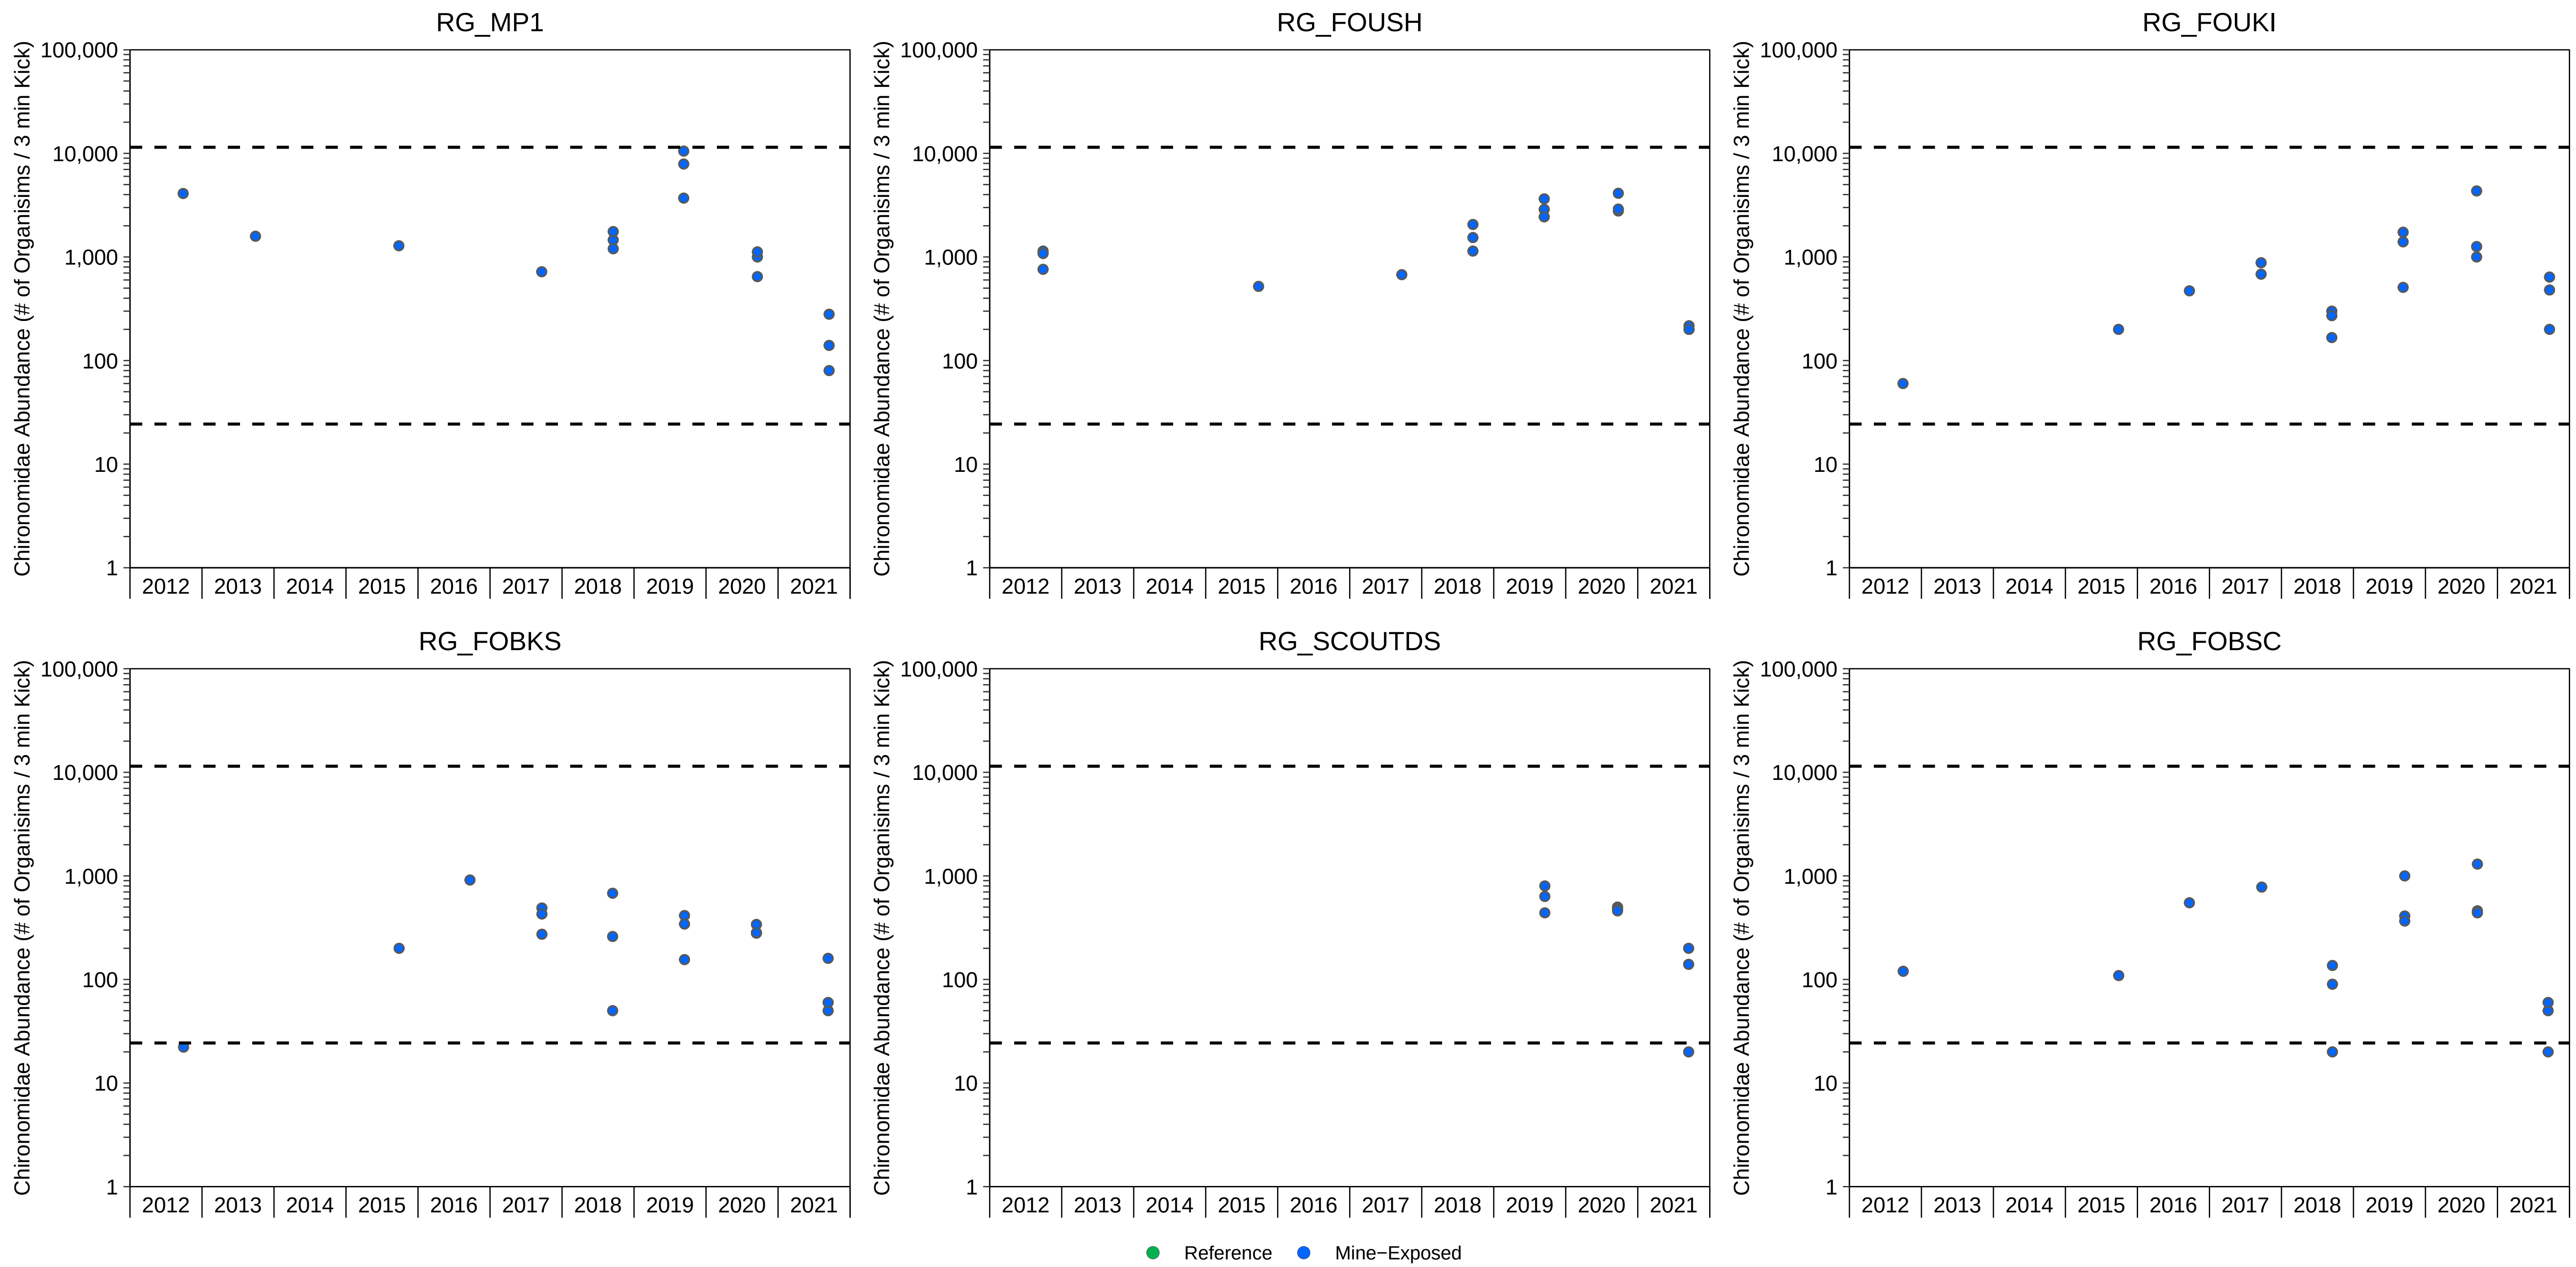

Figure E.18: Benthic Invertebrate Chironomidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

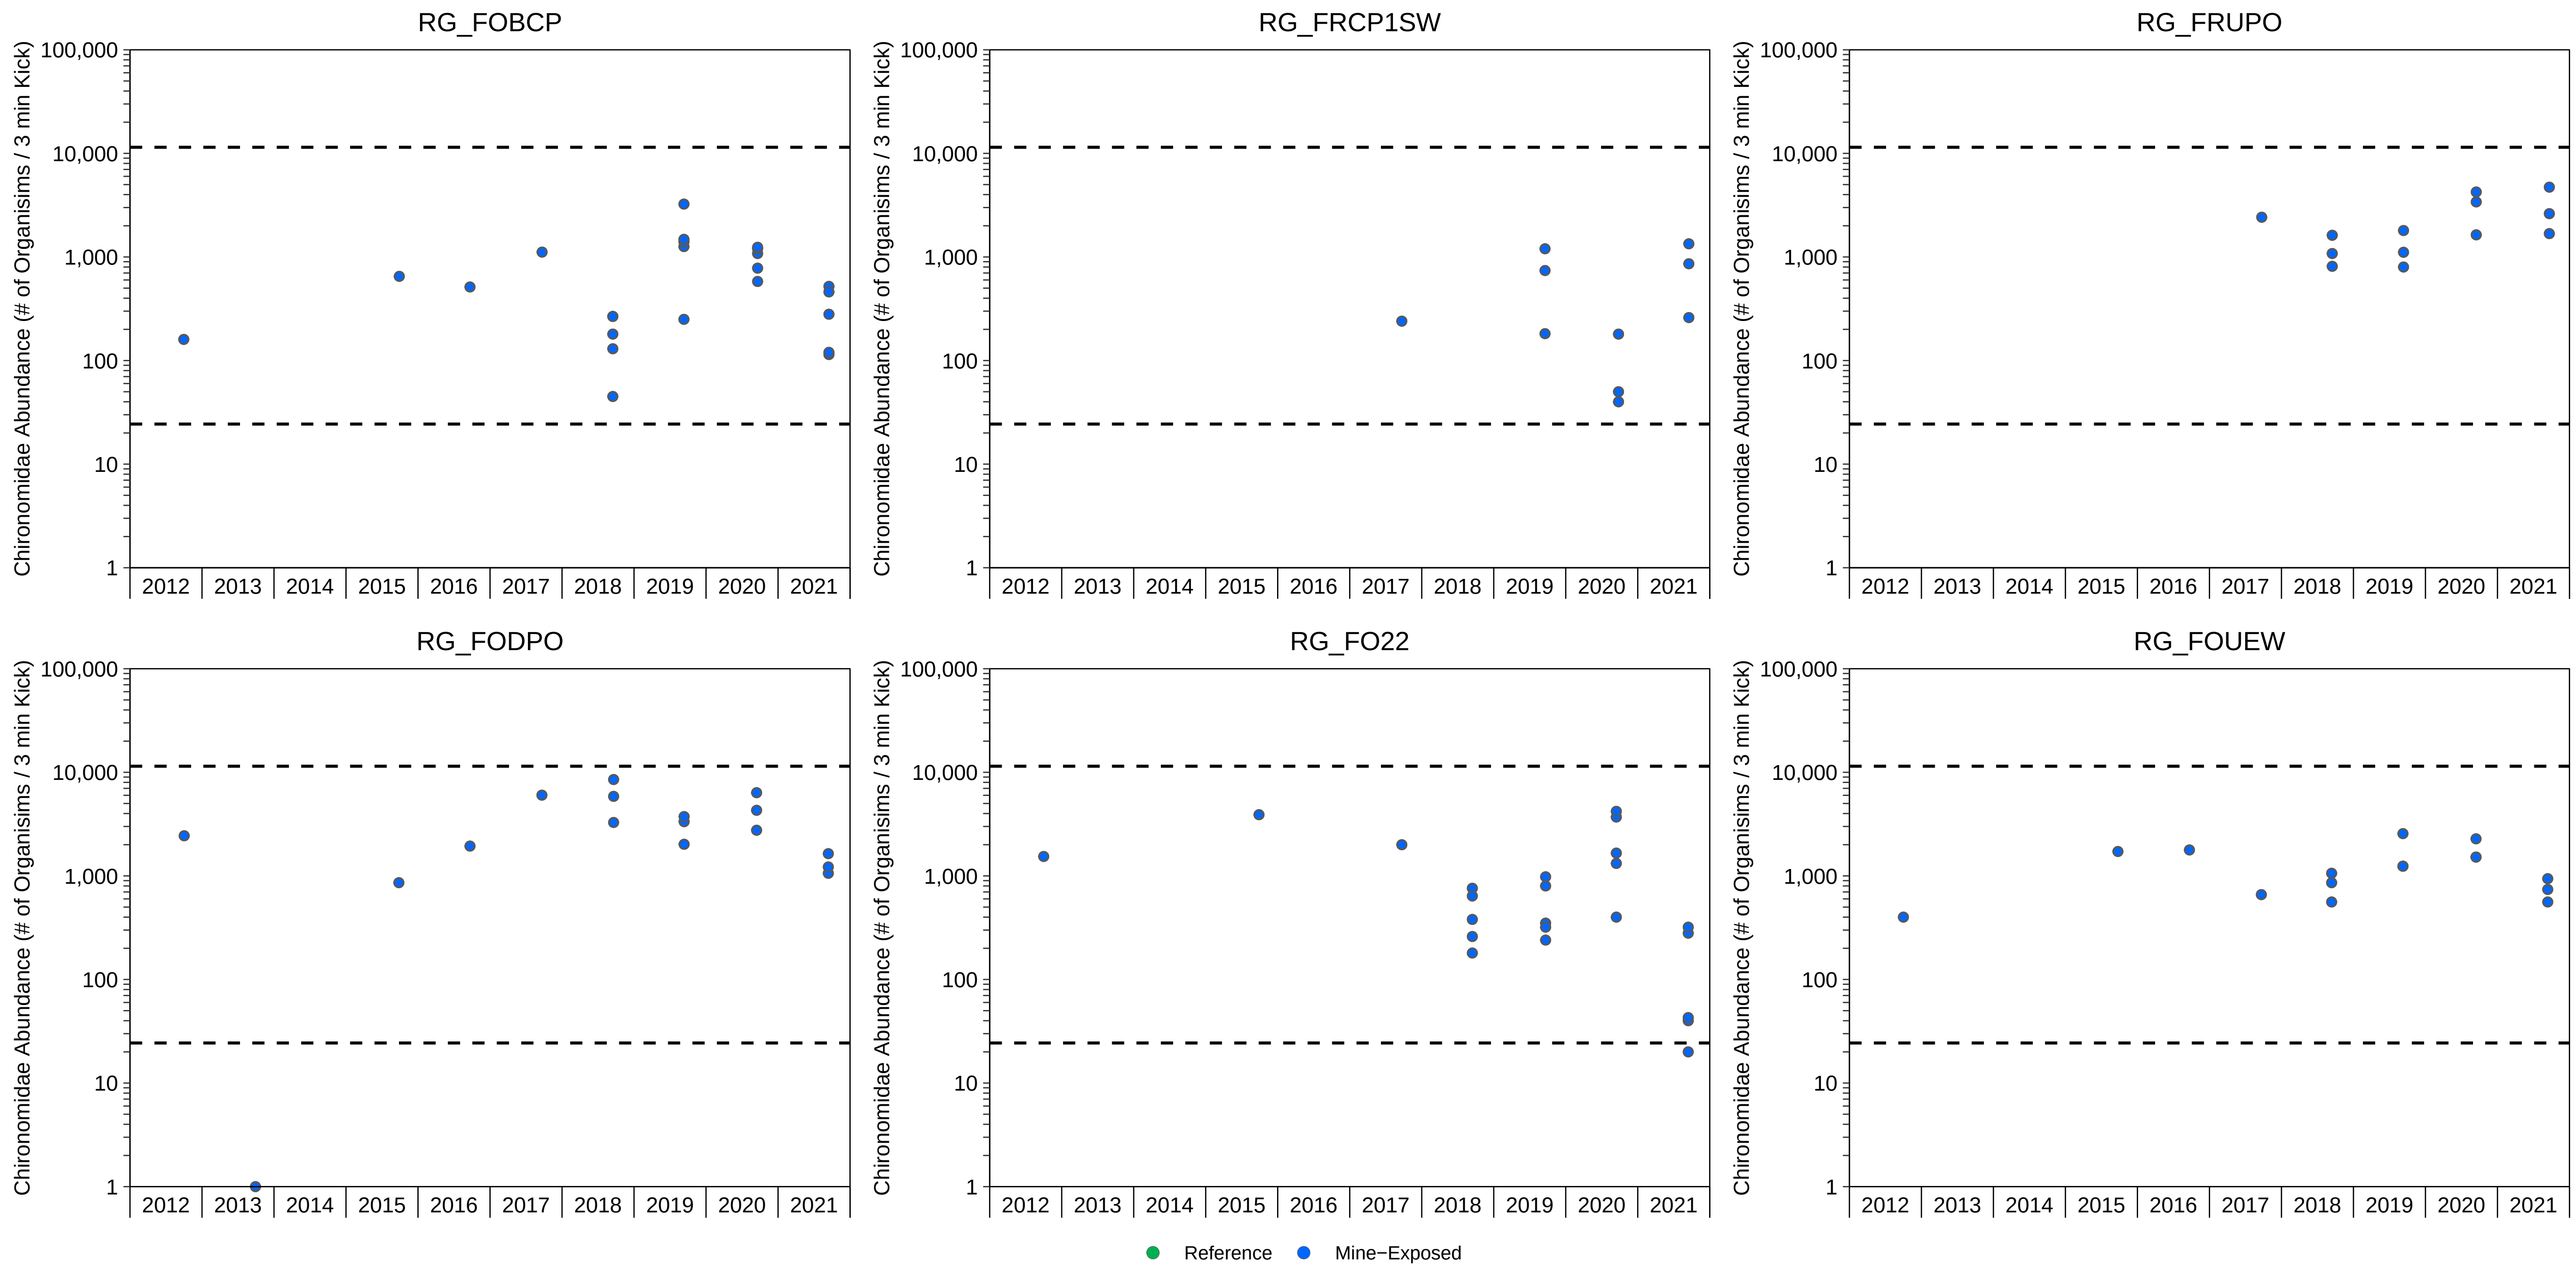

Figure E.18: Benthic Invertebrate Chironomidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

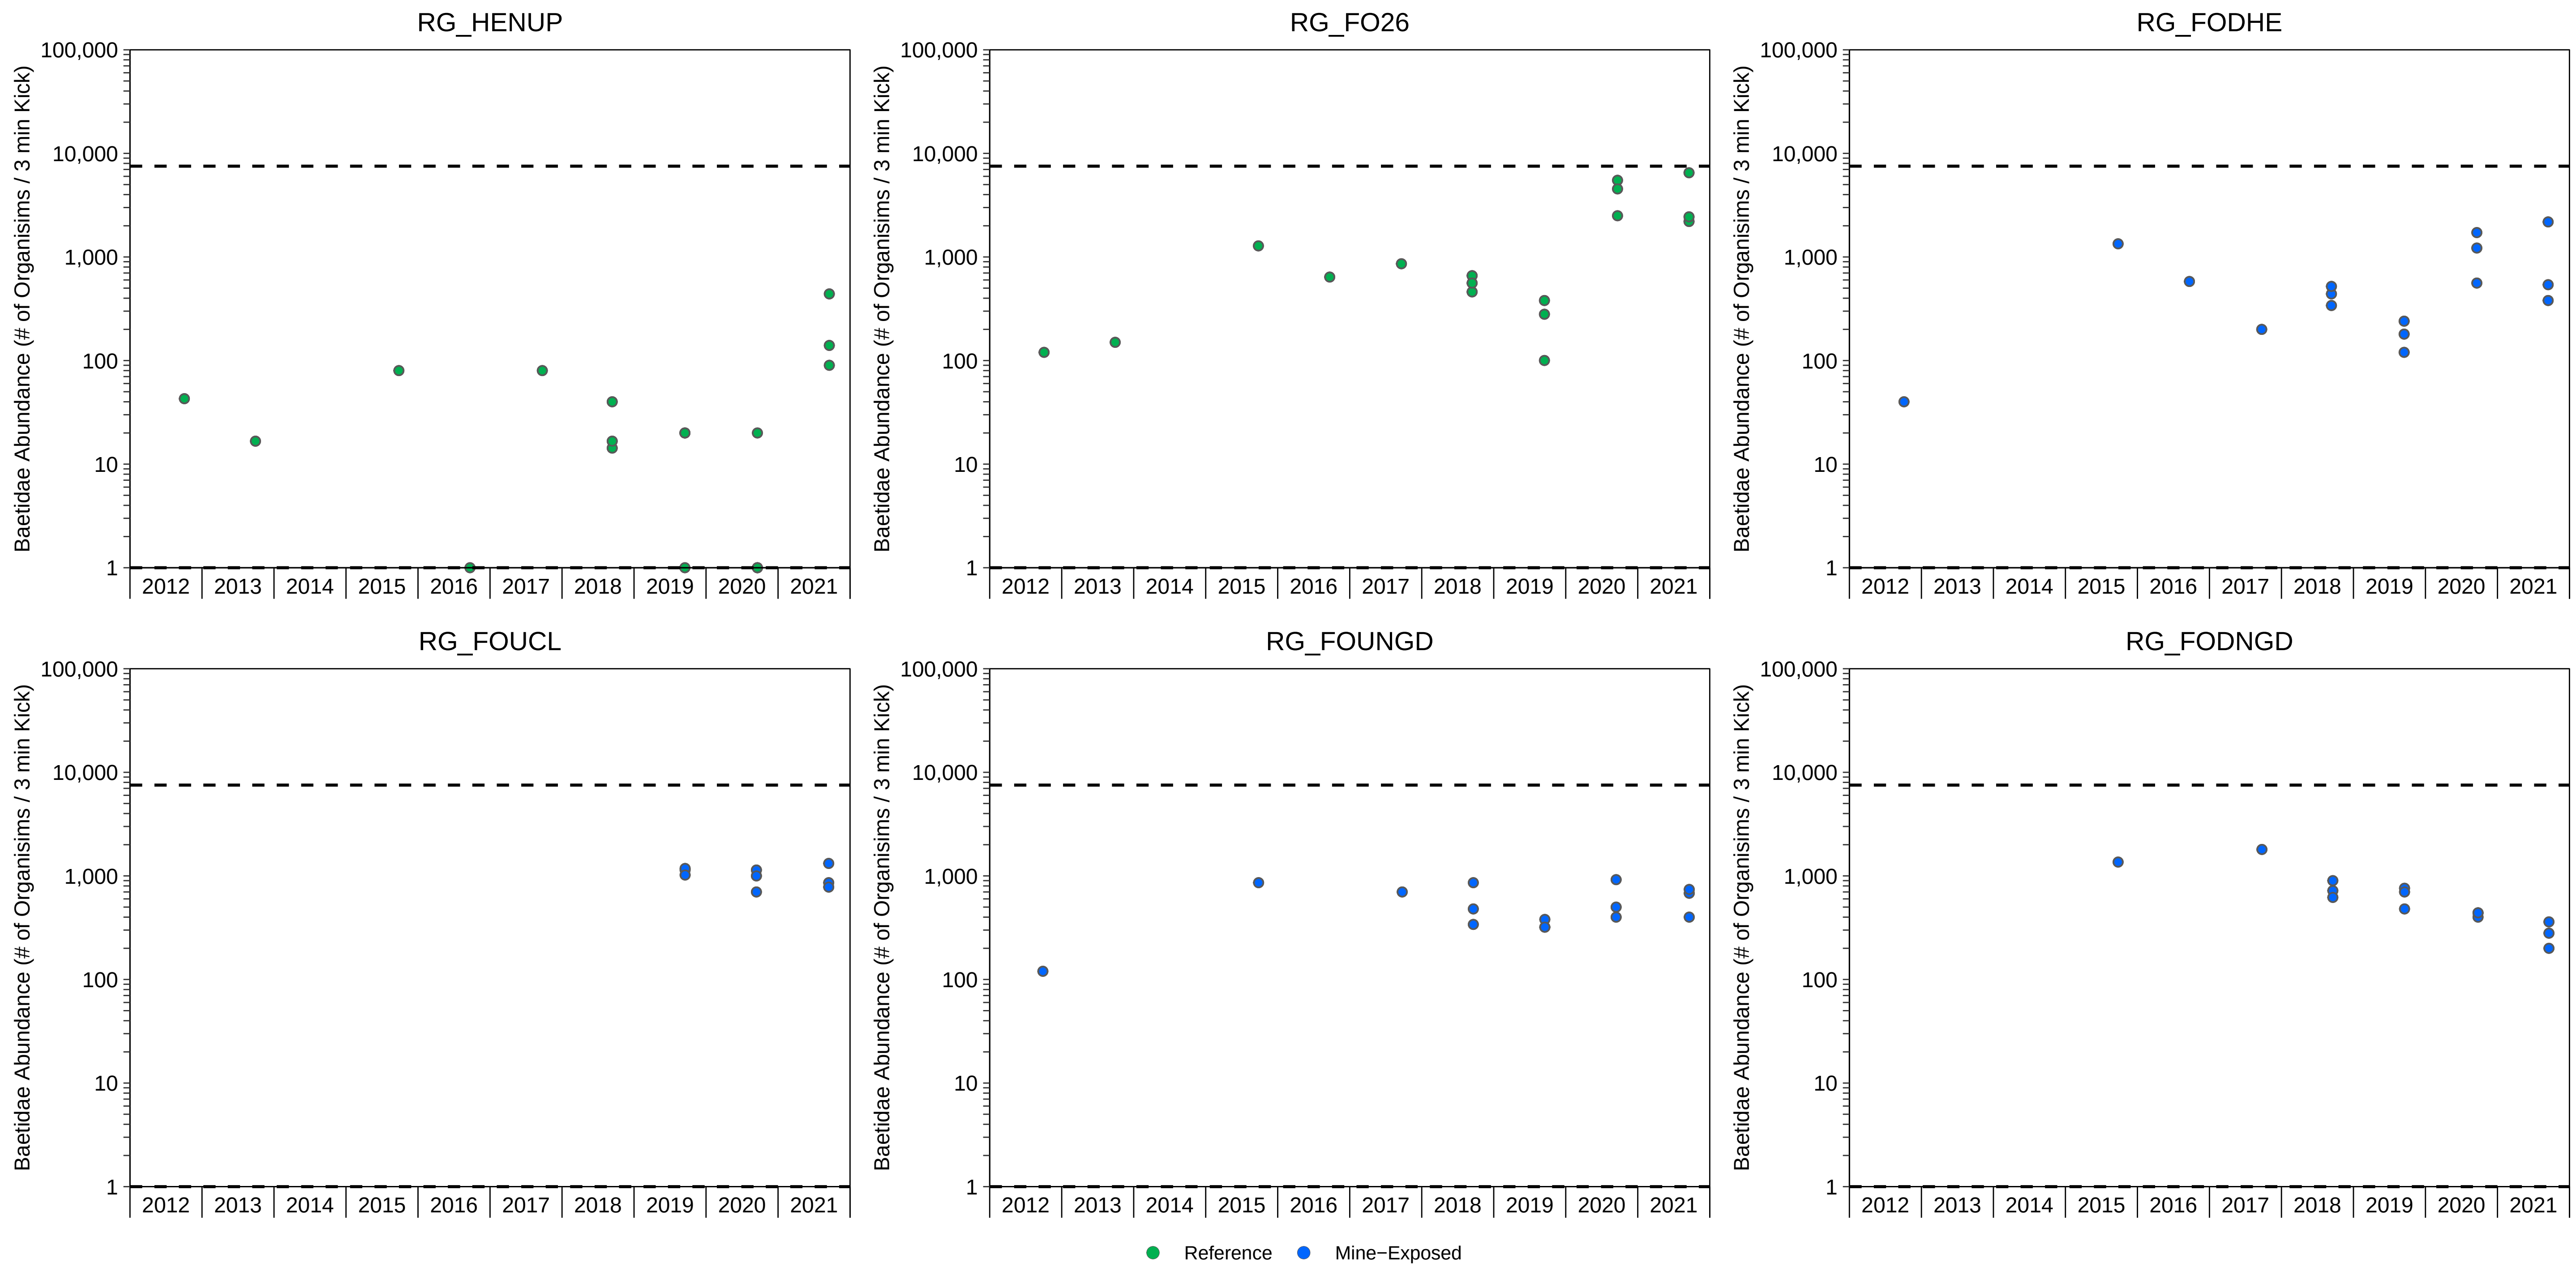

Figure E.19: Benthic Invertebrate Baetidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

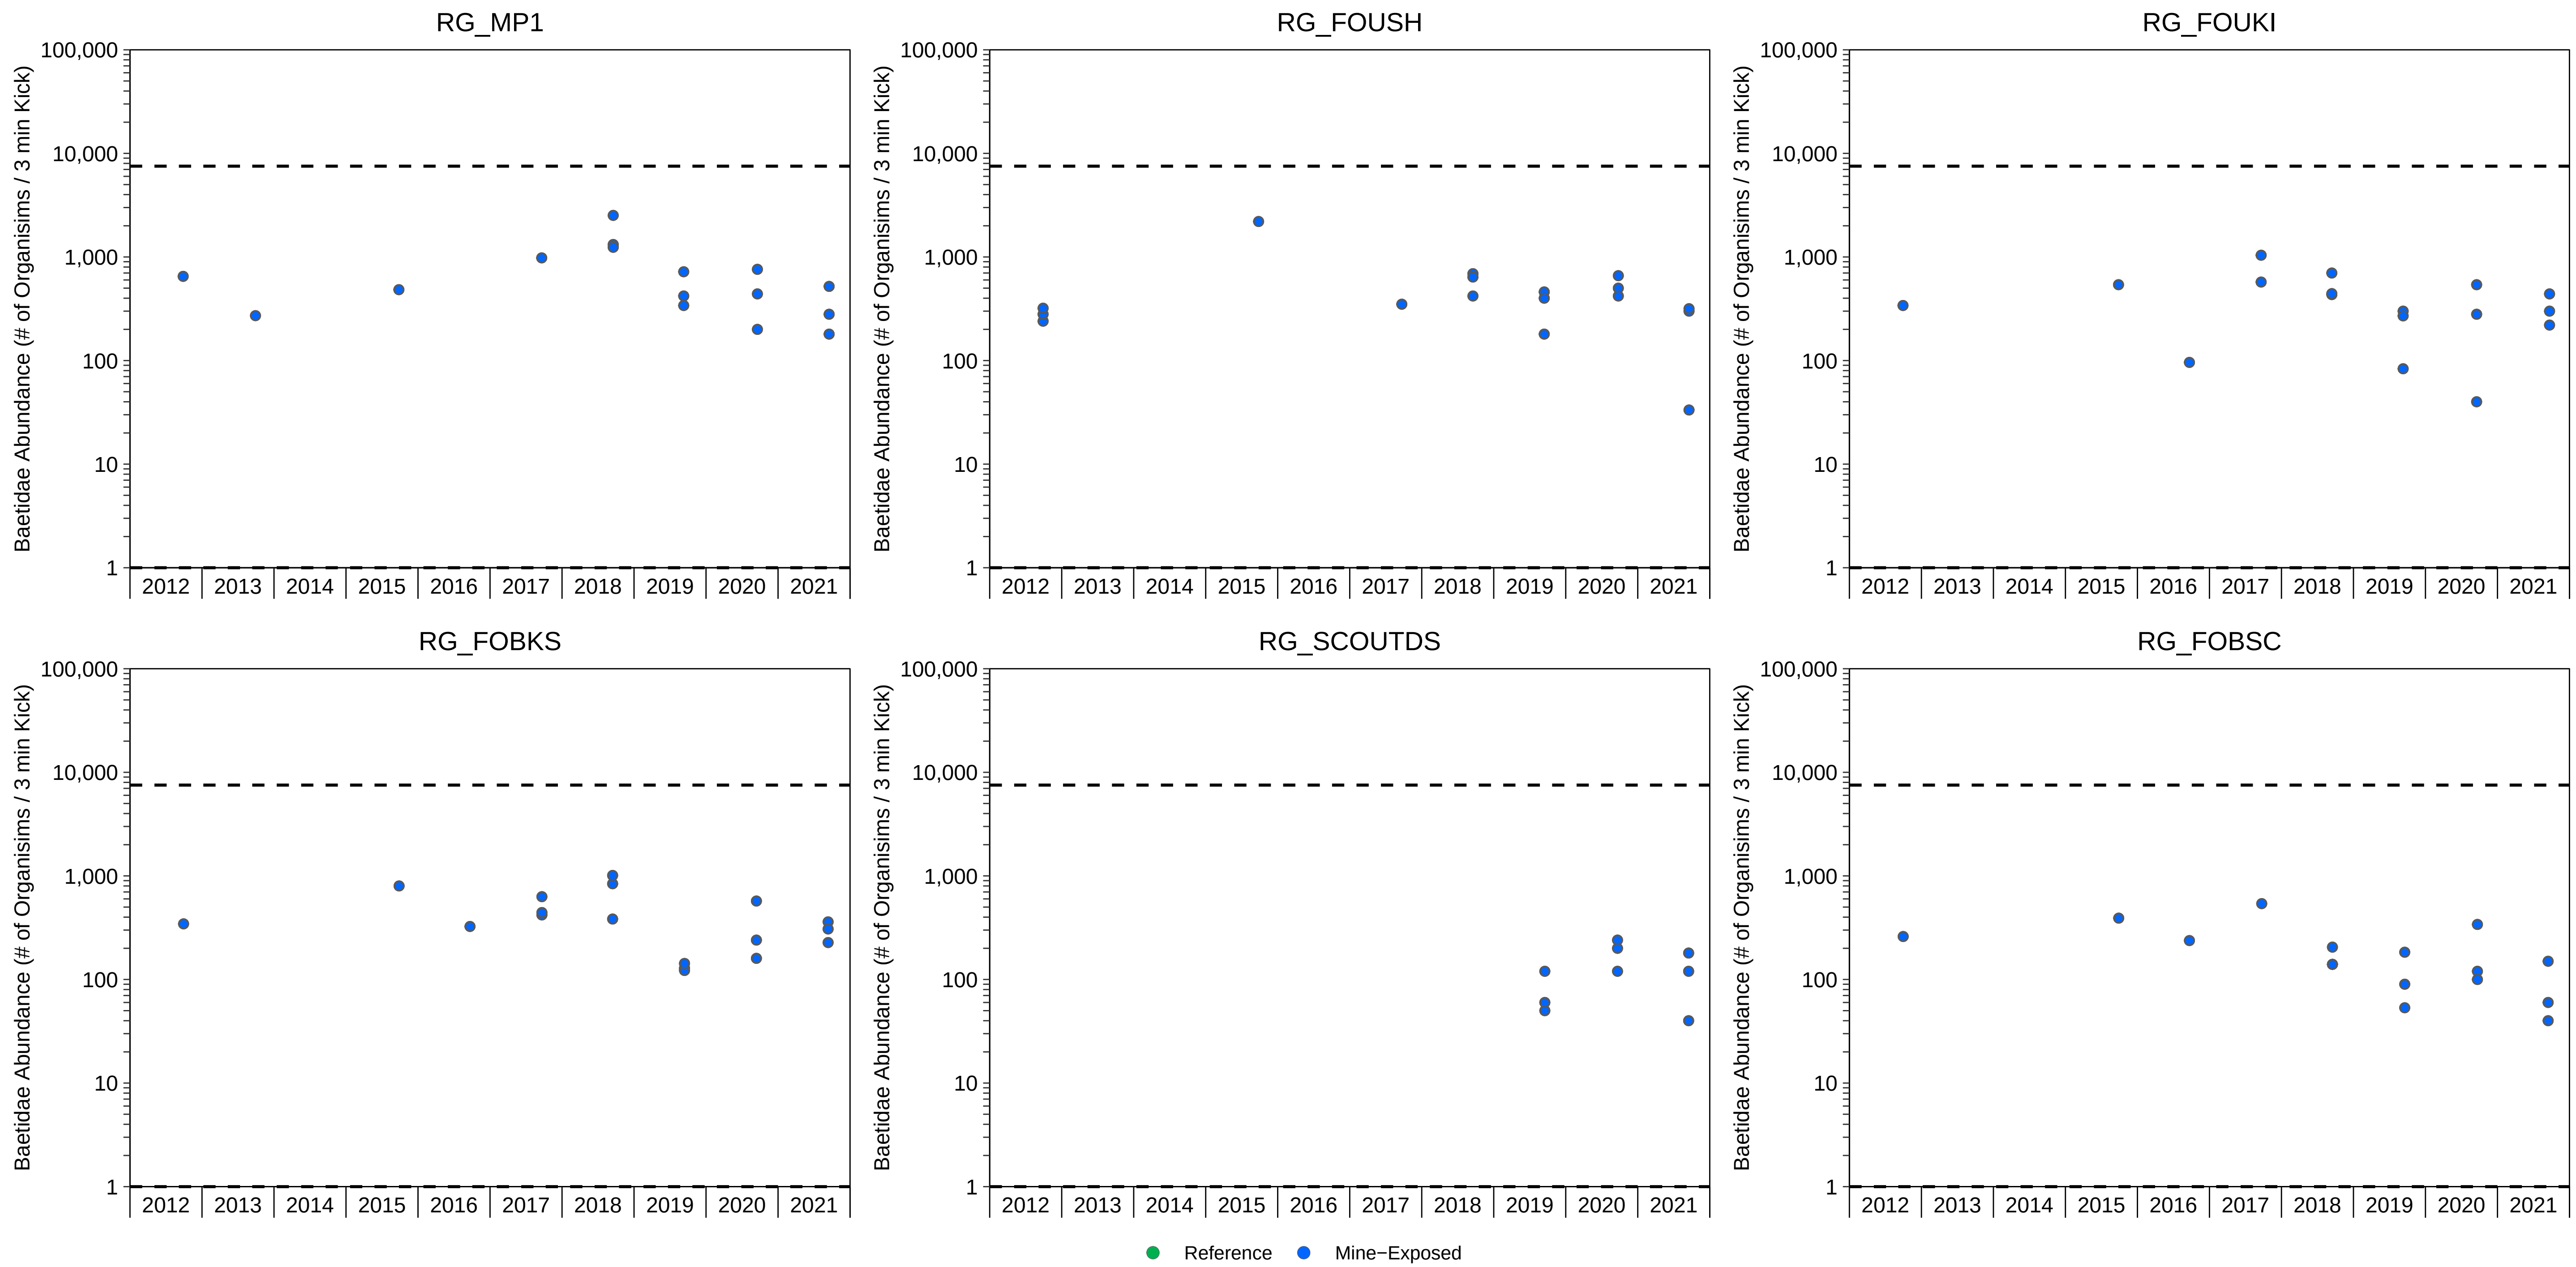

Figure E.19: Benthic Invertebrate Baetidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

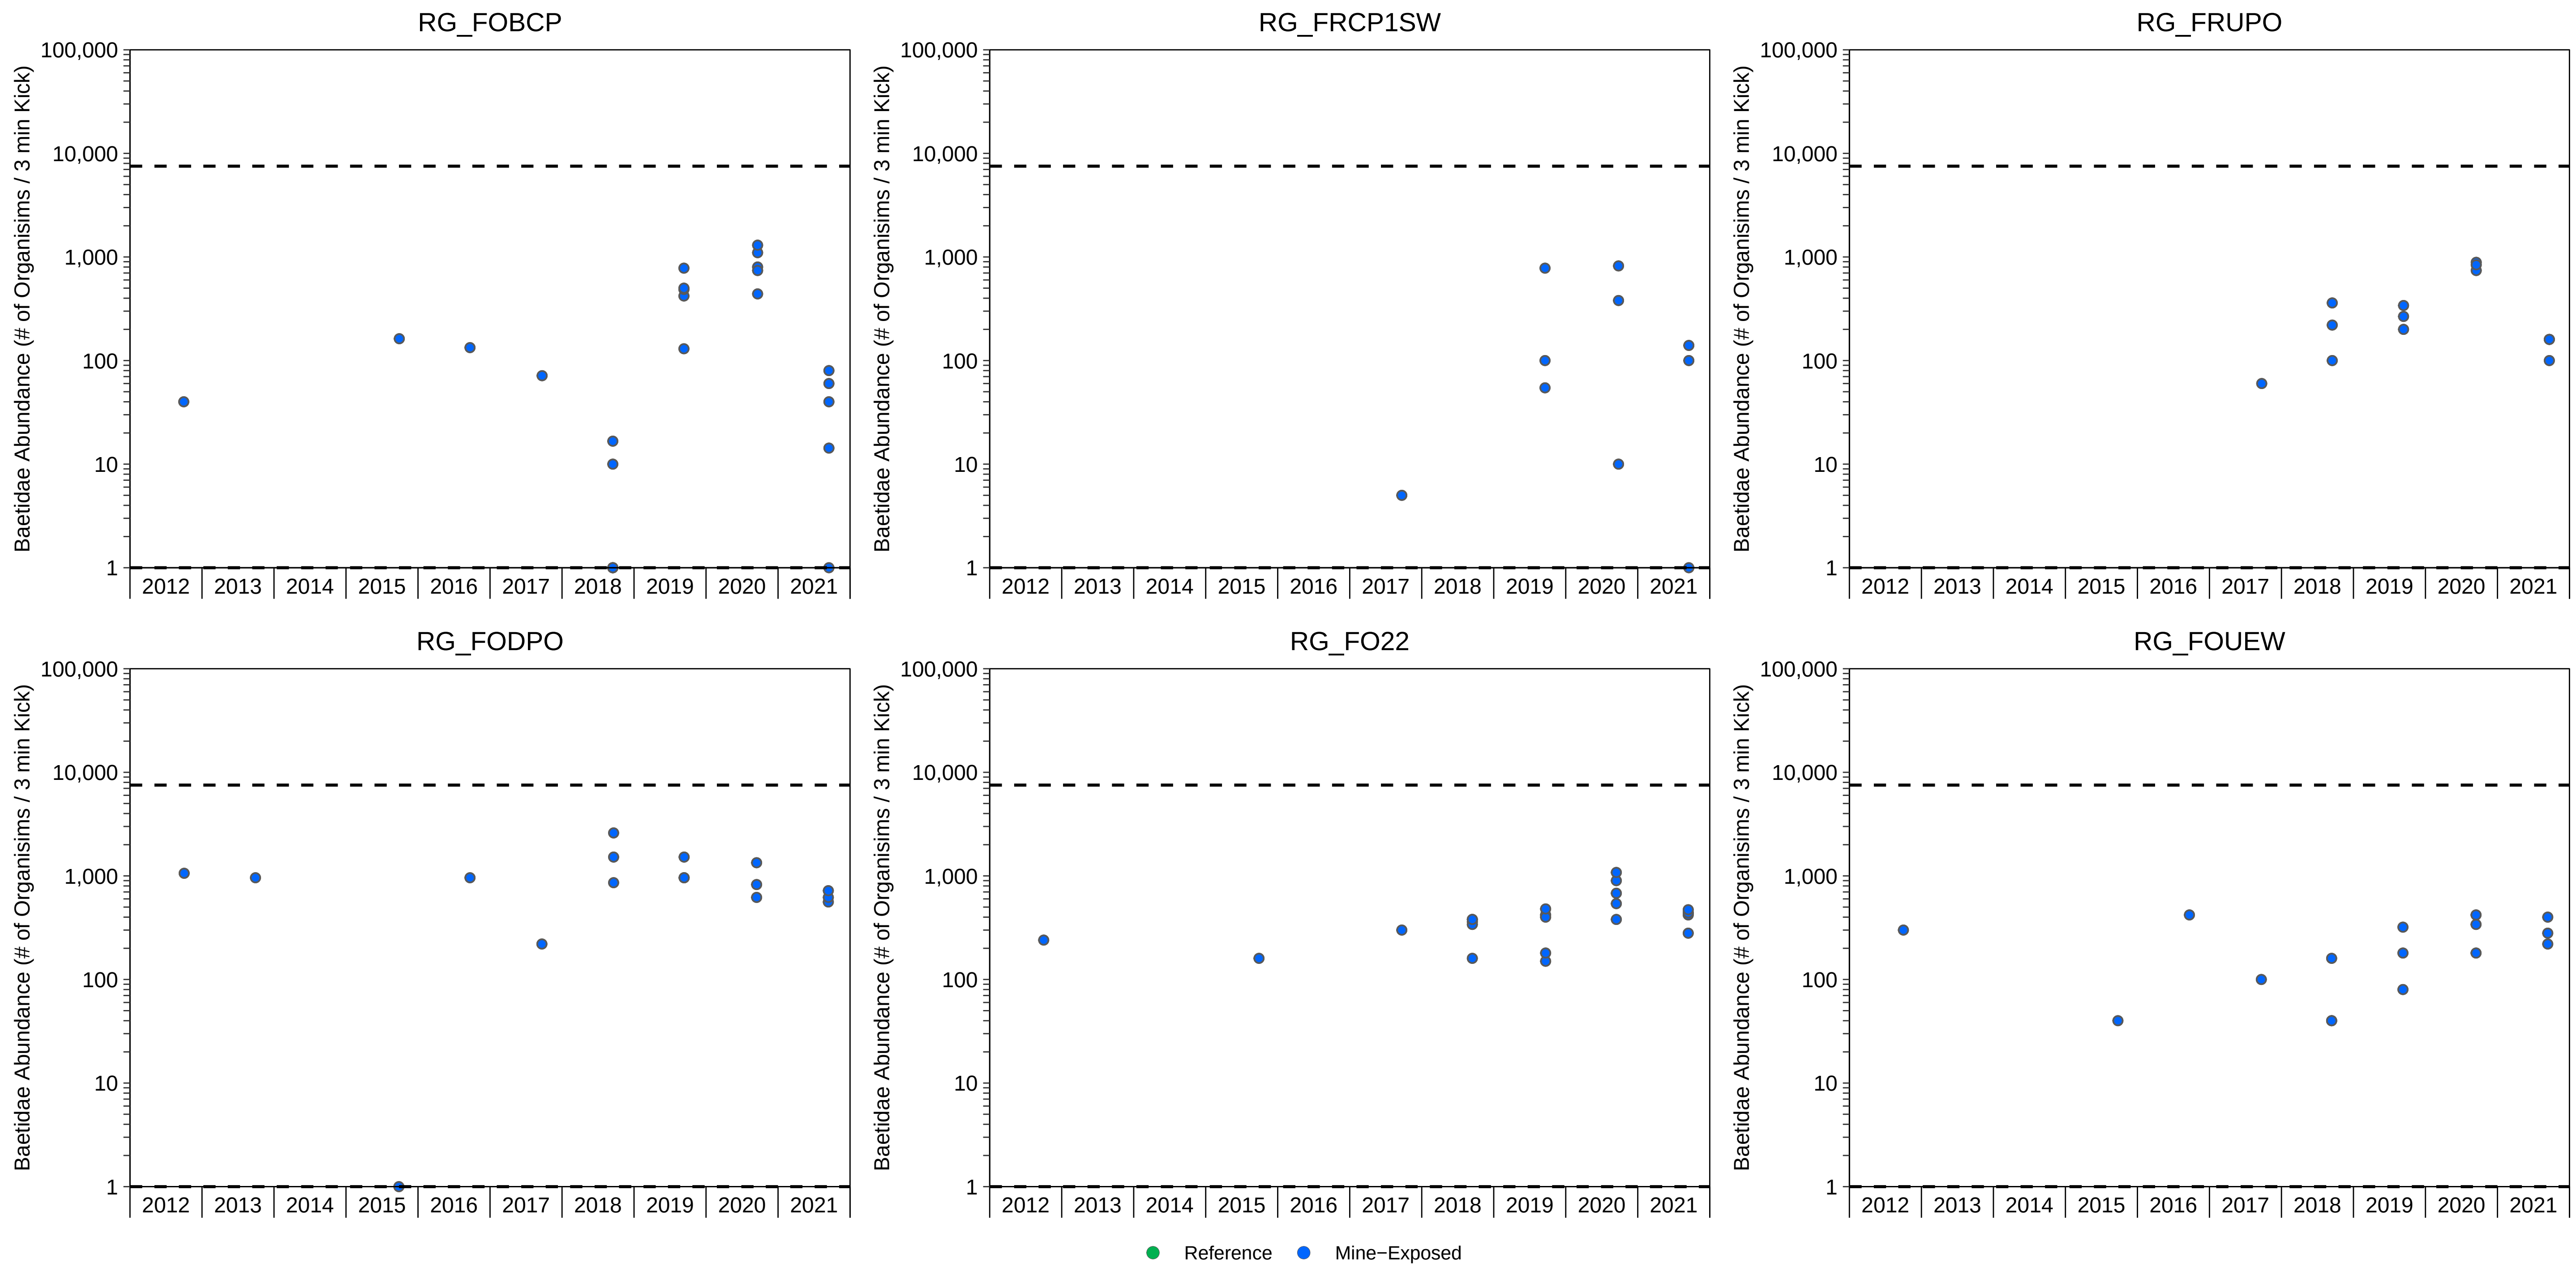

Figure E.19: Benthic Invertebrate Baetidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

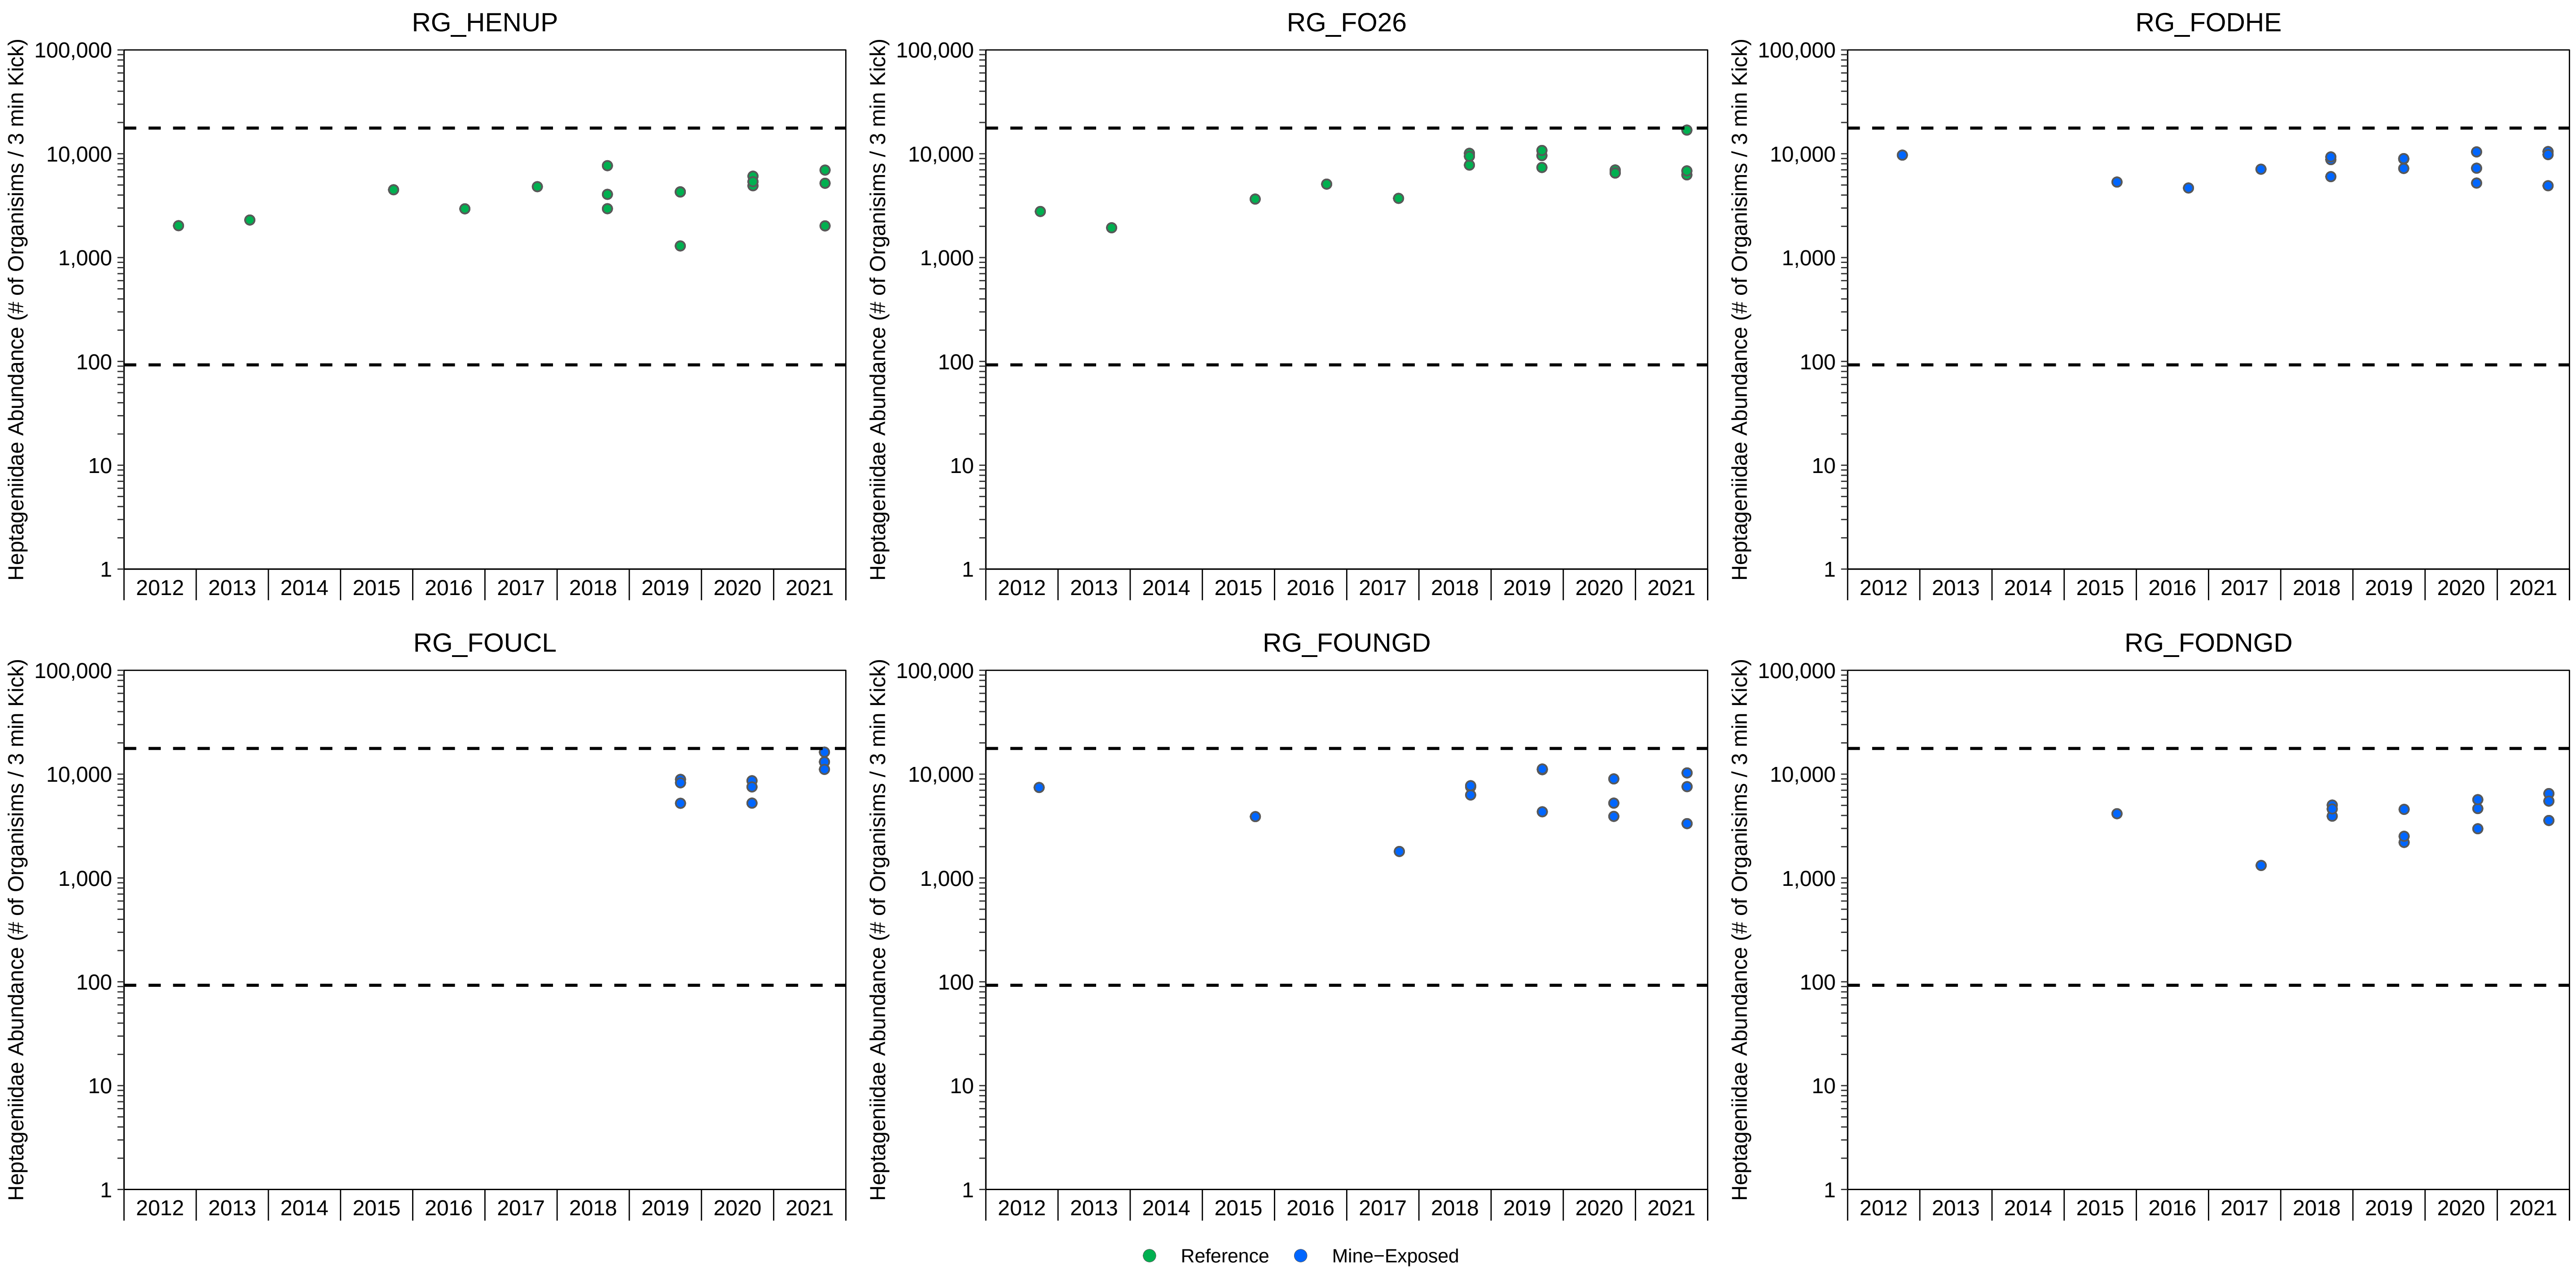

Figure E.20: Benthic Invertebrate Heptageniidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

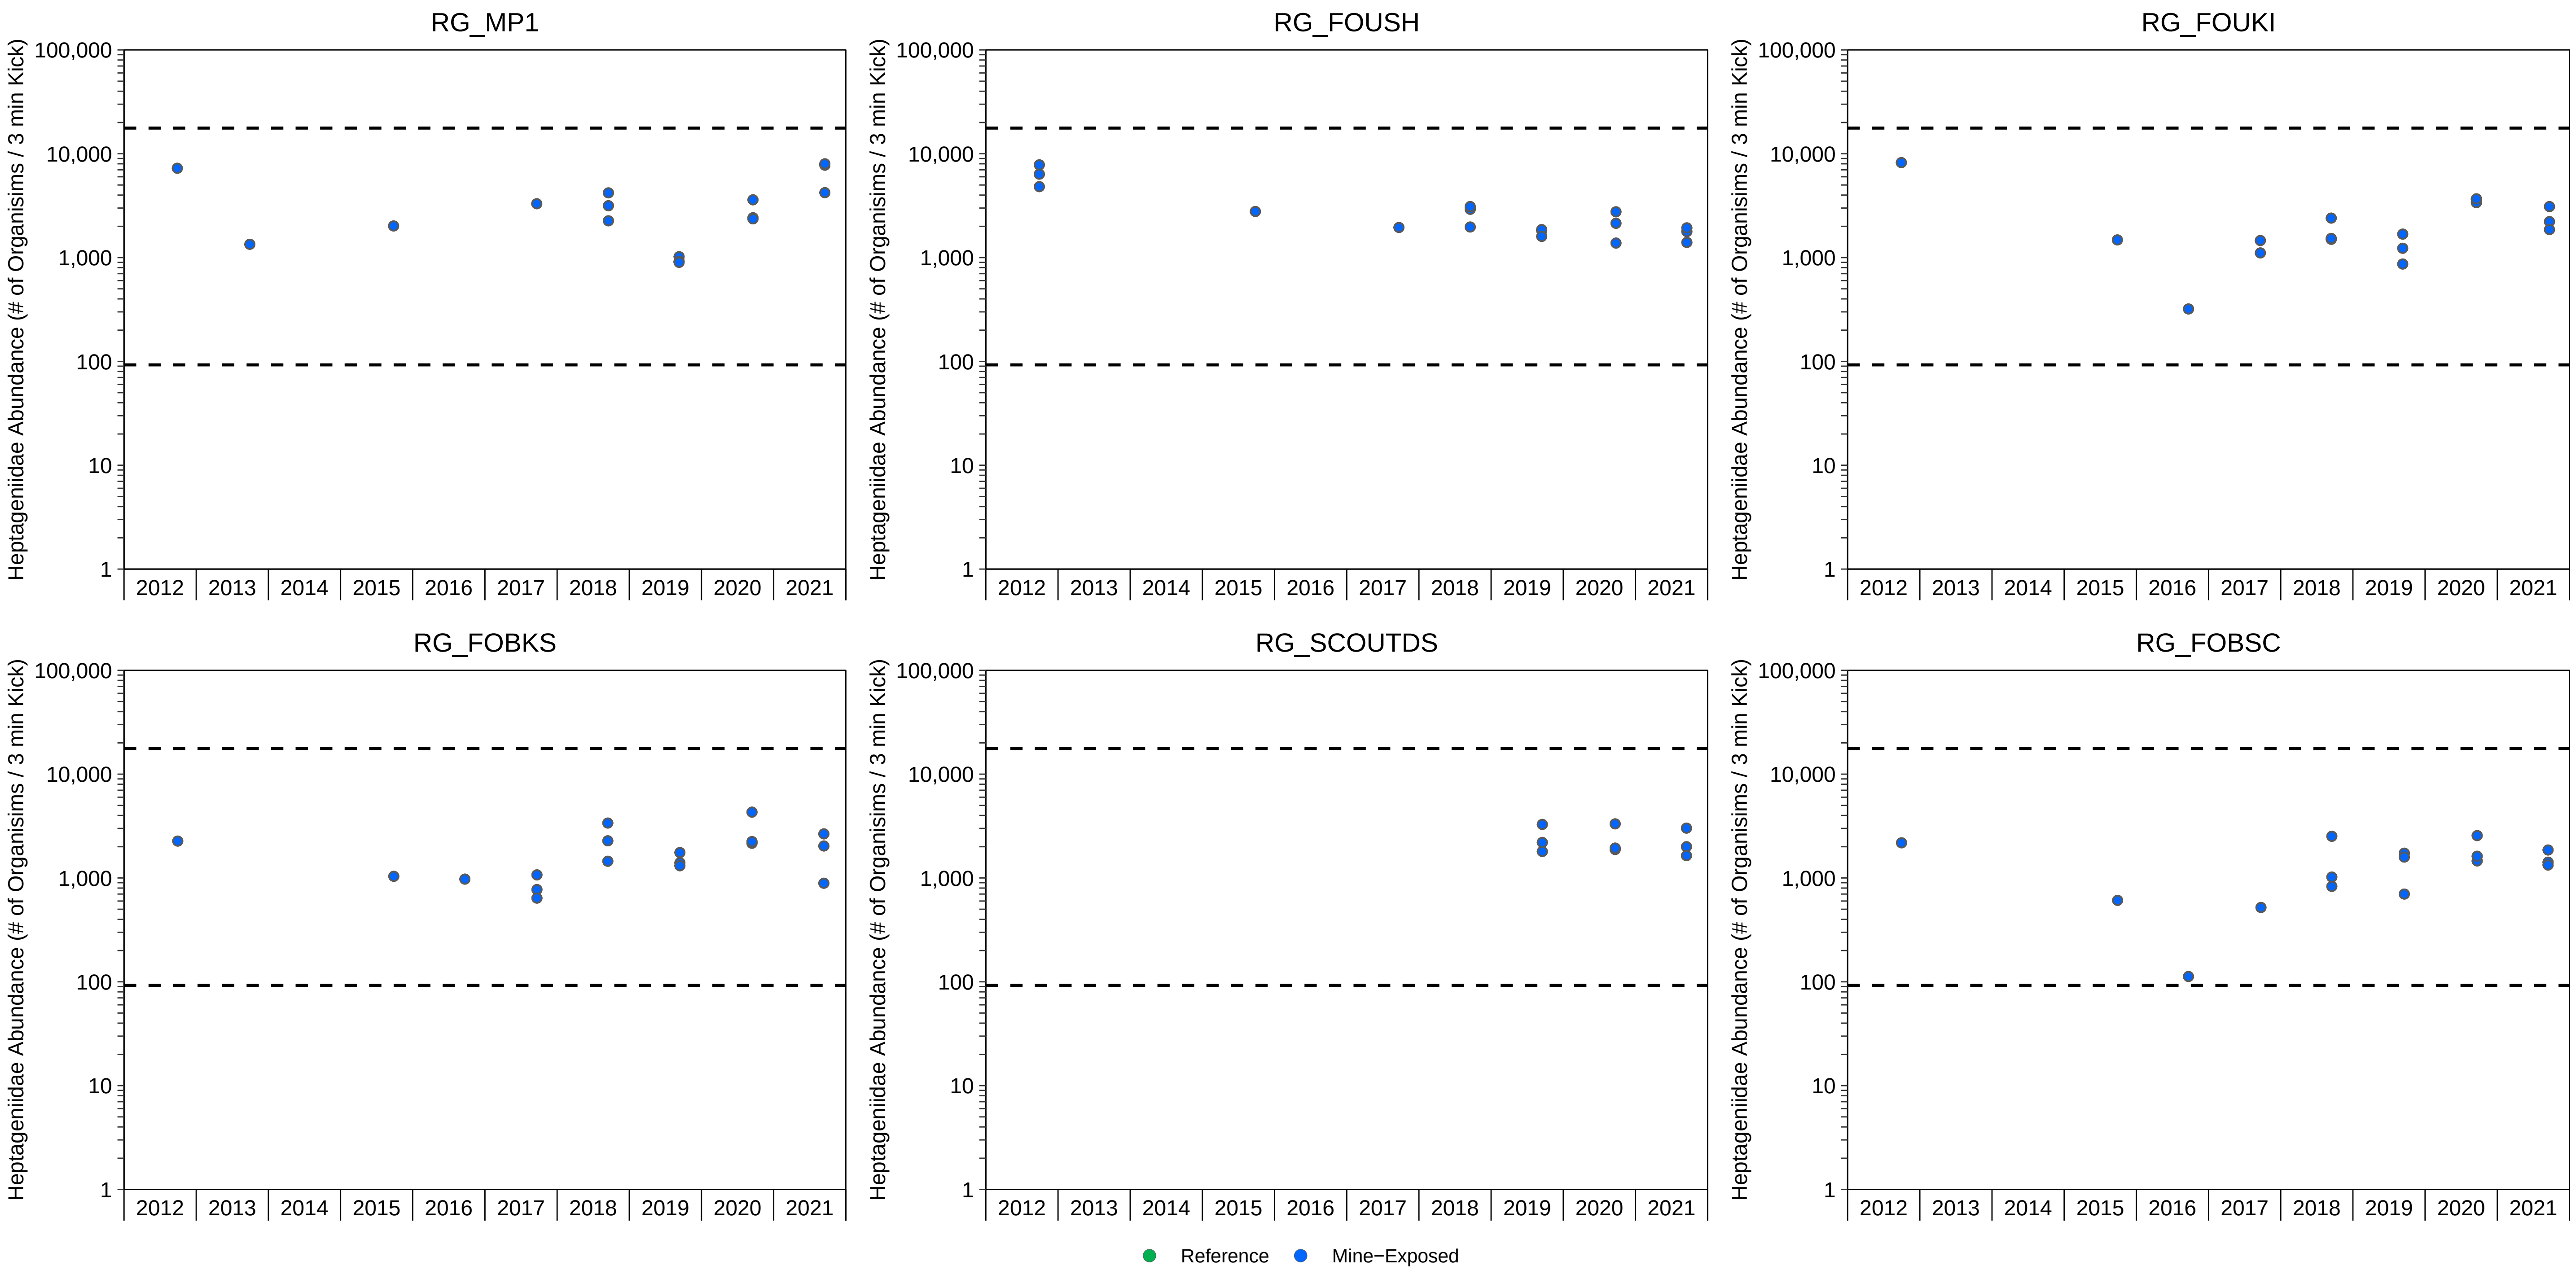

Figure E.20: Benthic Invertebrate Heptageniidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

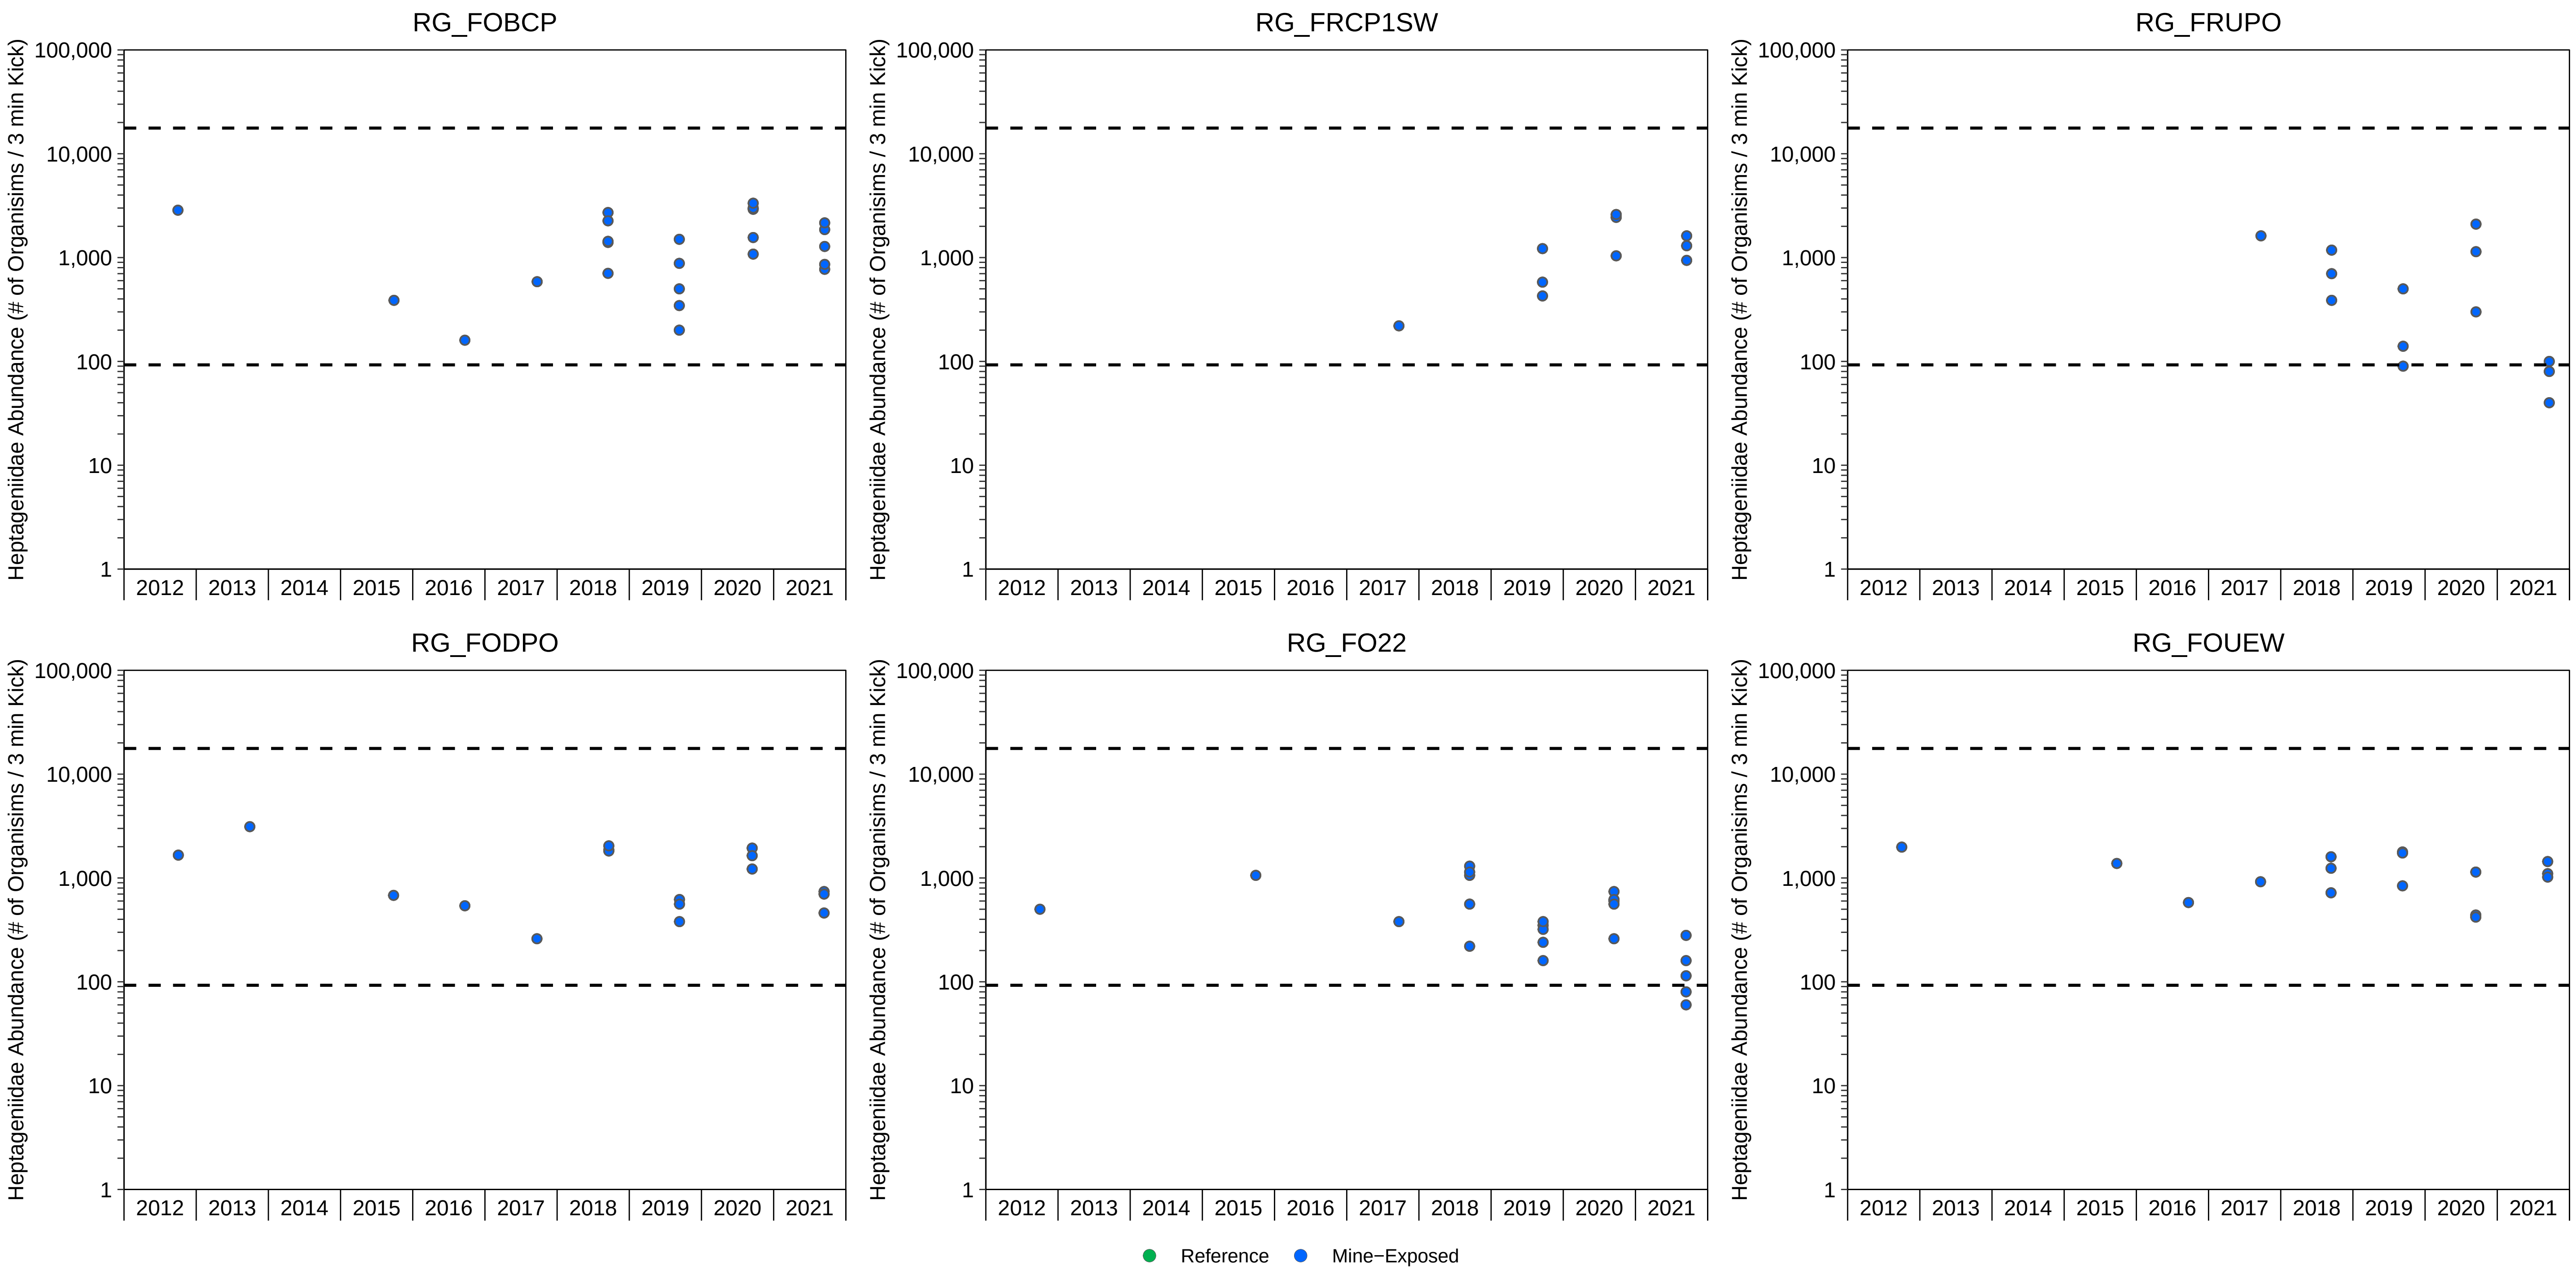

Figure E.20: Benthic Invertebrate Heptageniidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

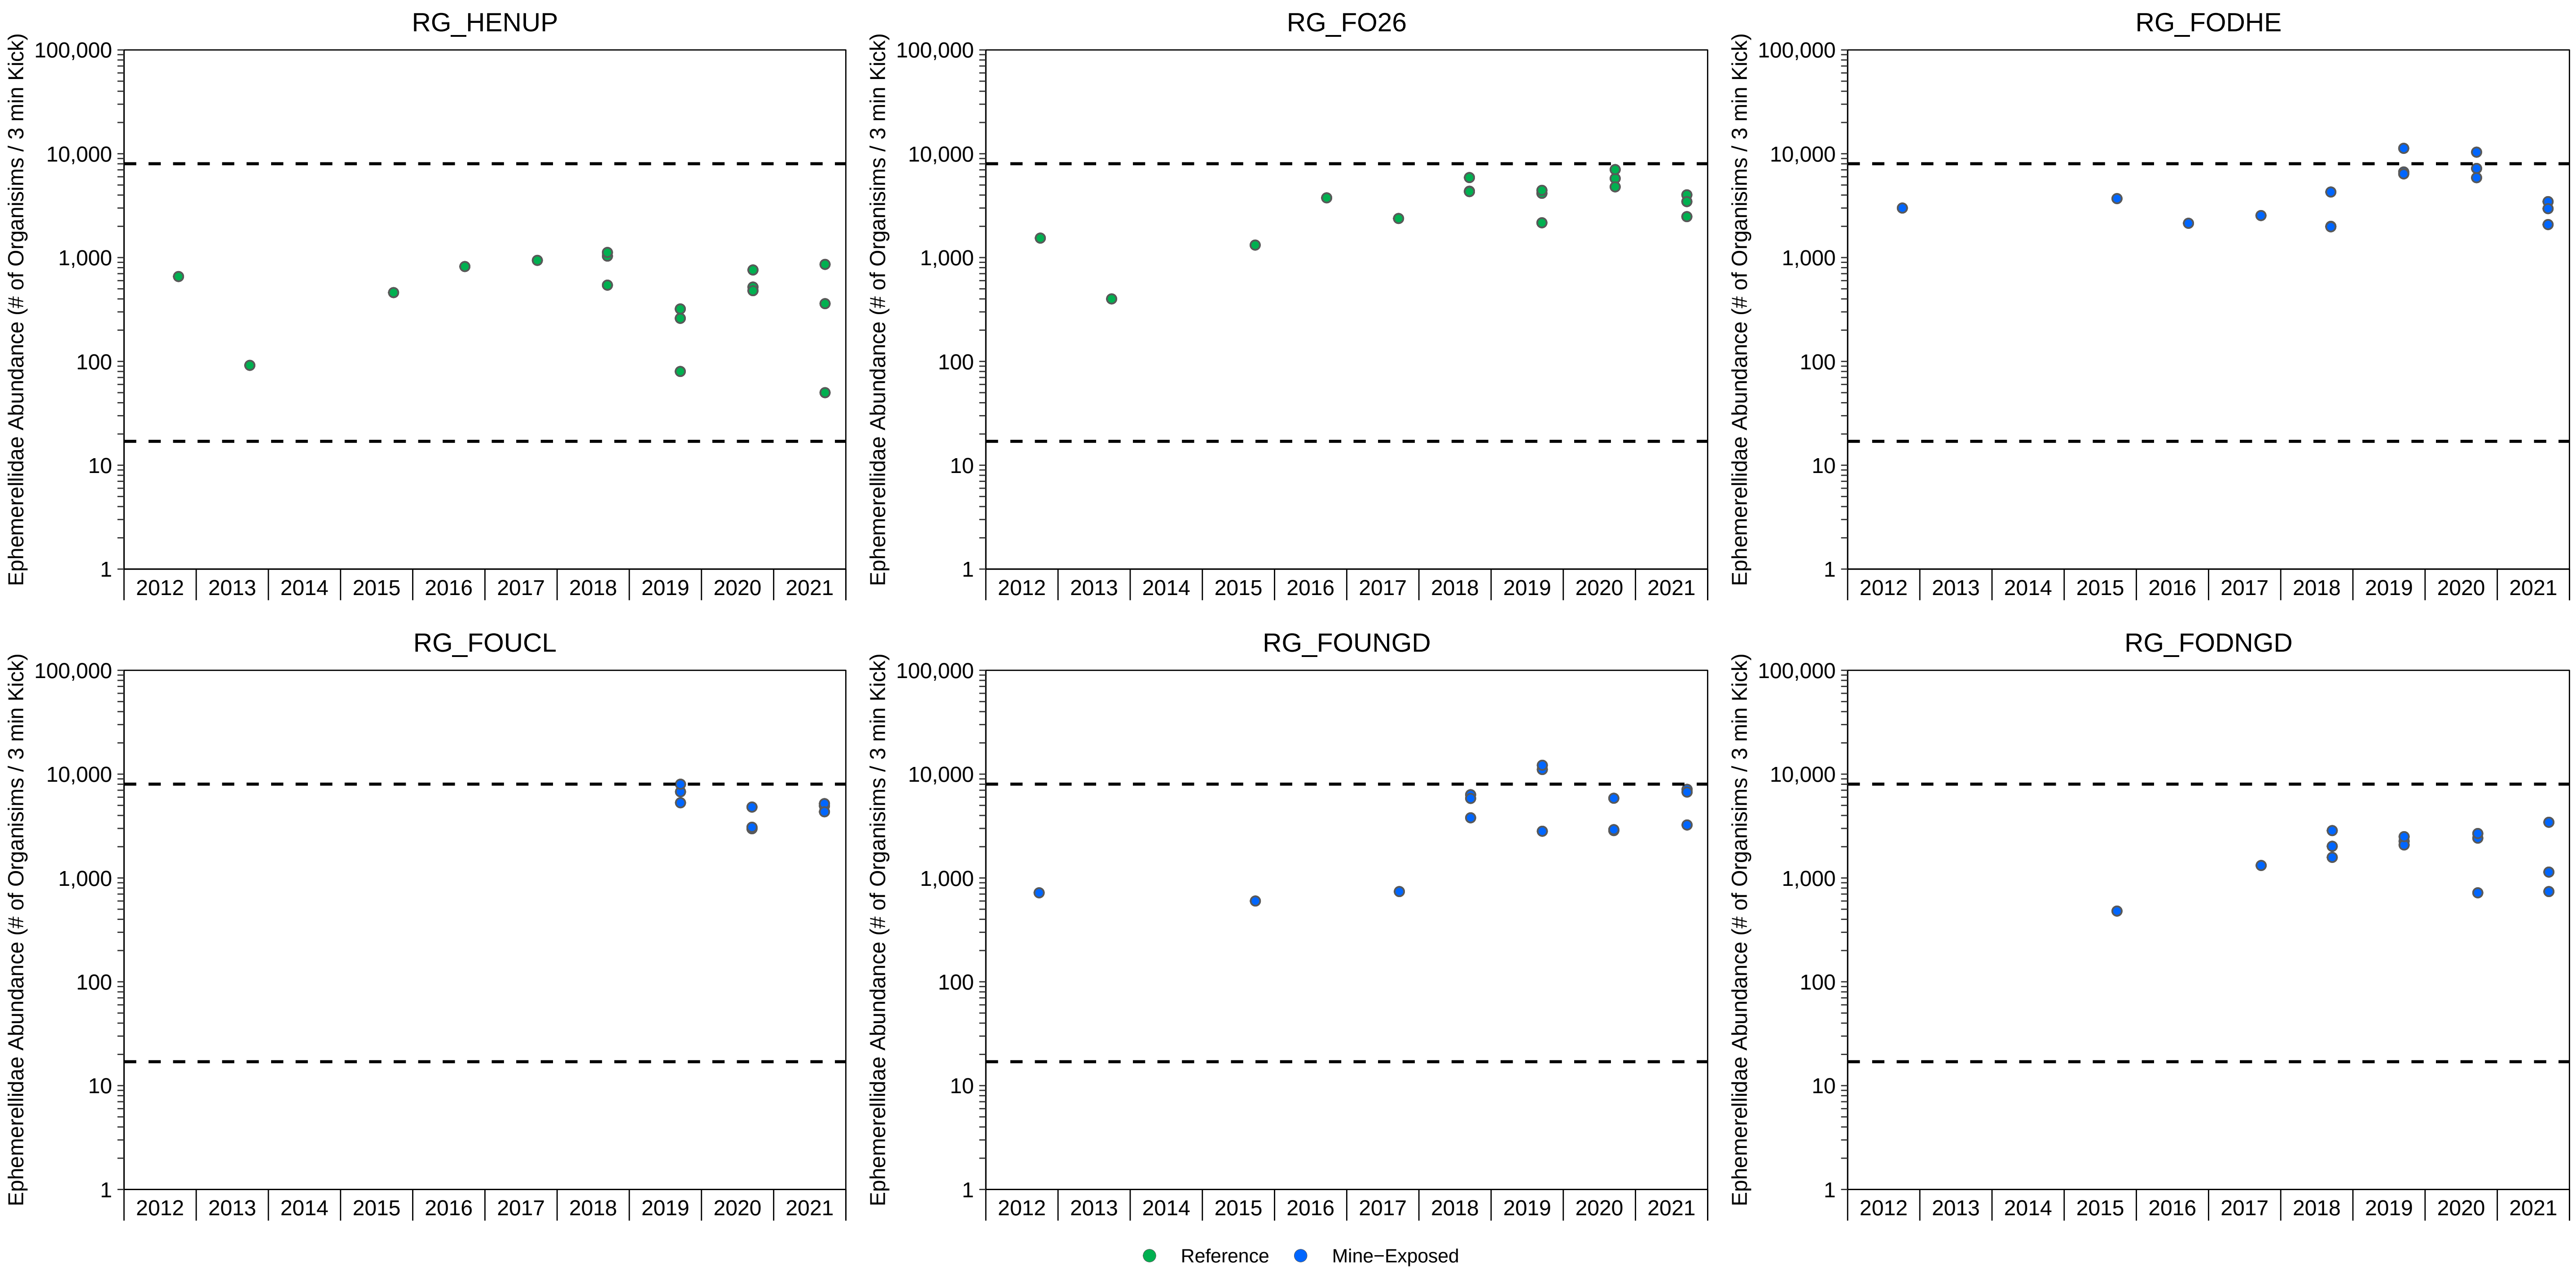

Figure E.21: Benthic Invertebrate Ephemerellidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

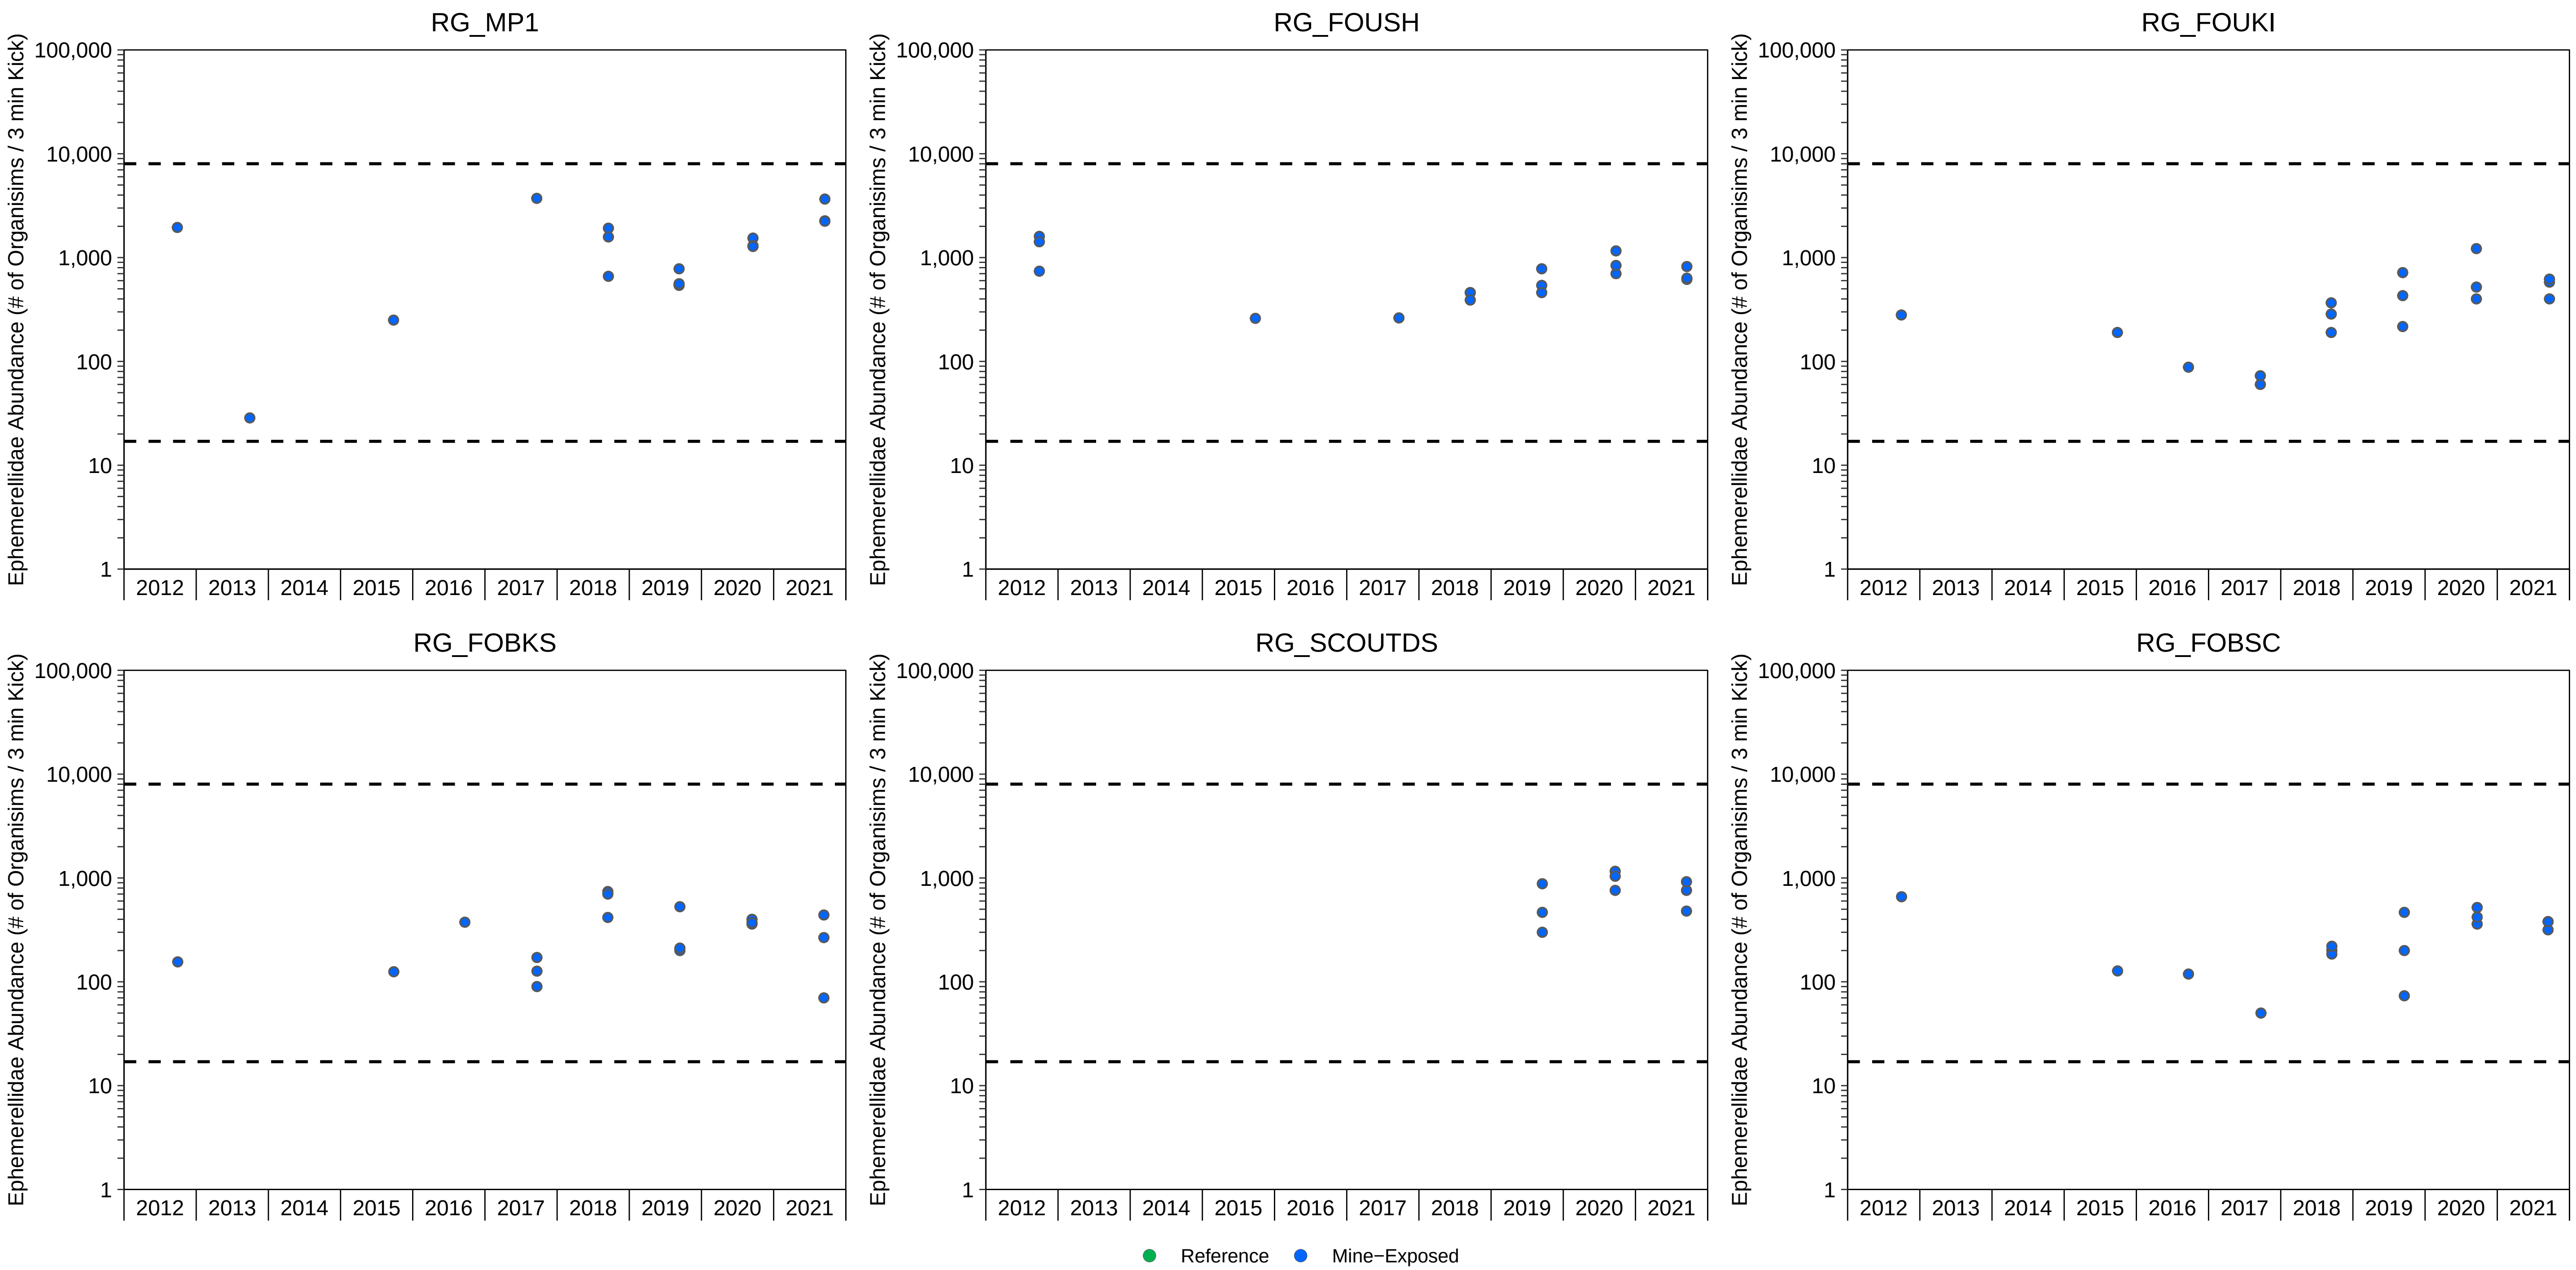

Figure E.21: Benthic Invertebrate Ephemerellidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

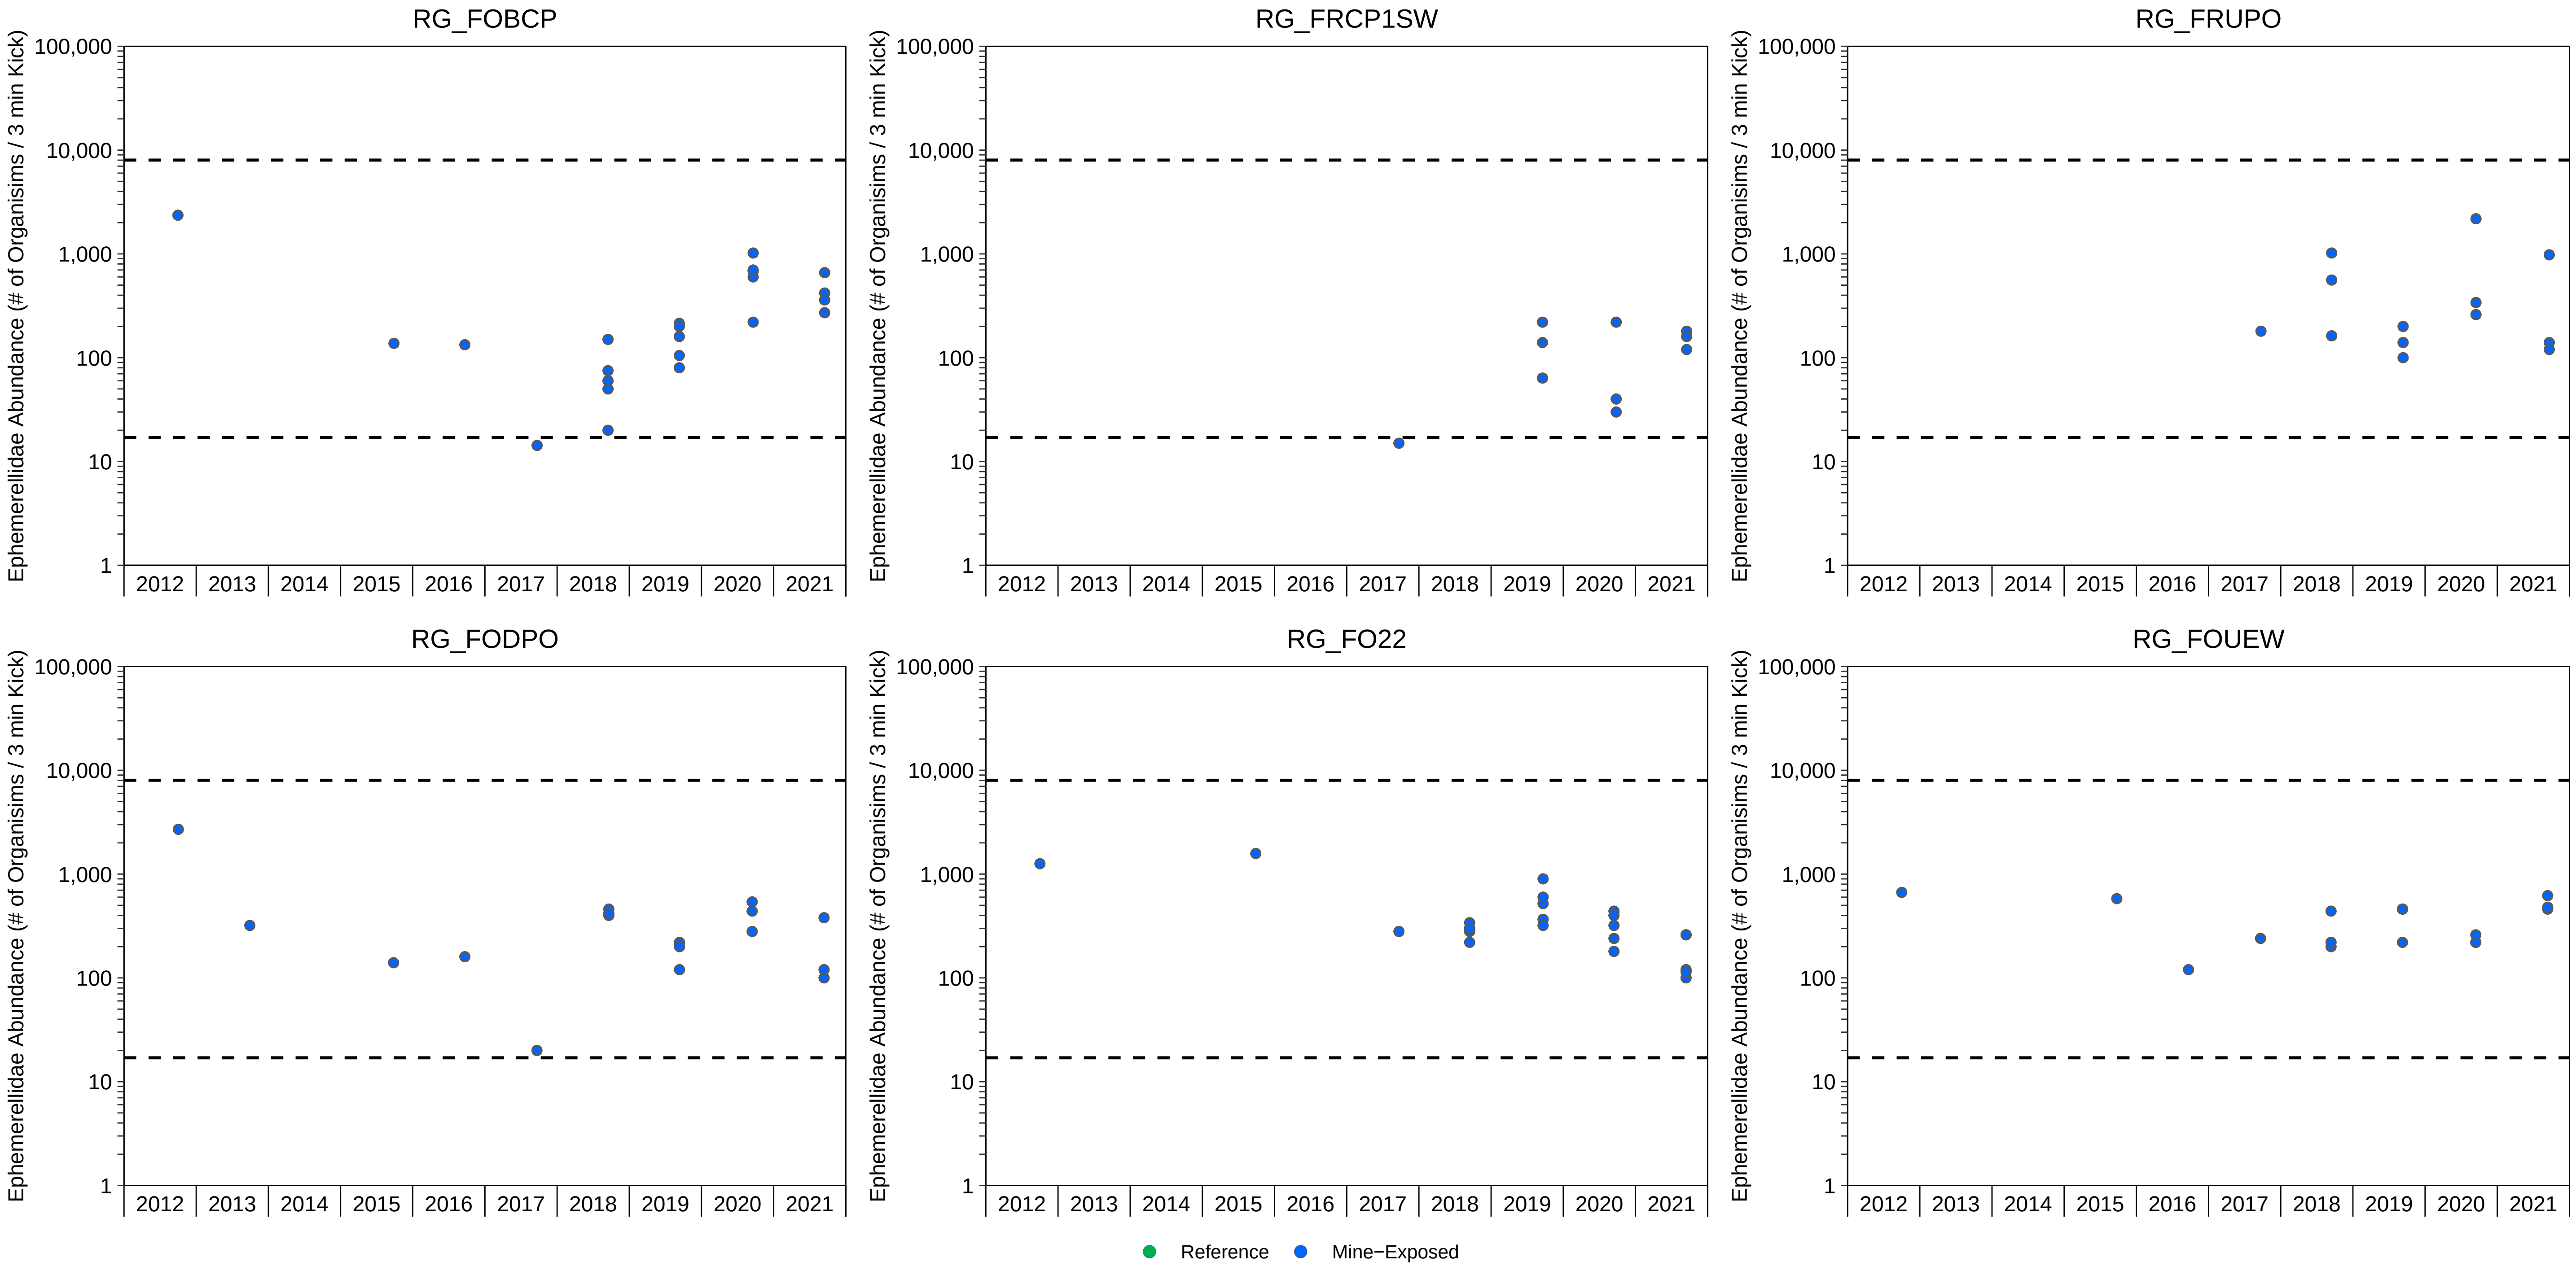

Figure E.21: Benthic Invertebrate Ephemerellidae Abundance in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

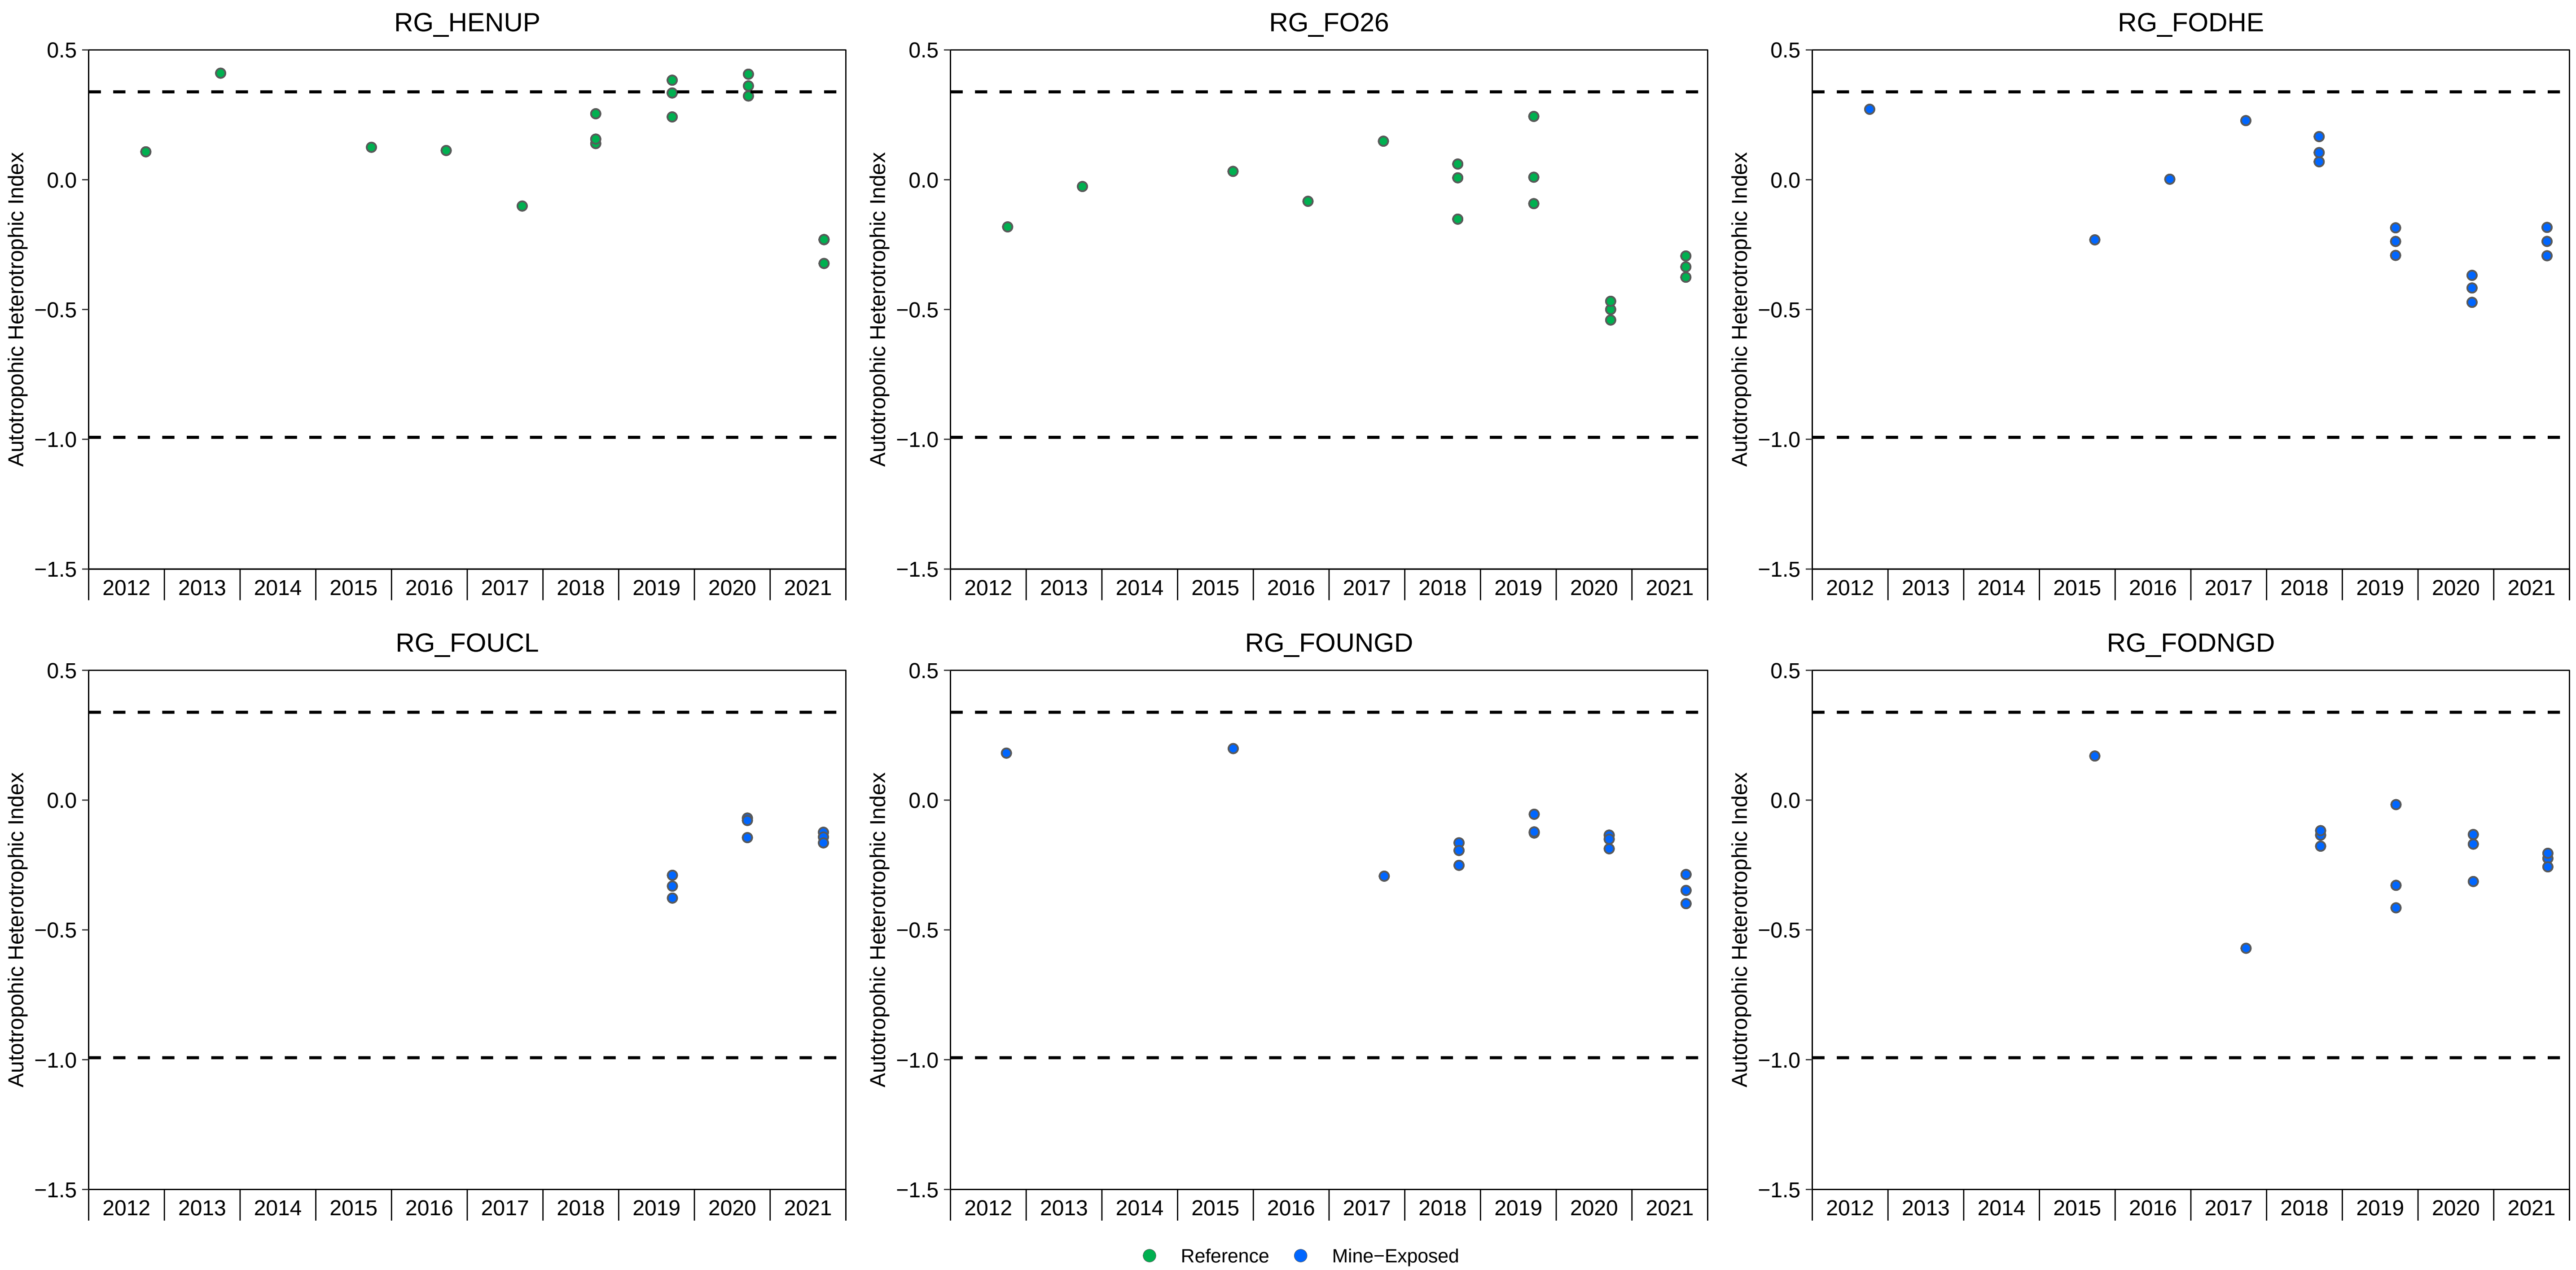

Figure E.22: Benthic Invertebrate Autotropohic Heterotrophic Index in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

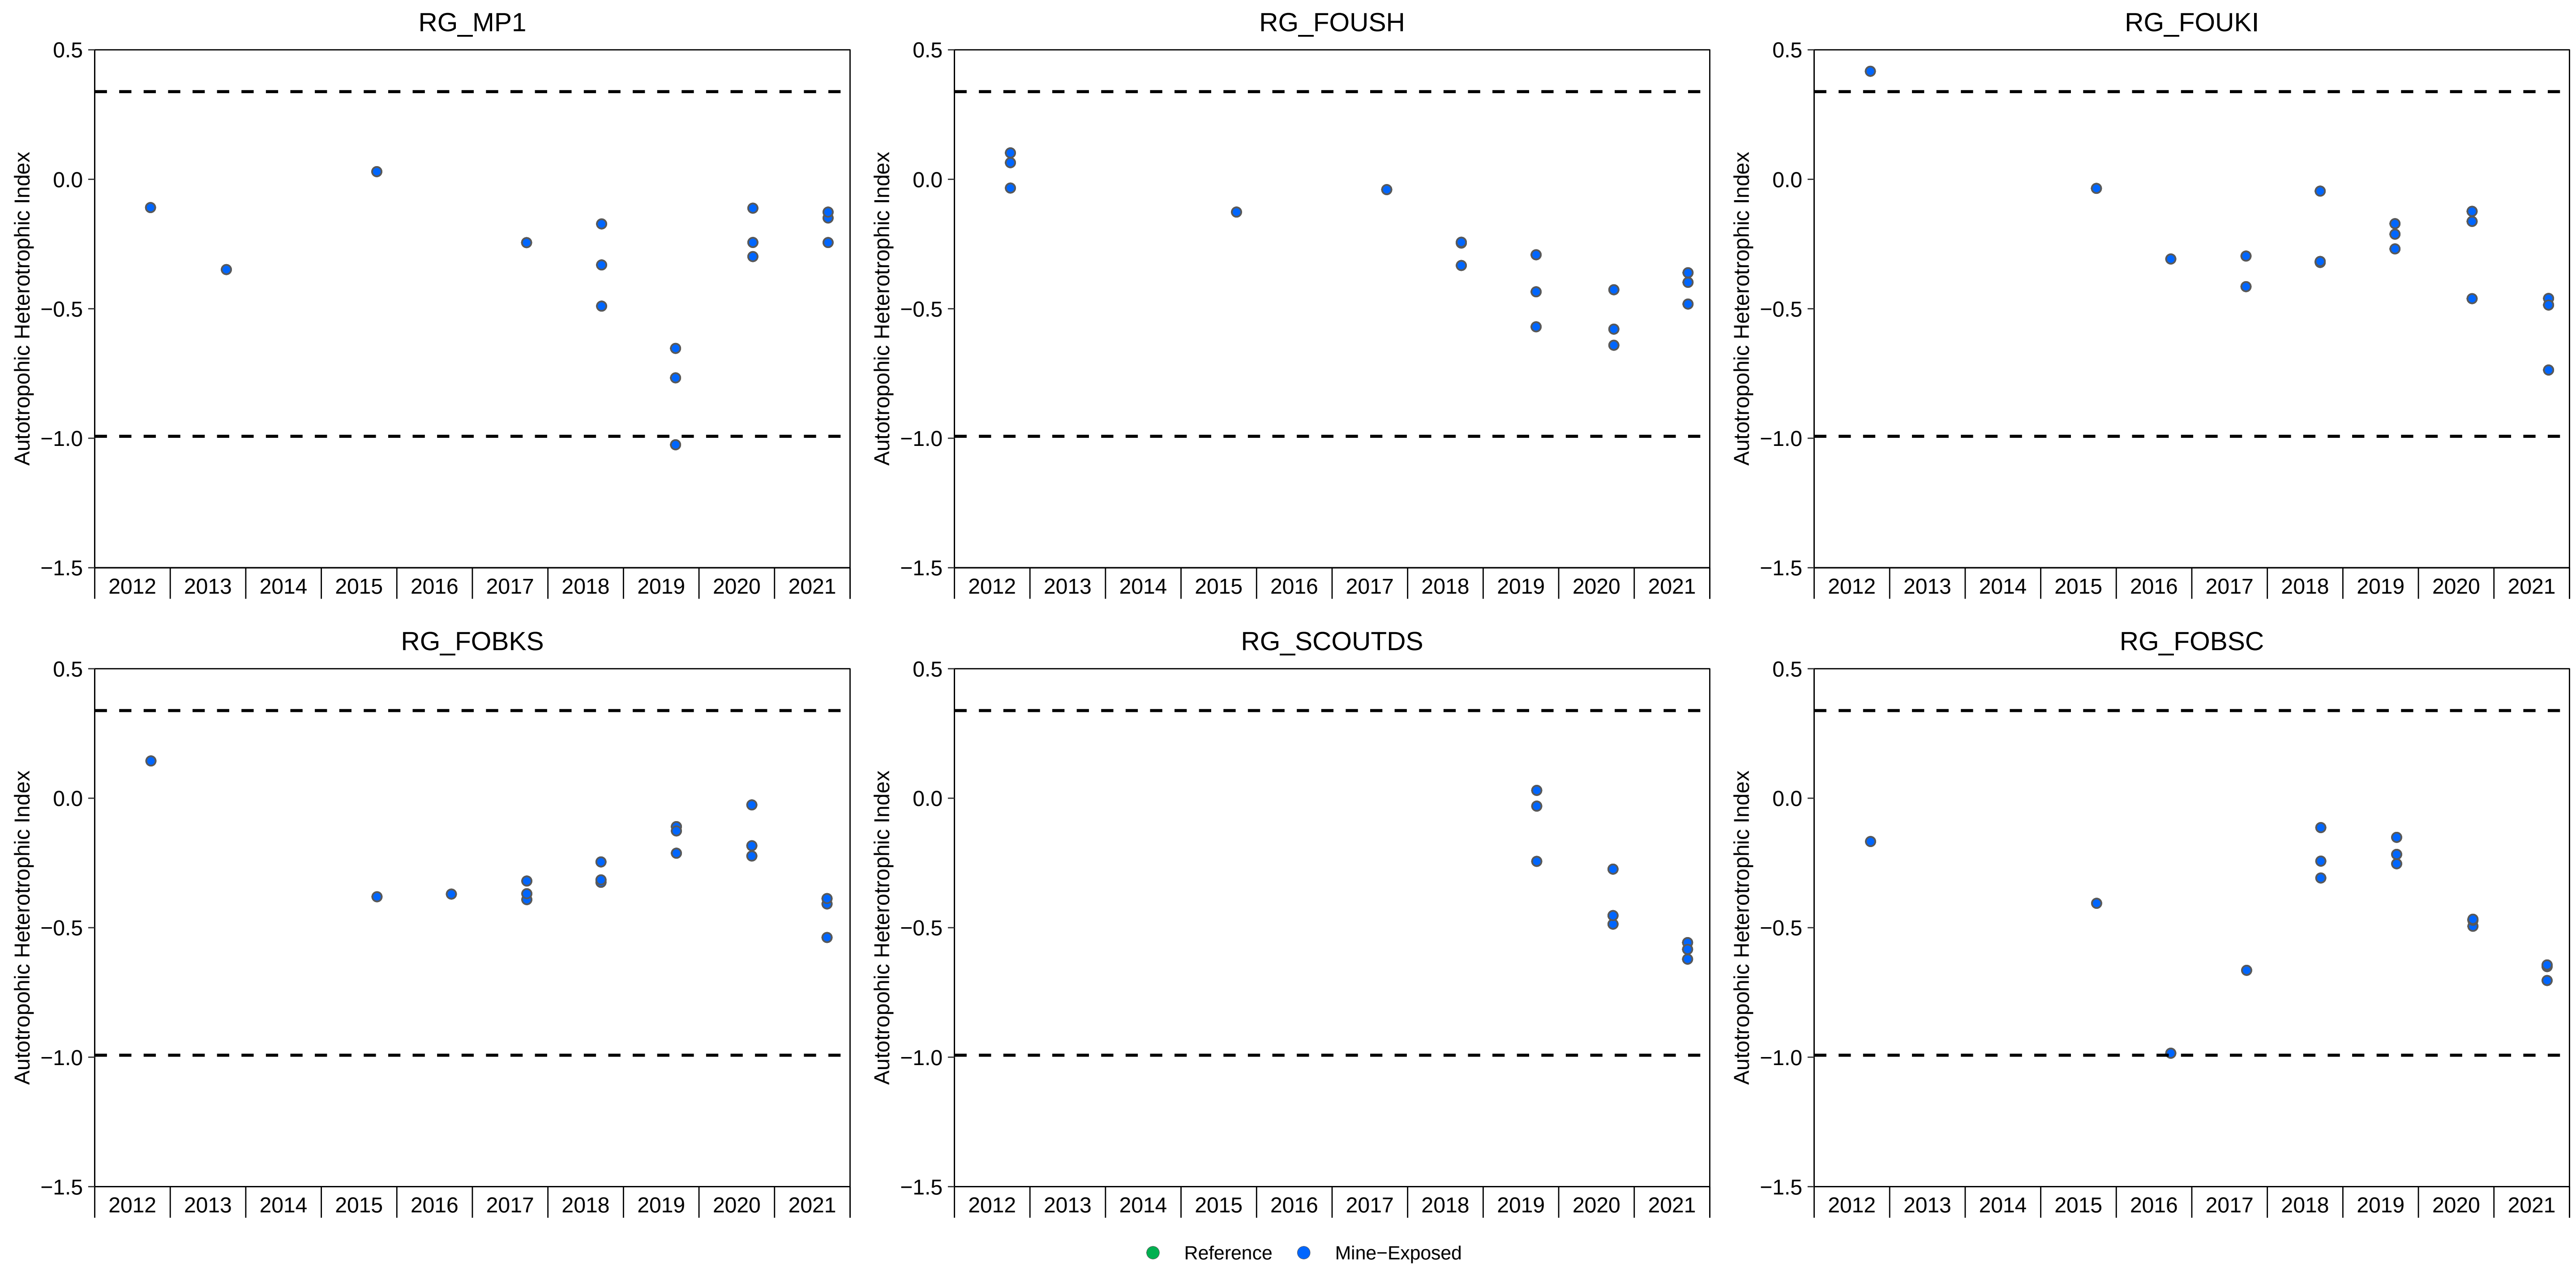

Figure E.22: Benthic Invertebrate Autotropohic Heterotrophic Index in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

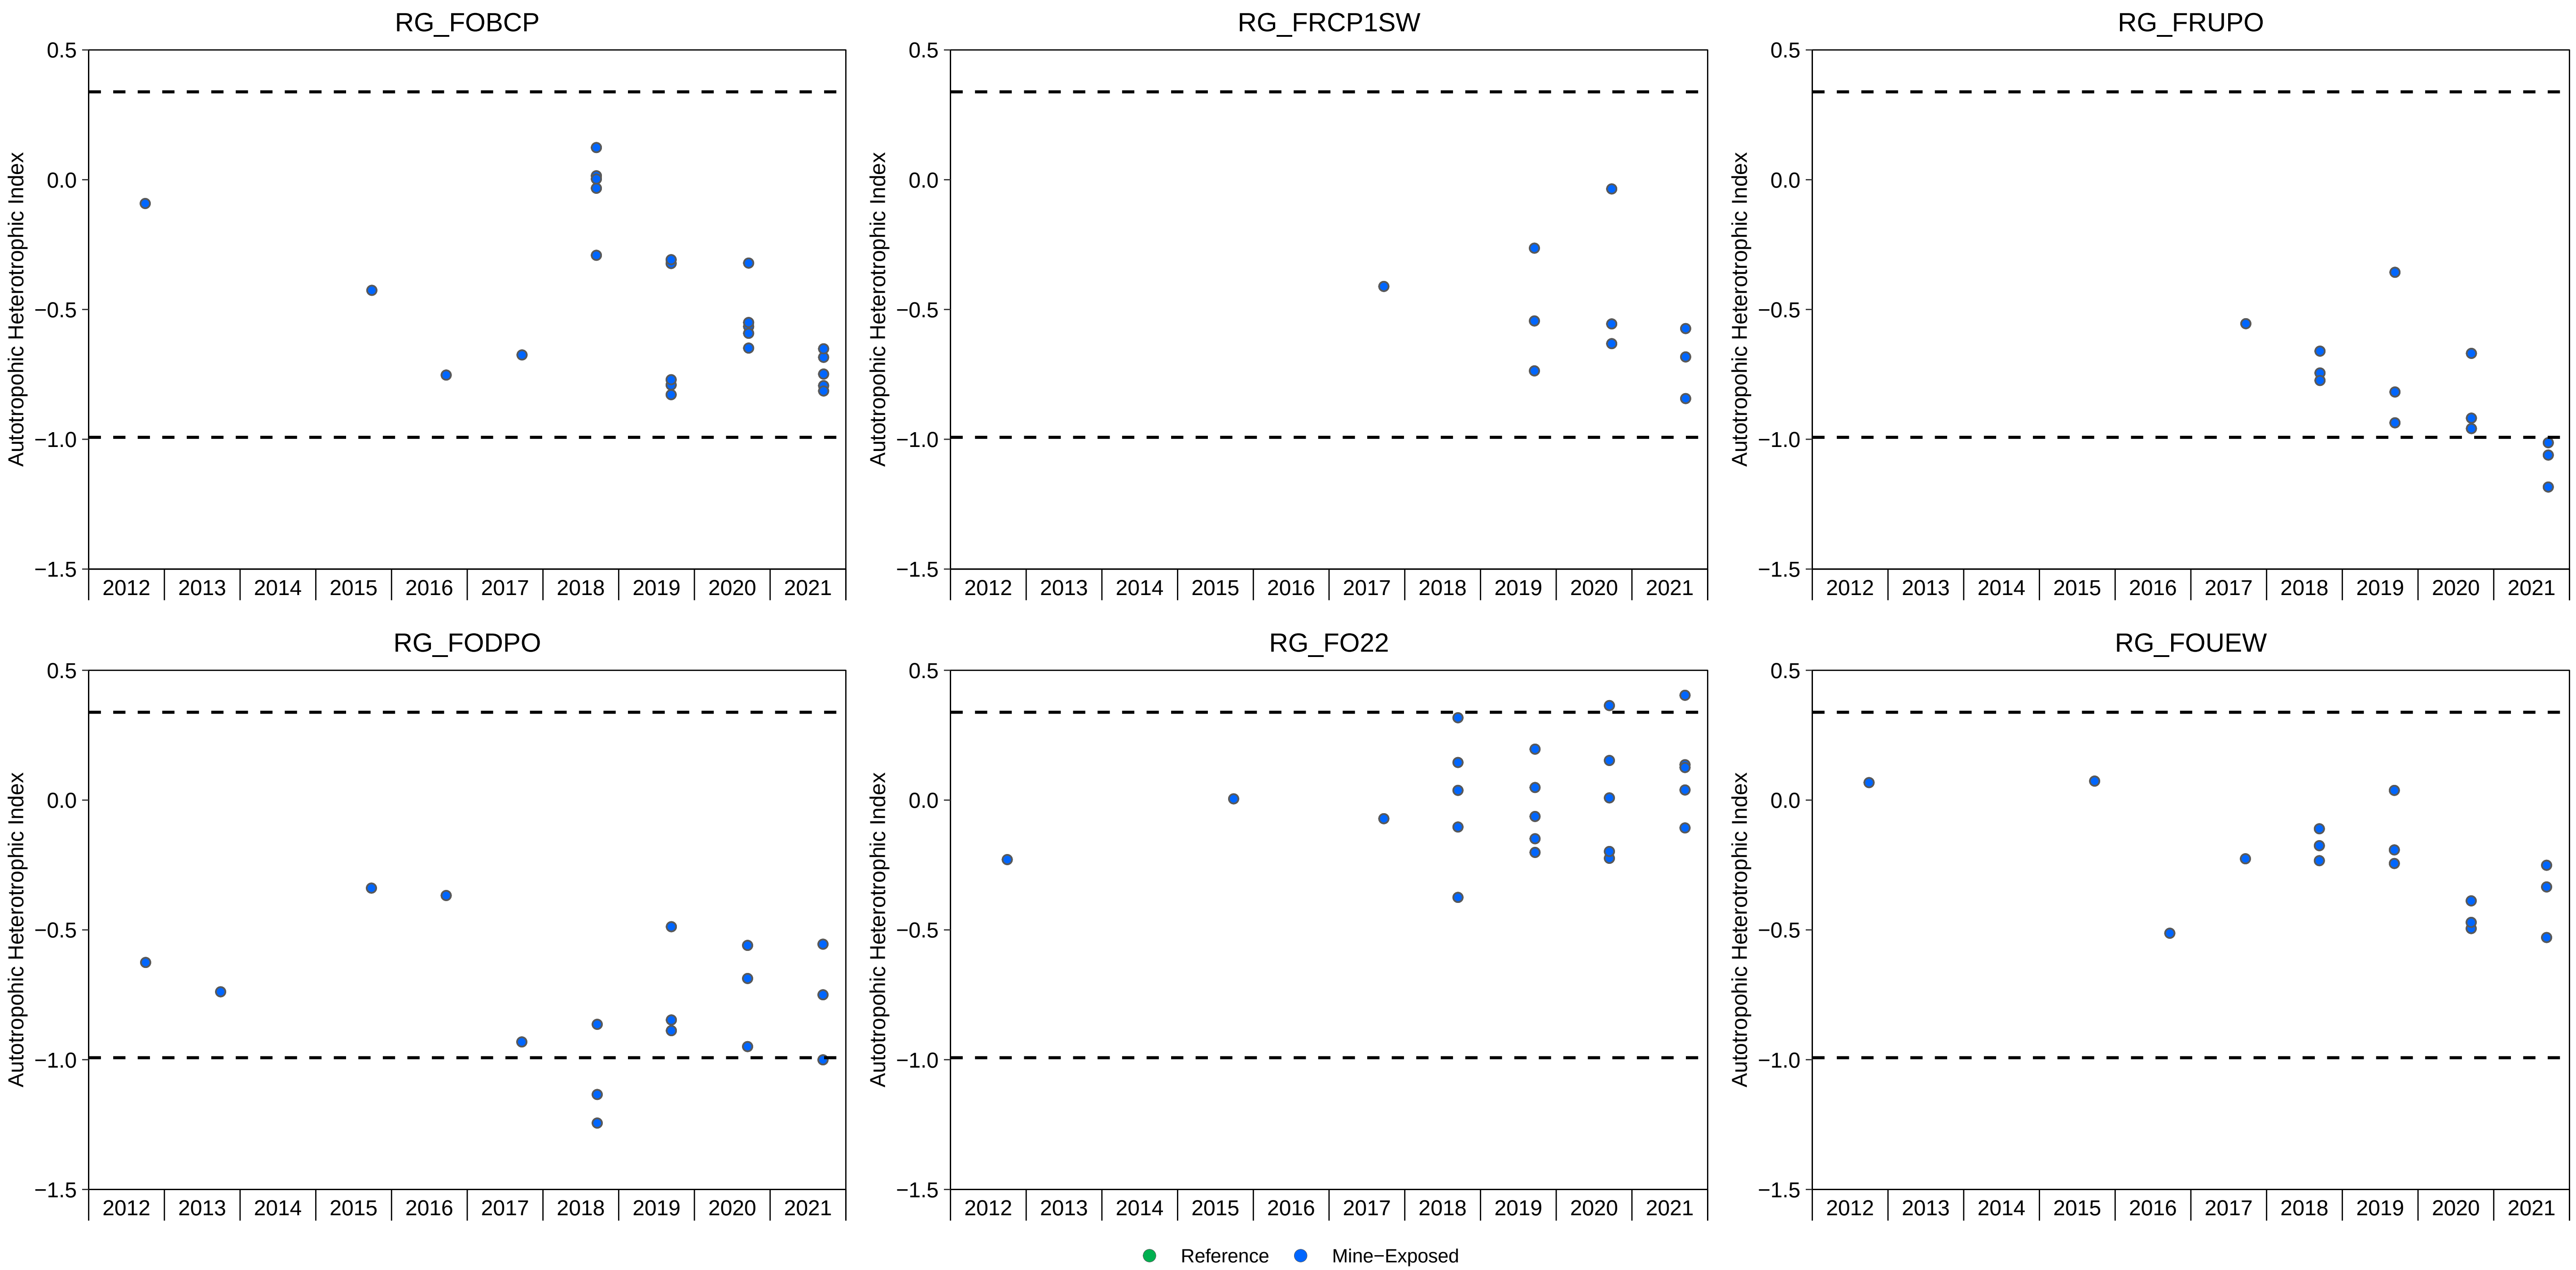

Figure E.22: Benthic Invertebrate Autotropohic Heterotrophic Index in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

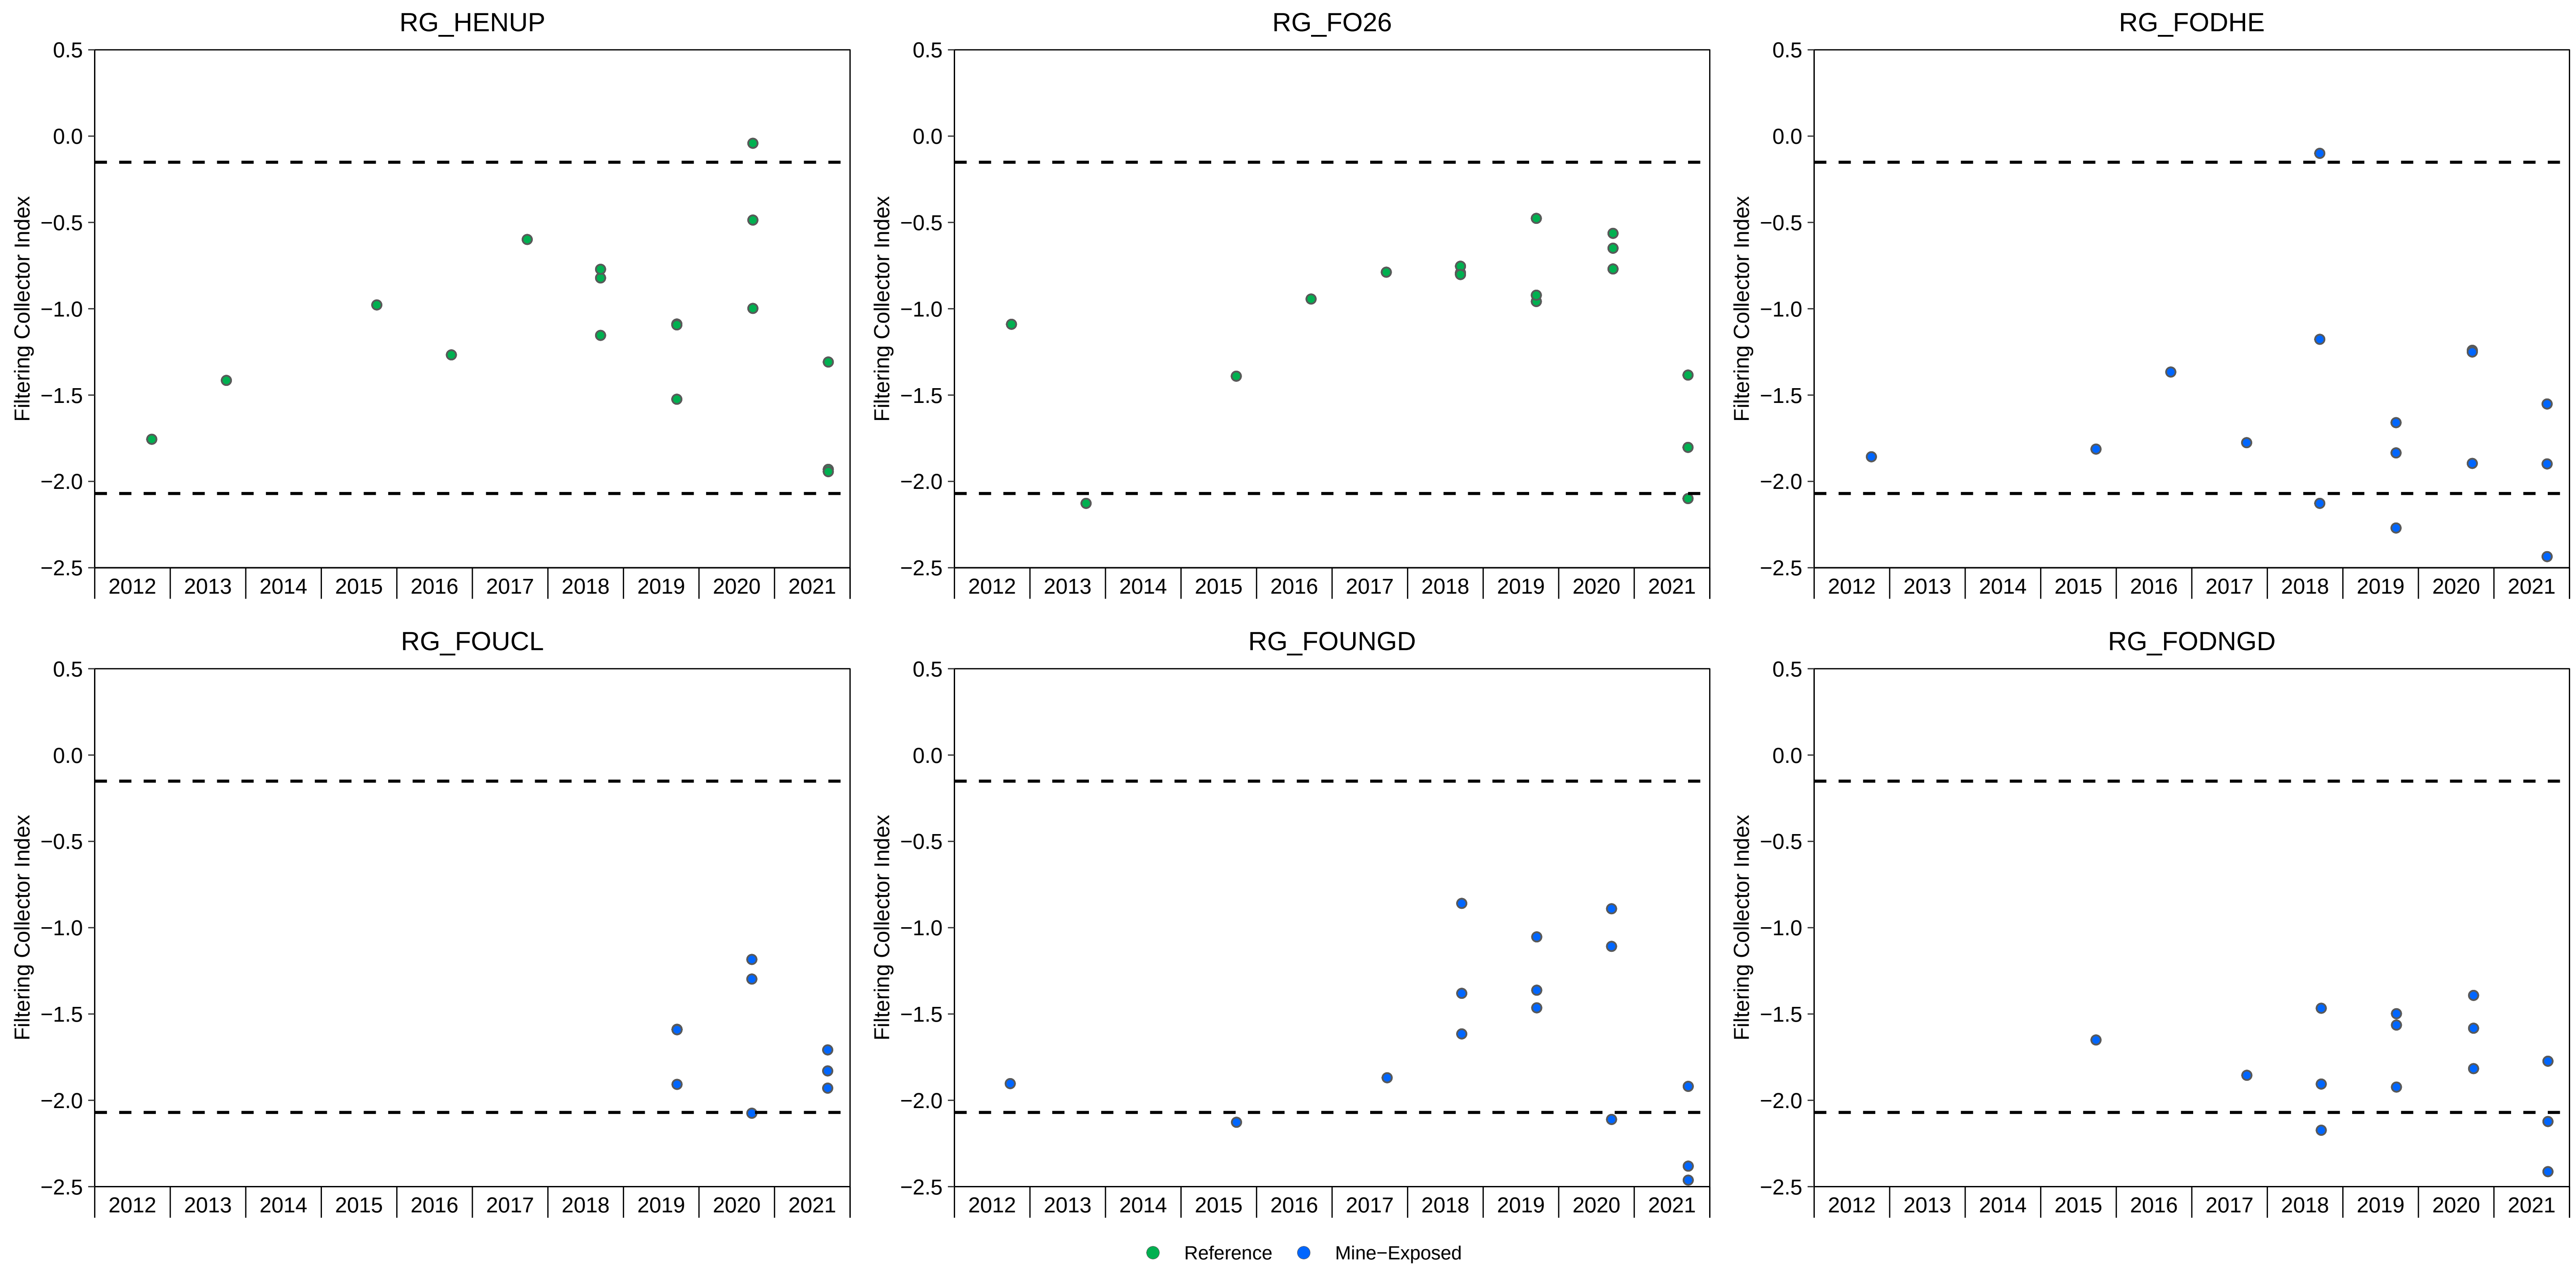

Figure E.23: Benthic Invertebrate Filtering Collector Index in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

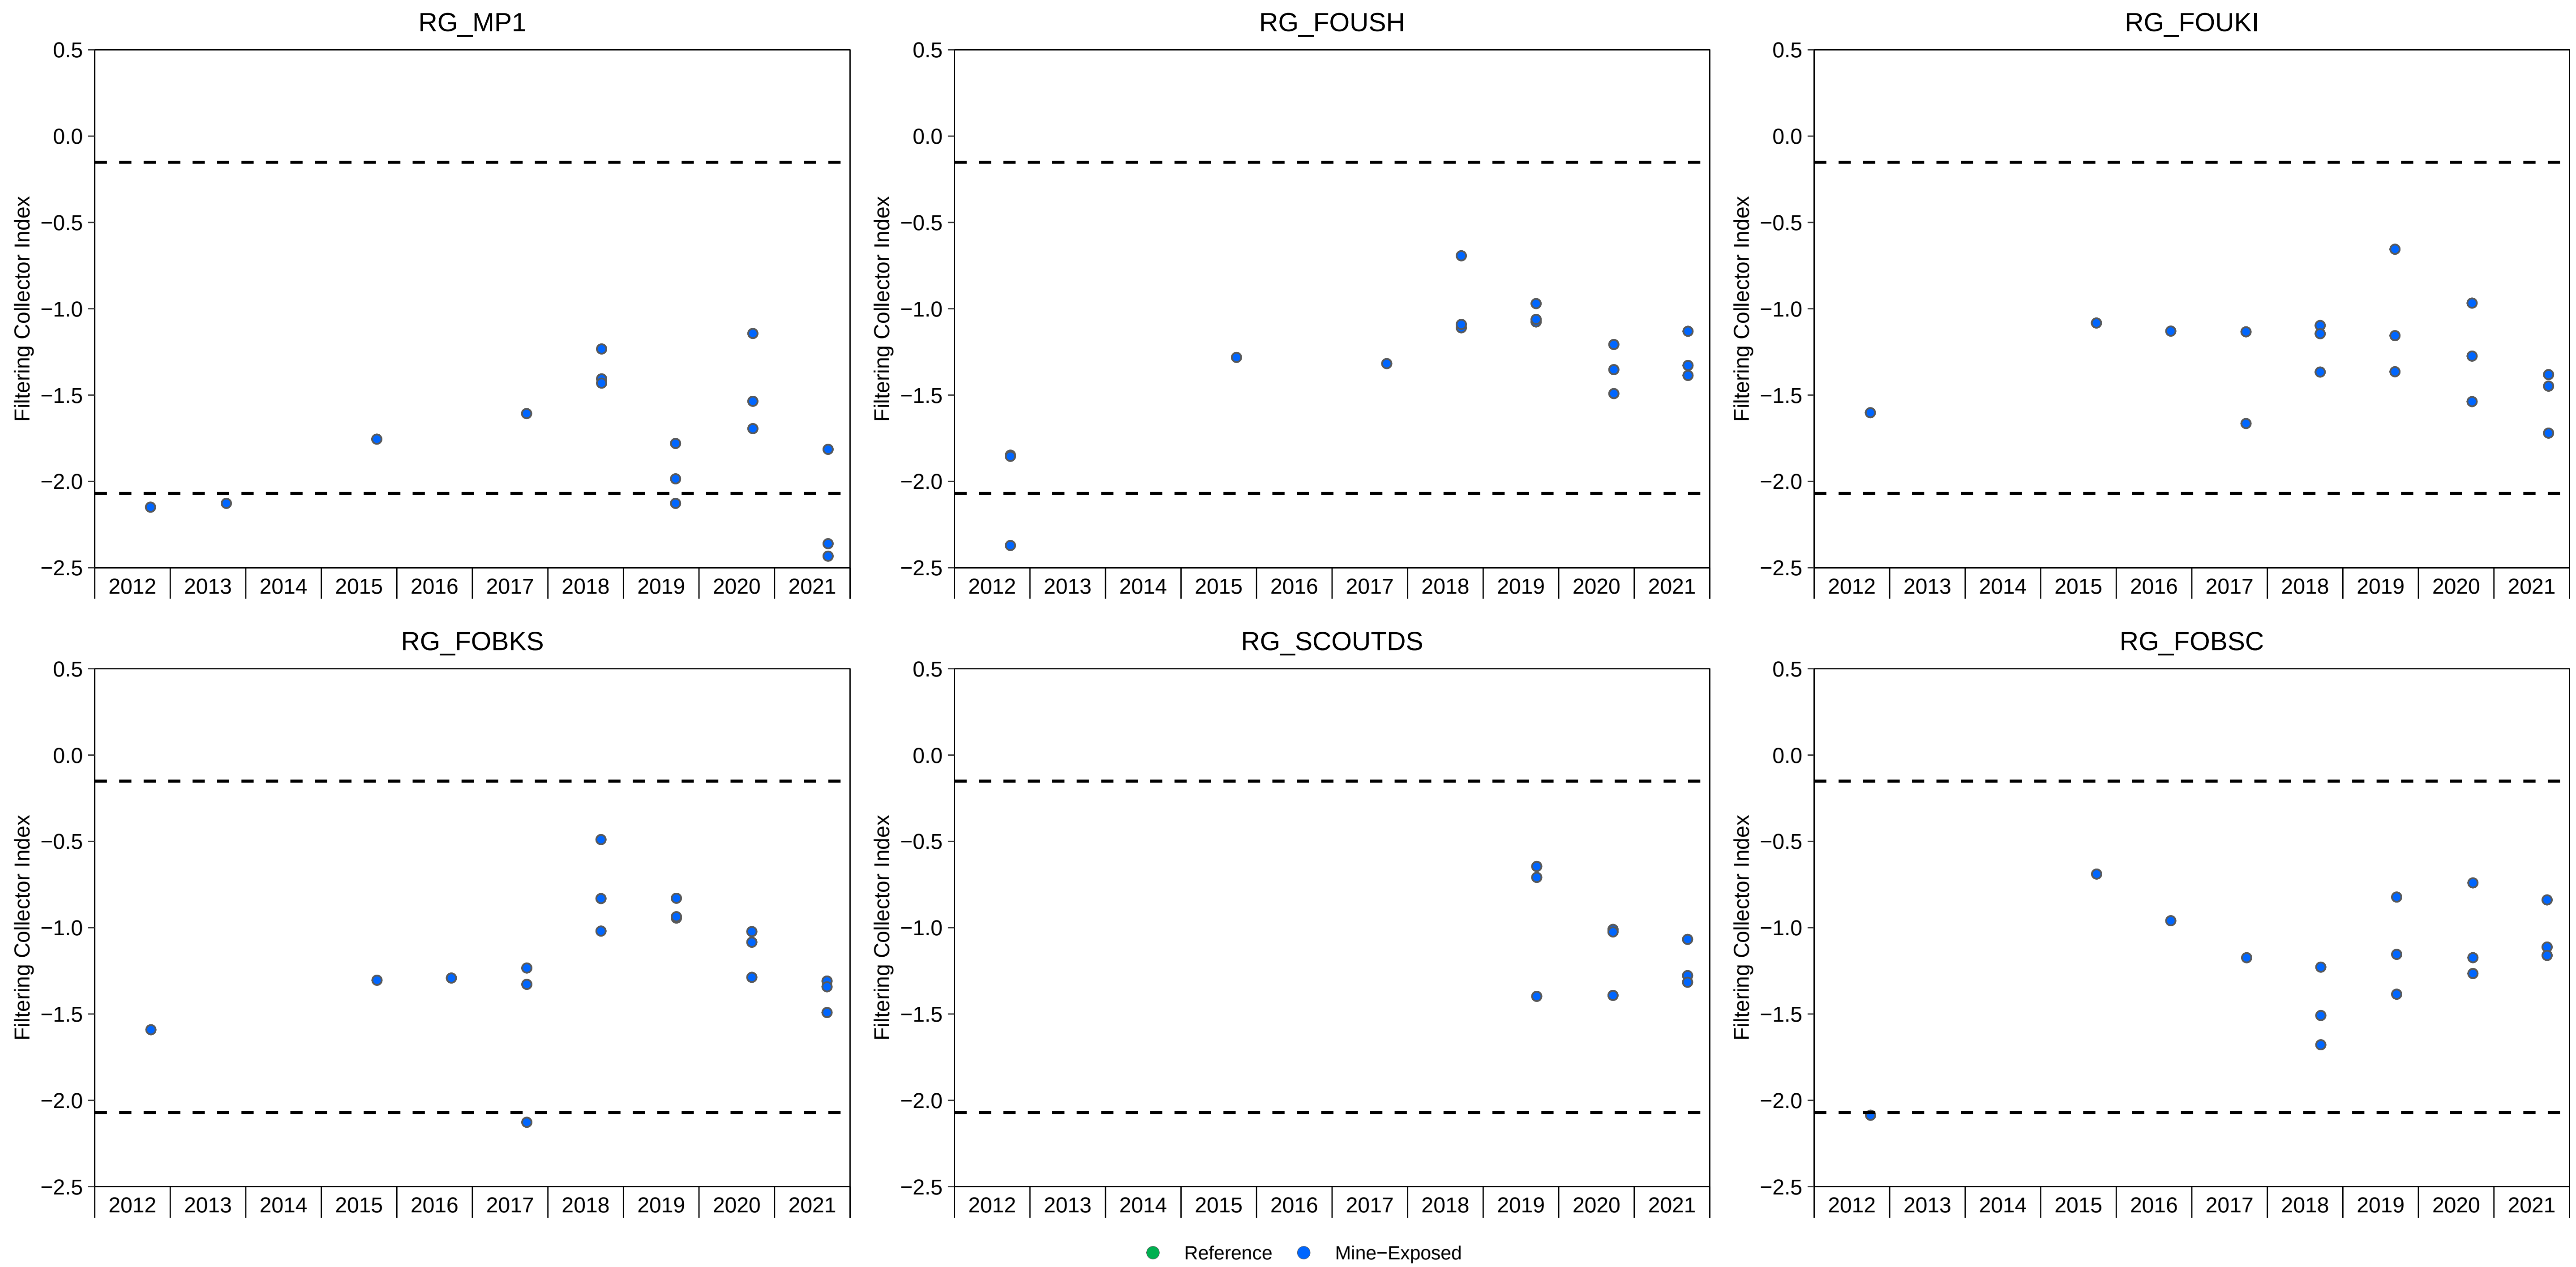

Figure E.23: Benthic Invertebrate Filtering Collector Index in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

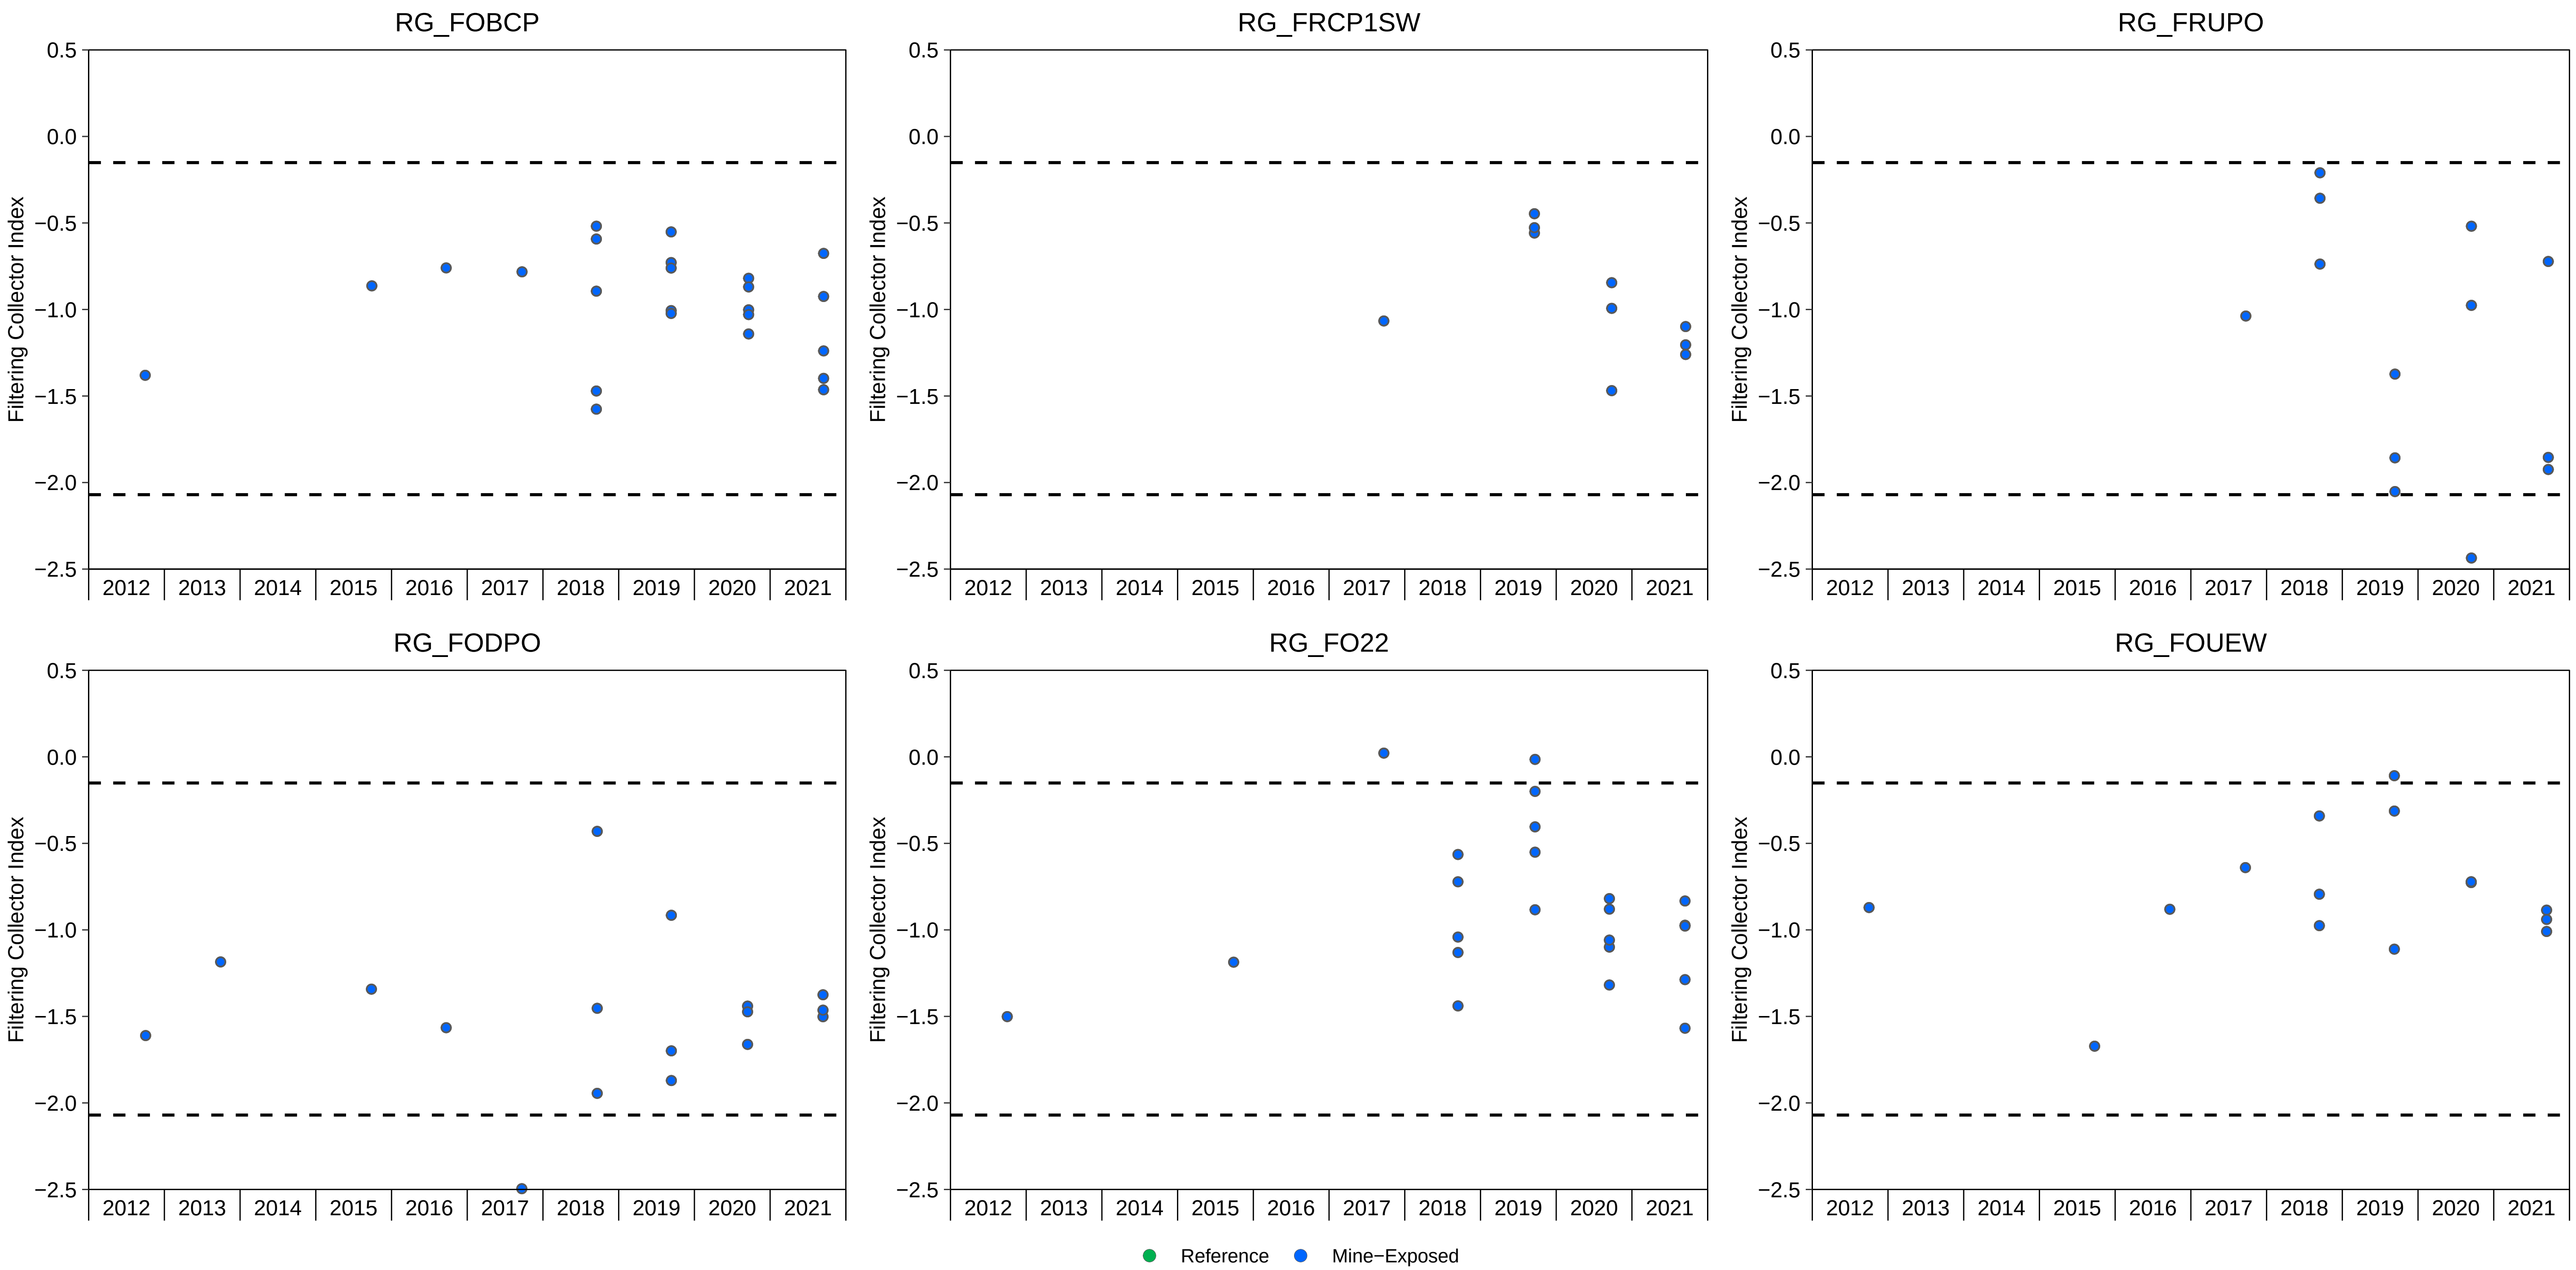

Figure E.23: Benthic Invertebrate Filtering Collector Index in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

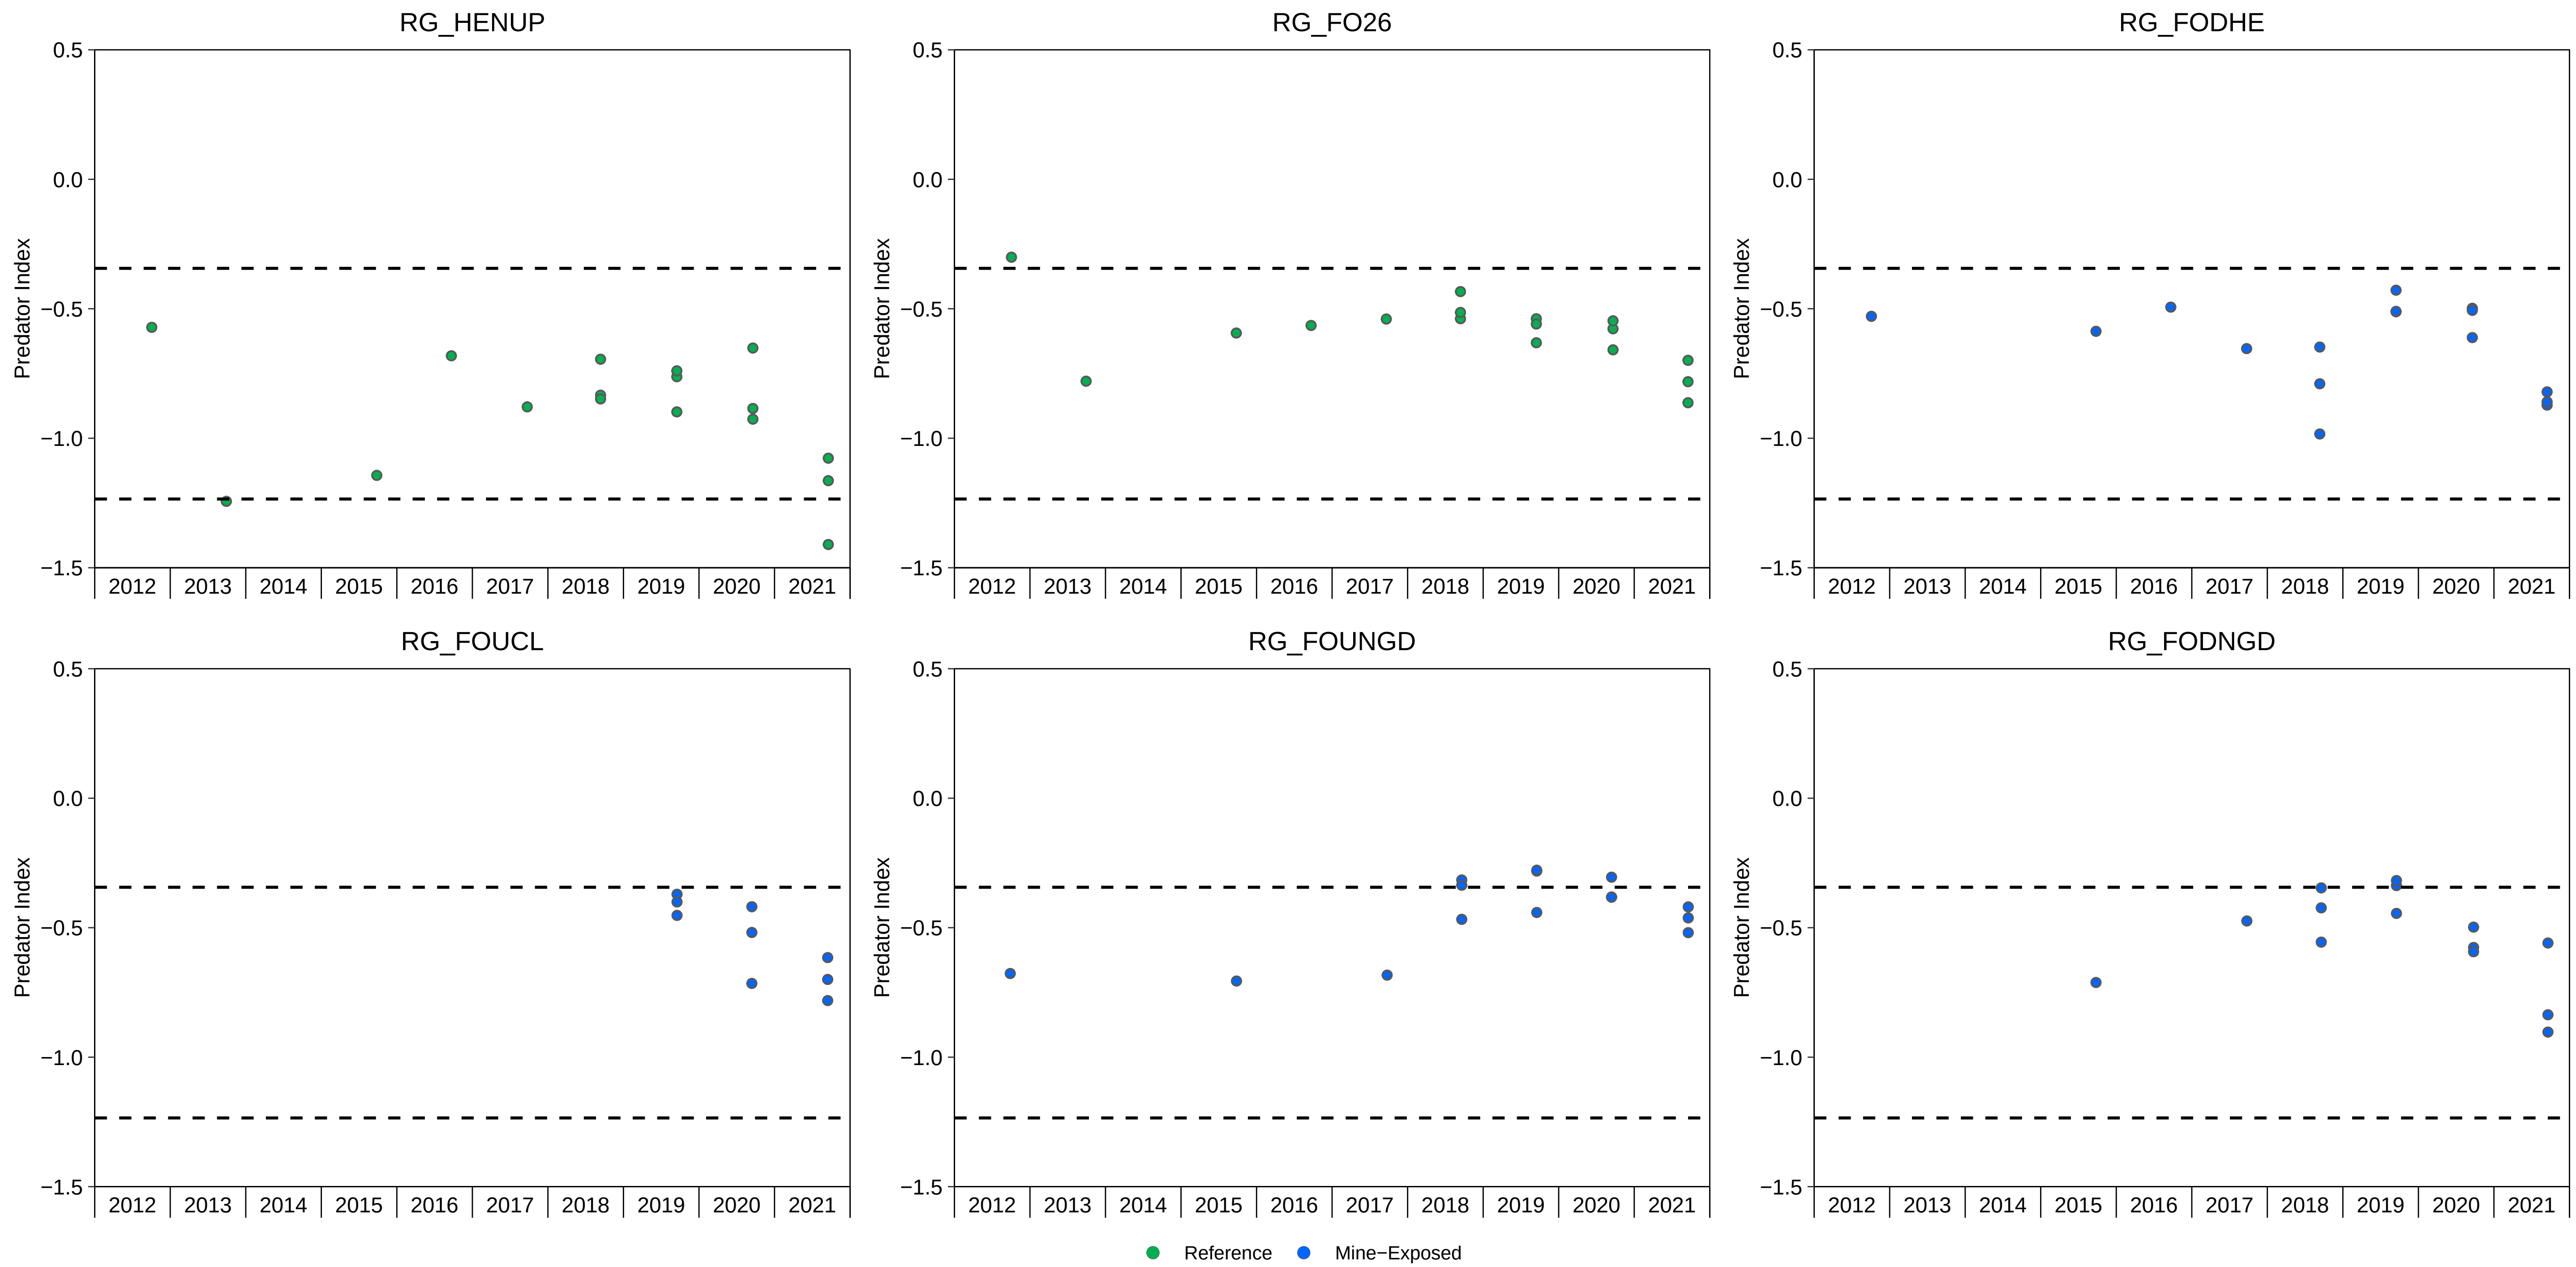

Figure E.24: Benthic Invertebrate Predator Index in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Figure E.24: Benthic Invertebrate Predator Index in September, FRO LAEMP, 2012 to 2021

Notes: Regional normal ranges using percentiles of reference areas from 2012 to 2019 are shown as dashed horizontal lines.

Notes: "-" indicates no sample collected, NA not applicable for these taxa.

[a] Hilsenhoff Biotic Index. Higher values indicate higher tolerance to organic pollution - Hilsenhoff, William L. "An improved biotic index of organic stream pollution." The great lakes entomologist 20.1 (1987): 7.

[b] Canadian Ecological Flow Index - Calculated based on velocity preference and specificity (high specificity indicate the organism has a lower tolerance for deviations from preferred velocity) - Peters, Daniel L., et al. "Establishing standards and assessment criteria for ecological instream flow needs in agricultural regions of Canada." Journal of environmental quality 41.1 (2012): 41-51.

[c] Multiple preferences separated by "\|". Value modified from USGS Trait Database (https://pubs.usgs.gov/ds/ds187/) and the bio.inf R package Lester L. Yuan (2014). bio.infer: Predict environmental conditions from biological observations. R package version

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPLATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUEW.

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPLATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUEW.

Notes: No concurrent water selenium data were available for 2016 tissue samples, so concentrations from the closest sample date from each associated Teck WQ monitoring station was used. No selenium water data was available for MP1 in 2012, so the corresponding data from FR_MULTIPLATE was used for that data point only in 2012. "-" indicates stations where benthic tissue samples were not taken because of frozen conditions. June 2019 water quality data were not available for RG_HENUP and RG_FOUEW.

bold Significant increase or decrease from base year.
Significantly > than all historical years (or 2020).
Significantly < than all historical years (or 2020).

Notes: "ns" = not significant; "-" insufficient data for comparison.

[a] *Year* p-value from an ANOVA

[b] Magnitude of Difference (MOD) = [$Mean_{given\ year}$ – $Mean_{base\ year}$] /$SD_{base\ year}$.

[c] Significance among year determined using all pairwise comparisons using Tukey's honestly significant differences method. Years that share a letter are not significantly different. Letters assigned such that the mean with highest magnitude is assigned "a".

bold Significant increase or decrease from base year.
Significantly > than all historical years (or 2020).
Significantly < than all historical years (or 2020).

Notes: "ns" = not significant; "-" insufficient data for comparison.

[a] *Year* p-value from an ANOVA

[b] Magnitude of Difference (MOD) = $[\text{Mean}_{\text{given year}} - \text{Mean}_{\text{base year}}] / \text{SD}_{\text{base year}}$.

[c] Significance among year determined using all pairwise comparisons using Tukey's honestly significant differences method. Years that share a letter are not significantly different. Letters assigned such that the mean with highest magnitude is assigned "a".

APPENDIX F
INTEGRATED ANALYSES

FIGURES

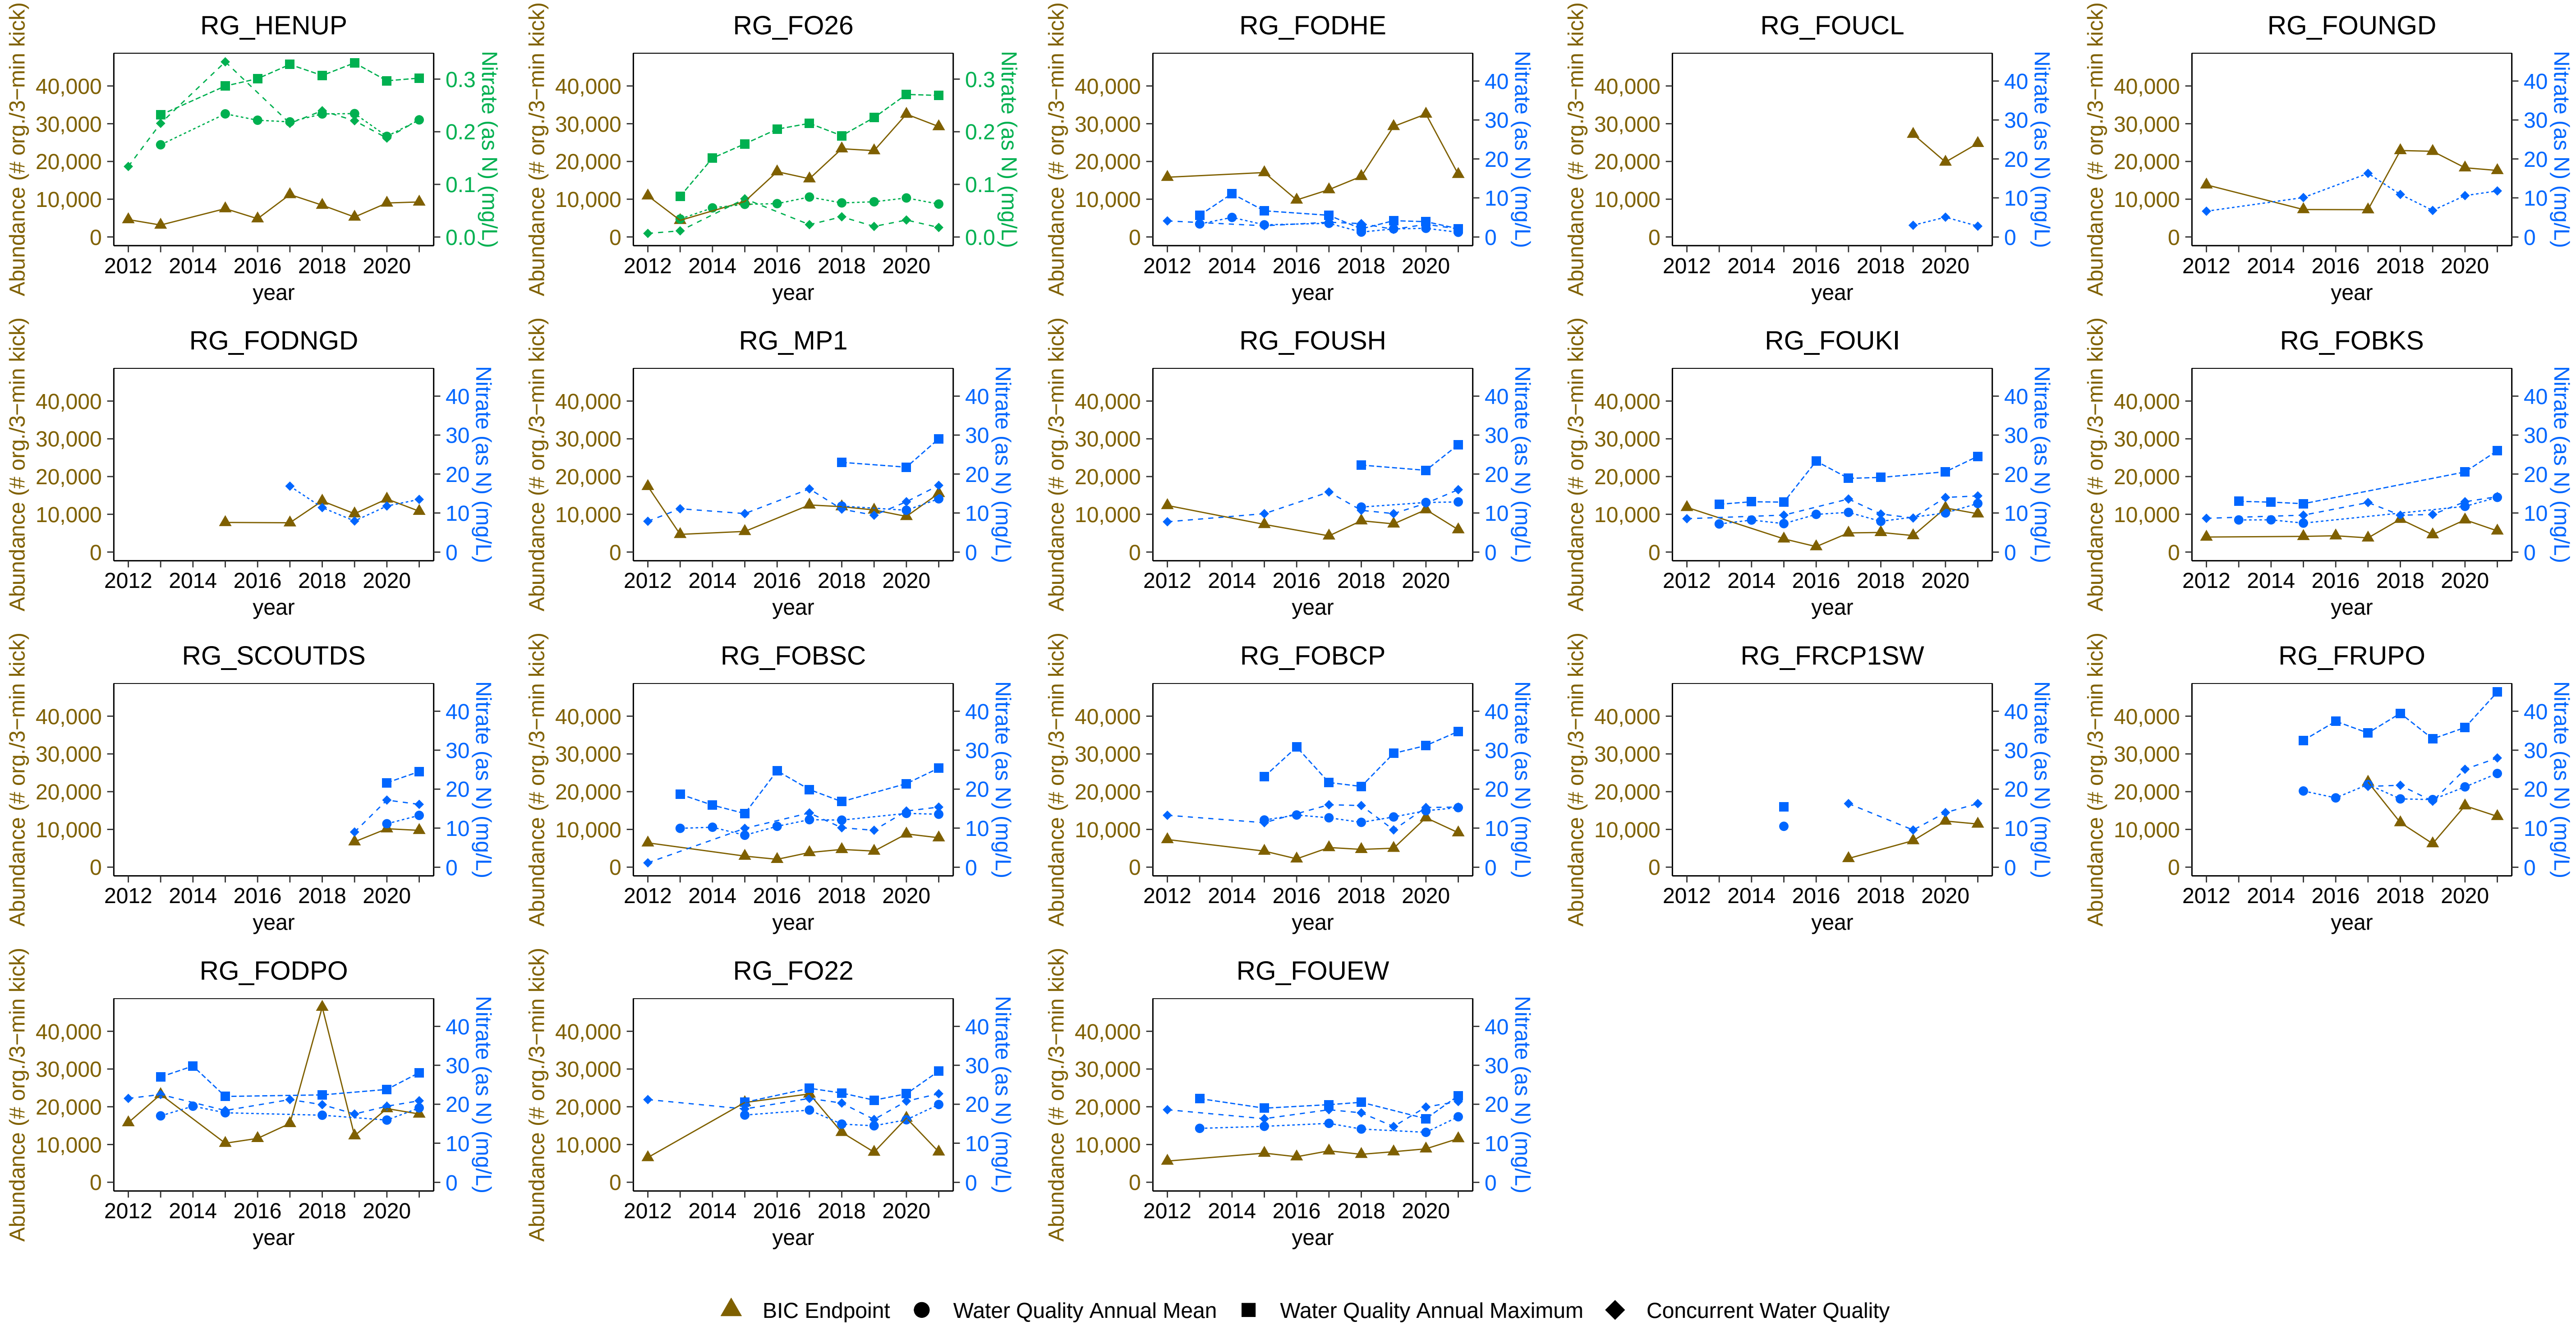

Figure F.1: Temporal Comparisons of Abundance (# organisms/3−min kick) and Nitrate (as N) (mg/L), FRO LAEMP, September 2012 to 2021

Notes: Water chemistry is shown in green for reference areas and blue for mine−exposed areas. Maximum calculated as the maximum monthly mean.

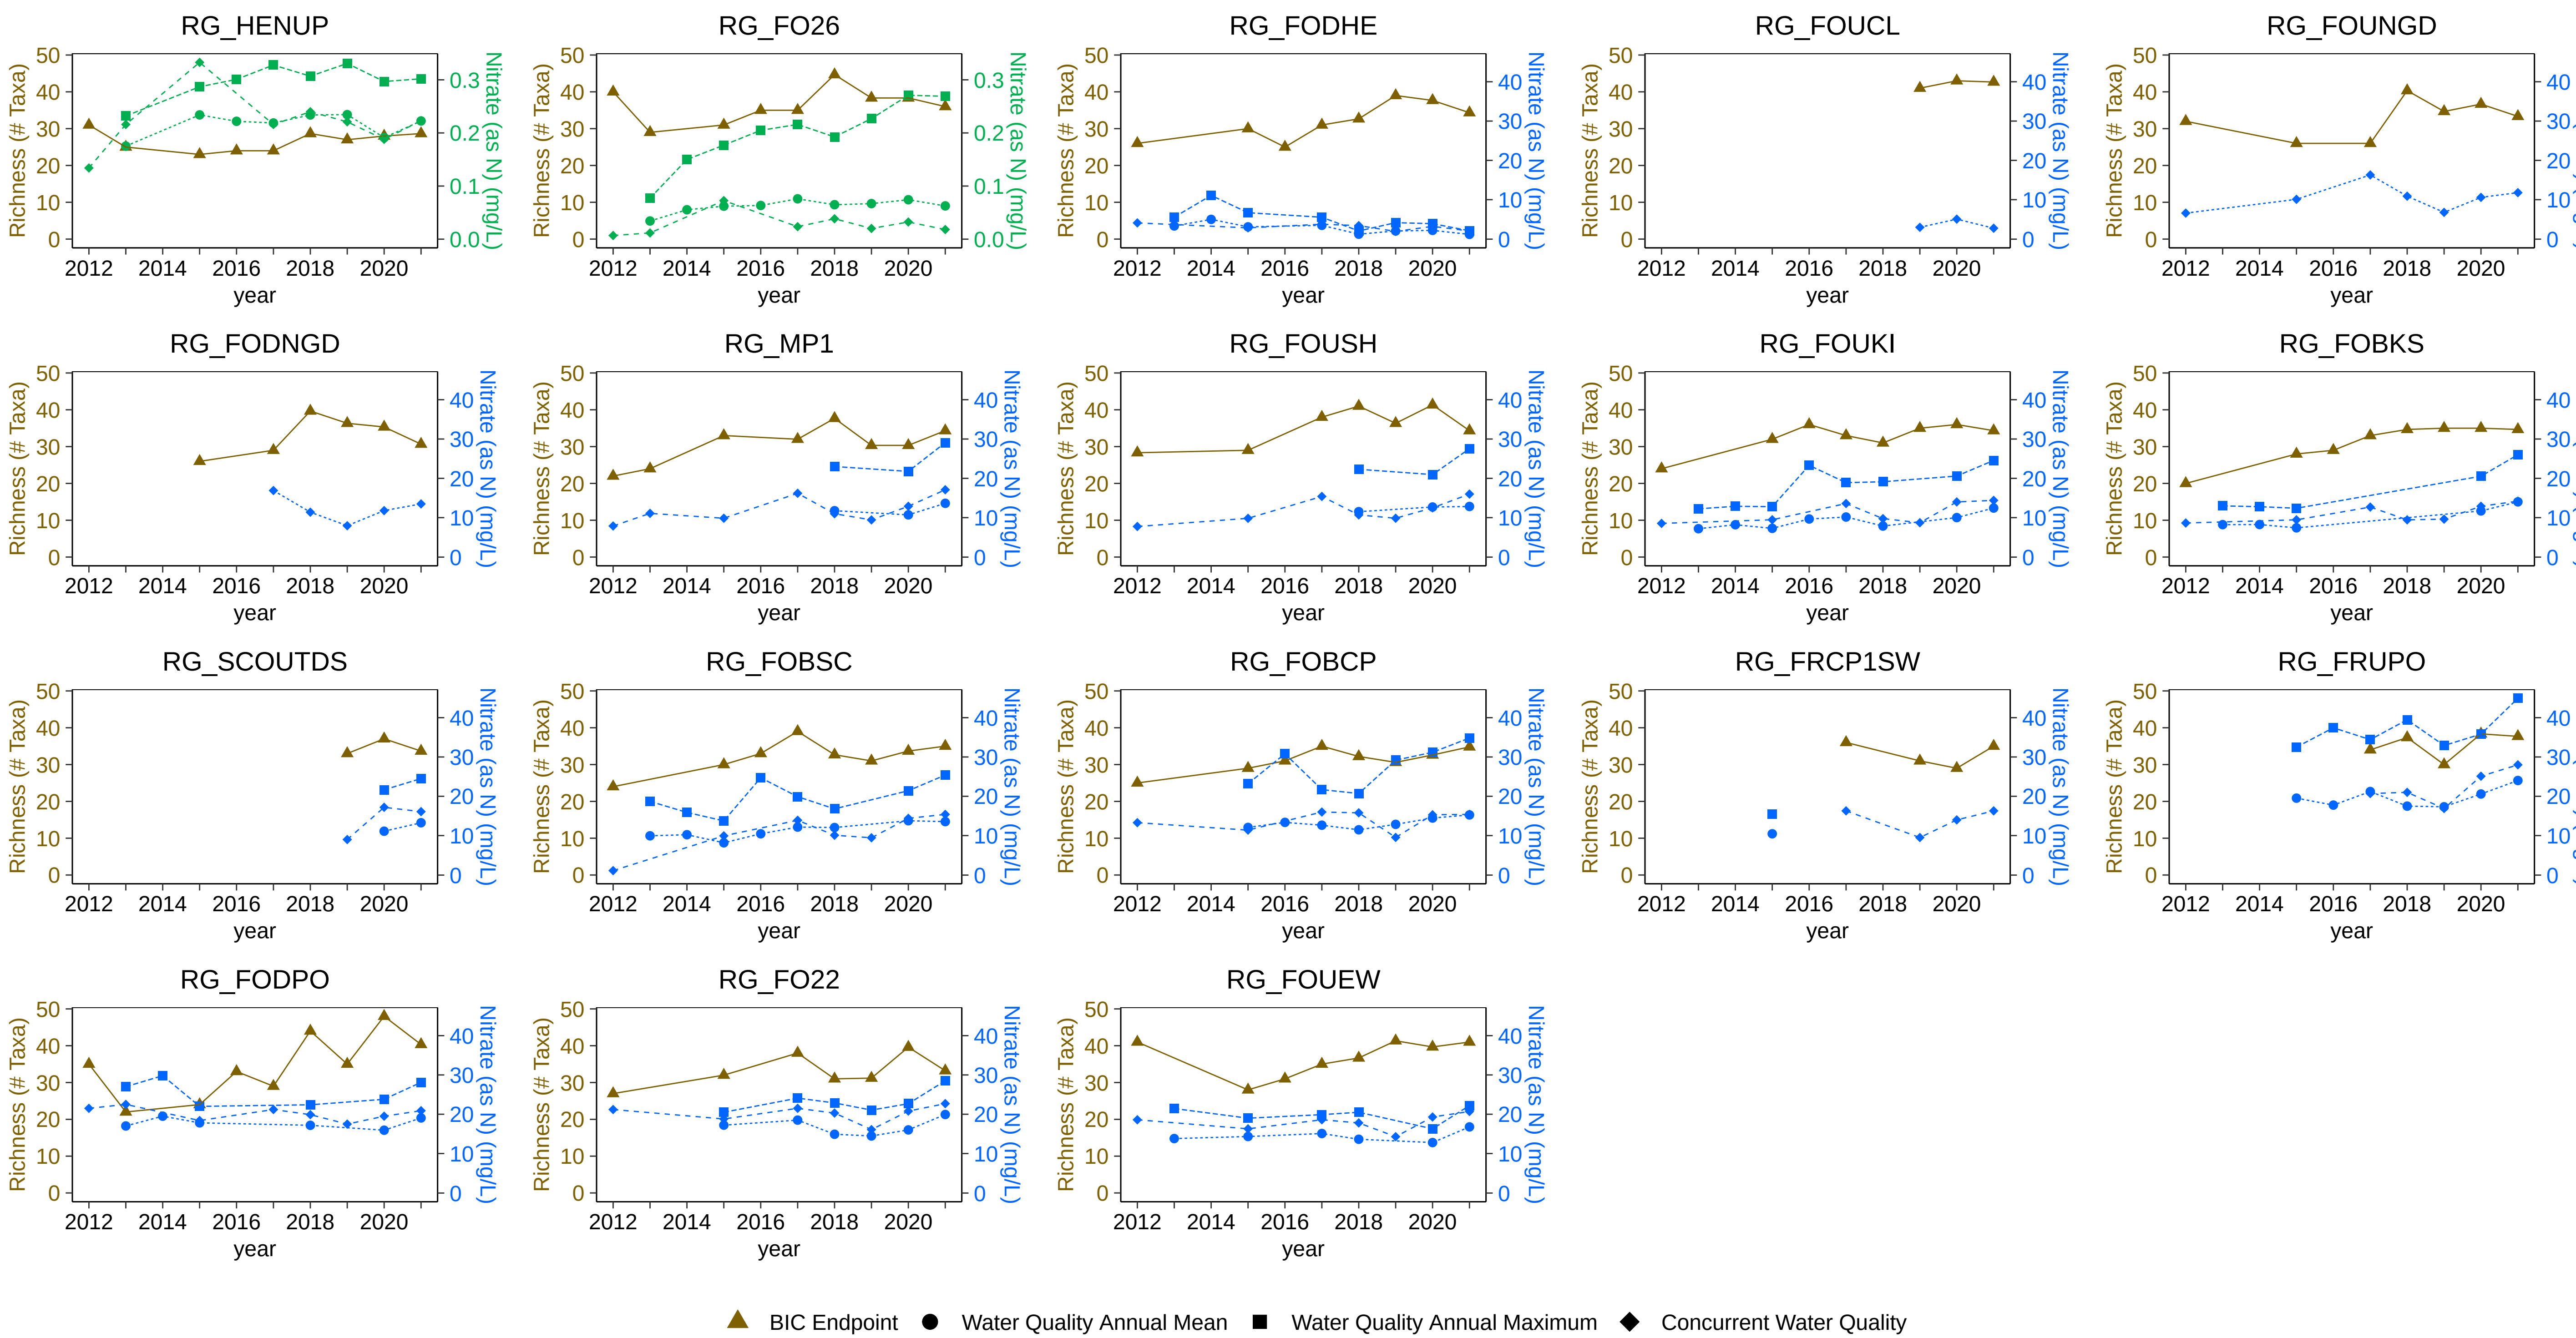

Figure F.2: Temporal Comparisons of Richness (# Taxa) and Nitrate (as N) (mg/L), FRO LAEMP, September 2012 to 2021

Notes: Water chemistry is shown in green for reference areas and blue for mine−exposed areas. Maximum calculated as the maximum monthly mean.

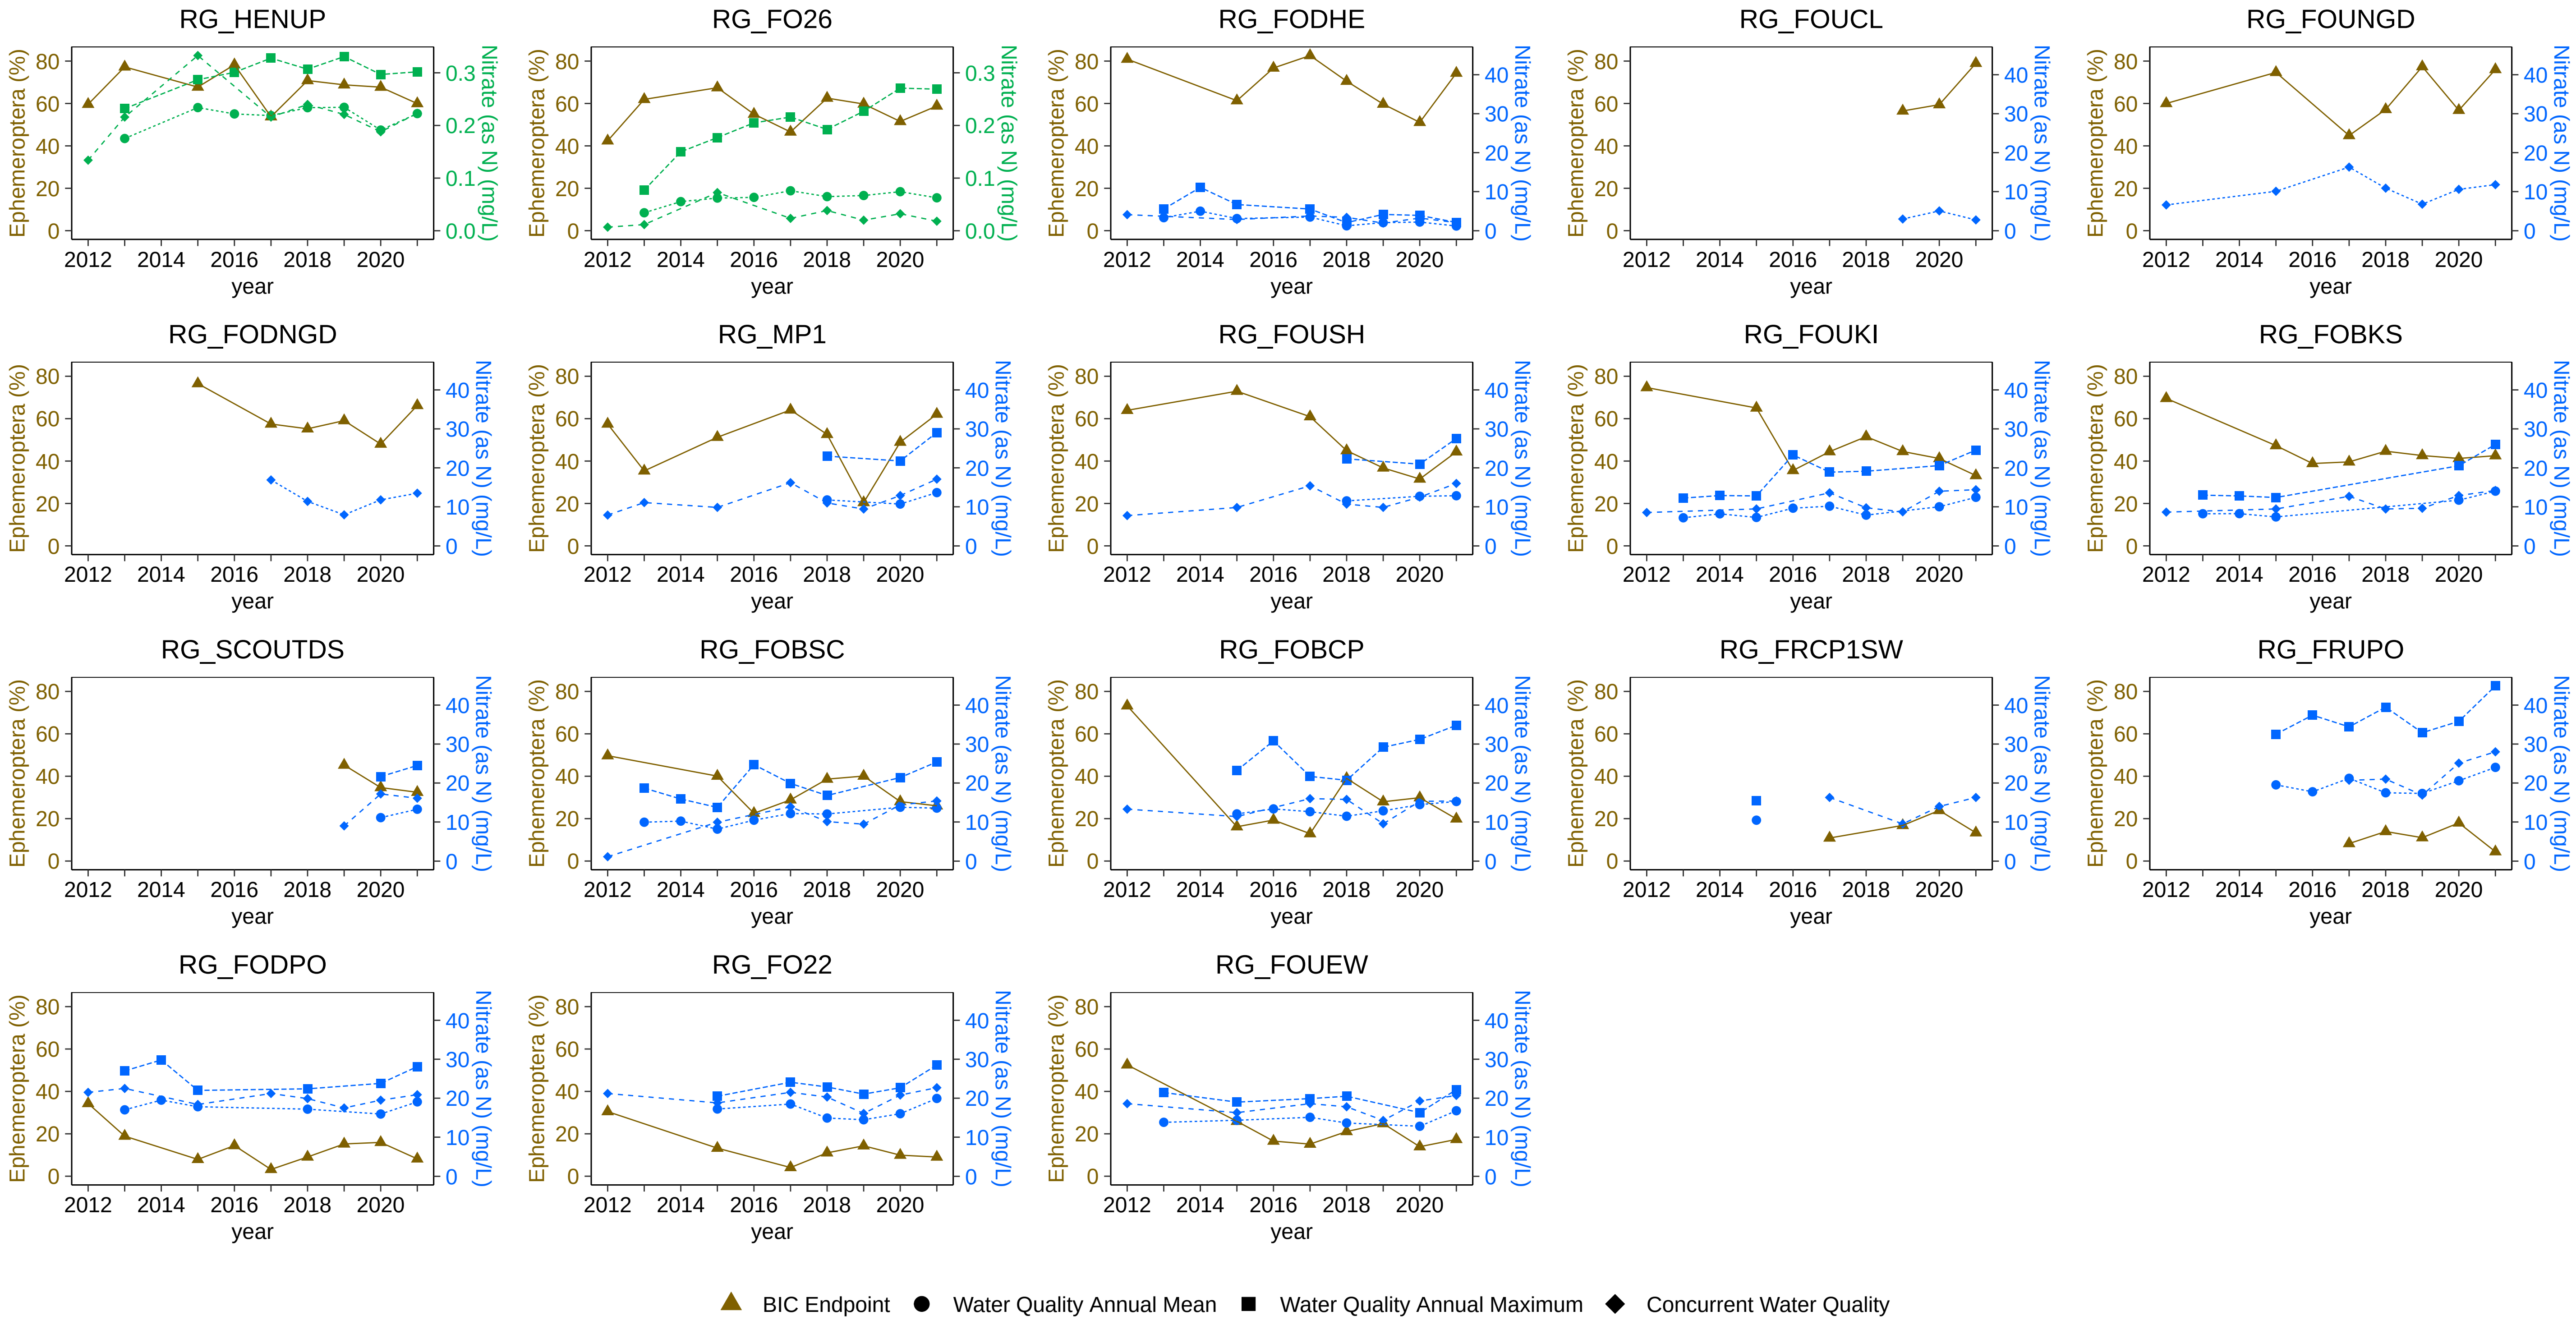

Figure F.3: Temporal Comparisons of Ephemeroptera (%) and Nitrate (as N) (mg/L), FRO LAEMP, September 2012 to 2021

Notes: Water chemistry is shown in green for reference areas and blue for mine−exposed areas. Maximum calculated as the maximum monthly mean.

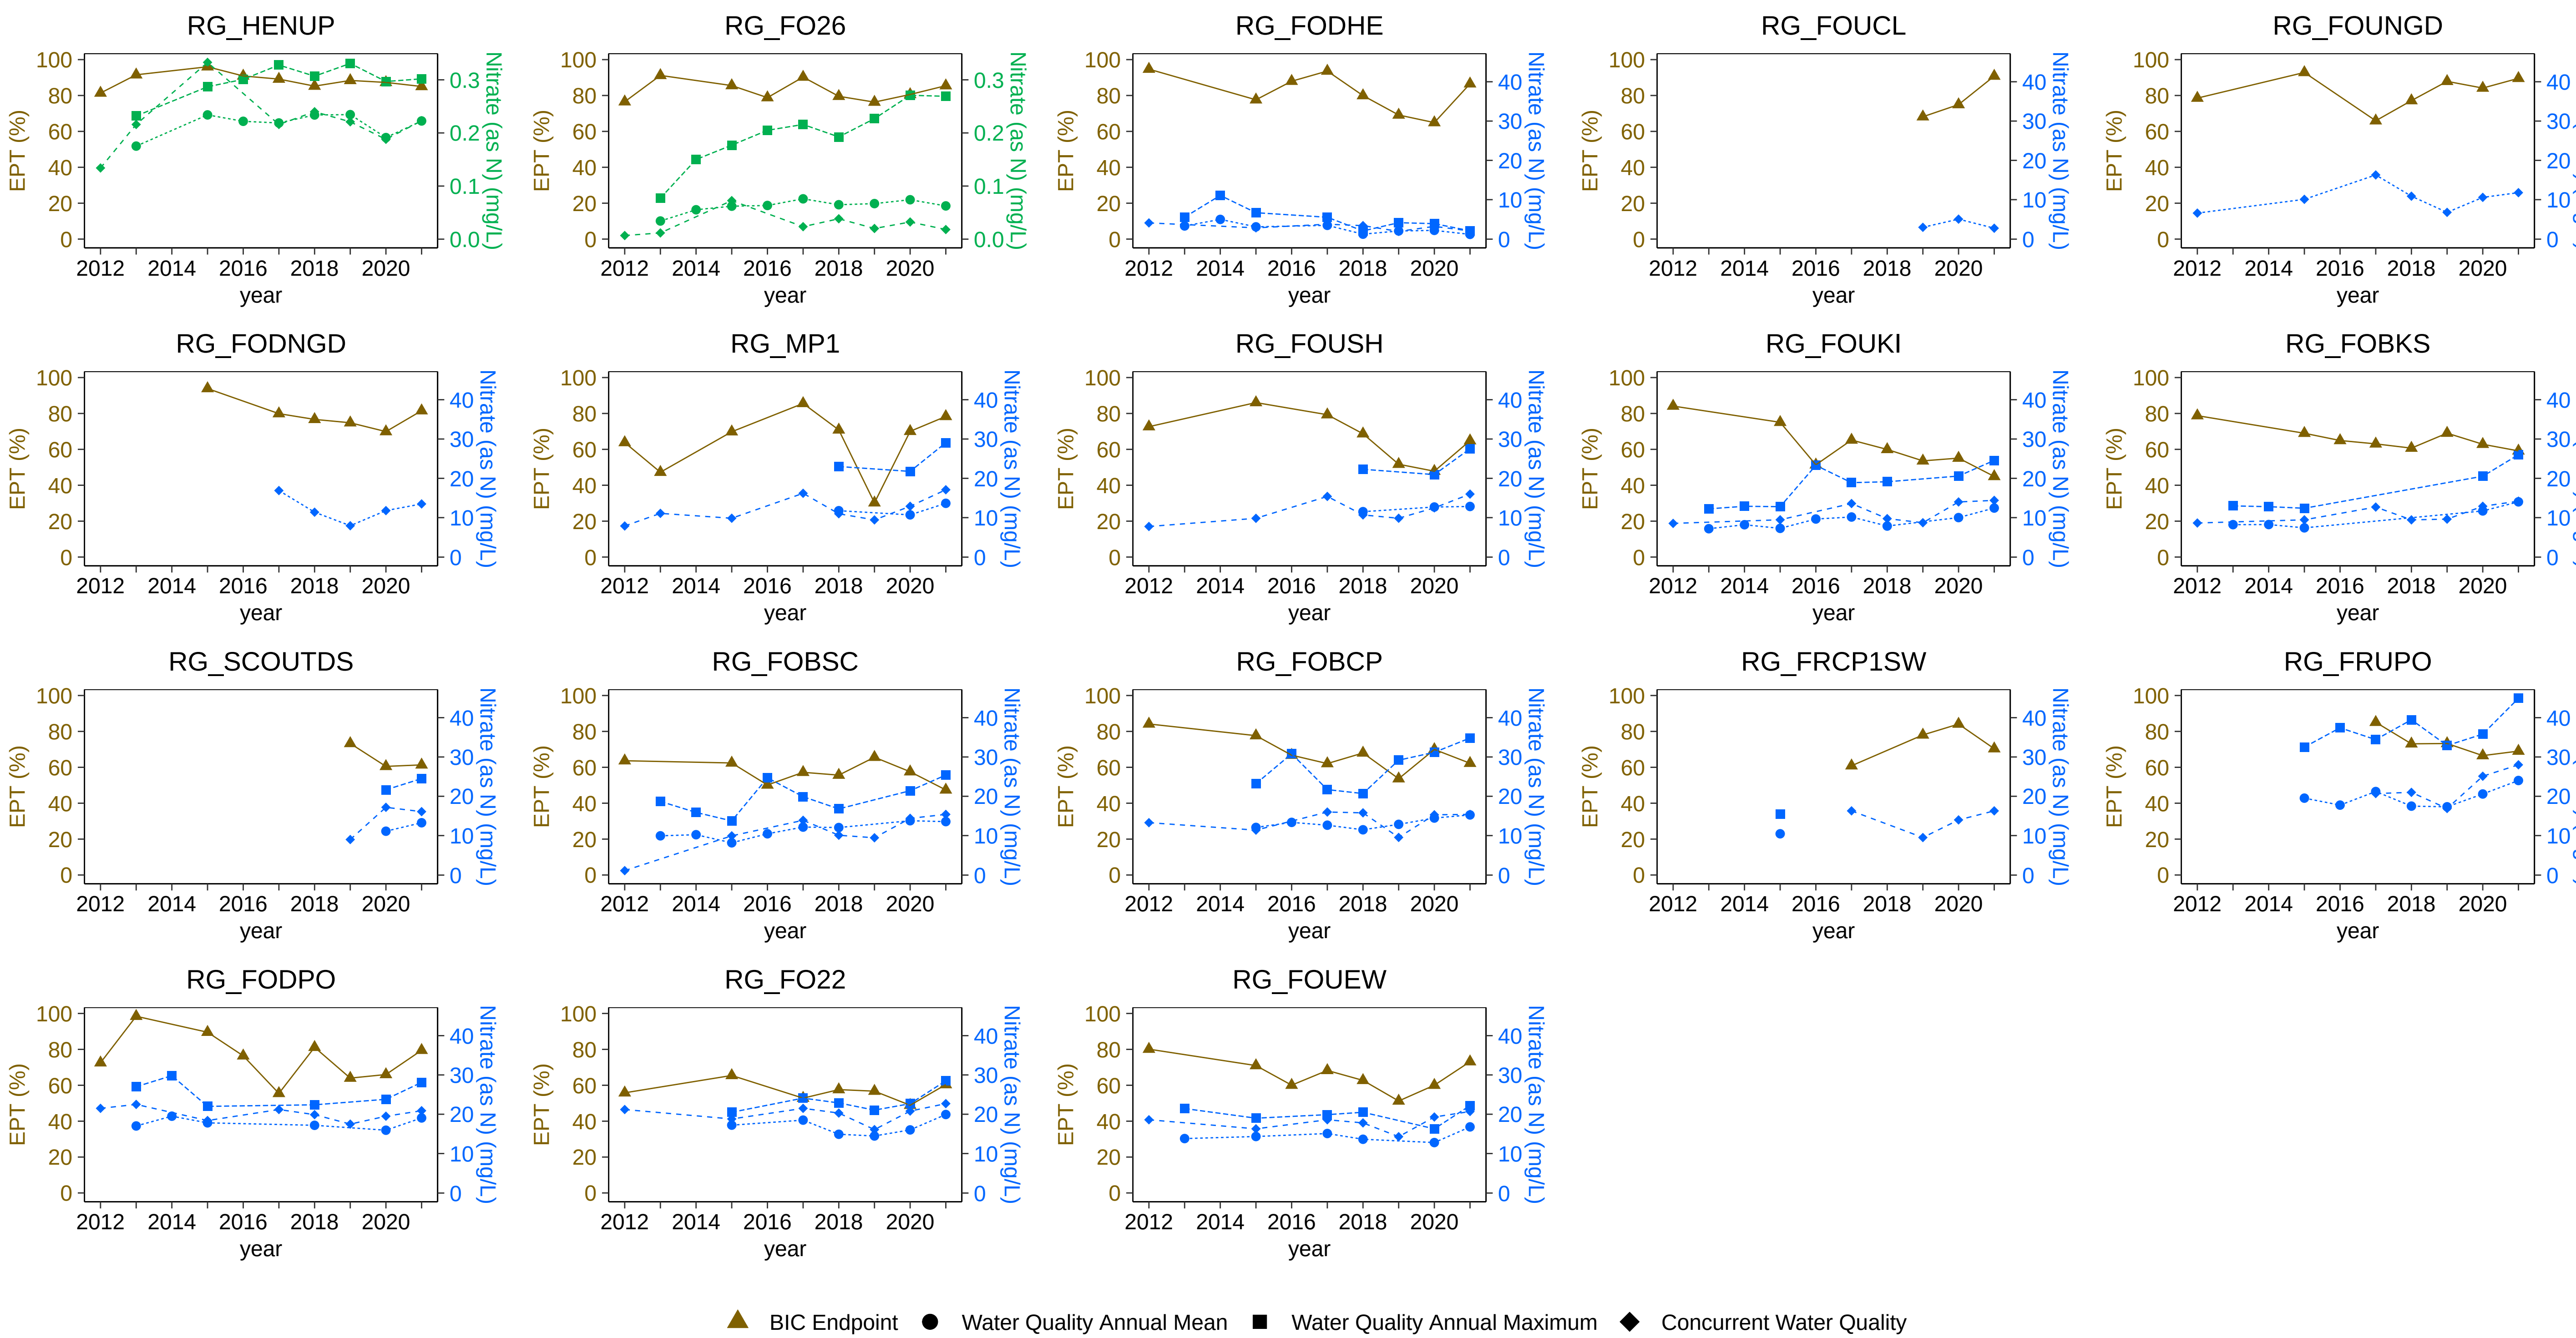

Figure F.4: Temporal Comparisons of EPT (%) and Nitrate (as N) (mg/L), FRO LAEMP, September 2012 to 2021

Notes: Water chemistry is shown in green for reference areas and blue for mine−exposed areas. Maximum calculated as the maximum monthly mean.

Figure F.5: Scatterplots of Spearman's Correlation Relationships Between Benthic Invertebrate Community Metrics and Physical and Chemical Parameters, Fording River, 2018 to 2021

Notes: Only relationships with at least one relationship with a significant p−value and abs(rho) > 0.6 are displayed. The Full correlations included reference areas as well as the upper, middle, and lower areas. Annual = Averaged mean based on the previous year of water quality sampling (see methods for details). Elk Valley Water Quality Plan (EVWQP) benchmarks were not shown where measured water quality values were below benchmarks and for constituents that have no benchmarks. The dashed lines represent interim screening values for nickel and screening values for total dissolved solids. Endpoint residuals represent the residuals of multiple regression models predicting the expected benthic invertebrate community given habitat at mine−exposed sites (RAEMP 2020a).

Figure F.5: Scatterplots of Spearman's Correlation Relationships Between Benthic Invertebrate Community Metrics and Physical and Chemical Parameters, Fording River, 2018 to 2021

Notes: Only relationships with at least one relationship with a significant p−value and abs(rho) > 0.6 are displayed. The Full correlations included reference areas as well as the upper, middle, and lower areas. Annual = Averaged mean based on the previous year of water quality sampling (see methods for details). Elk Valley Water Quality Plan (EVWQP) benchmarks were not shown where measured water quality values were below benchmarks and for constituents that have no benchmarks. The dashed lines represent interim screening values for nickel and screening values for total dissolved solids. Endpoint residuals represent the residuals of multiple regression models predicting the expected benthic invertebrate community given habitat at mine−exposed sites (RAEMP 2020a).

Figure F.6: Heatmap of Spearman Correlation Coefficients of Benthic Invertebrate Community Endpoints against Physical and Chemical Parameters, Upper Fording River, 2018 to 2021

Notes: Orange boxes show significant correlations (p−value < 0.05/38 for Bonferroni Correction), and red boxes show significant correlations with absolute coefficients > 0.6. Cluster diagrams on x− and y−axis represent similarities using Euclidean distances clustered according to Ward's minimum variance method.

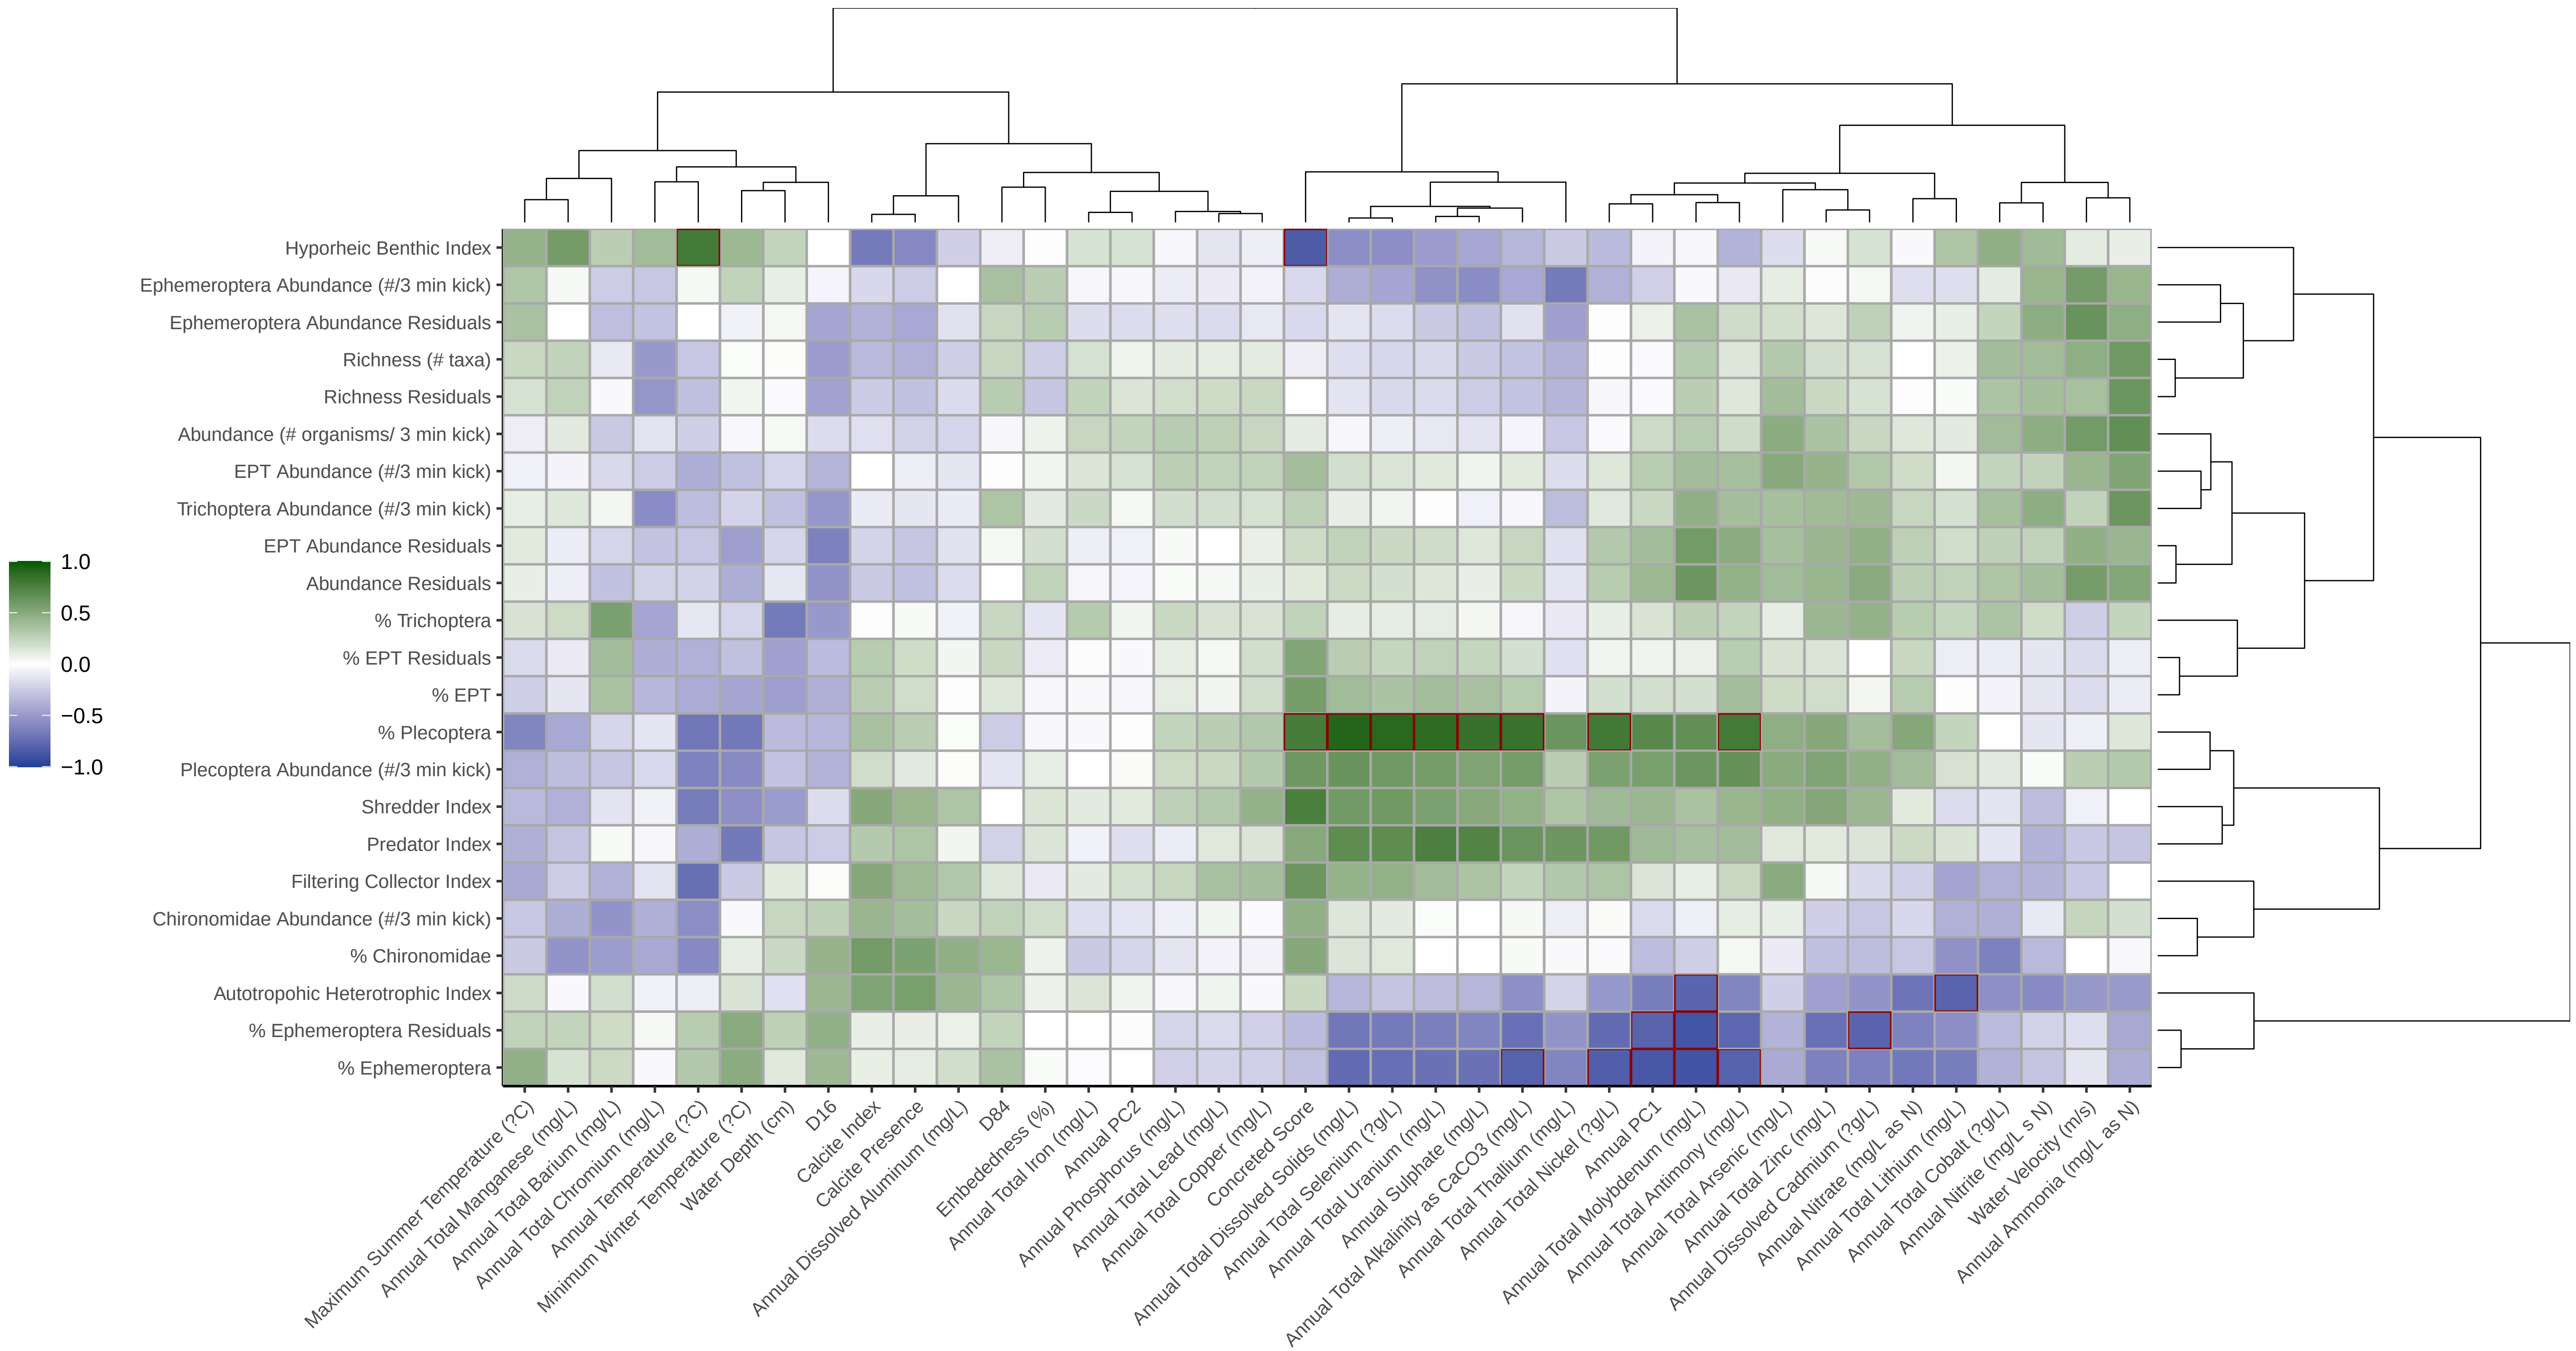

Figure F.7: **Heatmap of Spearman Correlation Coefficients of Benthic Invertebrate Community Endpoints against Physical and Chemical Parameters, Middle Fording River, 2018 to 2021**

Notes: Orange boxes show significant correlations (p−value < 0.05/38 for Bonferroni Correction), and red boxes show significant correlations with absolute coefficients > 0.6. Cluster diagrams on x− and y−axis represent similarities using Euclidean distances clustered according to Ward's minimum variance method.

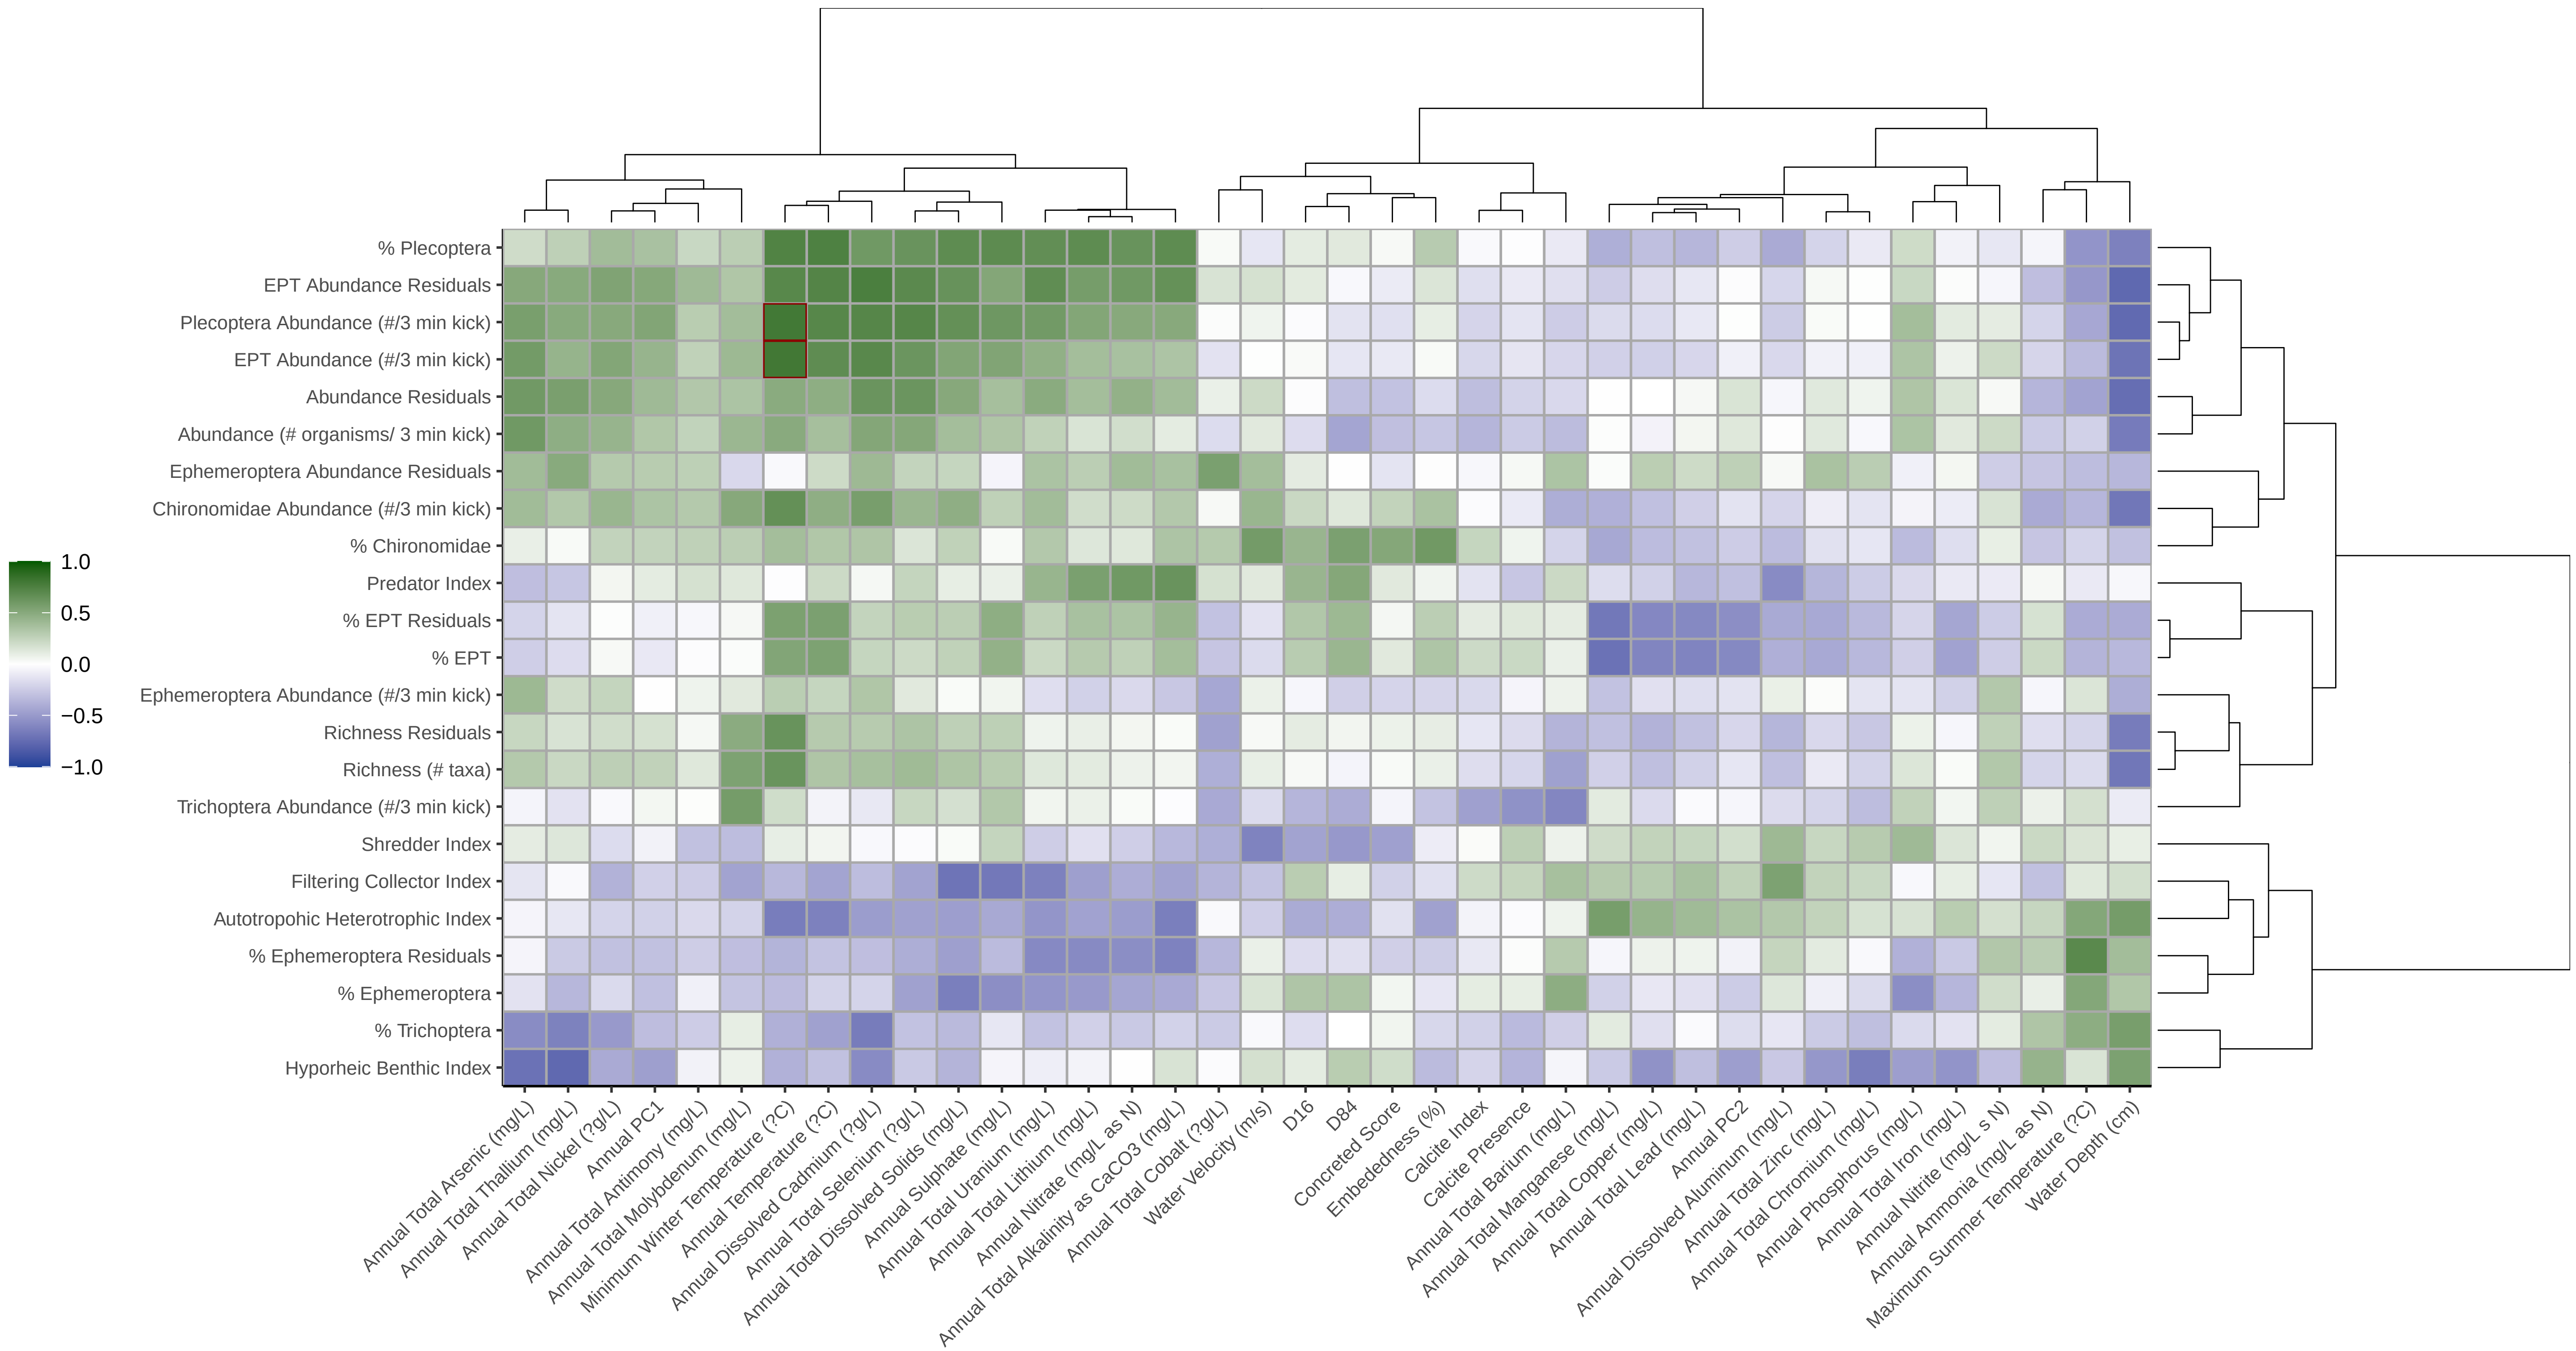

Figure F.8: **Heatmap of Spearman Correlation Coefficients of Benthic Invertebrate Community Endpoints against Physical and Chemical Parameters, Lower Fording River, 2018 to 2021**

Notes: Orange boxes show significant correlations (p−value < 0.05/38 for Bonferroni Correction), and red boxes show significant correlations with absolute coefficients > 0.6. Cluster diagrams on x− and y−axis represent similarities using Euclidean distances clustered according to Ward's minimum variance method.

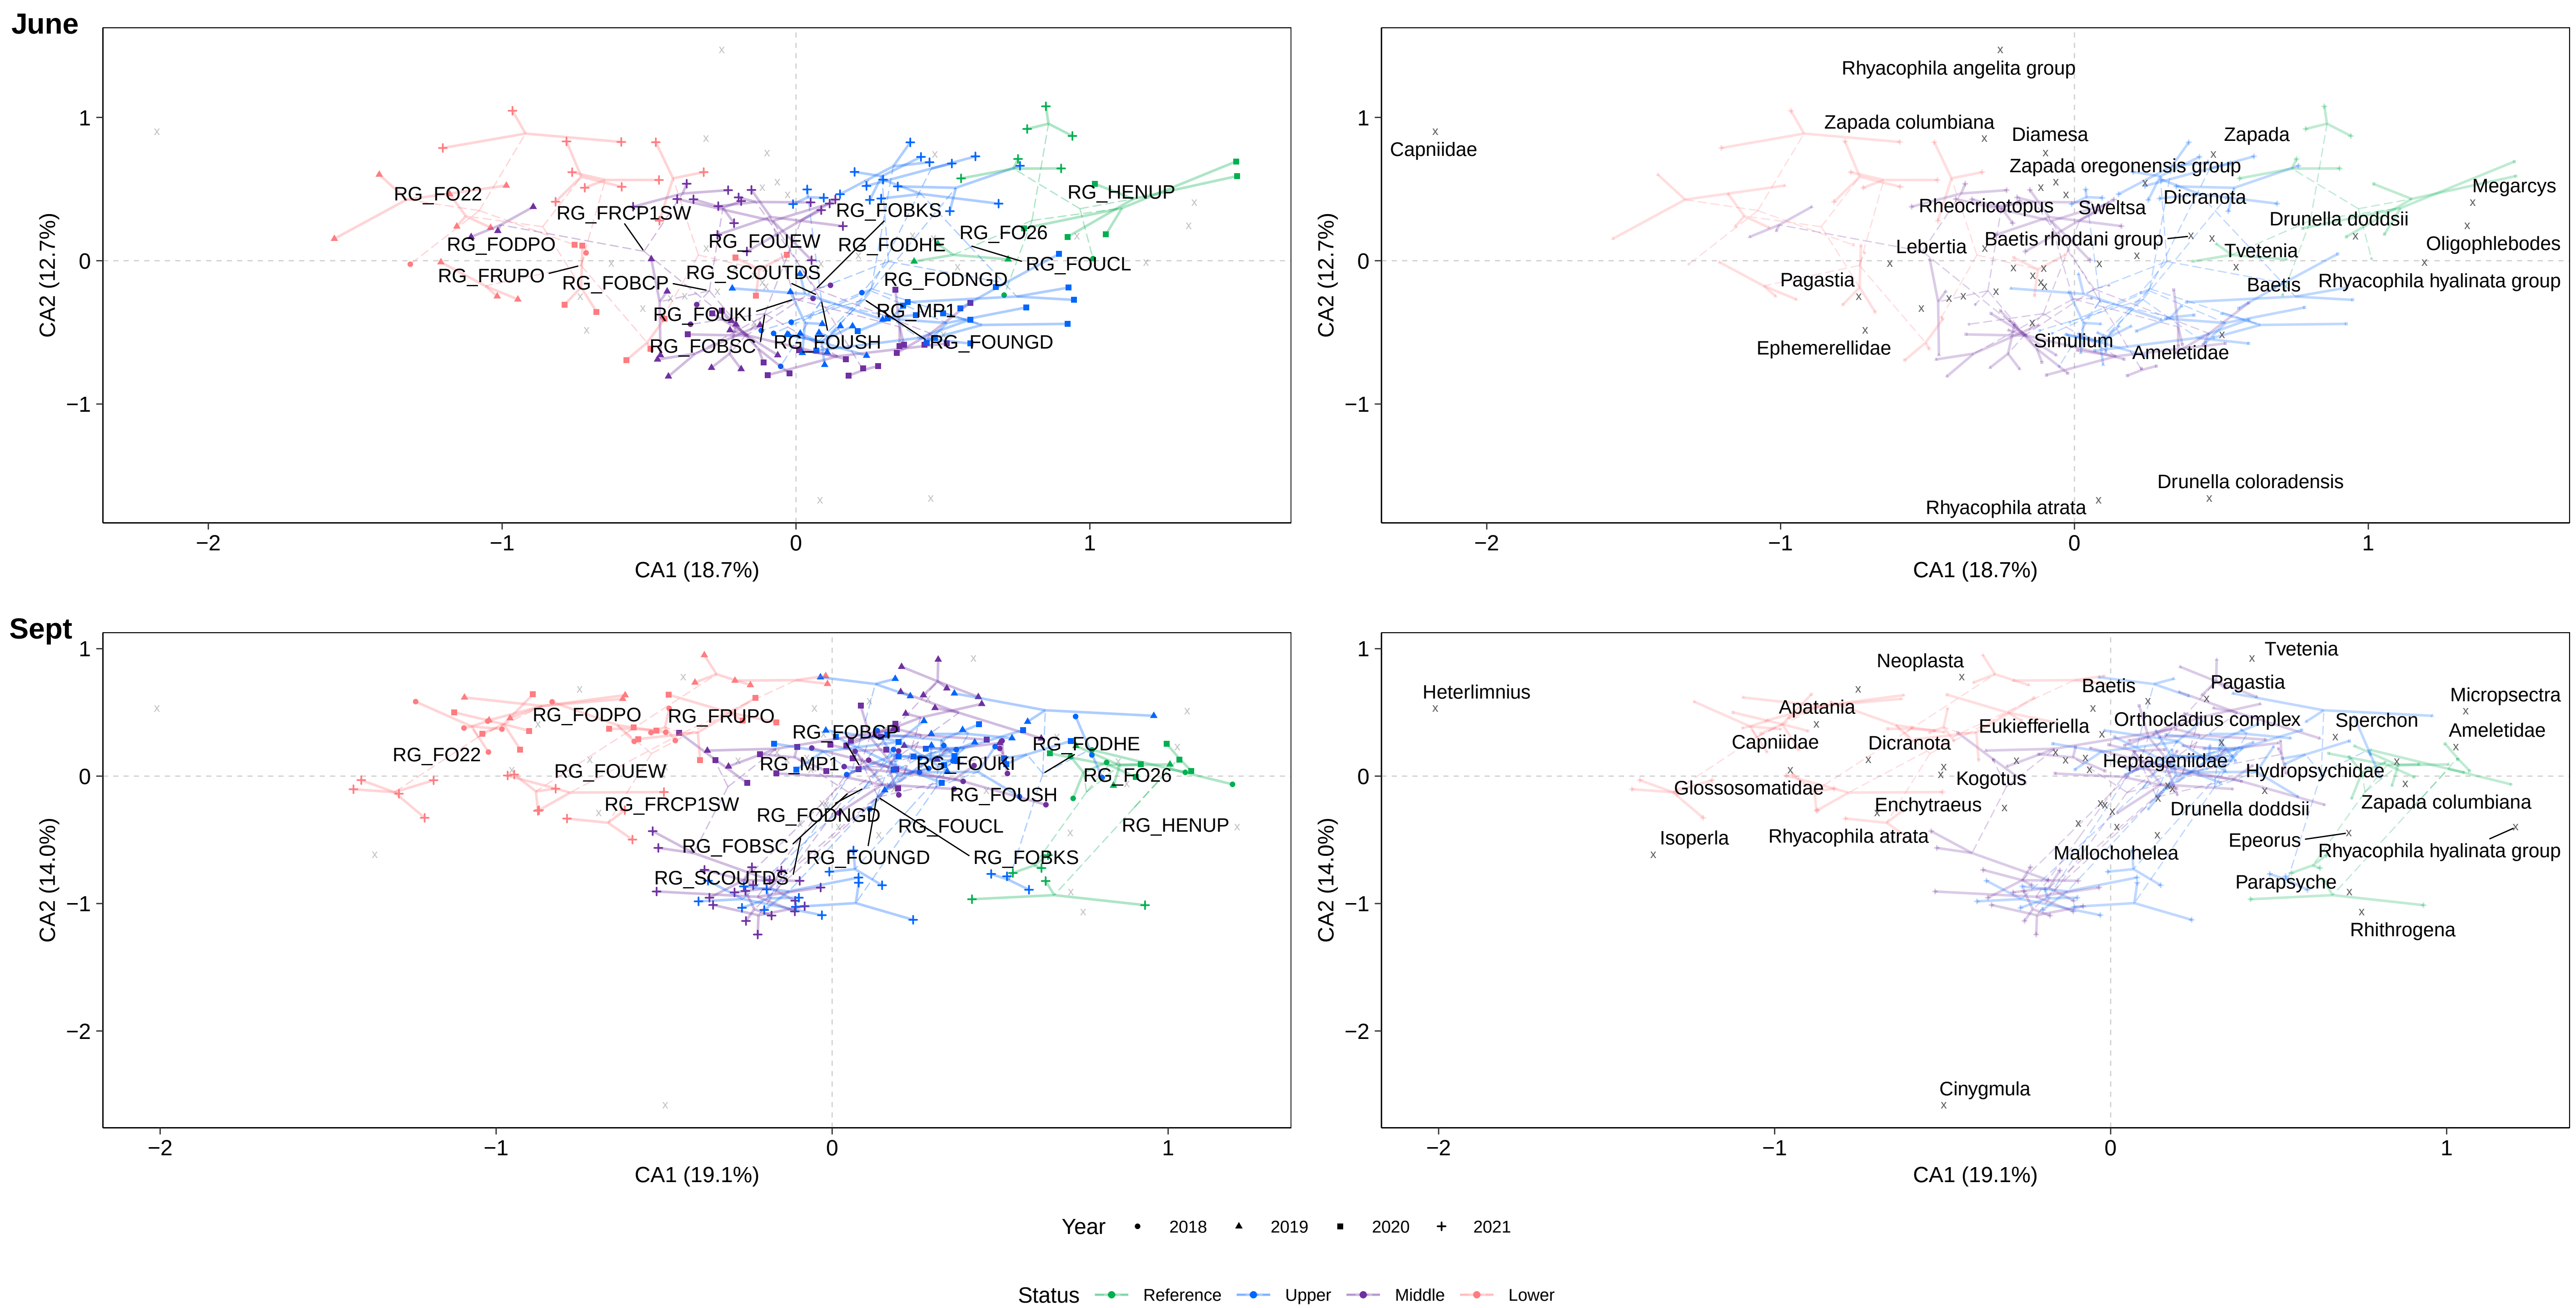

Figure F.9: Correspondence Analysis of Benthic Invertebrate Communities in June and September, FRO LAEMP, 2018 to 2021

Notes: Lowest Practical Level taxon abundances were ln(x+1) transformed prior to analysis. Taxa that made up less than 1% of total abundance (on the ln(x+1) scale) and occurred in fewer than 10% of samples were excluded from analysis. Mine−exposed areas included in the FRO LAEMP were divided into three sections from upstream to downstream: Upper Study Area, Middle Study Area, and Lower Study Area.

Notes: Lowest Practical Level taxon abundances were ln(x+1) transformed prior to analysis. Taxa that made up less than 1% of total abundance (on the ln(x+1) scale) and occurred in fewer than 10% of samples were excluded from analysis. Mine−exposed areas included in the FRO LAEMP were divided into three sections from upstream to downstream: Upper Study Area, Middle Study Area, and Lower Study Area.

Figure F.10: Canonical Correspondence Analysis of Benthic Invertebrate Communities in June and September Constrained by Habitat Variables, FRO LAEMP, 2018 to 2021

Notes: Lowest Practical Level taxon abundances were ln(x+1) transformed prior to analysis. Taxa that made up less than 1% of total abundance (on the ln(x+1) scale) and occurred in fewer than 10% of samples were excluded from analysis. Mine−exposed areas included in the FRO LAEMP were divided into three sections from upstream to downstream: Upper Study Area, Middle Study Area, and Lower Study Area.

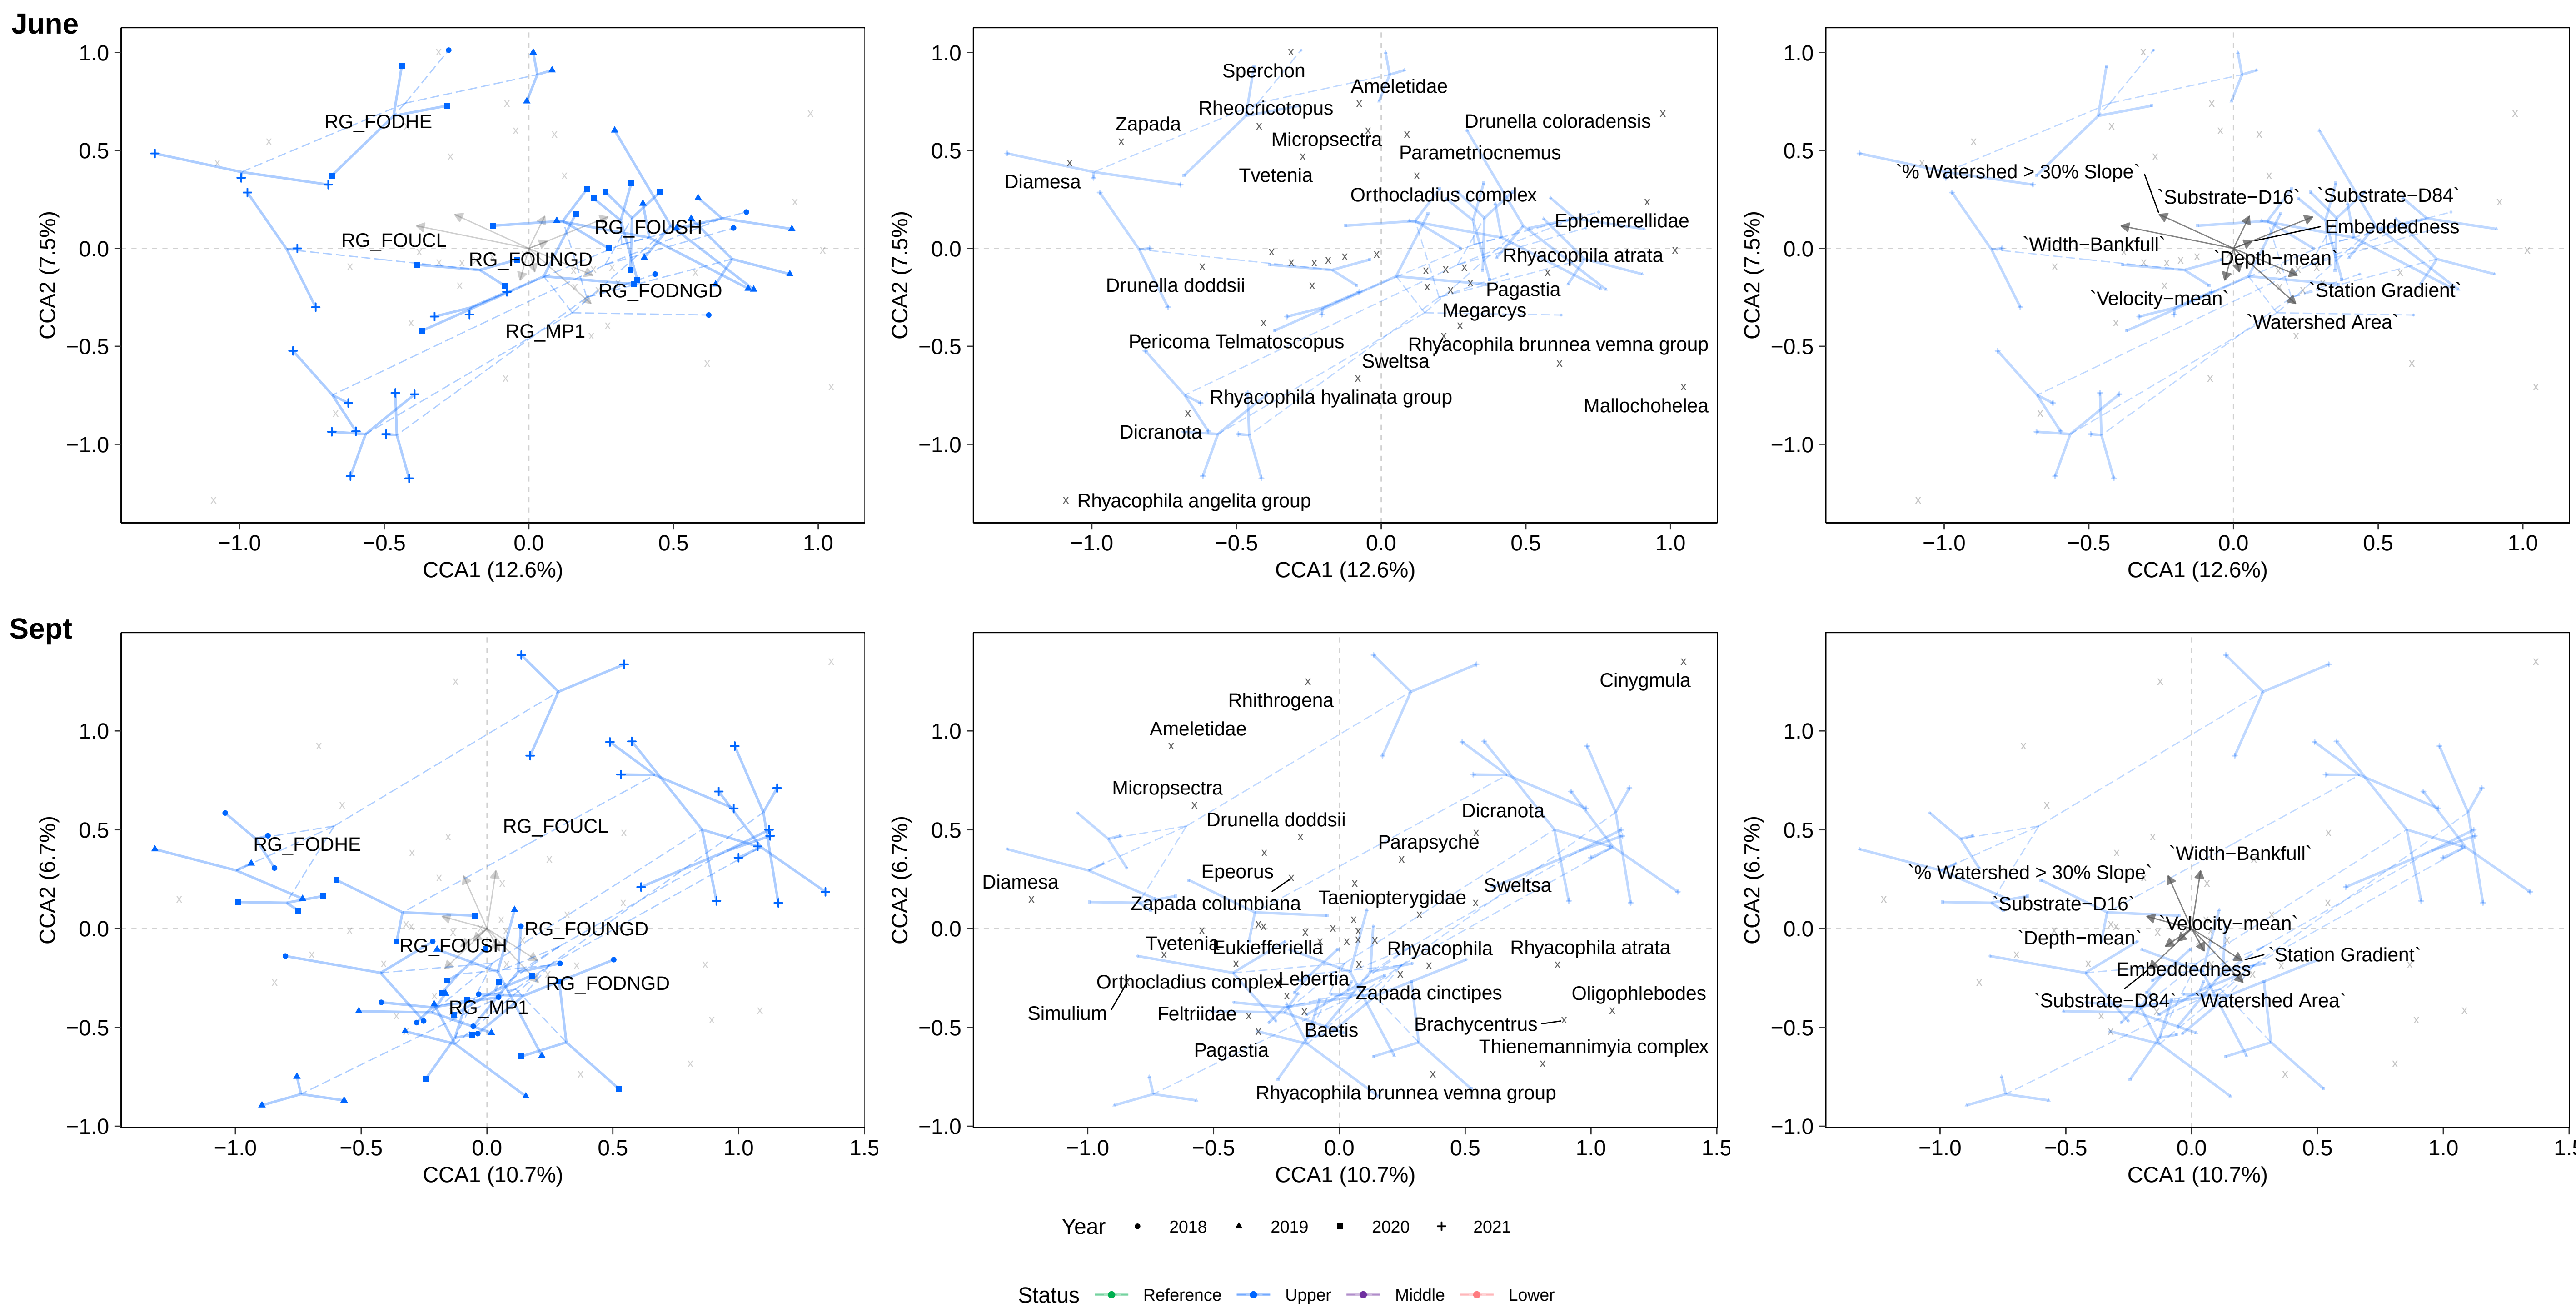

Figure F.10: Canonical Correspondence Analysis of Benthic Invertebrate Communities in June and September Constrained by Habitat Variables, FRO LAEMP, 2018 to 2021

Notes: Lowest Practical Level taxon abundances were ln(x+1) transformed prior to analysis. 0-25th Percentile & P-Value < 0.05.

25th-50th Percentile & P-Value < 0.05.

50th-75th Percentile & P-Value < 0.05.

75th-100th Percentile & P-Value < 0.05.

Notes: Cells are shaded only if the associated p-value from permutation based ANOVA was < 0.05. Shading is arranged from lightest to darkest according to percentile of F-Statistic distributions within each model to highlight which predictors most strongly influence Benthic Invertebrate Community responses. F-Statistics are shown for each term as Single and Marginal. Single represents the importance of the predictor in isolation of other predictors, while Marginal represents the unique contribution of the predictor to a model containing all other predictors. Separate analysis were conducted on September and June samples. Predictors were analyzed in one of three Canonical Correspondence Analysis (CCA) models, a Habitat model containing landscape and site specific variables relating to instream and landscape habitat, a Stressor model containing water quality analyte concentrations and calcite variables, and a Stressor after Habitat model, which uses partial Canonical Correspondence Analysis (pCCA) to remove the effects of habitat differences, and explains the remaining variability using variables from the Stressor model. Taxa that made up less than 1% of total abundance (on the ln(x+1) scale) and occurred in fewer than 10% of samples were excluded from analysis. Only water quality analytes which contained fewer than 15% of values below Laboratory Reporting Limits (LRL) were included in the final model. Values below LRL were included at the LRL. All water quality analytes, as well as Catchment Area were log10-transformed and scaled by subtracting the mean and dividing by the standard deviation prior to analysis. All remaining predictors were scaled by subtracting the mean and dividing by the standard deviation prior to analysis.
